Indian Journal of Public Health Research & Development

EXECUTIVE EDITOR

Vidya Surwade
Associate Professor, Dr Baba Saheb Ambedkar, Medical College & Hospital, Rohinee, Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. Dr. Abdul Rashid Khan (B. Md Jagar Din, (Associate Professor) Department of Public Health Medicine, Penang Medical College, Penang, Malaysia
2. Dr. V Kumar (Consulting Physician) Mount View Hospital, Las Vegas, USA
3. Basheer A. Al-Sum, Botany and Microbiology Deptt, College of Science, King Saud University, Riyadh, Saudi Arabia
4. Dr. Ch Vijay Kumar (Associate Professor) Public Health and Community Medicine, University of Kurunegala, Sri Lanka
5. Dr. VMC Ramaswamy (Senior Lecturer) Department of Pathology, International Medical University, Bukit Jalil, Kuala Lumpur
6. Kartavya J. Vyas (Clinical Researcher) Department of Deployment Health Research, Naval Health Research Center, San Diego, CA (USA)
7. Prof. PK Pokharel (Community Medicine) BP Koirala Institute of Health Sciences, Nepal

NATIONAL SCIENTIFIC COMMITTEE

1. Dr. Anju D Ade (Professor) Community Medicine Department, SVIMS, Sri Padamavati Medical College, Tirupati, Andhra Pradesh
2. Dr. E Venkata Rao (Associate Professor) Community Medicine, Institute of Medical Sciences & SUM Hospital, Bhubaneswar, Orissa
3. Dr. Amit K. Singh (Associate Professor) Community Medicine, VCSG Govt. Medical College, Srinagar – Gahrwal, Uttarakhand
4. Dr. R G Vivekki (Associate Professor) Community Medicine, Belgum Institute of Medical Sciences, Belgum, Karnataka
5. Dr. Santosh Kumar Mulage (Assistant Professor) Anatomy, Raichur Institute of Medical Sciences, Raichur (RIMS), Karnataka
6. Dr. Gouri K Padhy (Associate Professor) Community and Family Medicine, All India Institute of Medical Sciences, Raipur
7. Dr. Ritu Goyal (Associate Professor) Anaesthesia, Sarwahti Institute of Medical Sciences, Panchsheel Nagar
8. Dr. Anand Kalaskar (Associate Professor) Microbiology, Pratishtha Institute of Medical Sciences, AP
9. Dr. Md. Amirul Hassan (Associate Professor) Community Medicine, Government Medical College, Ambedkar Nagar, UP
10. Dr. N. Girish (Associate Professor) Microbiology, VIMS&RC, Bangalore
11. Dr. BR Hungund (Associate Professor) Pathology, JNMC, Belgaum
12. Dr Sartaj Ahmad, PhD Medical Sociology, Associate Professor, Swami Vivekananda Subharti University Meerut, UP, India
13. Dr Sumeeta Soni (Associate Professor) Microbiology Department, B.J. Medical College, Ahmedabad, Gujarat, India

NATIONAL EDITORIAL ADVISORY BOARD

1. Prof. Sushanta Kumar Mishra (Community Medicine) GSL Medical College, Rajahmundry, Andhra Pradesh
2. Prof. D.K. Srivastava (Medical Biochemistry) Jamia Hamdard Medical College, New Delhi
3. Prof. M Srirababu (General Medicine) GSL Medical College, Rajahmundry, Andhra Pradesh
4. Prof. Pankaj Datta (Principal & Prosthodontist) Indraprastha Dental College, Ghaziabad
5. Prof. Samarendra Mahapatra (Paediatrician) Hi-Tech Medical College, Bhubaneswar, Orissa
6. Dr. Abhiruchi Galhotra (Additional Professor) Community and Family Medicine, All India Institute of Medical Sciences, Raipur
7. Prof. Deepti Pruthvi (Pathologist) SS Institute of Medical Sciences & Research Center, Davangere, Karnataka
8. Prof. G S Meena (Director Professor) Maulana Azad Medical College, New Delhi
9. Prof. Pradeep Khanna (Community Medicine) Post Graduate Institute of Medical Sciences, Rohtak, Haryana
10. Dr Sunil Mehra (Paediatrician & Executive Director) MAMTA Health Institute of Mother & Child, New Delhi
11. Dr Shailendra Handu, Associate Professor, Phrma, DM (Pharma, PG Chandigarh)
12. Dr. A.C. Dhariwal: Directorate of National Vector Borne Disease Control Programme, Dte. DGHMS, Ministry of Health Services, Govt. of India, Delhi

Print ISSN: 0976-0245-Electronic ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare & Scopus database. The journal is now part of DST, CSIR, and UGC consortia.

Effectiveness of Prenatal Classes During Third Trimester to Reduce Anxiety Level and to Improve Birth-Preparedness among Primigravid Women ................................................................. 414
Divya Bhadran, Anusuya. V. Prabhu, Lakhra Alma Juliet
75. Knowledge, Attitude, Practice and Barriers for Self-care among Type 2 Diabetes Mellitus Patients in Rural Tamil Nadu ................................................................. 419
   Aliya Jasmine, Ramesh Harihara Iyer

76. Health Status of Assam: A District Level Analysis .......................................................... 425
   Bhargab Das

77. Acoustic Analysis of Infant Cry Using Multidimensional Voice Program—A Preliminary Study ....... 430
   Deepa N Devadiga, Remyasree T, Aiswarya Liz Varghese, Ananthakrishna T

78. An Analysis of Access to Primary Health Care Services: A Study in Jorhat District of Assam .......... 435
   Sampurna Khound

79. Adaptive Signal Enhancement in Clinical Cardiac Care Systems Using Normalized Median LMS Variants 441
   Asiya Sulthana, Md. Zia-Ur-Rahman

80. A Health Status of Assam: A District Level Analysis .......................................................... 447
   Bhargab Das

81. A Review of the Perception of Healthcare Quality among Patients and Employees ....................... 452
   Bijo Mathew, Raja Narayanan, Amit Mittal

82. Experience of Sore Nipple and the Remedies Used among Postnatal Mothers ............................. 457
   Janet Prameela D’Souza, Shobha Kamath, Elsa Sanatombi Devi

83. Prevalence of Insomnia, and Sleep Hygiene Techniques Practiced among Elderly Residing in Selected Old Age Homes of Udupi and Dakshina Kannada District, Karnataka ........................................... 462
   Laxminarayan Iyer, Renjulal Yesodharan, Asha K Nayak

84. Maternal Risk Factors and Demographic Profile of Neonates Presenting with Persistent Pulmonary Hypertension in a Tertiary Care Hospital, Odisha ................................................................. 468
   Santosh Kumar Panda, Manas Kumar Nayak, Soumini Rath, Nirmal Kumar Mohakud, Subhra Snigdha Panda

85. Awareness of Cancer and its Symptoms among the Rural Population .......................................... 473
   Kalyan Ram S, Muthulakshmi Muthiah

86. Prevalence and Antibiotic Resistance Profile of Coagulase Negative Staphylococci Causing True Bacteraemia in a Tertiary Care Hospital ................................................................. 478
   Nipa Singh, Srotaswini Hota, Subhra snigdha Panda, Dipti Pattnaik, Ashok Praharaj, Jagadananda Jena

87. Availability of Manpower Facilities in the Health Sector of Assam ............................................. 484
   Raju Saikia

88. Screening Urinary Methylmalonic Acid by Thin Layer Chromatography in Children with Suspected Inborn Errors of Metabolism ......................................................... 488
   Saritha Kamath U, Nalini Bhaskaranand, Anjali Rao

89. Lifestyle Practices and Glycemic Control among Type 2 Diabetic Patients in North Kerala ............. 491
   N. V. Fatimathu Zuhara, A. Thahira Banu, Najma Chokli

90. Determinants of Satisfaction Level of Medical Tourists with Reference to Healthcare Industry in Tamil Nadu, India: An Empirical Study ................................................................. 498
   Arunangshu Giri, Satakshi Chatterjee, Smita Chakraborty, Abanti Aich, Swatee Biswas
To Evaluate and Compare the Microleakage in Class Five Cavities Restored by a Nanohybrid and a Nanofilled Composite Resin by Dye Penetration Method—An in Vitro Study ......................................................... 504
Chitharanjan Shetty, Namrata Khanna, Mithra N. Hegde

A Clinical Investigation onto the Effect of Occlusal Interferences & Cognitive Behavioural Therapy in Temporomandibular Disorder Patients .............................................................................................................. 509
Jinal Barochia, Vignesh Kamath, Konark Patil, Roseline Meshramkar

Endodontic Management of Maxillary First Molar with Six Canals—A Case Report ..................................... 514
Karthick Arumugam, Paramasivam Vivekanandhan, Arunajatesan Subbiya, Malarvizhi Dhakshinamoorthy, Mensudar Radhakrishnan, Geethapriya Nagarajan

A Study on Issues on Environment Pollution and Health Hazard in Tamilnadu ........................................... 518
R. Bright Reginold Raja, S. Antony Selvi

Determination of Bacterial Contamination from Well water ........................................................................... 522
Rashmi Saliyan, Kusumakshi Nayak

Study of Orthophosphate, Pyrophosphate, Pyrophosphatase and Citric Acid in Saliva With Reference to Calculus Formation and Inhibition ........................................................................................................ 527
Rathinavelu Ganesan, Bhaskar J., Kadhiresan Rathinasamy, Arunmozhi Ulaganathan, Mohan Valiathan

Potential Protective Role of Beta Carotene on Cadmium Induced Brain and Kidney Damage ................. 532
Rekha D Kini, Nayanatara Arunkumar, Sneha Shetty B, Anupama N, Bhagyalakshmi K, Megha Gokul

Prevalence of Bacterial Vaginosis among Antenatal Women Attending to a Tertiary Care Hospital ...... 536
Roshini Gundapaneni, Ravindranath Gundapaneni, K. V. S. Prasad, Banerji Neerugatti

A Preliminary Study on Prevalence of Certain Risk Factors for Non-Communicable Diseases in a Rural Population of Karnataka, India ........................................................................................................ 542
Sachidananda K, Nanjesh Kumar, Shahul Hammed, Kurulkar P, Ullal Sheetal D

Perspectives on Mental and Physical Distress and School Counselling Based Interventions for Sexually Abused Adolescents ........................................................................................................ 547

178. An Exploratory Study on the Roles of Bhutanese Primary Health Care Managers in Responding to
   Childhood Obesity ......................................................................................................................... 970
   Chimi Wangmo, Phudit Tejativaddhana, Mary Cruickshank, David Briggs

179. Determination of Safe Benzene Concentration at Kebon Jeruk Toll Gate Keeper Jakarta Indonesia ...... 976
   Danang Setia Budi, Abdul Rohim Tualeka, Pudji Rahmawati, Syamsiar S Russeng, Bambang Wispriyono

180. Analysis of Patient Safety Culture and Work Team in Educating the Effect of Leadership Style on
   Patients Safety Performance ......................................................................................................... 982
   Dike Widyakti Sawfina Maharani, Margono Setiawan, Dodi Wirawan Irawanto, Mintarti Rahayu

181. Maternal Death Model Decreases the Expression of BDNF in Rattus Norvegicus Newborns’
   Cerebrum and Cerebellum ......................................................................................................... 987
   Duhita Dyah Apsari, Hermanto Tri Joewono, Widjiati

182. Lipid Accumulation Product: A Simple and Useful Surrogate Marker for Glycemic Control in
   Women with Type 2 Diabetes Mellitus ....................................................................................... 993
   Ekhlas Khalid Hameed, Noor Saadi Hassan, Zina Hassan Abdulqahar

183. The Safe Concentration Determination for Public Health Problems Due to Inhalation of Air Containing
   Hydrogen Sulfide Around Industrial Area of Medan Indonesia ................................................ 999
   Erlinda Rasikhah Hadi Salma, Abdul RohimTualeka, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu

184. Biscuit Enriched with Bilh Fish (Mystacoleucus-padangensis) Increases Cognitive in Experimental Rat
   1006
   Fivi Melva Diana, Rimbawan Rimbawan, Evy Damayanthi, Mira Dewi, Vetnizah Juniantito, Nur
   Indrawaty Lipoeto

185. Determination of Safe Duration of Exposure to Benzene at Public Gas Stations Around Diponegoro
   University Semarang, Indonesia ................................................................................................ 1011
   Genduk Lintang Rusmawarda, Abdul RohimTualeka, Dimas Triyadi, Pudji Rahmawati, Syamsiar S
   Russeng, Atjo Wahyu, Ahsan

186. Bacterial Uropathogens Isolated from Alkaline Urine and their Susceptibility to Antimicrobial Agents
   1017
   Ghofran Fiasal, Abbas A. Al-Duliami, Ali M. Jaafar, Abdulkarazak SH. Hasan

187. Aerobic and Anaerobic Bacteria in Tonsils of Different Ages with Recurrent Tonsillitis ...................... 1022
   Gulbahar F. Karim, Siham Sh. Al-Salihi, Qanat Mahmood Atya, Kasim Sakran Abass

188. Efficacy of the Health Belief Model in Enhancing the Oral Health of Female Middle School Students 1027
   Halah Kamal Ismael, Aysin Kamal Mohammed Noori

189. The Effect of Selection on Some of the Basic Determinants of Learning Some of the Basic
   Skills of Football ..................................................................................................................... 1033
   Hamid Abdul Shaheed Hadi, Hayder Jaber Mousa, Ali Hameed Ali, Hayder Naji Habash Alshawi

190. The Method of Learning in Order to be Able to Follow the Cognitive Method (Independence Versus
   Dependence on the Cognitive Field) and its Impact on Some Basic Skills in the Fencing of Students . 1038
   Hamid Abdul Shaheed Hadi, Ali Mahdi Ali Almadhloom, Zaid Sami yasir, Hayder Naji Habash Alshawi
191. The Development of Nursing Intervention Based on Indonesian Nursing Intervention Standard on Infarction Stroke in Hospital ................................................................. 1043
   Hani Riska Ariyanti, Nursalam Nursalam, Slamet Riyadi Yuwono

192. Relationship between Mental Workload and Fatigue of Motorcycle Rider among East Java Student ... 1049
   Hendrati LY, Martini S, Lestari K. S.

193. Single Nucleotide Polymorphisms in IL-10-1082 A\G Gene and Association with HCMV Infection in Abortion ................................................................. 1055
   Hiba A. Hatem Mayyada F. Darweesh

194. Molecular Study of Echinococcus Granulosus in Misan Province, South of Iraq ......................... 1062
   Hussain A. Mhouse Alsaady, Hussein Ali Naeem Al-Quzweeni

195. The Human Arthropathy Inflammatory and Immune Herd Plots ............................................... 1067
   Ibrahim M S Shnawa, Baha H H Alamidie

196. Congenital Lobar Emphysema—A Case Series for 2 Years ...................................................... 1071
   Ibrahim Shuker Mahmood, Fawzi Salih Shihab, Ahmad Mahmood Mohammed

197. The Carotid Intima-Media Thickness in Workers with High and Low Exposure to Air Pollution ....... 1077
   Isabella Lalenh, Muhammad Aminuddin

198. Using Species-Specific Polymerase Chain Reaction Technique for Detection of Cows, Buffallos, Seeps and Goats Milk and Cheeses in Basra City ........................................ 1082
   Jalal Yaseen Mustafa

199. The Effectiveness of Chelating Property of Chitosan Nanoparticles on Dentin ................................ 1088
   Jamal A. Abu Al-timan, Hussain F. Al-Huwaizi, Hayder H. Abed

200. The Collaboration of Health Workers in Providing Integrated Antenatal Care at Oepoi Health Center, in East Nusa Tenggara, Indonesia .................................................. 1094
   Jeffrey Jap, Stefanus Supriyanto, Nyoman Anita Damayanti

201. The Role of Zinc Sulfate in Reducing Levels of TNF-\alpha, IL-1\beta and IL-6 in Multi Basiler Leprosy Patients ......................................................................................... 1099
   Joko Kurnianto, Moh. Sulchan, Kabulrahman, Hertanto WS, Suharyo HS, Prasetyowati

202. The Status of Her2 Expression in a Group of Iraqi Women with Cervical Carcinoma .................. 1104
   Kawakeb N Abdulla, Basim M. Khashman, Saba Jassim Alheshimi, Ameer A. Oudah

203. The Immunohistochemical Evaluation of BRCA2 Expression with HPV Infection in a Group of Iraqi Women with Cervical Carcinoma ..................................................... 1108
   Kawakeb N Abdulla, Basim M. Khashman, Saba Jassim Alheshimi

204. Prognosis Within 24 Hours Using Nursing Early Warning Scoring System (Newss) Method On Left Heart Failure Patients At Mitra Delima Hospital, Malang .............................. 1112
   Luluk Nur Aini, Lilik Supriati, Titin Andri Wihastuti

205. Descriptive Mapping of Needs among Diabetes Mellitus Patients ................................................. 1117
   Made Kurnia Widastuti Giri, Adnyana Putra, I Made Kusuma Wijaya, Komang Hendra Setiawan, Ni Putu Dewi Sri Wahyuni

206. Evaluation of Malaria Surveillance Based on Attribute in Health Office of East Sumba District ........ 1123
   Margaretha Domingga, Atik Choirul Hidajah
207. Low Level Laser Therapy on Postoperative Trismus and Swelling after Surgical Removal of Impacted Lower Third Molar .................................................................................................................................. 1129
   Marwah Safaa Ali, Sahar Shakir Al-Adili

208. Role of Betatrophin and Irisin on Diabetes Mellitus Type1 Management (Experimental Study) .......... 1135
   Maysaa J. Majeed, Zainab A. Razak Al-Sharifi, Shifaa Jameel Ibrahim

209. Correlation between LDL, HDL, LDL/HDL Ratio and Preeclampsia Incidence at RSUD Pamekasan, Indonesia ............................................................................................................................. 1139
   Mazdalina Rahmawandari Nurhani, Kusworini, Bambang Rahardjo

210. Evaluation of the Antibacterial Activity of Iraqi Garlic Derivatives to Escherichia Coli ....................... 1145
   Minen Al-Kafajy

211. Effect of Using Zirconia and Metallic Bar Attachment Overdentures on the Supporting Structures of Mandibular Edentulous Ridge Area (Randomized Control Trial) ................................................................. 1150
   Mohamed Z. Devis, Amr I. Badr, Emad M. Agamy, Gehan F. Mohamed

212. The Construction, Effectiveness and Reliability of Mental Health Inventory among Students in Malaysia 1156
   Mohammad Aziz Shah Mohamed Arip, Ainiyusnita Abdul Rahim, Umah Devi Muthu Panjasaram, Anne Christina Amaladass

213. Effect of Immersion Time in 2,5% Sargassumpolycystum Effervescent Granule Denture Cleansing Agent on the Stability Acrylic Resin Plate Colour .................................................................................. 1161
   Mohammad Dharma Utama, Harun Achmad, Ikhiriahi, Andi Adytha M.I.R., Anissa F

214. Assessment of Vascular Endothelial Growth Factor in the Iraqi Patients with Ovarian Cancer and its Correlation with Angiogenesis ................................................................................................................ 1167
   Mohammed Sharem Mahbool, Abdul Hussein Razzaq Ali, Jabbar Fadeel Mahdi Alafloogee

215. The Usage of Low Level Laser Therapy Bio Stimulation and Bone Grafting in Accelerating the Healing of Chronic Intra-Osseous Defects: Vivo Study ............................................................................. 1172
   Muhammed Abouel Seoud, MedhatKataia, Mouchira Salah El Din, Magdy Ali, Adel AboelFattouh

216. The Effect of Polyamide Micro-Particles Addition on Some Mechanical Properties of Heat Cured Poly Methyl Methacrylate Denture Base Material .................................................................................. 1178
   Mithaq R. Mohammed

217. Effects of the Use of Self-Directed Video on Knowledge of Malang City’s Volunteer Communities in Conducting CPR Actions .................................................................................................................. 1185
   Apriyani, Retty Ratnawati, Ika Setyo Rini

218. Determination of Reference of Concentration (RFC) from Hydrogen Sulfide (H2S) Exposure in the Community Based on Weight in Industrial Area in Medan Indonesia ............................................... 1191
   Citra Dewi Puspasar, Abdul Rohim Tualeka, Pudji Rahmawat, Syamsiar S. Rusen, Atjo Wahy, Ahsa

219. Sexual Risk Behaviour of Men Who Have Sex with Men (MSM) in an Urban Society of West Sumatera Province of Indonesia ........................................................................................................... 1197
   Hardisman Dasman, Firda Firdawati, Yantri Maputra, Ilma Nuria Sulrieni, Faiz Nur Hanum

220. An Exploration of Health Beliefs Related to Fluid-Restricted in Patients Undergoing Hemodialysis ... 1202
   Inda Rian P, Nursalam, Ninuk Dian Kurniawati
221. Determination of Dosage Reference (RfD) of Mercury Based on NOAEL and Characteristics of Workers in the Area of Unlicensed Gold Mining (PETI) Maluku Province Indonesia ......................... 1207
  Vaninda Eka Pridianata, Abdul Rohim Tualeka, Bacrudin Lain, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu, Ahsan

222. Using of Blended Learning in Improving Collaboration Skill of Nursing Students ............................ 1213
  Musrifatul Uliyah, Luthfiyah Nurtaela, Mustaji, Abdul Aziz Alimul Hidayat

223. Maternal and Fetal Determinants of Stillbirth among Women Who Attending Maternity Departments of Basra Central Hospitals ................................................................. 1218
  Nadeem R Shiaa, Sajjad S. Issa, bd AL Kareem H Subber

224. Spiritual-Based Family Care Models to Improvement Family Health with Leprosy at Jombang Regency of East Java Indonesia ................................................................. 1224
  Nasrudin, Ah Yusuf, Rachmat Hargono, Tjipto Suwandi

225. Determining Mercury Safe Concentration in Shells in the Unlicensed Gold Mining Area of Kayeli Village, Buru Regency, Maluku Province, Indonesia ................................................................. 1230
  Nesya Eka Ramadhani, Abdul Rohim Tualeka, Bacrudin Lain, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu, Ahsan

226. Synapsin-I Expression in the Rattus norvegicus Pup’s Brain from Rat’s Maternal Death Model .......... 1235
  Nur Maziyah Hurin’in, Hermanto Tri Joewono, Widjiati

227. Toluene Safe Concentration for Toll Gate Keepers at Kebon Jeruk, Jakarta Indonesia ......................... 1241
  Nur Vita Widianingrum, Abdul Rohim Tualeka, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu

228. The Effect of Fermentation of Oyster Mushrooms on Millet Grain of Healthy Japanese Quail Diets on Some Productive and Physiological Traits ......................................................... 1247
  Ola H. Abdul Ameer, Yasser J. Jameel, Mahdi A. Ali

229. Effect of Acylation, Esterification and Deamidation on Functional Properties of Camel Milk Caseins 1252
  Qausar Hamed ALKaisy, Jasim M. S. Al-Saadi

230. Implementation Program of Child Under 5 Years’ Growth and Development Problems in Bangkalan, Madura ................................................................................................. 1257
  Qurnia Andayani, Toetik Koeshardiati, Windhu Purnomo

231. Effect of Exercises Using Devices to Develop Some of the Motor Qualities and Offensive Basketball Skills 1263
  Rasha Talib dheyab, Omar Saad Ahmed

232. Implementation of Speech Therapy and Social Stories Increasing Social Interaction in Children with Autism ................................................................. 1269
  Retno Twistiandayani, Khoiroh Umah, Dede Nasrullah

233. Determination of Safe Sulfur Dioxide (SO₂) Concentration among Street Vendors of Ampera Bus Station, Palembang, Indonesia ................................................................. 1274
  Rizqy Kartika Sari, Abdul Rohim Tualeka, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu

234. The Influence of Training Handover based SBAR Communication for Improving Patients Safety ...... 1280
  Roymond H. Simamora, Achmad Fathi

235. Effects of Nigella Sativa Oil on Biochemical Parameters of White Male Rats Exposed to Diazinon .... 1286
  Rusul M. Alhilo, Hussain J. Kadhim, Mohammed T. Abbas

Abstract

Background: S. aureus is one of the most common human pathogens and is capable of causing a wide range of infections. Although primary S. aureus infections are not familiar, a great deal of the virulence from this bacterium occurs through cross-infection by spread from patient to patient in hospitals and other institutional settings. In contrast, healthy individuals can be carriers of the organism but have a minimal risk of contracting an invasive infection caused by S.aureus, but

Aims and Objectives: To determine the nasal carriage status of the people working in the microbiology diagnostic laboratory with emphasis on MRSA.

Materials and Method: Swabs of both anterior nares of consenting persons were taken with a sterile swab & processed within 2 hours. Swabs were inoculated on Mannitol Salt Agar. The organisms grown were identified as S.aureus by using standard tests. Antibiotic susceptibility testing was carried on by a modified Kirby-Bauer method, whereas cefoxitin (30μg) disc was used to know the MRSA.

Result: A total of 80 healthcare workers with the age range between 20 and 60 years were screened. Out of 80 participants, 25 were nasal carriers of S.aureus. The S.aureus isolates were 100% sensitive to Gentamicin, Teicoplanin, Vancomycin and Cefoxitin, 80% susceptible to Ciprofloxacin and Linezolid, and 76% to Amoxyclav, 96% resistant to Penicillin, 84% Erythromycin and 76% Ceftriaxone.

Discussion: Nasal carriage rate of S.aureus amongst people working in the diagnostic microbiology laboratory of our institution was 31.25%. Of the 25 isolates of S.aureus, none of them were MRSA. So overall MRSA carriage rate was 0%.

Keywords: Nasal Carriage, S.aureus, MRSA, healthcare workers

Introduction

S. aureus is one of the most common human pathogens and is capable of causing a wide range of infections. Although primary S. aureus infections are not familiar, a great deal of the virulence from this organism happens through cross-infection by spread from one patient to another patient in hospitals and other institutional settings. In contrast, healthy individuals who can be the carriers of S.aureus have a small risk of contracting an invasive infection caused by the same, but they can be carriers of the organism. Because its primary habitat is moist squamous epithelium of the anterior nares, most invasive S.aureus infections are assumed to arise from the nasal carriage. The incidence of community-acquired and hospital-acquired S. aureus
infections has been rising with the increased blooming of drug-resistant strains named methicillin-resistant S. aureus (MRSA).3,4 MRSA is a confirmed pathogen in most health care facilities. Initially limited to hospitals, MRSA infections have been progressively reported in the community.5,6 A recent meta-analysis of 27 studies on the occurrence of CA-MRSA among hospital patients that used clinical specimens, as opposed to surveillance cultures performed at the time of admission, yielded a predominance of MRSA of 30.2%.7 Various studies have examined community prevalence of nasal carriage of S. aureus in multiple subpopulations, such as college students, adult outpatients, health care workers, and injection drug users.8,9 The predominance of S. aureus varies from 20% to 45%, with an estimate of 1.3% of MRSA colonization from 10 community surveillance studies.10 However few studies have focused on which individuals are most possibly to be colonized with S. aureus and which are most likely to have MRSA specifically. These are tasks that may be very useful to the clinicians when trying to decide the possibility that a given patient has a staphylococcal infection and, if so, whether antibiotic coverage should be provided for resistant strains.11 No previous studies of S. aureus carriage in the healthy population in India have been reported. This study has been designed to see the nasal carriage status of people working in the clinical microbiology laboratory of our institution. As they have been exposed to S. aureus and MRSA in particular while processing the clinical samples, the possibility of colonization by the same can’t be ruled out. Further, in this study, we would like to probe to see the role of clinical laboratory personnel transmitting MRSA from hospital to community.

Materials and Method

The study was conducted in the microbiology diagnostic laboratory of a Coastal Karnataka Medical College, India. All consenting people working in a microbiology laboratory were recruited into the study. The study proposal was submitted to the ethical review committee of the Institution for approval. The age, sex, work category, designation, duration of stay in the laboratory, and other relevant information about the participants were obtained in a pro forma designed for this purpose. Swabs of both anterior nares of consenting persons were taken with a sterile swab stick moistened with sterile physiological saline. Processing of the samples was done immediately within 2 hours after collection. The swabs were cultured onto Mannitol Salt Agar (MSA), and the inoculated MSA were incubated at 37°C for 18-24 h. The growth of the organism was identified as S. aureus by using standard tests, such as colony morphology, Gram stain, catalase test, coagulase test, and DNase test.12 The isolated strains of S. aureus were screened for methicillin resistance by modified Kirby-Bauer method using cefoxitin (30μg) disc on Mueller-Hinton Agar (MHA).13 The MHA on which cefoxitin is placed were incubated aerobically at 37°C for 18 h. Isolates with inhibition zone diameter ≤21 mm around cefoxitin disc were considered as MRSA strains.14 Antibiotic sensitivity to all S. aureus isolates against other antibiotics like penicillin, erythromycin, clindamycin, chloramphenicol, co-trimoxazole, ceftriaxone, gentamicin, Amoxicillin/clavulanic acid, linezolid, teicoplanin, and ciprofloxacin was determined by modified Kirby-Bauer method. All inoculum was adjusted with a density equivalent to a 0.5 McFarland turbidity standard from pure isolates in Muller Hinton broth incubated for 4-6 hours. S. aureus ATCC 25923, MRSA ATCC 29213, MSSA ATCC 33591 were used as control. The antibiotic discs were procured from HiMedia Laboratories Pvt. Limited, India. Antibiotic sensitivity testing and result interpretation were done according to CLSI guidelines.15

Statistical Analysis

Results were compelled and tabulated, and all data were subjected to SPSS version 16.4 software statistical package for analysis.

Results

A total of 80 healthcare workers with the age range between 20 and 60 years were screened. Distribution of the participants was depicted in Table 1. Age-wise 42 (52.5%) of the participants were less than 25 years of age. Gender wise 65 (81.25%) were females. Designation wise 53 (66.25%) were students. The nature of the organisms isolated was depicted in Figure 1. Coagulase-negative Staphylococcus (CoNS) was the predominant organism isolated 58.75% (48) followed by S. aureus 31.25% (25). But none of the S. aureus was found to be MRSA. The antibiotic susceptibility pattern of S.aureus was illustrated in Figure 2. The strains were 100% sensitive to gentamicin, teicoplanin, vancomycin, and oxacillin. 80% sensitive to ciprofloxacin and linezolid. And the isolates were shown 96% resistant to penicillin,
84% resistant to erythromycin, 76% to ceftriaxone.

Discussion

The anterior nares of humans found to be the primary ecological niches of *S. aureus*16. The carriage patterns are of three types. Approximately 20% of the individuals almost always carry a kind of strain, and they are called persistent carriers. A large proportion of the population (60%) harbours *S. aureus* intermittently, and the strains change with varying frequencies. Such persons are called intermittent carriers. Finally, minorities of the people (20%) rarely carry *S. aureus* and they are called noncarriers. The reasons for these differences in the colonization patterns are unknown.17

It is necessary to detect the MRSA carriers among health care workers (HCWs). These individuals act as a potential source of infection to susceptible people, causing community-acquired and nosocomial infections. The best methods which can be used for controlling this are a regular screening of the HCWs and taking the appropriate preventive measures. The prevalence of MRSA varies between institutions and geographic areas. The differences in the study design, such as the sample size and the method which is employed for MRSA detection, may account for the disparity in the carriage rate.

Nasal carriage of *S. aureus* amongst people working in the diagnostic microbiology laboratory of a medical college of coastal Karnataka, India, according to the results of this study was 31.25%. Out of 25 isolates of *S. aureus*, none were MRSA positive. So the overall MRSA carriage rate was 0%. In contrast, 25 persons (31.25%) were nasal carriers for MSSA. The MRSA carriage recorded in this study was lower when compared to 1.8% obtained among healthcare workers in Southern India.18 We have effectively functioning Hospital Infection Control Committee policies, which may be
responsible for the absence of MRSA carrier state among the people working in the diagnostic microbiology laboratory in spite of handling vast numbers of MRSA as clinical isolates and hence the same practice should continue. The zero prevalence of MRSA nasal carriage in the healthy population appears to contrast with the diverse dissemination of MSSA.

Mannitol Salt Agar was found to be very useful for the quick identification of S. aureus. However, the option of using oxacillin blood agar for selective isolation of MRSA is always helpful. Usage of cefoxitin discs was found to be convenient over that of oxacillin discs for the determination of MRSA.

**Conclusion**

In conclusion, S. aureus carriage status of people of microbiology diagnostic laboratory in a medical college of coastal Karnataka was 31.25%. In that MRSA carriage rate was zero. The existing control policy in our hospital seems to be effective, and the same should be maintained.

Sanitation and Hygiene Practices and their Determinants among the Rural Population of Vikarabad

Chandrasekhar Reddy Bolla¹, A. Revanth Kumar², Rajeshwar Rao Alwala³, Pavani Tunga⁴

¹Associate Professor, orcid-0000-0001-5146-0566, ²Assistant Professor, orcid-0000-0002-6980-4088, Department of Community Medicine, Santosh Medical College, Ghaziabad, Uttar Pradesh, ³Professor & HOD, ⁴Under Graduate Student, Department of Community Medicine, Mahavir Institute of Medical Sciences, Vikarabad, Ranga Reddy, Telangana

Abstract

Background: Sanitation is the basic & fundamental requirement to maintain good health. Poor sanitation and hygiene are linked to various diseases like, communicable diseases, diarrheal disease, worm infestation, etc., which are preventable. A remarkable reduction in the nations mortality & morbidity rates are possible by adopting sanitation and hygiene practices by the people. Various interventions have been formulated in India to establish proper sanitation and measures to monitor level of awareness among the people and their active participation is very essential. Objectives: To know the Knowledge, Attitude and Practices regarding sanitation and hygiene and their determinants, to know the proportion of population with and without sanitary latrines and to find out the extent of Open-Air Defecation practices and its determinants in the study area.

Methodology: A household based cross-sectional study was conducted in the Rural field practice area of a Medical College, Vikarabad from February to July 2018. Out of 488 households in Gottimukla village, 97 houses were earmarked for the study by systematic Random sampling method and information was collected from any resident available at the household at the time of visit. A pretested semi-structured questionnaire was used for data collection. Results: Majority (61.9%) of the participants had knowledge about Swatch Bharat Abhiyan. About 64.9% had better knowledge regarding Sanitation and Hygiene. Nearly 74.2% felt that maintaining good hygiene is important to stay healthy and to be free form sickness. A greater proportion of the study participants (91.8%) were disposing the solid waste in open drains though they had good knowledge and willingness it was not reflected in their practice. Conclusion and Recommendations: The villagers had ample knowledge and positive attitude regarding sanitation and Hygiene, but failed to apply the same in their practice. It can be overcome with repeated Awareness programmes to the target population.

Keywords: Hand wash, Hygiene, Open air defecation, Sanitary Latrines, Sanitation, Swachh Bharat Abhiyan, Water storage.

Introduction

Sanitation is one of the basic determinants of quality of life and human development index.¹ It is a fundamental requirement to ensure safe health, environment and the overall wellbeing of the society. Unless proper, functional sanitation facilities are in use complemented with the right types of hygiene behaviors, communities will be vulnerable to recurrent incidences of water and sanitation related diseases.² Poor sanitation and hygiene have been linked to specific negative health outcomes, including diarrheal disease.³ Although preventable and treatable, diarrheal disease remains the second leading cause of death in children under age five worldwide, resulting in approximately 5,25,000 deaths annually.⁴ Furthermore, observational data has shown an association between childhood diarrhea and height; interventions that encourage fecal containment are associated with reductions in diarrheal...
Given the scale and scope of these adverse effects, the UN had included sanitation as one of its Millennium Development Goals. Approximately 15% of the global population – nearly about 1 billion people – openly defecates and in India alone nearly 60% of its population practices open defecation. The problem is most acute in rural regions and the northern states, where about 70% of them openly defecate. Unsafe drinking water, poor hygienic conditions and improper disposal of human Excreta and refuse is one of the prime concerns in India. Sanitation and hygiene practices are heavily influenced by people’s knowledge and attitude towards it. The effects of poor sanitation seep into every aspect of life – health, nutrition, development, economy, dignity and empowerment. The Government had implemented many programmes like Central Rural Sanitation Program (CRSP) Total Sanitation Program (TSP), Nirmal Bharat Abhiyan (NBA). The NBA campaign was short-lived, as new Prime Minister Narendra Modi replaced it in October 2014 with the Swachh Bharat Abhiyan (SBA) or “Clean India Mission.” Prime Minister Modi updated the goal, calling for an Open Defecation Free (ODF) India by 2019.

In a study done by Kishore Yadav et al., the knowledge regarding Swatch Bharat Abhiyan was among 62.2% among rural people of Nalgonda district.

Defecating in the open is a very ancient practice. In ancient times, there were more open spaces and less population pressure on land. With development and urbanization, open defecating started becoming a challenge and thereby an important public health issue, and an issue of human dignity. People may choose fields, bushes, forests, ditches, streets, canals or other open space for defecation. They do so because either they do not have a toilet at home or due to traditional cultural practices.

In a cross-sectional study in rural area of Maharashtra people were afraid of getting diseases by consuming contaminated food and water by the fecal matter due to open air defecation (34.7%).

The findings of the study by National Sanitation and Hygiene Knowledge, attitudes and Practices (KAP) survey - final report, the respondents associated sanitation and hygiene was, (i) hand hygiene/cleanliness (72.4%), (ii) clean, safe water (71.5%), (iii) food hygiene/cleanliness (45.3%), (iv) personal hygiene (35.7%), and (v) general hygiene/cleanliness (31.3%). In a study by Rafiq Mohd et al., 92.9% of the respondent’s perception of clean house was the criteria for good sanitation.

With this background, an endeavor was made to assess the knowledge, attitude and practices regarding sanitation and hygiene and their determinants among the residents, proportion of population with and without sanitary latrines and find out the extent of Open Air Defecation practices and its determinants in the study area.

Materials and Method

A cross-sectional study was conducted from February to July 2018 in Gottimukla village, which is the rural field practice area of a Medical College, Vikarabad, Telangana State. Out of 488 households in the village, every fifth house was selected using systematic Random sampling method and a total of 97 houses were earmarked for the study.

After obtaining approval from the Institutional Ethical Committee, a formal permission was taken from the concerned authorities in the selected locality. An informed written consent was taken from the participants prior. Mentally challenged persons and those not consenting were excluded.

Information on Socio-demographic characteristics and existing knowledge, attitude & practices regarding sanitation and hygiene (along with sewage disposal and disposal of human excreta) were collected using a pretested, semi-structured questionnaire.

The data was compiled and analyzed in IBM SPSS Vr. 16 (Trial) and results shown in the form of tabulation and graphs.

Findings

Table 1. shows demographic profile of the study participants. The mean age of the study participants was 35.28. Among them, majority were youth (62.9%) followed by middle aged participants (25.8%) and very few old aged participants (11.3%).

Most of the study participants were males (81.4%) and majority of them were Hindus (93.8%). Majority of the respondents (90.7%) were found to be unemployed suggesting those were the ones present at home during the data collection.
Greater number of the study participants were Literates (52.6%) and 24.7% of them were graduates. Socio-economic status of majority of the study participants (84.5%) was Medium to High class. Nearly 53.6% were from nuclear families and 46.4% from joint Families.

Most of the households had sanitary Latrines (83.5 %).

Table 2 shows knowledge Attitude & Practices among the participants:

Knowledge: Among the participants about two thirds of them (64%) had knowledge regarding the importance of Sanitation & Hygiene and 61.9 % had knowledge regarding the Swatch Bharat Abhiyan Programme. Nearly 44.3% had knowledge regarding environmental hazards of Open Defecation (OD).

Attitude: Greater number of the study participants (80.4%) was willing for the proper disposal of solid waste and faeces to maintain cleanliness in the house. Nearly 78.3% of the study participants had a positive attitude regarding hand washing before taking food and after defecation. Among the study participants 74.2% think that maintaining good hygiene is important to stay healthy and to be from sickness. Among the study participants very few (14.4%) had a positive opinion on pretreatment of water before drinking.

Practices: Majority of study participants (91.8%) were disposing the solid waste in open drains; though the participants appeared to have good knowledge and willingness but it was not reflected in their practices.

Nearly 89.7% were cleaning water stored containers daily or on alternate days and 85.6% of them were drinking water without any pretreatment where as 81.4% of the study participants were using sanitary latrines. Source segregation of solid waste was followed by 75.3% of the participants. Hardly 38.1% of the participants washed their hands with water with soap.

Table 3. shows association of various demographic variables with the participants’ practice of open defecation. Literacy, occupation, Age, Family Type and Socio-economic status were found to be determinants for Open Defecation. Higher literacy, occupation, nuclear family, higher class of SES were major deterrents for the practice of Open Defecation.

Nearly 29.9% of the study participants were not using the sanitary latrines due to lack of provision of water. Some of the participants (25.8%) preferred not to answer the reason for not using the sanitary latrines, whereas 3.1% felt it’s an extra work for maintenance of sanitary latrine (Chart 1).

Nearly one third of the study participants (33%) responded that lack of money and space were the reasons for not constructing sanitary latrines. About 1% of the study participants responded that staying in rented house was the reason for not constructing sanitary Latrine (Chart 2).

Discussion

In the present study the knowledge on Swatch Bharat Abhiyan among the study participants was (61.9%) which correlates to the study done by Kishore Yadav et al., which was (62.2%) among rural people of Nalgonda district.

Nearly 35.1% of the study participants in the present study didn’t know the terms sanitation and hygiene and their importance and 20.6% of the study participants answered that sanitation and Hygiene reflects food hygiene and cleanliness. Some of the study participants felt that clean and safe water (14.4%), proper disposal of solid waste (11.3%), Hand Hygiene /cleanliness and safe disposal of waste (4.1%) reflects the sanitation and Hygiene. Among the participants 7.2% felt all the above variables can be considered for sanitation and Hygiene.

In contrary the findings of the study by National Sanitation and Hygiene Knowledge, attitudes and Practices (KAP) survey Final report, the respondents associated sanitation and hygiene with (i) hand hygiene/cleanliness (72.4%), (ii) clean, safe water (71.5%), (iii) food hygiene/cleanliness (45.3%), (iv) personal hygiene (35.7%), and (v) general hygiene/cleanliness (31.3%).

In the present study 80.4% of the study participants had positive attitude regarding clean house and proper disposal of solid waste and faeces is important, similar findings were observed in the study by National Sanitation
and Hygiene Knowledge, attitudes and Practices (KAP) survey Final report, to maintain good hygiene, 85% thought keep the house and 40% considered it was about disposing adult and infant faeces safely.

In the present study 41.2% of the study participants were not using sanitary latrines due to lack of awareness and 29.9% due to lack of water in contrary with the study by National Sanitation and Hygiene Knowledge, attitudes and Practices (KAP) survey Final report findings indicate that of the 3.8% who said that their latrines were not useable, the most common reasons given were (i) latrine was full (33.3%), (ii) broken or missing superstructure (22.2%) and (iii) other reasons (33.3%).

In the present study 33% of the study participant’s responded lack of money and space were the reasons for not constructing sanitary Latrines unlike the findings of the study by National Sanitation and Hygiene Knowledge, attitudes and Practices (KAP) survey Final report 70.4% of the household respondents did not have latrines mainly because they did not have money to buy one and the perceived cost of building a latrine as too high.

**Conclusion**

The present study was done to get the baseline information on the present knowledge, attitude and practices of sanitation and hygiene among the people of rural Vikarabad.

It was observed that even though the villagers had ample knowledge and positive attitude regarding sanitation and Hygiene, the researchers perceived failure in their practice. It can be overcome with repeated Awareness programmes to the target population.

Though the findings of the current study may not be exhaustive, yet, the villagers surveyed represent an important subgroup of the entire rural population and the information generated will be useful in the planning of future Sanitation and Hygiene education programmes in rural and urban slums.

**Conflict of Interest:** No conflict of interest.

Parental Alcoholism - Psychosocial Problems Faced by Adolescents

Chinnu Sebastian¹, Suja M.K²
¹PhD Scholar, ²Associate Professor, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract

Introduction: Alcoholism is a family disease; its affects everyone in the family. There are many psychosocial factors that are connected to alcoholism. Parental Alcoholism causes many family issues and the relationship between the family members is hampered due to this and in turn affects the psychological and social development of the children. Recently, schools have drawn attention on alcoholism of parents as one of the dominant factors for the psychosocial development issues of students. Parental drinking increases health risks in children and adolescents. Such risks include diminished intellectual capacity and development, increased neuroticism and a wide range of psychosocial and behavioural disorders.

Aim: This research work has made an attempt to study the psychosocial problems faced by adolescents due to parental alcoholism. This study sought to measure the level psychosocial problems and significant factors associated with psychosocial problem of adolescent students of Kottayam district of Kerala, India. Results: More than half of the respondents (57%) have moderate level of psychosocial problems. The study reveals that psychosocial problems are more in female children and religion has no significance in this matter. 27% of the respondents were severely affected by the parental alcoholism and out of this 87% were girls. Conclusion: This research gives us a clear picture of the consequences that could happen to the children of alcoholic parents. The researcher sees that alcoholic parents have strong influence on their children’s future. Physical, psychological, educational, economical, social and developmental issues can be counted as the major problems of the children of alcoholic parents. Children can’t do anything to control the alcohol consumption of their parents. Then only possible way in front of them is to discuss their issues with a trusted elder person. In school children a school counsellor can help them in offering good service, advice and self motivation practices to overcome the difficult experiences.

Keywords: Parental Alcoholism, Adolescents, Psychosocial problems.

Introduction

Alcoholism or alcohol dependence is defined by American Medical Association (AMA, 1956) as “a primary, chronic disease with genetic, psychosocial, and environmental factors influencing its development and manifestations”. In our country, alcoholic fathers outnumber alcoholic mothers. In Kerala it is socially accepted to drink alcohol during a public function, to appear drunk in public or the smell of alcohol is not considered as a serious matter¹. It is an accepted norm and no one cares about it as a social issue except when it affects the family and work. According to the National Council on Alcoholism and Drug Dependence (NCADD, 1987) alcoholism affects about 18 million adults in the U.S. Approximately 26.8 million children are exposed to alcoholism in the family and 6.6 million children age 18 and younger live in households with at least one alcoholic parent². These children are the unwilling victims of a disease which generally is the centre of their childhood existence and therefore shapes their personality and behaviour as adults.

Alcoholism is referred to as a family disease. Great awareness on the ill effects of alcoholism of different walks of life like job, health, family, mental and social status is being given and the awareness level is seemed to be increasing. From the researcher’s interaction with
the adolescents it was known that marital and family problems start due to alcoholism. It is also seen that children are more affected than the spouses since they are in the development phase. Children always suffer when they share a house with an alcoholic parent. There can be a real sense of shame and they always spend a lot of time living in fear. Many times the children of alcoholics have endured verbal abuse by way of harsh criticism and unfair judgement from a drunken parent. Children of alcoholic homes are at more risk to be a victim of physical, mental and sexual abuse. Parental alcoholism has a great impact on the overall development of a child and the living circumstances, where any one or both of the parents consume alcohol on a regular basis.

Adolescence is the transitional stage of development between childhood and adulthood, representing the period of time during which a person experiences a variety of physical, sexual, cognitive, social and emotional changes. Stanley Hall (1904) denoted this period as “Storm and Stress” and states “conflict at this developmental stage is normal”. During 10-19 years age group adolescents suffer from various forms of problems and conflicts. The behaviour of a child depends on social, biological and environmental factors and these variables contribute a lot to the growth and development of a child both mentally and physically. Children of alcoholic families develop a kind of behaviour which is disgusting to the adults and these children are also seen as introverts. Their adjustment pattern is very poor and most of them have a negative attitude towards life circumstances. Family support is the main factor for a child personality development. The quality and nature of the love, care and nurturing environment which the child receives is reflected in the whole life of that child. Schools also have a vital role in moulding a child because they spend most of their time in the school during their adolescent period. School is an organization where the overall development of a child happens because there he gets to mingle with the peers and teachers and he/she also learns the habit of social living. The “we feeling” and sharing mainly comes to his/ her mind from the school. Hence school plays a vital role in the overall educational, social and personality development of an adolescent.

Children of alcoholics are more likely than their peers to have problems in education, to be learning difficulty, lack of concentration & interest in studies, absenteeism, not getting desired marks, family economic problems and can’t submits school fees on time, restlessness and lack of aptitude for studies.

Parental alcoholism may have both short- and long-term negative consequences for adolescent’s psychosocial problems. Almost all adolescents from alcoholic families are at greater risk of poor psychosocial problems and adjustment. They experience an emotional consequence including mistrust, guilt, anger, shame, confusion, fear, insecurity, ambivalence, and stress, loss of self-esteem, anxiety, depression, suicidal thoughts and sexual conflict. This type of emotional experiences can led to eating disorders, bipolar disorders, drug or alcohol dependence and sociopathic, such as antisocial personality disorder. Social problems that adolescent’s faces are difficulty to mingle with opposite sex, poor peer relationships, no participation in culture activities, absence of good friends and lack of sociability.

The researcher visited a number of schools and interacted with school counsellors to get more knowledge about the effect of parental alcoholism in children. However it was difficult to find out the adolescents whose parents were addicted to alcohol. With the help of counsellors, researcher screened the students whose parents were addicted to alcohol. Researcher interacted and motivated them to participate in the study on “Parental Alcoholism - Psychosocial Problems faced by Adolescents”.

**Methodology**

This paper is based on the interview and discussions conducted with adolescent students in a school counselling centre of Kottayam district which belongs to rural area of Kerala, India in the year 2018. School counselling centre is a project under the psychosocial service scheme of the department of women and child development, Kerala Government. An interview schedule was used to collect data and the research is descriptive in nature. Total survey method is used to collect the samples. The criterion for selecting the respondents was that they were the beneficiaries of this counselling centre. They were facing various problems like abuse, parental issues, broken family etc. Among the 70 students 30 were having problems due to parental alcoholism. The researcher enrolled all 30 students for the study. It is otherwise known as Total population study. Analysis was done by simple percentage and Chi Square test.
**Major Findings:**

The simple percentage of socio demographic data reveals the following information. It is seen that 43% of the respondents are in the 13-15 years age group. 40% of the respondents are studying in high school classes and half of them are severely affected due to parental alcoholism. They were always conscious about their higher studies and future. The family issues or quarrel between the parents and physical abuse made them unable to concentrate in the studies. They also started to think about suicide.

53% of the respondents are female students, the study also identified that the severity of psychosocial effects of parental alcoholism in seen more in girls (87.5%). This huge difference in severity in the gender is due to the culture of restrictions on the activities of girls as they were in a puberty state and they didn’t have any way to release their feeling as their parent’s drink daily. Male children go out and play with their peer group, interact and involve in other social activities which helped them to reduce the burden of problems.

Nearly half of the respondents (40%) are in the first birth order and psychosocial problem is seen more in them as they have to take up alternate roles as mother or father to the younger siblings. Fathers of 33% of the respondents and mothers of 30% of the respondents have 10th standard education. The study revealed that the intake of alcohol and domestic violence were much higher in illiterate and matriculate parents than graduate parents. Half of the respondent’s fathers are coolie workers and mothers of 43% are unemployed. The researcher identified that only 2% of the mothers of the respondents were consuming alcohol and only during family celebrations. So mother’s alcohol consumption does not affect the psychosocial elements of the respondents. 57% of the respondent’s fathers are regular or daily drinkers. This lead to inability in playing school fee on time and this severely affected the student’s psychological wellbeing. They were unable to concentrate in their studies, worrying about their career, future. They also found it difficult to interact with classmates. Majority of the adolescents fathers (70%) quarrel at home after drinking. This affects their studies, they feel stigma to have social interaction and they also don’t have a healthy family atmosphere to flourish and grow.

Most of the adolescents (57%) are from nuclear family. These students are not able to spend good quality time with their family members mainly with their parents. This results in the lack of proper parenthood and related care. The role of grandparents is also very important in the development of a child. Earlier in joint families the unconditional love that was given by grandparents is not seen as the families because nuclear now a days. This care and love given by grandparents is also the main ingredient in the development of self esteem, self reliability, and efficiency and also contributes for the proper psychosocial development. Earlier it was joint families which helped a lot the family members to share the feelings with each other. The psychosocial problem faced by the adolescents is because of the fact that they are unable share their feeling. They also hesitate to share the feeling with their peer group. This causes loneliness and social isolation.

**Levels of psychosocial problems**

More than half of the respondents (57%) have moderate psychosocial problems. 27% have severe psychosocial problems and only 16% have mild psychosocial problems. The research throws light on the fact that psychosocial problems of majority of the adolescents are at the moderate level. A smaller group has severe psychological problems. This group has to be taken care of else this can lead to psychosocial maladjustments in the future.

The role school counsellor- The Kerala Social Welfare board has appointed qualified school counsellors in all government schools to give counselling and to conduct various awareness programs, to identify the psychosocial problems of children of all age groups. Secondly, parenting a child is an equal responsibility of a father and mother but if father is an alcoholic mother have to take more responsibility. This adds stress and strain on the mother and affects her psychological health also. Third, social support- peer support, local libraries, neighbours and religious support also plays an important role to overcome the psychosocial problems of adolescents due to parental alcoholism.

**Factors affecting the psychosocial problems**

The study reveals that psychosocial problems affect the female adolescents more than the male. There is no significant relation between age of children and
alcoholism in parents or religion and alcoholism. In the counselling session with the severely affected respondents it is seen that the family condition, income and family status of both girls and boys were almost similar, however the boys has more freedom in their home and society as compared to the girls. So the boys could go out and playing games talk with friends or share their feeling with close friends. In the case of girls they used to find solace in reading books, watching Television and playing indoor games with siblings. This shows that unwritten code of ethics imposed on girls by our society. Curtailed by the family as well as society to do the activities they like the girls keep their problems themselves and suffer in silence. Hence they spent more time in their home. It is also seen that the girls are facing harassment from their drunken father. The school counsellor is like a breath of fresh air to these girls. They find the counsellor as a person who would listen to them without bias.

Discussion and Conclusion

The study finds that the psychosocial problems of adolescent’s are at moderate level. But 27% of the respondents were severely affected with the parental alcoholism and out of this majority are girls. Students who were severely affected due to parental alcoholism are counselled frequently. Counselling sessions were conducted to the parents also. They were given awareness on the side effects of alcohol, health issues and psychosocial problems faced by children due to parental alcoholism. Counsellor refers the alcoholic parents to the de-addiction centre and gave necessary psychological support to the students. Legal interventions are also provided when required.

Children of alcoholic parents need attention and counselling and sometimes therapies to overcome their problems. The best therapy that can be given is emotional care and support. The school counsellor can contribute a lot in these areas and the counsellor can find appropriate resources for the child. Teachers also in other hand are the backbone of a child during his/her adolescent life. The teacher can also give moral and educational support and can give a special attention to these children. Classes and counselling session to be conducted in these groups and effective participation of the members to ensured. Other methods are practicing relaxation techniques (yoga, meditation), self-care (eating nutritious food, proper sleep, taking a warm bath) develop hobbies, involve in extracurricular activities, journaling to express thoughts and feelings and get regular physical activity. Successful interventions are most likely to be those which foster more effective communication among family members and reduce anxiety and depression through recapturing an atmosphere of cohesion and support.

Abstract

Background: Various curettes and lasers are used in periodontal therapy. Although curettes and diode laser have their own shortcomings compared to Er,Cr:YSGG laser, adequate evidence comparing their effects on root surface morphology and change in root surface composition is lacking.

Materials and Method: 7 periodontally compromised teeth were extracted, cut into 27 specimens and divided into 3 groups. All the groups were instrumented by Gracey curettes and the other groups were irradiated by diode and Er,Cr:YSGG laser respectively. SEM was employed to check the presence or absence of smear layer, roughness of tooth surface and loss of tooth substance. EDAX software was used to check the compositional changes.

Results: SEM results show that the groups where Er,Cr:YSGG was used as an adjunct, showed the least presence of smear layer, the roughest surface and most loss of tooth substance. EDAX results show that the most inorganic content in the Er,Cr:YSGG group.

Conclusion: Er,Cr:YSGG causes greatest amount of surface alteration. Its ability to ablate the smear layer without causing any changes in the composition at the structural level makes Er,Cr:YSGG a safe and effective adjunct in non-surgical periodontal therapy.

Clinical relevance: Er, Cr:YSGG is an excellent treatment modality to gain new attachment.

Keywords: Scaling and Root Planing, curettes, Diode laser, Er,Cr:YSGG laser, Scanning Electron Microscope.

Introduction

The focus of periodontal treatment is to eliminate pathogenic microorganisms, thus halting disease progression. A successful treatment outcome necessitates a thorough removal of plaque, calculus and diseased cementum. Scaling and root planing (SRP) are fundamental treatment modalities to achieve a disease free periodontium [1]. Many different modalities have been implemented to perform SRP.

Curettes are still considered the gold standard for performing SRP [2]. However, the use of curettes is limited by their difficulty in instrumenting at areas with compromised accessibility such as furcation defects and deep periodontal pockets; patient discomfort; requirement of exemplary operator skill to achieve a...
favourable treatment outcome \(^2,^3\). A smear layer is also generated during manual scaling, which compromises periodontal tissues regeneration \(^4\).

Usage of ultra-sonic scalers are easy, drastically reduce the patient chair time thus improving the overall clinical efficiency and outcome. However, power driven instruments may cause transient sensitivity and the noise and vibration generated have reportedly caused acoustic discomfort to some patients \(^5\).

Various laser devices have been used in periodontal therapy \(^5,^6\). Areas in the periodontal pocket like furcation septae or the concave root which are inaccessible to manual and ultrasonic instrumentation can be irradiated by laser energy via flexible and thin fibers \(^7\). It has been reported that laser irradiation has bactericidal and detoxification effects without producing a smear layer; therefore, the laser-treated root surface may provide favorable conditions for connective tissue attachment \(^8\).

Several different wavelengths of lasers can be used in periodontics. These include such as Er,Cr:YSGG (2780 nm) and diode lasers (810nm). With wavelength of diode laser the penetration into biological tissues is relatively high, approximately 0.5-3 mm \(^9\). So any accidental contact of laser energy to the root surface can lead to severe and irreparable damage to the root surface morphology and the pulp. There is no concrete evidence of the root surface morphology after diode laser treatment.

In the latter half of 90s, various literature had found the wavelength of erbium, chromium: yttrium-scandium–gallium–garnet (Er,Cr:YSGG) laser to be beneficial in periodontal therapy as it can be safely and effectively used on both hard and soft tissues. Dental calculus can also be removed by Er,Cr:YSGG laser \(^6\).

Materials & Method

This study was conducted in-vitro. 7 single rooted teeth affected with severe periodontitis and which were determined to have hopeless prognosis were extracted. Atraumatic extraction was done with the root surface remaining intact. Immediately thereafter distilled water was used to clean the teeth. They were stored in phosphate buffered saline, pH 7.4 at 37\(^o\) C until further procedures were carried out.

The cervical 3rd of the roots were marked with 2 parallel grooves with the 1\(^st\) groove made at the Cemento-Enamel junction and the other 5 mm apically from the 1\(^st\). Using a slowly rotating diamond bur the roots were cut along the 2 grooves. The resultant disc formed was cut bucco-lingually and mesio-distally. This resulted in 4 specimens per tooth of a size averaging (2X2) mm.

Specimens were randomly divided into 3 groups of 9 specimens each:

**Group I**: specimens instrumented with gracey curettes

**Group II**: specimens instrumented with gracey curettes followed by diode laser application (810 nm) (Picasso, AMD lasers) in noncontact mode (approximately 1 mm away from root surface) in linear motion at the power setting of 2 W for the time period of 30 s. Laser beam was maintained parallel to root surface.

**Group III**: specimens instrumented with gracey curetes followed by Er,Cr:YSGG with wavelength of 2.78μm and a sapphire tip (size 600μm; length of 4mm) with a frequency of 20 hz and 1.0 W power irrigated with 15% water and 10% air for 30 seconds(Waterlase, Biolase). The surfaces were scanned at an angle of 30\(^o\) to the surface in non-contact mode.

After treatment, the specimens were immersed in 2.5% glutaraldehyde in 0.1 M phosphate buffer (7.4 pH) for 24 hours. Increasing concentrations of ethyl alcohol (30%, 50%, 70%, 90% and 100%) were used to wash and dehydrate the specimens. They were air dried for the next 48 hours. Silver was sputter coated on the specimens for a thickness of 30-40nm after fixing them to SEM stubs.

The whole test surface of every specimen was initially scanned with SEM (Figure 1) to get a general idea of the surface profile of each specimen.

Sites which depicted maximum changes were focused and photomicrographs were standardized by obtaining them at a magnification of ×100 and ×500 for each specimen. (Figure 2)
Compositional changes of the roots of teeth in each group are assessed using EDAX software.

The following parameters were examined for each specimen:
- Presence or absence of smear layer
- Loss of tooth substance index (LTSI) \[^{10}\]
- Roughness loss of tooth substance index (RLTSI) \[^{11}\]
- Gross composition of root
- Composition of root at atomic level

**Statistical Analysis**

The statistical analysis was carried out using SPSS version 21.0. The presence or absence of smear layer is evaluated by using the Chi-Square test. To assess the significance of differences between the 3 groups regarding LTSI, RLTSI & compositional changes, the ANOVA parametric test complemented by the post hoc Tukey test was used. \( P \leq 0.001 \) is set for statistical significance.

**Results**

Figure 3 reveals that Group I showed the most amount of smear layer formation, while group III demonstrated the least.

Figure 4 reveals that Group III had the most loss of tooth substance as well as roughest surface of all.

Figure 5 reveals that Group III had the highest levels of calcium and phosphorous. Concurrently it’s been observed that the levels of carbon in that same group are the least across all groups.

Figure 6 reiterates the findings of figure 4A at the microscopic level.
Discussions

In this study the effects of manual scaling, diode laser & Er,Cr:YSGG laser on root surface have been evaluated. Parameters such as (i) presence or absence of smear layer (ii) roughness of tooth surface (iii) loss of tooth substance (iv) gross composition of root & (v) changes at atomic level have been analyzed.

In manual scaling gracey curettes have been used. The power of the diode laser was kept at 2W and root surfaces were instrumented for 30 seconds as Kreisler et al (2002)\cite{12} had analyzed the effects of diode laser irradiation at different power settings and time intervals and concluded that 2W is the threshold level at which carbonization occurs. The power setting of Er,Cr:YSGG laser is kept at 1W at 30 ° angulation for 30 seconds as Oliveira et al (2015)\cite{13} confirmed this is the optimum setting at which least alteration of the tooth surface occurs.

Analysis of the presence or absence of the smear layer (Figure 3) reveal that although there isn’t any significant differences between 3 groups but group III has quite a lower percentage of smear layer. These findings are similar to the results obtained by Theodoro et al (2006)\cite{14} and Oliveira et al (2010)\cite{15}.

Mechanical instrumentation causes smear layer formation. This is because the mineralized tissues are shattered to produce considerable amount of debris which instead of being shredded or cleaved, get spread over the surface to form the smear layer. Smear layer contains bacteria, their by-products and necrotic tissue and it acts as a substrate for bacteria to grow and survive. It also hinders periodontal attachment.

The diode laser acts by photothermic mechanism. Since the diode laser energy is poorly absorbed, only the surface temperature increases which ranges from 100°C to 400°C. This temperature rise removes the water & the organic matrix which are responsible for smear layer formation.

Er,Cr:YSGG laser acts by photoablative mechanism. The water molecules present between the hydroxyapatite crystals absorb the Er,Cr:YSGG laser energy better than diode laser. So both surface and the subsurface layer get superheated leading to controlled micro-explosions thus eliminating smear layer.

Analysis of the values of LTSI & RLTSI (Figure 4) reveal that Group II had the smoothest surface while Group III had the roughest. The results are similar to the outcomes got by Hakki et al (2010)\cite{16} and Oliveira et al (2010, 2015)\cite{13, 15} who analyzed the effect on root surface between manual scaling and irradiation by Er,Cr:YSGG using different power settings and angles thus concluding that the latter causes significantly more surface roughness and substance loss.

The curette removes a layer of root surface by scraping motion causing scratches, irregular roughness & flat notches on root surface which increases as the force and the number of strokes increase.

Diode laser has photothermic interaction with the mineralized tissue. The diode laser energy isn’t well absorbed by water or hydroxyapatite. This energy is converted to heat which increases the root surface temperature. The first chemical compound lost upon heating a tissue is water. Maximum degradation of collagen is seen around 320°C resulting in a relatively smoother surface.

The Er,Cr:YSGG laser photomechanically ablates dental tissue. This type of laser energy is well absorbed by water molecules present in the interprismatic substance which causes their rapid evaporation leading to controlled tissue microexplosions. Thus hydroxyapatite crystals are removed at much lower temperatures than their melting point. Following this, the ablated hydroxyapatite crystals coalesce together undergoing micro-recrystallization. This microablation and micro-recrystallization cycle is responsible for the formation of gross concave and convex surfaces. This rough surface is believed to help in the attachment of fibroblasts during resolution of periodontal pocket.

SEM-EDAX examination revealed that the
quantities of calcium and phosphorous (% weight & atomic weight %) increased from Group I to Group III while the quantity of carbon decreased (Figure 5 and 6). Although statistically not significant the increase in calcium and phosphorous weight % is thought to result due to evaporation of the organic components. Due to temperature increase substituent changes in the tissues are believed to occur.

The findings of this study are in accordance to a study by Kimura et al (2001) [17] who compared the calcium and phosphorous weight % between a control group and an Er,Cr:YSGG laser group. However the results of the present study aren’t in line with Hakki et al (2010) [16] who found that both calcium & phosphorous weight % had statistical significant differences when compared among the groups as well as when compared to a control. This maybe attributed to the fact of difference in the SEM-EDAX machines because even under the strictest conditions, the energy levels recorded by the detector is determined by the amount of interaction of the electron beam. The relative increase in the amount of calcium and phosphorous can be advantageous in reducing the solubility of hard dental structures. Hossain et al (2001) [18] had reported the increase in resistance to acids upon irradiation by Er,Cr:YSGG laser.

Progressive increase Ca/P ratio (weight as well as molar) is seen from Group I to Group III. This is because atoms other than Calcium decreased due to evaporation. But the increase being statistically non-significant it can be concluded that no chemical changes occurred at the molecular level. The findings are similar to the results obtained by Kimura et al [17] and Hakki et al [16].

Conclusion

The results of this study show that manual instrumentation generates highest amount of smear layer whereas Er,Cr:YSGG generates the least. The roughness and loss of tooth surface is highest when Er,Cr:YSGG laser is used adjunctively with manual instrumentation. There are no statistically significant changes in the gross composition as well as at the molecular level for all the 3 modes of instrumentation and hence it can be said that they don’t cause any structural damage.

So it can be concluded that although Er,Cr:YSGG causes greatest amount of surface alteration but its ability to ablate the smear layer without causing any changes in the composition at the structural lever makes Er,Cr:YSGG a safe and effective adjunct in non-surgical periodontal therapy.

Animal Bite Surveillance Data Quality at Primary Health Centres of Hassan District

G.M. Venkatesh1, C.R. Hiraniah2, M. Sundar3

1Associate Professor, Department of Community Medicine, Hassan Institute of Medical Sciences, Hassan, 2District Surveillance Officer, District Surveillance Unit, District Health System, Hassan, 3Professor & Head, Department of Community Medicine, Hassan Institute of Medical Sciences, Hassan

Abstract

Introduction: As animal bite surveillance provides the first step in identifying the need to prevent animal bite and rabies in humans, this study is undertaken to explore the quality of surveillance data available at primary health centres.

Material and Method: A Cross sectional study was carried out among the primary Health Centres of Hassan District, which has 8 talukas and 134 Primary Health Centres. Seven Primary Health Centres from each of the eight talukas across the district were visited and data was collected through record review and interview from the designated staff on a predesigned Proforma.

Findings: All 57 (100%) of the Primary Health Centres recorded the demographic information. None recorded the place of bite, 53(92%) recorded the animal biting the victim and 1(2%) of them tried to understand if the biting animal was rabid. However, 19(33%) of the centres classified the wound into 3 categories. Only 2(3%) of centres advised wound wash at the centre and 12(21%) offered antiseptic application but all 57(100%) the provided vaccine irrespective of category of bite and rig administration were done in none. Completion of PEP prescription was observed only in 35% of records. No action was taken to reduce the animal bite incidence at the population within the preview of Primary Health Centres

Conclusion: District Health Authorities should take measures to improve data collection for action and appropriate treatment of animal bite cases at primary health centres.

Key Words: Rabies, Animal Bite, Surveillance, Primary Health Centres

Introduction

Rabies is an acute encephalitis caused by a lyssavirus infection and is almost always fatal once clinical signs appear.2 3 The incubation period of the majority of cases is 1–3 months, 4 however an incubation period longer than 1 year has also been documented.3 Rabies viruses belong, the Rhabdo viridae family and is an un segmented, single-stranded, negative sense, enveloped RNA virus.6 All mammals are susceptible to infection by the rabies virus (RABV). Transmission of RABV by dogs is responsible for up to 99% of human rabies cases in rabies-endemic regions, with a small proportion due to transmission via wildlife (such as foxes, wolves, jackals, bats, racoons, skunks or mongoose).7 Globally an estimated 59 000 human deaths and over 3.7 million disability-adjusted life years (DALYs) are lost every year.8 An estimated 20,000 rabies deaths and 17.4 million exposures to animal bite occur every year in India.9 Rabies occurs mainly in underserved populations, both rural and urban, with approximately 40% of cases in children aged <15 years.10 The comparatively long incubation period provides an opportunity for highly effective PEP. Also thorough wound washing with soap or detergent and

Associate Professor, # 66 Doctors Quarters, HIMS, Hassan. PIN; 573201
e-mail: drvenkateshgm@gmail.com
water and/or viricidal agents reduces the viral inoculum at the wound site. Antibodies induced by post exposure vaccination lower the risk of RABV entering peripheral nerves after a bite from a rabid animal. Additionally, timely administration of RIG neutralizes RABV at the wound site. Prompt PEP following severe exposures is 100% effective in preventing rabies. However, delay in seeking PEP, improper wound care, unnoticed wounds, direct nerve inoculation, and lack of patient compliance with vaccination schedules, among other factors, contribute to PEP failure and subsequent death. Prevention of rabies relies heavily on the awareness of at-risk populations about the disease. Efforts to promote awareness should include education, engagement with relevant sectors on animal bite prevention, responsible dog ownership and prompt first aid after exposure. WHO and its partners have endorsed a target of Zero Human Rabies Deaths from dog-transmitted rabies by 2030 (Zero by 30). Which requires accurate data for setting regional, national and local priorities for control programmes. Surveillance covering rural and marginalized populations, with emphasis on improving PEP utilization and patient compliance with PEP regimens should be available at Primary Health Centres as animal bite patients report to primary health centres for PEP.

Need for the Study

Also, primary health centres record and report surveillance information to IDSP for action. As animal bite surveillance provides the first step in identifying the need to prevent animal bite and rabies in humans, this study is undertaken to explore the quality of surveillance data available at primary health centres.

Material and Method

A Cross sectional study was carried out among the primary Health Centres of Hassan District to examine the surveillance data recorded / captured at the centres. Hassan District has 8 talukas and 134 Primary Health Centres. The no of centres to be included was calculated using a sample size calculator at 80% Confidence Interval using the Sample size formula of \( n = \frac{\text{DEFF} \times N \times p(1-p)}{\left(\frac{d^2}{Z^2}\left(1-\alpha/2\right)\right) + p(1-p)} \), the calculated number was 57. We selected 7 Primary Health Centres from each of the eight talukas across the district. After enumerating the number of centres to be visited, based on the feedback of animal bite case load that was available at the district IDSP office, these centres were visited along with district IDSP officer, and data was collected through record review and interview from the designated staff on a predesigned Proforma. After obtaining the information the data was entered excel format and analysed and expressed as percentages. Ethical Approval was taken from the Institutional Ethics Committee.

Findings: A total of 57 (100%) units were enrolled into our study. The mean population covered by these Health Centres were 14715, SD 9927. All the units had animal bites reported and managed. The mean annual dog bite cases reported in these centres was 103, SD 181. All 57 (100%) of the units recorded the demographic information such as name, age and sex of the bite victim and address of the victims. None recorded the place of bite and 53(92%) recorded the animal biting the victim and details of biting animal was of interest to only 10(17%) and only 1(2%) of them made an attempt to understand if the biting animal was rabid. None of the centres recorded the wound site and characteristic of the wound as aberration and laceration and only 19(33%) classified the wound into 3 categories. Only 2(3%) of centres advised wound wash and 12(21%) offered antiseptic application but all 57(100%) the centres provided vaccine irrespective of category of bite and rig administration were done in none of the bite victims but were referred to district hospital. Completion of PEP prescription was observed only in 35% of records. No action was taken to reduce the animal bite incidence at the population within the preview of Primary Health Centre.

Discussion

A total of 57 units were enrolled into our study. All the units had animal bites reported and managed. Animal bite management is important and should be available at our Primary Health Centre. A study done in 2004 estimated that the incidence of animal bites as 17.4 per 1000 population. However, 7 Animal bite cases per 1000 population in 2018 reporting to public health care facilities and the remaining got reported to private providers as revealed by Masti et al.\textsuperscript{18}
All 57 (100%) of the units recorded the demographic information such as name, age and sex of the bite victim and address of the victims but none recorded the place of bite, where as in a similar study conducted by Tapas Ranjan Behera et al, the place of bite was recorded in 30% of cases. This may be because the importance of the place is not known.

53(92%) recorded the animal biting the victim and details of biting animal was of interest to only 10(17%) and none of them tried to understand if the biting animal was rabid. However, Ramesh Masti et al in their study on rabies exposure through contact tracing in Bengalure reported that 69.5% of the bites were by stray dogs. This means that major proportion of animal bite are by dogs which are stray. only 1(2%) of them tried to understand if the biting animal was rabid, whereas Masti et al recorded 7.2% of their bite victims had exposure to 3 probable rabid dogs and 1 probable rabid cat. As animal with a sizable number are rabid documenting animal characteristics are important to eliminate rabies in India and globally.

None of the centres recorded the wound site and characteristic of the wound as aberration and laceration and only 19(33%) classified the wound into 3 categories. Whereas characterisation of wound is important for appropriate advice and prevention of rabies deaths.

Kaplan MM et al. (1962) recommended, vigorous wound wash with soap and water followed by local infiltration of wound with immunoglobulin to prevent rabies. However, only 2(3%) of patients received wound wash and 12(21%) wound care with antiseptic at our centres which is a poor practice compared to the practice in PHC/CHC of Orissa where 21% were advised wound wash and 50% received antiseptic application.

No action has been taken to reduce the animal bite incidences among the population with animal bite reporting. Though Hampson K et al. reported that the greatest impact on variation in estimated human rabies deaths were bite incidence, followed by the probability of receiving complete post exposure prophylaxis after a rabid animal bite.

Strength. A unique approach to understand the gaps in health system which can help us strengthen the health system and population health at large. Limitation: A cross sectional study.

Conclusion

This study revealed higher incidence of animal bite in the study setting. District Health Authorities should take measures to improve surveillance data at primary health centres and train Medical Officers to categorise the wound and use appropriate treatment modality and reduce the incidence of animal bite through community engagement initiatives.

Abstract

The advent of global modernisation presents itself with multitudes of challenges for the growing elderly population one of which is the challenge of productive aging which inadvertently affects their overall quality of life. Many senior citizens are now engaging in work either in paid form or in volunteer work. Aligned to this view the present research was conducted in the Delhi/NCR region to study the quality of life of persons who are formally retired from work organisations and those who have attained re-employment post-retirement. The study consisted of a sample of sixty elderly persons aged between 58-80 years. The study applied a t- test to assess the average difference in the scores. The findings of the study revealed a significant difference in the quality of life of persons who were retired and for those employed post-retirement.

Keywords: Quality of life, Retirement, Post- Retirement Employment

Introduction

Global modernisation has put the society in a state of a constant flux with changing value systems and systems of family, profession, workplace and workplace culture. Adapting to these changing systems is still easier for the young, but for those who are set in their ways such as the silver citizens of the country it may pose a greater challenge. Quality of life as defined by the WHO is “an individual’s perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns.”¹ A report jointly brought out by UNFPA (United Nations Population Fund, 2007)² and Help Age India stated “India has around 100 million elderly at present and the number is expected to increase to 323 million, constituting 20 per cent of the total population” (Tara D, 2017)³. Although many processes have been set in motion to help the aged cope with the today world, ageing still remains a natural and a gradual process bringing with it several complexities. These complexities may vary from physical ailments and suffering to mental and emotional changes in the state of mind of an individual.

Many organisations both in the private and government sectors are now extending the age of retirement age for their experienced and seasoned employees. In India big entrepreneurial organisations such as Reliance telecommunication group initiated this trend by increasing the retirement age of its employees from 58 years to 65 years (Gupta, 2013)⁴. Government bodies such as the All India Institute of Medical Sciences through their faculty association also reported a retirement extension from 58 years to 70 years (Sharma P., 2017)⁵. According to the United Nations 55 countries expect their older population (65 and above) to constitute to 20% of the total population, India being among them. Additionally, statistical reports have also estimated that the world’s population aged 65 & above will increase from 7.6% to 16.2% by 2050, implying that it would be double (Preeti Tarkar, 2016)⁶. Released by the (Central Statistics Office Ministry of Statistics and Programme Implementation Government of India, 2016)⁷ the latest reports show that 8.6% of the total population is of elderly persons in India, that is, any person aged 60 and above.

A news report drawing from the Census of India (2011) suggested that the percentage of nuclear families existing in India is about 70%. Along with this, the report
also suggested a 33% increase in the number of single person households, which is anticipated to be greater than even the overall population growth (John Samuel Raja D, 2014)\(^8\).

Such situations have also brought about a change in the attitude of the elderly people of India. Many elderly suffer from ailments such as of heart, liver and lung apart from loss of vision and impairments in hearing, loss of control of motor activities etc. which leads to a feeling of loss in self – confidence, control and autonomy with age, which are directly related factors to the quality of life as it is a perception of one’s position in life. Thus the overall Quality of life for the elderly has been deteriorating despite the numerous medical advancements and technological achievements. Lack of government amenities and incapable institutions that are present in functioning for the elderly have compelled the senior citizen society to tackle this situation by involving themselves in engaging activities where they feel positive about themselves and that which boosts their self- esteem. Many elderly are often seen engaging in community welfare and development or joining clubs with fellow members of that age group. A report on the status of elderly people in India (Government of India, 2016)\(^4\) revealed that 28.5% of the total urban elderly population of India is also employed in formal sector jobs. Off- late the elderly are also seen joining work post- retirement either as an employee or even as a trustee/ volunteer/ supervisor.

**Review of Literature**

Discussed in the following part are some of the significant literature studies conducted on similar lines as the present research.

A health related quality of life survey was done among the elderly in northern India. The cross sectional survey consisting of hundred elderly from the urban area and hundred elderly from the rural areas were taken as sample. The study used the HRQOL and the Perceived health inventory (PHI). The results revealed that those in the lower age group, literates and urban residents held a higher quality of life. In addition to this those with a high personal income and living in larger households also had a higher quality of life than those who did not (Kamalesh Joshi, 2003)\(^9\). The preceding research sheds light on some more demographic factors affecting the quality of life of an elderly in India. Having a stable source of income even in old age also affects the quality of life led by the elderly.

A study analysis on the changing modern society and its impact on social life and mental well-being of elderly women was done on a sample of 120 women from six cities or urban Punjab. The study took into consideration both the positive and negative impacts of the changing scenario. The results of the study revealed the positive impacts on their social life were better communication systems and transport facilities. While the negative impact of the changing times on mental well- being were expressed through views of loneliness and a sense of alienation and lack of moral support (Bakshi, 2004)\(^10\).

Another research conducted in Hong Kong among the older Chinese population was aimed at understanding the demographic and psychological differences between older Chinese volunteer workers and non- volunteers (Anise M.S Wu, 2005)\(^11\). The results of the research showed that Chinese volunteers had higher educational attainment and reported better physical health, higher self-efficacy, greater life satisfaction and less psychological distress. Re- ensured self- efficacy through work and the perceived rewards of the work indicated a higher life satisfaction among the older Chinese volunteers as opposed to the non- volunteers.

A research paper based on the geriatric health in India; its concerns and solutions drew out the harsh reality of policy making and programme implementations by the Indian government over the last few years which has been overtly focussed on population stabilisation, disease control and maternal health. The researcher highlights that though these are important and crucial problems, the aging population also needs some changed reforms and policies to enable better living conditions rather than simply prolonging life expectancy (Gopal K Ingle, 2008)\(^12\).

An article highlighting the issues and problems of the elderly in India by HelpAge India in (2011)\(^13\) addressed the various challenges faced by the elderly population in India. It highlighted health facts about the Indian elderly such as that over 10% of the elderly population in India suffers from depressions. 6.5 million Elderly in India are blind due to cataract. Economic insecurity and lack of proper health and sanitation facilities are also a packaged problem faced by the elderly in India. In the urban areas elderly abuse was brought to light as a major
challenging factor faced by a majority of the elderly. In such stances autonomy and health and independence were also contributing factors to deteriorating quality of life among the elderly.

A study conducted among Canadian retirees was aimed at understanding the determinants to post-retirement employment. The study addressed the factors associated with post-retirement employment. The results indicated an increasing incidence of post-retirement employment. It was unveiled that higher education, age and the timing of initial retirement were determinant factors wherein persons who held a higher education degree were more inclined to joining work post retirement. Similarly persons who were sixty and close were more likely to be employed again as compared to persons aged seventy as above. Financial gains were other factors affecting the post-retirement employment (Hiscott, 2013).

A study conducted on the quality of life satisfaction and physical health determinants was conducted in Varanasi (Dharma raj, Prafulla kumar Swain et.al, 2014). The mean scores of quality of life satisfaction score dependent on various factors under the area of Physical Health, Interpersonal life, Economic status, Physical Environment were calculated. An aggregate of 166 elderly were incorporated into this investigation. Out of 166 elderly 121(72.89%) were Males and remaining were females. Loss of sight is the most prominent issue among the older. 61.45% of the elderly had a normal quality of life, where as 24.10% and 14.45% elderly had a poor and good quality of life individually. In conclusion there is a pressing need of social security in type of guaranteeing old age pension and obligatory medical coverage.

Another research aimed at understanding the factors affecting adjustment to retirement among retirees was done in Egypt. The study sampled two hundred and ten retired elderly who had been retired since one year and more. The data was collected using Retirement adjustment scale and retirement resources inventory. The results of the study concluded that adjustment to retirement was affected by the gender, marital status, level of education, type of job before retirement, job condition and place of work. In addition, adequate resources as physical, financial, social support and mental capacity were associated with a better adjustment to retirement (Fadila, 2016).

An analysis on post retirement intention to work was conducted examining the predictability of job related factors on future prospects of retirees in terms of their intention to work after retirement. The results indicated that intimacy with co-workers has the largest effect on the attitude of retirees towards work. Availability of jobs prospects also, full time and part time had a significant effect on the intention to work after retirement (Aruna Dhamija, et.al, 2016). It can be concluded from these findings that a positive attitude and acceptance of co-workers towards the retirees are dependent factors for retirees to re-gain employment.

A news article released by the All India Press Trust of India (Shekhar, 2018) on the lines of employment opportunities for the elderly community was published. The article claimed that during the course of the research 22% of the elderly interviewed cited a lack of gainful employment/engagement opportunity as the biggest problem to the declining health of the elderly. The respondents also stated being a burden and lack of autonomy and financial independence discouraged them. Amidst such negative feelings, it is not hard to comprehend a bleak future for the elderly of India.

Research Methodology

Objectives:

1) To study the Quality of Life of unemployed retired & employed post-retirement professionals.

Hypotheses:

There will be significant difference in Quality of Life of unemployed retired & employed post-retirement professionals.

Sample Size and Description:

A sample of sixty retired and employed post retirement professionals was taken from different communities and neighbouring societies and senior citizens welfare association groups & from different work organisations.

Procedure of data collection:

The researcher personally gave the questionnaires to the respondents after verbally taking informed consent and any queries that the Respondents had were clarified and explained by the researcher wherein the time convenience and schedule was selected by the
respondent.

**Tools Applied:**

The Quality of life measuring CASP-19 is a questionnaire developed by Richard D. Wiggins (2004) to measure the quality of life of the elderly. The questionnaire is based on four domains namely:

- Autonomy
- Control
- Pleasure
- Self-Realisation.

The capacity of a person to settle on his own choices and be free from the undesirable obstruction of others can be comprehended as ‘Autonomy’. ‘Control’ refers to the capacity of a person to effectively intercede in his condition. ‘Pleasure’ is a functioning procedure of being human. As such it very well may be comprehended as inferring joy and fulfilment. ‘Self-realisation’ alluding to Maslow can be characterized as the capacity of a person to utilize his full close to home potential and accomplish a condition of satisfaction. In otherworldly terms it very well may be comprehended as ‘satisfaction without anyone else of the conceivable outcomes of one’s character.’

**Results and Discussion**

The data was analysed in a two-step procedure. First the average for thirty responses in each of the groups was calculated. Then a T-test was applied to obtain the level of significance and the difference.

Table. 1 Displays the average and the significant difference of the data N=60

<table>

<td>0.029</td>
</tr>
</tbody>
</table>

*The results are significant at .01 level

**The results are significant at .05 level**

The results conclude that there is a significant difference in the quality of life of persons who are re-employed post retirement and unemployed retired persons. Persons who are working again after retirement seem to have a significantly better quality of life.

Being employed may give a sense of autonomy over the life choices and lifestyle one has lived in and with pressing ailments any change in that lifestyle of an elderly individual may lead to a feeling of helplessness which may further lead to bleaker path. Thus employment post retirement may give a feeling of autonomy and independence in a both physical and economic sense. In comparison to those individuals who are retired taking up an employment opportunity may also give a sense of control and can help in alleviating the stress of modern day life and challenges. Having attained a sense of financial, physical and social independence it leaves room for a person to enjoy the joys of life and gain more pleasure in life. Employment opportunities at an age where one’s social roles may be confusing and the norms of the society are laid down, it can help one gain perspective about their life and may lead to a more self-fulfilling life. It may encourage one to do more to the best of their capabilities.

Thus the quality of life or personal satisfaction may be dependent on external factors such as financial security, attaining perfect health or having a social environment but are also dependent on the way one perceives his or her own life in the midst of these external influencers.

**Conclusion**

The results help make a fair assumption that having a work role indeed has helped define social and personal identities of the aging citizens and have in fact made better the quality of life of these citizens.

Abstract

Introduction: Mortality rates not only reflect a country’s health status, level of socio-economic development and quality of life. Child mortality is considered as both, a health indicator and also as a fundamental measure of human development. The levels of under-five mortality have been very high in India. Over past few decades the country witnessed reductions in mortality rate at almost all ages. Under-five mortality rate (U5MR) declined from 200 per 1000 live births in 1960’s to the level of 118 in 1990, 49 in 2013 and 50 in 2015 of India. However in Empowered Action group states of India U5MR not declining as much we needed to achieve sustainable development goals of U5MR for India.

Material & Method: Data has been taken from National family Health Survey (NFHS-4) for Empowered Action group (EAG) states of India. Our objective of this study to estimate average survival time of under-five children of EAG states of India. For the estimation of mean survival time we have used Kaplan Meier survival product limit estimation method. Distributions among different mean survival time were compared by log rank test.

Results: This analysis was includes 157358 live births of EAG states of India. We were found highest mean survival time in Jharkhand 549.92 (95% CI: 543.72-556.12), Odisha 549.72 (95% CI: 543.79-555.65), Bihar 549.45 (95% CI: 545.61-553.29), Assam 545.88 (95% CI: 540.61-551.15) and Uttarakhand 545.98 (95% CI: 537.59-554.36). However low mean survival estimates were observed in state Uttar Pradesh 537.76(95% CI: 534.84-540.68), Chhattisgarh 536.79 (95% CI: 530.67-542.90) and Madhya Pradesh 539.79 (95% CI: 535.27-544.32). A significant difference was found among survival distributions associated determinants of under-five mortality (p=<0.0001).

Conclusion: The reduction of under-five mortality and achieve the sustainable development goals we would enhance the child survival programmes in empowered action groups states of India. It will help to increase the survival time of under-five children.

Keywords: EAG, U5MR, NFHS, child survival.

Introduction

India, the largest democracy of the world, is also largest number of children in the world. About 1.83 million children die annually in India before completing their fifth birthday and most of them die due to preventable causes¹. Although at national level U5MR has declined, there are many states whose U5MR is greater than the national average. Though the mortality in India has been declining over the last few decades, the rate of reduction is not fast enough. India still contributes to more than 20% of child deaths in the world². The Millennium Development Goals (MDG), in the year 2000, world leaders agreed to set of 8 goals and 48 indicators; one of them was to reduce the under-five...
mortality and infant mortality rate by two-third at the end of 2015. The global under-five mortality per 1000 births has been declined from 91 in 1990 to 43 in 2015\(^3\). In the year 2016 world leaders adopted 17 Sustainable Development Goals (SDG) and 169 indicators to achieve by 2030 with an agenda of sustainable development. The third goal of Sustainable Development Goals focuses to ensure healthy lives and promote well-being at all ages. In these goals, there are wide range of indicators indicating the quality life and one of the indicator is to reduce under-five mortality to as low as 25 per 1000 live births by the year 2030\(^4\). According to National Family Health Survey (NFHS) fourth round it is estimated that under-five mortality of India is 50 per 1000 live birth in the year 2015-16\(^5\). Even though the after MDG the acceleration of under-five mortality has increased but with the current rate of decline India, may not meet their current goals of SDGs. As per data of NFHS-4 some states including Union Territories (UTs) like Goa, Kerala, Manipur, Tamil Nadu and Andaman are already near to SDGs but Empowered Action Group (EAG) States Bihar, Chhattisgarh, Jharkhand, Madhya Pradesh, Orissa, Rajasthan, Uttarakhand and Uttar Pradesh are still far away from the goal of SDGs. In order to meet the required goal and to achieve the SDGs agenda by year 2030, the under-five mortality in India has to be critically studied. Under-five mortality is a leading indicator of child health and overall development of a nation, as it reflects the social, economic, environmental conditions in which children live, including their healthcare\(^6\). The present study which was based on for estimation of average survival time of under-five children EAG states of India.

**Material & Method**

**Data Management:** The present study used data from fourth round of National Family Health Survey EAG states of India\(^6\). NFHS-4 was taken information on 1,315,617 children born of 699,686 women in 601,509 households with a response rate of 98%. The NFHS-4 provides information on fertility, mortality, family planning, and important aspects of nutrition and health. For this study we used live births of preceding five years which has been extracted from birth history of children EAG states of India.

**Objectives:** For this study our primary objective is to estimate mean and median survival time for the determinants which is directly and indirectly affect the under-five mortality EAG states of India. Secondary objective is to compare all survival distributions of different determinants of under-five mortality.

**Dependent variables:** Under five mortality as the probability of dying children before the fifth birthday.

**Independent variables:** considered were mother’s age at the time of child birth (15-19, 20-29, 30+ yr), gender of the child (female /male), birth order (1, ≥2 ), mothers education (illiterate, literate); place of residence ; (rural / urban ), wealth status (poor/ rich); sanitation facility (unsafe /safe); cooking fuel (unsafe /safe); drinking water (unsafe /safe).

**Statistical Analysis:** We have taken failure or dependent variable as death of children before completing five years of age. Independent covariates were assumed on the basis of Mosley and Chen framework of socio demographic determinants for child survival\(^9\). For the estimation of mean and median survival we have used Kaplan Meier Survival product limit estimation method\(^10\). Here, we estimated survival time in century month code (cmc) which was based on birth history of preceding five years of live births. In this study we have observed more censored events occurred so we could not able to estimate median survival estimates for some covariates of under-five mortality of children. After that for comparison of their survival distribution of different covariates of under-five mortality used Log rank test\(^11\). For the survival probability graphs for some covariates we also used Kaplan Meier method. Nelson Aalen method used for the cumulative hazard estimates plot which shows hazard of under-five mortality EAG states of India. All statistical Analysis was performed on STATA 13.0 version\(^12\). A p value is less than 0.05 has been taken as a statistical significant.

**Results**

A total of 157358 live births were included in this study from EAG states of India. Out of them 8654 number of events (under-five mortality) occurred in preceding five years of birth history. Firstly we found mean survival estimates with 95 % CI for determinants of under – five children. We observed mean survival range (537.76-545.98) of children. Majority of states had mean survival of under – five children more than 545. Highest mean survival 549.92 (95 %CI: 543.79-555.65) was reported in state Odisha however minimum mean survival 537.76 (95 %CI: 534.84-540.68) was found.
in Uttar Pradesh. Mean survival range of the children under-five whose mothers were aged 20-29 years, was 353.05 (95 % CI: 352.90-353.19), less mean survival range 237.51 (95 % CI: 237.34-237.68) was found in the children of the mothers aged 15-19 years and mothers who were above 30 years had 560.39 (95 % CI: 558.65-562.13).

Higher survival mean was reported in the female children 560.39 (95 % CI: 558.65-562.13) as compared to male children 544.22 (95 % CI: 541.90-546.54). Children who were residing in urban place had higher mean survival estimates 551.01 (95 % CI: 546.05-555.98) as compared to children living in rural areas 542.93 (95 % CI: 541.14-544.73). On comparison of the educational status of the mothers, children whose mothers were literate had more mean survival rate 545.57 (95 % CI: 543.68-547.45) than children of the illiterate mothers 543.11 (95 % CI: 538.76-547.46). Less mean survival rate was reported in the children who had first birth order 518.44 (95 % CI: 514.53-522.35) and comparatively higher mean survival rate 550.90 (95 % CI: 549.07-552.73) was noted in the children of second birth order.

Children whose mothers were severe anemic had less mean survival rate 521.84 (95 % CI: 510.32-533.35) which followed by moderate anemia 539.79 (95 % CI: 535.73-543.84), mild anemia 547.95 (95 % CI: 545.33-550.57) and non-anemic 542.62 (95 % CI: 539.96-545.27) mothers.

Lower mean survival rate 543.11 (95 % CI: 541.25-544.97) was reported in poor children as compared to the rich 545.34 (95 % CI: 541.26-549.42).

We also found mean survival estimates for environmental factors like water facility, toilet facility and type of fuel have been used in households. Less mean survival 541.90 (95 % CI: 542.90-546.45) was reported in the children who had unsafe water facility as compared to using safe facilities 544.68 (95 % CI: 542.90-546.45). Similarly, we found less mean survival in children who were using unsafe toilet facility and type of fuel.

However, more censored events occurred in this study we could not find out median survival estimates of few variables. We also found highest median survival in state Odisha 594 (95 % CI: 564.07-623.92) and lowest in state Assam 585 (95 % CI: 566.39-603.61).

Lower mean survival rate was found in the mothers aged 20-29 years as compared to the mothers who were above 30 years 594 (95 % CI: 587.98-600.02). Lower median survival rate 589 (95 % CI: 581.96-596.04) was found in male children as compared to the females 594 (95 % CI: 587.19-600.81). Due to excessive censoring, we could not estimate median survival for Urban children and for rural children median survival time was 589 (95 % CI: 584.34-593.66).

On comparing the educational status of the mothers, higher median survival 590 was found in the educated mothers however comparatively less median survival was observed in the illiterate mothers 586.

Children who were born with first birth order had less median survival 560 and higher median survival was found in the children with second or more birth order 595. Poor wealth children had less median survival 589 (95 % CI: 583.17-594.83) as compared to rich wealth children 594 (95 % CI: 571.57-616.42). Among environmental factors, water facilities, toilet facilities and safe practices of using fuel had higher median survival for children. Distributions among different mean survival time were compared by log rank test.

A significant difference (p <0.0001) was found on comparing the survival distributions of EAG states of INDIA such as age-Group of the mothers (In Years), gender of child, place of residence, educational status of mothers, birth order, anemia levels of mothers, wealth status, water facility, toilet facility and type of fuel.
Discussion

In this present study we have estimated average survival time of under-five children EAG states of India. Few EAG states were found very poor child survival time. We have observed that mother’s age is most prominent factor to affect the survival time of children. In both the estimation mean and median mother’s age 15-19 age were found least child survival time as compared to other age-groups. First birth ordered children also having less survival time compared to other second and more order of birth. This study also found children living in household with poor wealth status were less mean survival than those living in rich wealth status. Median survival time of male and female children also found dissimilar. Similar studies were observed with same findings of under-five mortality. In environmental factor we had seen that limited access safe water, safe toilet facility, and safe fuel were affecting factors of under-five mortality. Furthermore, children living in rural areas were found with less survival time than those living in urban places. Most of previous studies were based on identify the risk
of under-five mortality of associated determinants of mortality. However present study was focused only non-parametric method Kaplan Meier survival estimation and Log rank test. We can conclude that proper steps can be taken both at individual family and community levels in any planning for child survival programmes in all EAG states of India.

**Ethical Clearance:** The study is based on an anonymous publicly available NFHS -4 data; no ethics statement is required for this study.

**Funding:** No funding was available for this study.

**Competing Interest:** No competing interest exists.

Neurobehavioral Effects of Losartan on Rotenone Induced Parkinsonism in Rats

Prakash KG1, Bannur BM2, Madhavrao C3, Saniya K4

1Professor and Head, Department of Anatomy, Azeezia Institute of Medical Sciences and Research, Kollam, Kerala, India, 2Professor and Head, Department of Anatomy, BLDEU’s Shri B M Patil Medical College, Vijayapura, Karnataka State, BLDE University, Bijapur, 3Professor, Department of Pharmacology, Azeezia Institute of Medical Sciences and Research, Kollam, Kerala, India, 4Assistant Professor, Department of Anatomy, Azeezia Institute of Medical Sciences and Research, Kollam, Kerala, India

Abstract

Background and Objectives: Reticular activating system is increasing implicated as new target for therapeutic approaches in Parkinsonism. The objective of the present study was to evaluate the neurobehavioral effects of losartan in rotenone rat model of Parkinson’s disease.

Methodology: Adult Wistar albino rats were divided into four groups of six each. Parkinsonism was induced with rotenone (3 mg/Kg intraperitoneal) in three groups. One group (positive control) was treated with levodopa (12 mg/Kg) and Benserazide (3 mg/Kg). Other group (losartan group) was treated with losartan (90 mg/Kg). Motor functions were evaluated by rota rod test and spontaneous locomotor activity. Exploratory behaviour was evaluated by hole board test. Depression influences on behaviour was studied with forced swim test. Elevated plus maze test was used for analysing anxiety influences on behaviour.

Results: The mean time of losartan pre-treated rats that stayed in the accelerating rota rod was significantly shorter compared the control, rotenone and levodopa group. Locomotor activity as measured by actophotometer was significantly decreased in the losartan group rats. The time spent by losartan group rats as immobile in water was significantly higher than the other groups. Losartan group rats had significantly higher number of head dipping in the hole board test. There was no significant change in the open arm activity both in duration and in number of entries among rats treated with levodopa and losartan.

Conclusion: Losartan improves neurobehavioral indicators in rotenone rat model of Parkinson’s disease.

Key words: angiotensin receptor blocker; parkinsonism; renin angiotensin system; behavioural study

Introduction

The progressive degeneration of dopaminergic neurons in substantia nigra pars compacta is the established neuronal change in the Parkinsonism. Neuroinflammatory processes accelerate the process of neuronal loss, oxidative injury resulting in alterations in mitochondrial membrane permeability, enzyme metabolism and mitochondrial genome changes.1 the symptomatic triad of bradykinesia, tremors-at-rest, and rigidity occur. Progressive neurodegeneration may also impact non-DA neurotransmitter systems including cholinergic, noradrenergic, and serotonergic, often leading to the development of depression, sleep disturbances, dementia, and autonomic nervous system failure. L-DOPA is the most efficacious oral delivery treatment for controlling motor symptoms; however, this approach is ineffective regarding nonmotor symptoms. New treatment strategies are needed designed to provide
neuroprotection and encourage neurogenesis and synaptogenesis to slow or reverse this disease process. The hepatocyte growth factor (HGF In addition to these mechanisms the brain renin angiotensin system (RAS) maintaining the body water balance, blood pressure, sexual behaviours and pituitary glandular secretions with influences in the learning and memory functions of the brain has been repeatedly established.2 This brain RAS system plays a role in pathogenesis of certain neurodegenerative disorders like Alzheimer’s disease1 and Parkinson’s disease.5,6 Angiotensin II acts on the certain areas of the brain influencing the drinking behaviour and natriuresis.6 It stimulates the vasopressin release, modulate the sympathetic outflow and decrease the baroreceptor reflex.7 It is postulated that most of these effects are through AT1 receptors. Animal studies have added the necessary evidence to the notion that AT1 receptor influences the cell proliferation, water intake and blood pressure.7,8 Angiotensin II can stimulate catecholamine release through AT1 receptor stimulation.9 Rodent studies have also shown that angiotensin receptor binding in substantia nigra pars compacta and bring about presynaptic effects in the dopaminergic neurons in the region.10–12

Studies have shown that losartan, the antagonist of AT1 receptor, protects dopaminergic neurons against 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) toxicity both in primary ventral mesencephalic cultures as well as in the substantia nigra pars compacta of mice.13 Few interventional trials in atypical Parkinsonism have also ascribed promising role for losartan in neuroprotection.14 Effects of losartan on midbrain dopaminergic neurons against rotenone-induced cell death has been positive.15 Another AT1 receptor blocker, candesartan, has shown promising results in rotenone rat model of Parkinson’s disease.16 However, the neuroprotective role of losartan in rotenone rat model has not been established.

The objective of the present study was to evaluate the neurobehavioral effects of losartan in rotenone rat model of Parkinson’s disease.

Methodology

Animals and groups

Healthy adult Wistar albino rats of either sex weighing 180-250g were selected and divided into four groups. All rats were obtained from animal house, BLDEU’s Shri B M Patil Medical College, Vijayapura, Karnataka state & KMCH College of Pharmacy, Coimbatore, Tamil Nadu. Institutional animal ethics committee, BLDEU’s Shri B M Patil Medical College, Vijayapura, Karnataka state, (with CPCSEA, India registered) (approval letter number: 33/16, dated-16.01.2016) and also Institutional animal ethics committee, KMCH College of Pharmacy, Coimbatore, Tamil Nadu, (approval letter number: KMCRET/PhD/21/16-17, dated-22.02.2016) approved the study before the start of the study.

Table 1: Four groups (each having 6) of rats that were used in the study (n=36).

Parkinson’s disease induction with end points

All rats were divided into four groups having six each (table 1). Three groups underwent Parkinsonism induction with rotenone. The Rotenone (Sigma Chemicals, Mumbai) solution was freshly prepared at 3 mg/kg. The Rotenone was dissolved in dimethylsulfoxide and adjust to pH 7.4 with potassium hydroxide. Rotenone injected i.p at the dose of 3 mg/kg body weight, 7 days. The solution was used immediately after preparation as it was stable only for a period of 24 hours at 25°C. All the rats were monitored with a check list twice daily for the appearance of parkinsonian features, bradykinesia, postural instability, gait disturbance and rigidity.

Animals that died after the intraperitoneal injection were excluded from the analysis. Animals that failed to experience the parkinsonian symptoms were also excluded.

Animals that died within minutes of an injection and that did not experience parkinsonian symptoms were excluded from analysis.
Group 4 rats were given losartan (90mg/kg body weight) intraperitoneally for 7 days. All animals that did not survive 7 days of intraperitoneal injections were excluded from the study.

**Behavioural Analysis**

Motor functions were evaluated by rota rod test and spontaneous locomotor activity. Exploratory behaviour was evaluated by hole board test. Depression influences on behaviour was studied with forced swim test. Elevated plus maze test was used for analysing anxiety influences on behaviour.

Rotarod test\(^2\) largely replacing rats as the behaviorist’s animal of choice. Before aspects of behavior such as emotionality or cognition can be assessed, however, it is vital to determine whether the motor capabilities of e.g. a mutant or lesioned mouse allow such an assessment. Performance on a maze task requiring strength and coordination, such as the Morris water maze, might well be impaired in a mouse by motor, rather than cognitive, impairments, so it is essential to selectively dissect the latter from the former. For example, sensorimotor impairments caused by NMDA antagonists have been shown to impair water maze performance\(^2\) . Motor coordination has traditionally been assessed in mice and rats by the rotarod test, in which the animal is placed on a horizontal rod that rotates about its long axis; the animal must walk forwards to remain upright and not fall off. Both set speed and accelerating versions of the rotarod are available. The other three tests described in this article (horizontal bar, static rods and parallel bars): Motor co-ordination test was conducted by placing the rats on the horizontally placed rotating rod. The time taken by animals to fall from the rotating rod was noted. The length of time (duration) the animal stay on the rod without falling, gives a measure of their coordination, balance, physical condition and motor-planning.

**Spontaneous locomotor activity**\(^1\). Spontaneous horizontal activity was measured using actophotometer that operates on photoelectric cells connected with a counter. All the rats were placed individually in the activity cage for 3 min to habituate them before starting actual locomotor activity task for the next 3 min. the basal activity score was noted. Counts per ten min is used as an index of locomotor activity.

**Hole board test**\(^1\). Rats were placed on a 25 cm elevated wooden board (40 cm X 40 cm) with 16 holes. A head dipping is counted when the animal introduces its head into any hole of the box up to the level of the ears. Decrease in anxiety shows increased exploration of the holes.

**Forced swim test**\(^\text{20}\): Rats were forced to swim in a glass cylinder (20 cm height, 14 cm diameter) containing 10 cm depth of water. Animal were considered to be immobile, when they made no further attempts to escape except the movements necessary to keep their heads above the water. The time spent by the rat as immobile in water represented the measure of depression – like behaviour.

**Elevated plus maze test**\(^\text{21}\): The rats were placed at the junction of the maze with four arms, facing an open arm. The duration in each arm were recorded by a video tracking system and by an observer simultaneously for 5 minutes. The duration of the test period was 10 minutes, the number of entries into the open arm, number of entries into the closed arm, the time spent in open arm, and closed arm were noted.

**Statistical analysis**: The data obtained was expressed as mean ± standard deviation. Comparison of the data was done by one way ANOVA, followed by Dunnett comparison. P value of less than 0.05 was taken as significant.

**Results**

Table 2 shows the tabulation of all the parameters observed. Motor co-ordination and balancing was tested with rota rod test. The mean time of losartan pre-treated rats that stayed in the accelerating rota rod was significantly longer compared the control, rotenone and levodopa group. Particularly, the latency to the fall in losartan group was increased gradually as early as 7 days of losartan treatment. Locomotor activity as measured by actophotometer was significantly increased in the losartan group rats. The time spent by losartan group rats as immobile in water was significantly lower than the other groups. Indicating the drug used in the rats has taken away depression like behaviour. Losartan group rats had significantly higher number of head dipping in the hole board test, indicating the decrease in anxiety among these rats. There was no significant change in the open arm activity both in duration and in number of entries among rats treated with levodopa and losartan.
Table 2: Neurobehavioral effects of losartan among various groups of rats; mean ± standard deviation from each group of six rats each. *** p <0.001 and *p<0.01

Discussion

Animal studies and clinical trials using losartan reported to have variable effects on dopaminergic function in substantia nigra pars compacta. 22 Physiological and functional studies suggest that the brain renin-angiotensin system (RAS) is constant addition of evidence to establish a stronger association of brain RAS system with neurodegenerative disorders. 1,4,14,16,22 The symptomatic triad of bradykinesia, tremors-at-rest, and rigidity occur. Progressive neurodegeneration may also impact non-DA neurotransmitter systems including cholinergic, noradrenergic, and serotonergic, often leading to the development of depression, sleep disturbances, dementia, and autonomic nervous system failure. L-DOPA is the most efficacious oral delivery treatment for controlling motor symptoms; however, this approach is ineffective regarding nonmotor symptoms.

New treatment strategies are needed designed to provide neuroprotection and encourage neurogenesis and synaptogenesis to slow or reverse this disease process. The hepatocyte growth factor (HGF) on the contrary, a case report highlighted worsening of Parkinson symptoms with losartan. 23 However, the angiotensin receptor blockers are here to stay and continue to be experimented for the possible neuroprotective roles.

In the present study, the behavioural changes were observed even with a seven day administration of losartan to the rats that were induced with parkinsonism with rotenone. Rota rod rest and spontaneous locomotor activity evaluated motor functions. The losartan treated rats showed significant improvement in the motor functions. Similar improvement in the motor actions were noted in rats treated with Pseudoginsenoside in MPTP model. 24
Hole board test evaluated exploratory behaviour in rats. Losartan treated rats had significantly higher head lowering exploratory activity indicating decrease in anxiety. Depression influences on behaviour was studied with forced swim test. Elevated plus maze test was used for analysing anxiety influences on behaviour. In the present study, the elevated plus maze test has no significant differences among rats treated with levodopa and losartan.

Overall, as there was significant improvement in the neurobehavioral activity among rats treated with losartan. Similar neuroprotective role is seen with candesartan and Azilsartan. Our study results are in line with many previous studies using captopril, perindopril, enalapril and moexipril in neuroprotective actions.

**Limitations of the study**: administration of losartan for more duration would have resulted in more pronounced and equivocal neurobehavioral changes. A study design to note the specific nigrostriatal loss of neurons, either microscopic evaluation or molecular evaluation of apoptotic indicators would have resulted in unambiguous outcomes with regard to neuroprotection.

**Conclusions**

Losartan improves neurobehavioral indicators in rotenone rat model of Parkinson's disease

An Ensemble Model for the Prediction of Gestational Diabetes Mellitus (GDM)

Prema N S¹, Pushpalatha M P²

¹Associate Professor, Department of Information Science and Engineering, Vidyavardhaka College of Engineering, Mysuru-02, India, ²Professor, Department of Computer Science and Engineering, Sri Jayachamarajendra College of Engineering, Mysuru-06, India

Abstract

Diabetes is the common chronic disease and a major health challenge in all population. Gestational Diabetes Mellitus (GDM) is a type of diabetes developed in women at the time of pregnancy. Our study is about predicting GDM by considering various risk factors using ensemble classification techniques. In this paper different ensemble learning models are used for prediction of GDM. A new ensemble model is proposed where ensemble stacking is done for the results of k-means clustering. Where clustering is done by excluding the class attribute of the data set. The data samples used for testing the model is collected from the local hospitals of Mysuru, Karnataka state, India. The performance of the classifiers have been measured and compared in terms of accuracy.

Keywords: Gestational Diabetes Mellitus, SMOTE, Ensemble, Stacking, k-means. KNN, RandomForest, Logistic Regression

Introduction

It is estimated that complications of pregnancies by diabetes mellitus is one out of every 200 and in every 200 pregnant women five will develop GDM. Globally prevalence of diabetes is increasing and India is no exception. Four million women have GDM in India alone. So it is important to identify the GDM at the earliest; else it threatens lives of mother and baby¹.

The factors for increasing prevalence of GDM in India are;

- The age of the women
- Obesity
- Lack of physical activity
- Modern lifestyles, smoking, alcohol consumption etc.

Diagnosing a pregnant woman with GDM is very important because diabetes mellitus is associated with significant metabolic alterations, increased perinatal mortality and morbidity, maternal morbidity and exaggerated long span illness among the mothers and their off springs². Since there is a scarce of healthcare resources and medical practitioners and patient’s ratio is low, providing value care is very challenging task.

To meet the trial of saving lives we provide a combined e-health solution – using Clinical Decision Support System (CDSS) which is based on data mining, which analyzes the patient’s data and classifies as either normal or high risk.

Data mining is the process of extracting useful knowledge from large data repository. Medical data mining is one of the applications of data mining, where analysis of medical data is done using different data mining techniques. Medical data mining approaches are applied for the following tasks: diagnosis, treatment, prognosis, monitoring and management. The aim of medical data mining is to help and assist physicians, improve public health and support patients.
The main two approaches of data mining are prediction and description. Prediction includes classification and regression whereas description includes cluster analysis and association analysis. Applications of both in the field of healthcare can be found in literature.

In most of the work referred in this paper, the data set used is the Pima Indian diabetes data set from UCI machine learning repository which contains data about female patients. Many classification algorithms are applied on Pima diabetes data set. Their objective is to classify the data into either diabetic or non-diabetic and they have considered only Type-I and Type-II diabetes they have not taken gestational diabetes into consideration.

To mention few, Alexis et al., proposed diagnosis of type II diabetes by applying artificial metaplasticity on multilayer perceptron, the data set used is Pima Indians diabetes. Patil et al., have proposed a hybrid prediction model for the diagnosis of Type II diabetes, which uses k-means clustering and C4.5 classification algorithm. Similarly Nahla and his team have used support vector machines (SVMs) for the prediction of diabetes.

In literature we could find many works related to maternal healthcare data, to mention few; Jamal Afridi and Muddassar Farooq presents a novel data mining model for the classification of high risk pregnant women. The four major risk factors considered are hypertension, hemorrhage, septicemia and obstructed labor. They have developed an intelligent tool called OG-Miner, for the classification of risk factors and they have obtained about 98% of accuracy for their data set. They have used different feature selection techniques and combined various data mining algorithms.

Aparna Gorthi et al, proposed a machine learning approach for early determination of the risk category of pregnancy based on patterns extracted from profiles of known clinical parameter. Here classification techniques are applied just to identify the severity of risk like low, medium and high. Mário et al. compared two Bayesian classifiers to classify hypertensive disorders in pregnancy care. In Longfei Han work, support vector machines are used for screening diabetes, and SVM decisions are converted into rules by adding ensemble learning which helpful for solving imbalance problem. Results on data (China Health and Nutrition Survey) shows that the proposed methods generates rule sets with weighted average precision 94.2% and weighted average recall 93.9% for all classes. Further, the hybrid system can be used as a tool for diagnosis of diabetes, and supports for lay users as a second opinion.

The classification of diabetes is done by using two step approaches. First effective attributes are selected using feature weighting methods. In the second step Gradient Boosted Trees, Random forest, AdaBoost ensemble learning methods are used. The result shows that the prediction accuracy of the combination of Stability Selection method and AdaBoost learning algorithm is a little better than other algorithms.

Ensembling learning methods with Synthetic Minority Over-sampling Technique (SMOTE) is proposed for predicting diabetes using cardiorespiratory fitness data and an improved the prediction accuracy to AUC = 0.922 is obtained.

In our previous work we have used SVM and logistic regression for the diagnosis of preterm birth in the pregnant woman having either diabetes mellitus or GDM, the highest accuracy obtained is 86%.

The purpose of this work is to apply data mining techniques in the early detection of gestational diabetes by using limited identified risk factors of the pregnant woman.

**Materials and Method**

There is no dataset of pregnant women having gestational diabetes exists; therefore, we have made an attempt to create a new dataset which contains information about diabetes in pregnancy. The data used in this experiment are collected from local hospitals of Mysuru, Karnataka state, India. The medical records are taken after removing the identity of patients in order to ensure confidentiality. The data set has been developed by keeping obstetrics and gynaecology consultants in a feedback loop. We have collected about 1352 pregnant women details. The final GDM data set is developed using the following methods dataset.

**Relevant Feature selection:** The data taken from hospital contains more than 20 attributes. The reduction of features is done manually by taking the help of gynaecologists. As a result, only 10 relevant features are retained that consultants use to detect gestational diabetes.
Data cleaning and transformation: This step is very important in developing a complete data set which can be used further in any machine learning techniques. It was very challenging task to extract useful information from a manually entered medical record, as the entry was made manually there was lots ambiguity for entering the values of some of the attributes for example for the attribute number of time pregnant (Gravida) some have entered in numbers and some have specified as multigravida etc. In order to have a meaningful dataset, we applied data cleansing and transformation cycle. Once we have the meaningful attributes, the datasets is finalized on the basis of short listed 10 attributes. Most of the attributes the values will be of type nominal and values will be either yes or no.

GDM data set has totally 10 attributes, they are

1. Age
2. Past history of fetal loss (abortion or IUD)
3. Congenital anomalies in previous pregnancy
4. Macrosomia in previous pregnancy
5. Family history of Diabetes mellitus
6. Obesity
7. Past history of Pre-eclampsia
8. Number of times pregnant
9. Unexplained neonatal loss
10. Previous history of GDM

Age is the major risk factor of GDM, older the age more chances of developing gestational diabetes. It is found that women with age more than 25 are having more chances of development of GDM.

Many attribute are about previous pregnancy, they might be the cause for GDM, the selected attributes for this study are history of fetal loss by abortion or IUD, Congenital anomalies, GDM, unexplained neonatal loss, Macrosomia and Pre-eclampsia. Macrosomia is the situation where the birth-weight is over 4,000 g and is not depending on gestational age. Macrosomia affects about 3-15% pregnancies\(^1\). (16)

Family history of diabetes can also be the reason for developing GDM, in the used dataset there about 138 cases where family history of diabetes is positive in that more than 90% cases we can see the development of GDM. Obesity is the common risk factor for many deceases, for GDM also it can be considered as the major risk factors. The dataset contains about 95 obese women details where 95% of them have gestational diabetes.

Class imbalance problem: Data used is imbalanced; imbalanced classification is a supervised learning problem where one classes out numbers other class by a large proportion. In medical datasets high risk patients tend to be the minority class, so the cost of miss predicting the minority class will be more. Therefore, there is a need of a good sampling technique for medical datasets\(^1\). The technique used for oversampling is SMOTE; here the oversampling is done with minority calluses by creating synthetic samples instead of going for duplicate entries. Minority class samples are generated blindly without considering majority class samples and may thus cause over generalization\(^1\).

Ensembling Model

Combining two or more models of similar or dissimilar type (base learners) is ensembling, which makes a more robust system by incorporating the predictions from all the base learners. It is the best method for improvement of the accuracy of the model and best suited for most the cases.

Types of ensembling techniques

- Averaging: Here the average of the predictions is taken from the multiple models.
- Majority vote: Here prediction is done by taking majority vote or major recommendation from multiple models.
- Weighted average: Here models output is given importance by using weights then average of predictions is taken.
- Bagging: Here multiple models are built using different subsamples of the training dataset.
- Boosting: Here fixing of the prediction errors of the models is done by learning multiple models of same type.
- Stacking: Here the multiple classifiers are combined through Meta classifiers\(^1\).
We have used Random Forest, Logistic Regression and KNN classifier for ensembling.

**Stacking with clustering:**

Clustering is an unsupervised techniques of grouping the data into different groups, the clustering methods considering here is k-means, it is a type of partition clustering, where the objects are grouped into k number of clusters by taking centroid of the clusters as reference.

Here we applied k-means by taking k as 2. Ensemble Stacking is done for the individual clusters, later the stacking is done for the results of the individual clusters. The complete process is shown in Fig.1.

The outcome of the classifiers is combined using Averaging, majority voting and weighted average. The accuracy obtained is respectively 86%, 86.9% and 87%. The accuracy obtained using boosting and stacking are as shown in Fig.2.

k –means clustering of the dataset is by considering only the dependent attributes (after removing the class attribute)by taking k=2.Cluster-0 contains 54% of instances where as Cluster-1 covers 46% of the instances. The clusters are evaluated by referring the class-label; it is observed that 19% of the instances are wrongly clustered.

Conclusion

We have proposed a new ensemble model by combining clustering with ensemble stacking for the prediction of GDM. The classifiers achieve higher accuracy of 94% for the balanced data. The data is balanced by applying SMOTE; the various ensemble techniques results are compared with results of the proposed model.

**Results and Discussions**

The classifiers namely Random Forest, Regression and KNN are trained using 70% of the data then they are tested for remaining 30% of the data. The criteria taken for our comparison of classifier are Accuracy, Sensitivity and Specificity. For calculating these criteria we used the confusion matrix in our calculation process.

The Accuracy of the classifiers are shown in Table.1.

“Gypsy” Narikuravar Community: Problems in Accessing Health Care Services

R. Kanthiah Alias Deepak¹, C. Velaudham², M. Manivannan³

¹Assistant Professor, Department of Business Administration, G.Venkatashwamy Naidu College, Kovilpatti,
²Assistant Professor, Department of Business Administration, Joseph Arts & Science College, Thirunavalur, Tamilnadu, ³Assistant Professor, Department of Business Administration, Nazareth College of Arts & Science, Avadi, Chennai

Abstract

The importance of the research was to identify the Narikuravar community: problems in accessing health care services. Snowball sampling technique was adopted to collect primary data. The sample size was 750 women Narikuravars. Path analysis was assumed for primary data analysis. Path analysis found that there is no influence of socio economic condition and education/literacy level of Narikuravar community has influence on Discrimination in society. It is also identified that there is influence of discrimination in society on health care access towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu. Hence, it is concluded that the Appropriate action campaigns should be drained for the analysis of Narikuravar community through health awareness programs and provided that health education opportunities. The Narikuravar community is normally flat to health hazards. Hence, they need correct medical facilities as well as insurance in the health sector.

Keywords: Narikuravar community, health care access, health awareness, Tamil Nadu.

Introduction

The present research intends to review the intersection of gender, socio-economic status, education, nomadism, and discrimination and its imoact on health-seeking behaviour, health care utilization and health care access of the Narikuravar community. The Narikuravars are a “GYPSY”, semi nomadic society that falls across borders, but mostly live in Tamilnadu of India. They are acknowledged to face inequity that transforms into low socio-economic status, low education level and lack of suitable access to health care. The tribal population of India constitutes nearly eight percentage of the total population. Among them the Narikurava community is playing a significant role. The Narikurava is a native community from Tamil Nadu state of India. The major profession of the people, who initially belong to the indigenous family, is hunting. But as they were forbidden access into the forests to follow this livelihood, they were compulsory to obtain other options such as selling beaded ornaments to live. Hence, they journey from place to place to discover a marketplace for their beads. Children convoy the adults wherever they go, which means they not at all get chance to attend the school. The major issues confront Narikurava are illiteracy, poverty, discrimination and diseases.

Statement of Problem

Tamil Nadu is believed to be one of the mainly advanced Indian states in terms of health outcomes. The Tamilnadu state’s health care organization comprises a primary health system comprised of Health Sub-Centers and Primary Health Centers, a secondary health system that consists of Taluk Hospitals, District Head Quarters Hospitals, Dispensaries, Women and Children Hospitals, Mobile Hospitals etc., and a tertiary healthcare system that comprises multi-speciality hospitals (Government of Tamil Nadu 2017)¹. However, the complex health care structure and the good statistical averages of health

Corresponding Author:
R. Kanthiah Alias Deepak
Assistant Professor, Department of Business Administration, G.Venkatashwamy Naidu College Kovilpatti.
results do not replicate the circumstances of marginalized categories that don’t have access to health care, financial problems, because of structural issues, socio-cultural mismatches, or stigma and discrimination. One such susceptible group that faces problems while trying to get health care is the Narikuravar community. Generally acknowledged as containing a low socio-economic level, the Narikuravars are struggle with admission to public services like pathetically enough and healthcare. Without getting awareness about how to lead their life, children become young parents. Poverty, social setup and lack of citizenry rights deny them access to basic healthcare.

Significance of the Study

The formulation of a health policy was in 2013 onwards by the state with special emphasis on low-income, disadvantaged communities alongside efficient implementation of The Tamil Nadu Health Systems Project (TNHSP). Moreover, the economic growth of the state, low literacy rate, gender inequality in the last few decades brings importance to this study. Government of Tamil Nadu decided to provide round the clock services in the primary health centres to offer outpatient services in the evening hours and also to improve the access to women for routine emergency and essential obstetric care, meanwhile the range of services provided by the primary health centres and sub centres were also expanded. Also, Tamil Nadu included the practice of indigenous system of medicine in its health care service at a very early stage. This rapid implementation must reach “Gypsy” Narikuravar Community.

Review of Literature

Boorah2 (2004) concluded that girls are more likely to be neglected than boys, through an Indian-wide econometric analysis. However, the treatment of girls is closely linked to the level of literacy of mothers: while illiterate mothers engaged in gender discrimination for access to health, literate mothers did not discriminate between genders; the literacy of the father had no effect on reducing gender discrimination.

Acharya3 (2017) discusses the concept of unfair exclusion, “the complete exclusion of a group of people from availing some services for caste-based reasons”, while the state health care system is meant to provide services to all citizens without discrimination. She therefore identifies access, availability, self-perception and utilization as the key for assessing differences in opportunities.

Devansenapathy4 et al. (2016) boys are likely to be 2 to 5 percentage points more immunized than girls. Gender disparities are an important factor affecting access to health care. Gender gaps have been highly prevalent in India, which can be noted from the immunization rate by gender.

United Nations5 (2015) the “reduced inequalities” and “well-being and good health” are two major aims of the United Nations Sustainable Development Goals, providing suitable and reasonable health care access for susceptible populations is a worldwide priority.

Mathew6 (2012) undergoes a systematic review of the existing literature on the inequities in childhood vaccination and their social and demographic causes: there are correlations between the level of child vaccination and factors related to the individual (such as gender and birth order), family (such as wealth, area of residence, parental education), demography (caste and religion) and the society (community literacy level and access to health-care) characteristics. Mathew emphasizes that inoculation rates are lower among newborns with mothers with no or low literacy, and families where women are not empowered.

Sachdev7 (2012) study reveals semi-nomadic tribal populations in Rajasthan reveals their main challenges in accessing care: lack of appropriate infrastructure, lack of accessibility to hospitals and clinics, the discrimination and poor treatment by the public sector medical staff, their reluctance to seek allopathic medical treatment, as well as their inability to afford it.

Research GAP

Although there has so far not been any research assessing the influence of different social factors, such as socio-economics status, discrimination, gender bias and education, on the access to health care of the Narikuravar community, previous studies on vulnerable or impoverished populations represent a good starting point for creating a theoretical framework. The current literature conveys the effects of education, gender, poverty and nomadism on healthcare-seeking behaviour and access to care in India, finding a strong correlation between them and discussing both causes and their implications. However, no research had been earlier
done on the community’s health admittance and health behaviours.

**Objectives of the Study**

1. To know the influence of Socio economic condition and education/literacy level of Narikuravar community has influence on Discrimination in society.

2. To identify the influence of discrimination in society on health care access towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**Hypotheses of the Study**

There is no influence of Socio economic condition and education/literacy level of Narikuravar community has influence on Discrimination in society.

There is influence of discrimination in society on health care access towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**Methodology**

**Frame work of the study**

The study has been framed with the scope of analysing the dependent variable namely ‘health care access of Women in Narikuravar community’. The Socio-economic status, Education/literacy level has taken as independent variable, while Discrimination acted as a mediate variable.

**Data Collection**

The study employs both primary and secondary data. The primary data will be collected through face-to-face interview method using well-structured and pre-tested interview schedule. Secondary data have been obtained from Book, Website, Census Report, District Report and Tribal Department, Government of Tamil Nadu and India. The interviews will be conducted with women above 18 years old from the Narikuravar community, both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu. The interviewer will travel to the community’s settlements or work places, and the interviews will be taken place in public spaces.

**Sampling Method**

Although they currently present across the state of Tamil Nadu, a huge part of the population contained on 8,500 families, or 30,000 individuals, live in Tamil Nadu (Dragomir, 2017). In the above stated population with an assumption of half of the population are women. In that proposition five percent of population that is 750 women from Narikuravar community will be taken as sample for the purpose of the study. The snowball sampling method has been considered for this study because the Narikuravar community in Tamil Nadu has Nomadic nature of life style. The researcher shall apply snowball sampling method of non-probability sampling method for selection of sample in the study area.

**Analysis and Interpretation**

**Table 1: Model Fit Indication**

Source: Primary data

**H\textsubscript{1}**: Socio economic condition of Narikuravar community has influence on Discrimination in society.

Influence of socio economic condition of Narikuravar community on discrimination in society computed CR value was 1.718 and the probability value was 0.086. Hence, the framed null hypothesis was accepted. The computed standard regression weight was 0.148. It shows that the one unit increase of socio economic condition of Narikuravar community leads to increase of 14.8 percent on discrimination in society. Hence, it is finished that there is no influence of socio economic condition of Narikuravar community on discrimination in society towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**H\textsubscript{2}**: Education/literacy level of Narikuravar community has influence on Discrimination in society.

Influence of Education/literacy level of Narikuravar community on discrimination in society computed CR value was 1.326 and the probability value was 0.185. Hence, the framed null hypothesis was accepted. The computed standard regression weight was 0.114. It shows that the one unit increase of education/literacy level of Narikuravar community leads to increase of 11.4 percent on discrimination in society. Hence, it is finished that there is no influence of education/literacy level of Narikuravar community on discrimination in society towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**H\textsubscript{3}**: Discrimination in society has influence on Health care access.

Influence of Discrimination in society on health care access computed CR value was 7.918 and the probability value was 0.001. Hence, the framed null hypothesis was accepted. The computed standard regression weight was 0.558. It shows that the one unit increase of discrimination in society leads to increase of 55.8 percent on health care access. Hence, it is finished that there is influence of discrimination in society on health care access towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**Table 3: Covariance**

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Socio Economic Condition</td>
<td>Education/Literacy Level</td>
<td>5.668</td>
<td>1.924</td>
<td>2.946</td>
<td>0.258</td>
<td>0.003</td>
</tr>
</tbody>
</table>

Source: Primary data
H$_{0}$: Socio economic condition of Narikuravar community has significant positive relationship with education/literacy level.

Co-varience between socio economic conditions of Narikuravar community with education/literacy level computed CR value was 2.946 and the probability value was 0.003. Hence, the framed null hypothesis was rejected. The computed co-variance weight was 0.258. It shows that the one unit increase of socio economic condition of Narikuravar community leads to increase of 25.8 percent on education/literacy level. Hence, it is finished that there is significant relationship between socio economic condition of Narikuravar community and education/literacy level towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**Findings**

Path analysis found that there is no influence of Socio economic condition and education/literacy level of Narikuravar community has influence on Discrimination in society.

It is also identified that there is influence of discrimination in society on health care access towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu.

**Recommendations**

The Government should play a major role in converting the lives of Narikuravar community through enhanced participatory communication and development programs.

Appropriate action campaigns should be drained for the analysis of Narikuravar community through health awareness programs and provided that health education opportunities. The Narikuravar community is normally flat to health hazards. Hence, they need correct medical facilities as well as insurance in the health sector.

The NGOs and educational institutions have an enormous social responsibility of shifting the attitude of the Narikuravar community and inspiring them to become the champion of human rights and safety life of Narikuravar community.

**Conclusion**

The importance of the research was to identify the Narikuravar community: problems in accessing health care services. Snowball sampling technique was adopted to collect primary data. The sample size was 750 women Narikuravars. Path analysis was assumed for primary data analysis. Path analysis found that there is no influence of socio economic condition and education/literacy level of Narikuravar community has influence on Discrimination in society. It is also identified that there is influence of discrimination in society on health care access towards Narikuravar community both from an urban and a rural setting, Tuticorin and Tirunelveli and districts of Tamil Nadu. Hence, it is concluded that the Appropriate action campaigns should be drained for the analysis of Narikuravar community through health awareness programs and provided that health education opportunities. The Narikuravar community is normally flat to health hazards. Hence, they need correct medical facilities as well as insurance in the health sector.

Implications of Low-Carbohydrate -High Fat Diet on Weight Management

Kanagala Anusha, Anuradha Averineni

Assistant Professor, Department of MBA, Koneru Lakshmaiah Business School, Guntur, A.P.

Abstract

The leading concern in terms of public health today is primarily obesity or weight management. Because of the fact, people in the countries being obese there is a rise in a number of weight loss diets programs. Especially, the low carbohydrate diets were attracted by public as the results in this particular diet are rapid. Evidence indicates the advent of media today is not letting the public to take appointment with the registered dieticians. Public through audio-visual aids are trying to participate in veeramachaneni low carbohydrate-high fat diet. The diet is resulting in reduction of weight (in kgs). In this article we discuss the current practical implications on the efficacy of high-fat, low-carbohydrate dietary patterns for weight loss, and their potential action in execution of the diets further.

Keywords: Ketogenic Diet, Weight Loss, Public Health, Dietary Promotions.

Introduction

Obesity is an excessive fat accumulation that is prevailing in health problems, especially in non communicable diseases such as diabetes, cardiovascular disease and even some type of cancers. India is becoming obese. National family health survey states, women and men of 15-49 years are obese. The overweight is higher in urban areas compared to rural areas.

Obesity is also observed in children, it causes hypertension, breathing issues, increased risk of fractures. In later life they might have high chances of diabetes and premature death, by making the choice of heartier food, overweight can be prevented.

In a life course, healthy diet consumption helps in prevention of malnutrition and a wide range of non communicable diseases. A balanced healthy diet may vary depending on the individual needs; a healthy diet consists of energy rich foods (Carbohydrates and fats), body building foods (proteins), and protective foods (minerals and Vitamins).

For any individual, it is very important to understand that diet varies depending on different stages of life. Diet is very important for all round development of individual. One should be conscious of getting a balanced diet.

Ketogenic diet that became viral in Andhra Pradesh: A low carbohydrate diet being well known as keto diet today, in this diet the body produces ketones in the liver that in turn converted as energy, it is referred under different names as low Carbohydrate, High fat, low carbohydrate diet, ketogenic diet etc.

Recently the social media and television channels have introduced a new diet Regime by Veeramachaneni Ramakrishna who is Charted Accountant turned Nutritionists.

Liquid diet plan:

He took a diet plan based on 4 things and called them 4 pillars.

Consumption of 70-100 grams of fat

3 lemons

4 liters of water

1 multivitamin tablet a day.

The diet recommends to consume coconut oil orally or to be used for cooking for effective weight loss.

Diet plan has been introduces in an effective manner stating that it is going to cure, PCOD, kidney, diabetics,
and many more.

General rule of the diet is different for vegetarians and non vegetarians.

**Solid diet plan:** The day to be started with warm water with lemon recommended diet first, boiled eggs with vegetables before lunch, a clear soup with recommended fats, then a multivitamin supplement, curries suitable for lunch included are chicken, fish or vegetarian curry prepared with olive oil, dinner is with soup with fat,. The daily recommendation of fat intake is mandatory.

**Eat only when you are hungry**

**Foods allowed** in the diet are meat, chicken, fish, eggs, tomatoes, carrot, cabbage, cauliflower, Almonds, garlic, chilies, turmeric, coconut oil, butter, cheese, ghee, olive oil, blueberries, raspberries, strawberries.

**Foods not allowed** are whole wheat, Rice, sugar, all other fruits.\(^1\)

**Marketing of Low Carbohydrate-high fat diet**

The process of marketing involved in promoting a dietary service by veeramachaneni is mentioned below:\(^2\):

### Dietary services management process

<table>
<thead>

<td>Benefits and preferences of public through dieticians/nutritionists.</td>
<td>Efficacy and safety implications</td>
<td>Weight loss, decrease in diabetics and neurological disorders and cardio vascular.</td>
</tr>
</tbody>
</table>

Media Strategies used in promotion of Ketogenic Diet:

The Nutritionist held Public Meetings and penetrated the diet and the process. Later chosen, television, social Media strategies as Youtube, Wats app, Facebook etc. The penetration of diet was high it was participated by thousands of public. Later even the restaurants and small business have also took the diet and made it available at the counters.\(^3\)

Marketing techniques used currently are:

Review of Literature

Fred Brouns (2018)\(^4\), suggested that low carb diet results in reduced energy intake which certainly results in metabolic and functional changes which leads to weight loss, lifestyle intervention in people is a determinant factor in choosing of the diet. Cara B. Ebbeling (2018)\(^\)\(^5\), stated that a low Carb diet is effective in weight loss maintenance for patients with high insulin secretion. According to Detlev Boison (2017)\(^8\), ketogenic therapy for the treatment of epilepsy shown a broad benefits of suppressing Seizures. Sunymo (2017)\(^9\), conducted a study and revealed. Initially hunger feelings for 3 weeks were high, once the participants were into keto diet 10-17% of weight loss is not associated with increased appetite. Hyun-Scung Rhyu (2014)\(^10\), The study is conducted for 3 weeks on 20 taekwondo athletes, the fatigue resistance capacity and aerobic capacity was improved after the diet. Kriesten E .D.Anci (2009)\(^11\), reveals that memory impairment is recorded in low carbohydrate diet, also suggest a better vigilance and confusion, while undertaking a low carbohydrate diet to be taken in having an impact on cognitive behavior. Alexandra M John stone (2008)\(^12\), studied in altering macro nutrient composition of diet observed on 17 men for a trial and identified in a short term low carbohydrate diet reduces hunger and lower food intake, compared to high protein diet. Hussain M Dashti (2004)\(^13\), studied obese patients with high glucose and cholesterol levels, monitored for 16 and 24 weeks and found a decrease in cholesterol and reveals the diet is beneficial. C. Tissa, Kappagoda (2004)\(^14\), states that the diet cannot be recommended to be safe because of the absence of long-term data and advocates low fat diets have established a record of safety and efficacy. Stephen B Sondike (2000)\(^16\), concluded that the diet is effective for short term weight loss in obese and adolescence.

Research Gap: Keto Diet is considered as a mechanism to reduce weight. Public have participated in this diet voluntarily. The ketogenic diet is capable of reducing weight, PCOD and diabetes. As a result, loss in weight is recorded but the marketing of diet is so intense that they come to know about the diet through audio-visual aids rather from a nutritionist/dietician. The present study is undertaken to know the implications of low carbohydrate diet in weight management and the respective side effects if any.

Research Methodology: The study is descriptive and the data is collected from 76 Employees who have practiced in Veeramachineni keto diet of KL deemed to be University, Guntur. The primary data is collected through a questionnaire; the sampling design for the research is simple random sampling method. The data is collected from the employees before the diet (weight in Kgs) as well after 3 months of the diet their weights (in kgs) are interpreted to draw conclusion using SPSS.

Research Objective:

1 To examine the effectiveness of low carbohydrate diet by veeramachineni on weight of the respondents.

2 To analyze the gender and age of the respondents in managing keto-diet.

3 To analyze the mode of awareness and side effects (if any) in personnel weight management.

Findings and Discussion

The study is conducted on the public who have undergone with low carbohydrate diet. Their distribution of weights in Kilograms is shown below

<table>
<thead>

<td>3</td>
<td>3.9</td>
</tr>
</tbody>
</table>

**Graph: 2 Mean Weights of Respondents on basis of age their weights before and after the diet**

The above chart shows the means of weights of different age groups before diet and after diet. The mean weight of 20-30 years age group before and after the diet is same this implies that the keto diet does not have any impact on this age group. Considering the age group of 31-40 years it is observed that the mean weight before the diet is 80.00 kgs and the mean weight after the diet is 77.48 kgs. The mean weight for age group 41-50 years before the diet is 84.50 and after diet is 82.38 kgs. The mean weight for age group of 51-60 years before diet is 81.37 kgs and after diet is 79.00 kgs. The mean weight of respondents of age group above 60 years before the diet is 76.67 kgs and after diet is 74.67 kgs.

**Table no: 4 Respondents and their consultations for weight management**

<table>
<thead>
<tr>
<th>S.No</th>
<th>Respondents Opinion</th>
<th>Frequency</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Audio-visual</td>
<td>58</td>
<td>76.3</td>
</tr>
<tr>
<td>2</td>
<td>Dietician</td>
<td>18</td>
<td>23.7</td>
</tr>
</tbody>
</table>

**Graph: 3 Mean Weights of Respondents and their consultation for weight management**
From the above chart it is observed that the mean weights of respondents before considering the audio-visual aids is 80.81 Kgs and after following diet as per audio visual aids is 78.52 Kgs. The mean weights of respondents, before consulting dietician is 86.56 Kgs and after consulting the dietician is 84.39 Kgs.

Conclusion

From the discussions it is observed that the mean differences of weights after the diet decreased. But, the mean difference of weights decreased before and after the diet had very slight change. States that most of the public participated in the diet were not directed by the Nutritionist himself. They were taking up this diet through nutritionist directions which are present on social media videos, at public meetings and word of mouth. The respondents were into the diet mostly to manage their weight and diabetes. But the average weight loss was minimum and could not retain it and also faced certain side effects such as giddiness, kidney related problems. Finally, the ketogenic diet is in need for promoting to one to one solution because the problem of obesity is different from one person to another.

The Behavioural Risk Factors Contributing to Non-Communicable Diseases among Women

Sheeba S1, R. Rima2, Parvathy Suresh2
1Assistant Professor, Department of Community Health Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India, 2Fourth Year B Sc Nursing students, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India

Abstract

Objective: To assess the prevalence of behavioural risk factors for non-communicable diseases in working and nonworking women.

Materials and Method: Quantitative approach with descriptive survey design and convenience sampling technique was used. The study conducted among 70 working and 70 nonworking women above the age of 20 years, residing at Nayarambalam Panchayath, Ernakulam district. Data were collected by house-to-house survey using World Health Organization STEP-instrument for the surveillance of noncommunicable disease risk factors (WHO-STEP 1 & STEP 2 questionnaires). Descriptive statistics and Chi-square test were used for analysis.

Result: Majority of the working women (71.4%) and non working (61.4%) was in the age group of 31-50 yrs. The mean age was 44.7 years for working and 41.32 years for nonworking women. Overweight was found high among (41.42%) working women, when compared to (21.42%) nonworking women. Abdominal obesity is found high 34.28% and very high 11.42% among working women when compared to 10% and 7.14% among nonworking women. It was found that non working women had inadequate vegetable intake compared to working women ($x^2 = 34.392$, df = 5, $p = 0.000$) and also fruit intake was higher among working women compared to non working women ($x^2 = 14.3313$, df = 3, $p = 0.002$). Working women (52.85%) had low physical activity when compared to nonworking women (22.85%). It was also found that diabetes mellitus was diagnosed among working women compared to nonworking women during the study ($x^2 = 5.1853$, df = 1, $p = 0.023$) and dyslipidemia was higher among working women ($x^2 = 6.2693$, df = 1, $p = 0.012$).

Conclusion: Behavioural risk factors like overweight, obesity, abdominal obesity and low physical activity were higher among working women. There is an urgent need of community based screening and health promotional activities to reduce the burden of non communicable disease.

Key Words: Behavioural risk factors, Noncommunicable diseases, Working women, Non working women.

Introduction

Global burden of disease has continued to shift from communicable to non-communicable diseases and from premature deaths to years lived with disability. Non-communicable diseases (NCDs) kill 41 million people each year, equivalent to 71% of all deaths globally. 4 groups of disease (cardiovascular diseases, respiratory
diseases, cancers and diabetes mellitus) account for over 80% of all premature NCD death. In the year 2015, 56.4 million global death occurred among that 39.5 million occurred due to non-communicable diseases out of that 30.7 million occurred in low and middle income countries. As India is a developing nation it is under the rising burden of NCDs causing significant morbidity and mortality. India State Level disease burden initiative done along with global burden of diseases study 2016 showed high rate of NCDs in states like Kerala, Goa and Tamil Nadu.

Behavioural risk factors play an important role in causation of NCDs. Ischemic heart disease and stroke are projected to increase further by 2020, and developing countries will experience the highest burden. Non-communicable disease behavioural risk factors such as tobacco smoking, heavy alcohol consumption, physical inactivity, and unhealthy eating are socially patterned in high-income countries, with individuals of low socioeconomic status generally experiencing a higher burden of risk factors.

India is in the grip of an epidemic posed by non communicable diseases and a rising trend is even being witnessed in low socio-economic urban areas. Two in every three deaths among women are caused by non-communicable diseases-largely heart disease, stroke, cancer, diabetes and chronic respiratory diseases. Risk factors for heart disease and stroke are the leading cause for death in women. Factors such as age and family history play a role, but the majority of CVD deaths are due to modifiable risk factors such as tobacco use; diets high in fat, salt, and sugar; high blood pressure; high cholesterol; obesity; and diabetes. The epidemiological risk factors for cervical cancer are early age at marriage, multiple sexual partners, multiple pregnancies, poor genital hygiene, malnutrition, use of oral contraceptives, and lack of awareness. A multipronged approach is necessary which can target areas of high prevalence identified by registries with a combination of behavior change communication exercises and routine early screening.

Recent findings Systems for control of noncommunicable diseases (NCDs) in the low-income contexts are poorly developed and health services are often overwhelmed with high levels both of NCD and communicable disease. Multidisciplinary and holistic approaches to disease management are often lacking in these settings. Developing an integrated primary care approach to NCD management is increasingly recognized as a key strategy and this should include palliative care.

Prevalence of risk factors varies among working and non working women. Therefore it is important to detect the presence of risk factors among women at the earliest to reduce the prevalence of NCDs. Hence the investigator is interested to assess the prevalence of behavioural risk factors contributing to non communicable diseases among working and non working women.

**Materials and Method**

A community based descriptive study was conducted to assess the behavioural risk factors contributing to noncommunicable diseases among 70 working and 70 nonworking women above the age of 20 years, residing at Nayarambalam Panchayath of Ernakulam district. Subjects included were women residing at Nayarambalam panchayath and who are mentally fit without debilitating disease or bedridden. Convenience sampling technique was used. The researcher explained the purpose of the study and obtained an informed consent from each subject. World Health Organization-Step instrument surveillance of noncommunicable disease risk factors (STEP 1 & STEP 2) Version 3.0. WHO-STEPS instrument covers three different levels of steps of risk factor assessment. These steps include questionnaire (STEP-1), physical measurements (STEP-2) and biochemical measurements (STEP-3). For the purpose of our study WHO-STEPS questionnaire 1 (history of risk factors) and 2 (simple physical measurements) were suitably modified and translated to local language to collect data from subjects. WHO step 1 tool includes Demographic information and behaviorameasurements (details regarding tobacco use, alcohol consumption, diet, dietary salt, physical activity, history of raised blood pressure, history of diabetes, history of raised total cholesterol, history of cardiovascular disease, lifestyle advice, history of cervical screening) and WHO step 2 includes physical measurements (Blood pressure, height, weight and waist circumference). Standard procedures were followed for anthropometric and BP measurements. Calibrated aneroid BP apparatus and personal weighing scale was used. Data analysis was done by using descriptive statistics and Chi-square test.

Data presented in Table 1 shows that majority of the non working women (90%) had inadequate vegetable intake daily when compared to working women (72.86%) and nonworking (100%) had inadequate fruits intake when compared to 81.42% of working women. Working women (52.85%) had low physical activity when compared to nonworking women (22.85%). None of them were using tobacco or alcohol.

Data presented in Table 3 shows that non working women had inadequate vegetable intake compared to working women (X² = 34.392, df = 5, p = 0.000) and also fruit intake was higher among working women compared to non working women (X² = 14.3313, df = 3, p = 0.002). Physical inactivity was higher among working women when compared to nonworking women (X² = 13.390, df = 1, p = 0.000). It was also found that diabetes mellitus was diagnosed more in working women as compared to nonworking women during the study (X² = 5.1853, df = 1, p = 0.023) and dyslipidemia is higher in working women (X² = 6.2693, df = 1, p = 0.012) than nonworking women.
women.

Discussion

The findings of the present study revealed that Majority of the working women (71.4%) and non working (61.4%) was in the age group of 31-50yrs. Overweight (41.42%) and obesity (11.42%) was found higher among working women, when compared to nonworking women. Abdominal obesity is found higher among working women when compared to nonworking women. Working women (52.85%) had low physical activity when compared to nonworking women (22.85%). It was found that non working women had inadequate vegetable intake compared to working women ($x^2 = 34.392, df = 5, p = 0.000$) and also fruit intake was higher among working women compared to nonworking women ($x^2 = 14.3313, df = 3, p = 0.002$).

A similar study was conducted among 400 women (200 working and 200 nonworking women) of urban slums at Karnataka in the age-group of 30-45 years on a voluntary basis, using WHO-STEP 1 and 2 questionnaires shows that 49% women were in the age-group of 30-35 years, with 60.5% belonging to Class IV socioeconomic status. 11% women were newly diagnosed with hypertension. 92.5% were not in a habit of consuming fruits adequately. Most of the women also opined that they consume junk food once in 7 days. It was found that 350 (87.5%) were physically inactive. Overweight was found among 17.5% working women, and 14% nonworking women. Obesity was present among 12% working women, and 6% of nonworking women.

A similar study was conducted among 130 apparently healthy women of age 20-60 years in randomly selected wards of Eloor municipality, Kochi, Kerala. WHO STEPS instrument was administered to eligible subjects. Their anthropometric measurements were also taken using standardised tools. The mean age of the women surveyed was 38.9 years (SD 10.2). Majority (71%) of the study participants were home makers. Majority (97.2%) consumed less than 5 servings of fruits and vegetables a day. Of them, 79.3% were in the low physical activity category. Around 55% of the women were either overweight or obese.

Conclusion

In our study prevalence of behavioural risk factors for non communicable diseases were high among women. Behavioural risk factors like overweight, obesity, abdominal obesity and low physical activity were higher among working women. But they have adequate fruits and vegetable intake when compared to nonworking women. Presence of diabetes mellitus, hypertension, dyslipidemia were higher among working women. There is an urgent need of community based screening and health promotional activities to reduce the burden of non communicable disease.

Mental and Physical Wellbeing of Elderly

Sunitha P P, Surya M Nair, Swapna S Nair

1Lecturer, 2IV year B.Sc. Nursing Students, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala

Abstract

Background of the Study: Elderly person constitutes growing section of population. Today the society emphasizes the importance of physical activity to maintain and enhance the strength and function of the body.

Objectives: To identify the relation between mental and physical wellbeing of elderly and its association with selected demographic and clinical variables.

Materials and Method: Descriptive design was adopted for this study. The study conducted among 45 young old people attending Geriatric OPD using convenience sampling. The data collected using structured questionnaire on socio-demographic and clinical data, Rapid Assessment of Physical Activity questionnaire (RAPA) to assess the physical wellbeing and Warwick Edinburgh Mental Wellbeing Scale (WEMWBS) to assess the mental wellbeing of elderly.

Results: The results showed that the mean RAPA-1 score of the samples were sub optimal (3.47 ± 1.57) whereas the mean mental wellbeing score was high (64.44 ± 6.66). There was no significant relation between mental wellbeing and physical wellbeing \( r=0.175 \). And also found that there is a significant association between physical wellbeing and presence of co-morbidities \( p=0.042 \).

Conclusion: The study concluded that physical wellbeing and mental wellbeing is not related.

Key words: Mental wellbeing, Physical wellbeing, elderly

Introduction

Age is not merely a biological function of the number of years one has lived, or of the physiological changes the body goes through during the life course. Age represents the wealth of life experiences that shape whom we become\(^1\). Ageing involves physical, cognitive, social and familial losses and brings with it an increased incidence of disability and the need for assistance with activities of daily living\(^2\).

The world’s population is ageing rapidly. Between 2015 and 2050, the proportion of the world’s older adults is estimated to almost double from about 12% to 22%. This is an expected increase from 900 million to 2 billion people over the age of 60. Older people face special physical and mental health challenges which need to be recognized. Older adults, those aged 60 or above, make important contributions to society in different roles such as family members, volunteers and as active participants in the workforce\(^3\).

Mental wellbeing is an integral part of overall health. It responds to life’s ups and downs\(^4\). The World Health Organization describes mental well-being as a state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community\(^5\).

DOI Number: 10.5958/0976-5506.2019.02750.5
According to studies, elderly patients have a reduced performance status and more co-morbid illnesses. Today’s society often emphasizes how important it is for people to be physically active in order to maintain and enhance the body’s strength and function. Older adults continue patterns of physical activity throughout their lifetime, but with adaptations due to age-related limitations.

While there is a lot of emphasis on the physical well-being of older people, the same emphasis or importance has not been placed on their mental health and wellbeing. Promoting successful ageing is an important part of maintaining physical and mental wellbeing in the elderly. Evidences shows that adults’ participation in self-care activities such as leisure time physical activity and walking are positively related to mental wellbeing whereas total levels of free living physical activity are not.

Materials and Method

This descriptive study was conducted in Geriatric OPD, AIMS, Kochi. The study included 45 samples selected using convenience sampling method. The tool for data collection were structured questionnaire on demographic and clinical data, Warwick Edinburgh Mental Wellbeing Scale (WEMWBS) to assess the mental wellbeing which is a 14 item scale of mental wellbeing in which all items are worded positively and address aspects of positive mental health. The scale is scored by summing responses to each item on a 1 to 5 Likert scale. The minimum scale score is 14 and the maximum is 70. The Rapid Assessment of Physical Activity (RAPA) questionnaire was used to assess the physical wellbeing. In the present study the physical wellbeing denotes the physical activity of the elderly. The RAPA questionnaire was a nine item questionnaire with the response options of yes or no to questions. The questions covering range of levels of physical activity from sedentary to regular vigorous physical activity (RAPA-1) as well as strength training and flexibility (RAPA-2). A score of 6 or above signifies optimal physical activity and below 6 indicates suboptimal physical activity.

Procedure for data collection: The ethical clearance was obtained from Institution Review Board and Head of the Department for conducting the study. The purpose of the study was explained and informed consent was taken from the samples. The data was analyzed using descriptive and inferential statistics.

Results

Section A: Sociodemographic characteristics of the samples

Out of the 45 samples, 62.2% (28) were males. Majority (97.8%) were married and 32% were residing in rural area. More than half of the samples (57.8%) belongs to nuclear family.

<td>03(75%)</td>
</tr>
</tbody>
</table>

Table 4 shows that there is an association between physical wellbeing and presence of co morbidities at 0.05 level.

Discussion

The present study aimed to assess the relationship between mental wellbeing and physical wellbeing of elderly. According to the study, 91% of samples were in the suboptimal level of physical wellbeing according to RAPA-1 (mean score was 3.47 ± 1.57) and the mean score of 64.44 ± 6.66 for mental wellbeing indicates high mental wellbeing.

One study conducted using RAPA questionnaire showed that the mean RAPA-1 score of samples categorized into two were suboptimal (group 1: 2.514 ± 0.901 and group 2: 3.215 ± 1.257)\(^9\). In another study of physical activity and mental wellbeing in a cohort aged 60-64 years showed the mean WEMWBS score was 51.6 ± 7.9\(^8\). The difference in mean value may be the result of less sample size of the present study.

The result of the present study also revealed that there is no relationship between mental and physical wellbeing of elderly (p=0.251). Contradictory to this results, a study conducted to assess the relationship between physical inactivity and mental wellbeing, showed there is a weak positive correlation between physical activity and mental wellbeing (rs(1684)=0.316, p<0.001)\(^9\). Another study to assess the physical activity level and wellbeing in older adults illustrated that light physical activities were positively associated with wellbeing among the retirees over 60 years of age\(^11\). The possible reason for this two results could be the less sample size.

Limitation of the study: The limitation of the study was that long term assessment of wellbeing was not done and the generalization of findings was limited due to small sample size.

Conclusion

From the result, we found out that the physical wellbeing of elderly was suboptimal but they maintain a high mental wellbeing state. And also concluded that there does not exist a relationship between mental wellbeing and physical wellbeing. Therefore the study identifies the need for regular assessment of physical activity as well as mental wellbeing for the elderly not only at the institutional level but also at the community level so that more findings could be elicited.

But there is an association between physical wellbeing and presence of comorbidities. So one of the reason for not actively participating in the physical activities by the elderly may be the disease cascade. Therefore it is very important to emphasize the type of light activities that can be done by them in order for maintaining better physical wellbeing.

Effects of Birth Order on Morbidity of Under-5 Children in Rural Tamil Nadu

V. Samya¹, A Meriton Stanly², Ramesh Harihara Iyer³

¹Assistant Professor, ²Professor, Department of Community Medicine, SRIHER, Chennai

Abstract

Background: The health and well-being of under-five children depends on various factors including maternal age, birth order, etc. Birth order is a significant predictor of the under-five mortality and morbidity. This study was carried out to evaluate the impact of birth order on the morbidity of under-five children in rural Tamil Nadu.

Method: This cross sectional study was carried out on 370 under-five children residing in the rural field practice area of our institution for a period of three months. A structured interview schedule was used to obtain information regarding the obstetric history, birth history and medical history of the participants.

Results: Children whose birth order was more than 2 were at a higher risk of getting more than 3 episodes of diarrhea (OR 3.5, p<0.05) Overcrowding and under nutrition were also significantly associated with increased birth order (p<0.05).

Conclusion: Although the prevalence of birth order beyond three children has drastically come down in the recent decades, it is continues to persist in rural pockets and groups with low socio economic status. There is a need for revisiting the family welfare strategies in order to minimize the birth order.

Key words: Acute diarrheal diseases, Birth order, malnutrition, overcrowding, under-five mortality

Introduction

The health policies addressing the health issues of the people in India as designed by the Ministry of Health and Family Welfare focuses on strengthening the maternal and child health. Child health is determined by various mortality and morbidity indicators including infant mortality rate, under five mortality rate etc. Under-five age group is the age between birth (0 months) and up to five years of age, which corresponds to 60 months. The health and wellbeing of this age groups determines the growth and development of the child in the future years. Several physical, mental, social and economic factors play a major role in determining the health and well-being of these under five children. There has been a considerable drop in the under-five mortality rate all over the world, more so in developing countries like India. From 52.4 deaths per 1000 live births in 2012, India has significantly lowered the rates to 39.4 per 1000 live births in 2017¹. According to the World Health Organization, at risk under-five children have been identified as the vulnerable populations who are prone to an increased risk of diseases, growth retardation, mental illness and physiological problems in the adulthood. There are several criteria which determine the at risk status of these children, including low birth weight less than 2.5 kg, early initiation of artificial feeding, presence of twins, weight below 70% of the expected weight, birth order etc².

In order to ensure that the wellbeing of the under five children, it is essential to address the issues concerning

Corresponding author:
Dr V. Samya,
Assistant Professor, Sri Ramachandra Institute of Higher Education and Research. ph: 9003027485.
the maternal health and health services provided to
the mothers during pregnancy. A healthy mother is
a guarantee for a healthy child. Birth order is a subtle
indicator of the well being of both the mother and child.
It not only determines the health status of the child, but
also reflects the attitudes of the parents towards family
planning and contraception. Birth order significantly
influences the risk exposures of the child towards the
physical and socio economic conditions at home; it also
signifies the amount of care given by the parents which
is indirectly influenced by the health status of the mother.

Several studies have been undertaken in the
western world to elucidate the impact of birth order
on the cognitive abilities, psychosocial development
and predictive risk for certain diseases during the adult
hood\(^3\). Several psychological studies have implicated
birth order with the IQ level of the children. Although
birth order does not exert any biological influence, the
relationship between the birth order and socio economic
status of the household plays a key role in determining
the exposure of the child to certain experiences and these
in turn are the risk factors for several psychological
issues. In developing country like India where the socio
economic situation is diverse and varied, birth order a
plays a key role in determining the access to health care
and better living conditions. A typical rural middle class
family with an increased birth order has greater risk for
communicable diseases, parasitic infections, nutrition
deficiencies and as a result of these they are prone for
substance abuse, social behavioural problems and other
non communicable diseases during the adulthood.
It is important to evaluate the birth order and risk
factors associated with birth order in order to get a vivid
picture of the impact of a family planning programmes
and initiatives taken by the Government in this regard.
Although several studies have been carried out in the
developed countries, very few studies have been done
in India especially in the rural sector to explore the
pattern and impact of the birth order on the childhood
morbidities.

**Objectives**

1. To evaluate the effects of birth order and certain
   morbidities among under-5 children in a rural
   area.

2. To analyze the sociodemographic and
   environmental risk factors influencing the birth
   order.

**Methodology**

**Study setting and participants**

This population based cross sectional study was
carried out in the rural field practice area of our tertiary
teaching institution for a period of three months. All the
under five children residing in the field practice area
formed the study population. A total of 2373 children
were present in the study area during the study period.

**Sample size and sampling**

Based on intensive literature review, the lowest
prevalence of risk factors in under-five children was
found to be 9% for diarrhea, according to NFHS-3
statistics\(^4\). At 95% level of significance and 3% absolute
precision, the sample size was calculated as 349.43.
Accounting 5% for non response, the sample size was
calculated as 366.9 and was rounded off to 370. The
entire list of under five children residing in the study
area was procured from the Village Health Nurse. The
required sample size of 370 was selected from the total
of 2373 children by simple random sampling based on
computer generated random numbers.

**Ethical approval and informed consent**

Approval was obtained from the Institutional Ethics
Committee prior to the commencement of the study.
Each participant’s mother was approached and explained
in detail about the study. Informed consent was obtained
from each participant prior to the commencement of data
collection.

**Data collection tools**

A structured interview schedule was used to
obtain information regarding the sociodemographic
characteristics, birth history and presence of risk factors
and morbidities among the study participants.

**Data analysis**

Data was entered and analyzed using SPSS version
16 software. The prevalence of risk factors was expressed
in percentages. Chi square test was used to analyze the
statistical significance between the birth order and risk
factors.

**Results**

Overall, majority of the participants were first born
(48.9%) followed by second born (42.9%). Among the
first born, majority of the participants belonged to 13-24 months, while among the second and third born, majority of the participants were 37-48 months old (24.5% and 36% respectively). Among the fourth born, majority belonged to 49-60 months old (40%). (Fig. 1)

Majority of the participants were males (51.3%). Majority of the males belonged to birth order four (60%) while majority of the females belonged to birth order three (56%). Overcrowding and nutritional status were important risk factors for increased birth order in this study. Participants with moderate under nutrition (6.2%) were at increased risk for increased birth order compared to those with mild (1.4%) or severe (4.4%) undernutrition. (Table 1)

There was a significant association between the birth order and risk for diarrheal diseases and infections. It was observed that the children whose birth order was more than 2 had a 3.5 times increased risk of having more than 3 episodes of diarrhea (OR 3.5, 95% CI 1.4-8.5, p 0.03). Details given in table 2. Birth order of four was at increased risk of low birth weight (40%) compared to first born (12.2%) and second born (13.2%) children. This difference was statistically significant (p<0.05). (Table 3)

There was a significant association of birth order of 2 or more and exclusive breastfeeding of the children. (OR 4.2 95% CI 1.2-4.5). (table 4)

**Discussion**

Birth order is significant predictor of mortality and morbidity among the infants and under five children. Majority of the participants in our study were first born or second born. However there was prevalence of 6.7% who belong to birth order three and 1.35% belong to birth order four. Overall birth order greater than three was prevalent in 8.1% of the study participants. The key risk factors which were associated with birth order of more than three included overcrowding under nutrition substantiated by low mid arm circumferences. These factors were associated with birth order of more than three and this association was statistically significant (p value <0.05). While we analyzed the impact of birth order on the morbidity of these under five children it was observed that birth order beyond three had an increased risk of diarrheal infections, increased episodes of diarrhea with the frequency of more than three episodes and this observation was statistically significant (p value < 0.05). Similarly the birth weight of these participants was less than 70 percent of the expected birth weight for children of birth order beyond three. This observation was also statistically significant (p value <0.05).

According to nationwide data generated, the sex of the child, mother’s age at birth, birth order and previous birth interval were predominant risk factors for infant mortality, child mortality and under-five mortality. Among these birth order had a severe impact on these mortality rates. As per NFHS data, birth order beyond three children was associated with an under-five mortality of 62 per 1000live births and as the birth order increased to seven and above, the under-five mortality rate shot up to 116 per 1000 live births. Similarly increase in the birth order beyond two children increased the risk for infant mortality rate to 62 per 1000 live births. Increase in the birth order significantly impacted the neonatal mortality, thereby highlighting that apart from external socio economic factors, birth order inherently induced risk for mortality at the time of delivery.

Gender differences play a major role in determining the morbidity and mortality of the under five children. In our study majority of the children beyond second birth order were females (53.3%) compare to males. Large scale nationwide surveys have shown that gender differences are increasingly linked to infant mortality, especially those with higher birth order. This association has not been influenced by socio economic factors. The study done by Victoria et al has shown that a girl has 40% increased chances of dying between a first and fifth birth days compared to a boy child and this increases as the birth order increases.

Malnutrition is a perennial problem developing economies and India continues to struggle to combat malnutrition especially among under five children. There are several factors which influence malnutrition of which birth order is a significant one. Our study has demonstrated a statistically significant association between malnutrition and increased birth order. A study done by Sagu S.K et al also showed similar findings. Similarly, combating acute diarrheal diseases and infections in under five children has been the goal of several national programmes. Although the etiology of acute diarrheal diseases is predominantly viral, extraneous socio economic factors including birth order have also been implicated. In our study, we found an increased risk of diarrheal diseases among children of
higher birth order compared to their first born or second born counterparts. In a study done by Mihrete T.S et al a bivariate analysis showed that higher birth order was significantly associated with childhood diarrhea. It is also worth mentioning that prolongation of these risk factors not only increases the morbidity of the patient, but also increases the risk of malnutrition and chronic diseases both direct and indirectly predisposed by increase birth order.

Conclusion

Overall birth order has been emphasized as a significant risk factor for several communicable and non-communicable diseases in the under-five age group. It is essential that note that birth order indirectly reflects on the reach of family planning programmes that have been implemented at the nationwide level. Although the prevalence of birth order beyond three children has drastically come down in the recent decades, it is continues to persist in rural pockets and groups with low socio economic status. This study also indicates that the there has been significant gap in the implementation of family welfare strategies and interventions. Therefore there is an emergent need to revisit the strategies of family planning interventions in order to expand the strategies to an inclusive one so as to minimize the birth order up to three children thereby improving the health and quality of life of children.

Abstract
Tribes are one of the major contributors for the diversified culture of India and their development is essential for country’s development. This study aims to understand the pattern of diseases among tribes in Nilgiris district and their health care practices. This study emphasizes on Survey research and non-probability sampling is applied in which respondents are selected using convenient sampling. The study was conducted among 94 respondents from Gudalur taluk, Pandalur taluk and Kotagiri block of Nilgiris district. The data was collected using semi-structured interview schedule and analysed. The findings of the study shows that more than half (55.5%) of the respondents are affected by non-communicable diseases and 44.5% are affected by chronic diseases. More than half of the respondents (56.4%) defecate in open and majority (87.7%) of the respondents have the habit of using substances and 80.9% of the respondents are not having the knowledge of the disease they are suffering.

Keywords: word; Tribes, Health, Communicable diseases, Non –communicable diseases, Health care

Introduction
The ancient epics such as Mahabharata, Ramayana, and Silapathigaram speak volumes about the tribal in India and their way of living. Chattopadhyay defines tribes as the homogeneous group which lives in a definite geographical area with unifying culture. They are the original inhabitants of the land and have cultural life congenial to the environment and India has second largest population next to Africa. Though the Indian Constitution recognizes them with a special status as scheduled Tribes and provides safeguards to protect their rights, it still remains a question as to whether all their rights are met. Though there are health programs for the rural and the tribal communities, the tribal people have remained marginal. Programs that are meant for the rural community may not be appropriate for the tribal community as the live in a different terrain, with a different lifestyle, culture and practices. According to the 2011 Census, Tribes constitute 104 billion in India, but still remain marginally secluded geographically, economically, socially and politically.

As per census of India, tribes constitutes about 8.6% of total population (Census of India, 2011) and in Nilgiris district of Tamilnadu they are about 4% of the total population. Their health status is less when compared with the general population. There are stark differences in their level of literacy, nutrition, age at marriage, insufficient potable water, lack of personal hygiene, illiteracy, poverty and poor maternal and child health services. Tribes in India have nutritional related disorders where men have under nutritional disorders then women. An alarming prevalence of the Triple Burden of disease(Undernutrition, overweight or obesity, Hypertension) has also been identified among the tribes in West Bengal Odisha and Gujarat and tribal women have low health standards than non-tribal women in areas of antenatal, delivery, Post natal and Post partum

DOI Number: 10.5958/0976-5506.2019.02404.5
Nutritional status of the community is influenced by many factors such as belief, customs, and the food materials available in their region. The consumption of nutrients is less in tribal population, especially among pre-school children which is far beyond the recommended Dietary Allowance prescribed for children of that age. This may be because of poverty, less awareness, non-availability of microcredit and social mobilisation.

Poor sanitation is also a reason for disease causation and the consumption of tobacco need to be reduced among the tribal people needs to be reduced. Tribal women and men also face problems due to lack of latrines as they have to travel to faraway places when they are sick or have undergone surgery for birth control. The tribal women though felt the need for construction of toilets are not able to do so as the soil structure was not conducive for construction of pit latrines.

The pattern of diseases among the disadvantaged sections includes both communicable and non-communicable diseases and their health is influenced by multiple factors such as social, environmental, genetic, cultural and behavioural factors. Non-communicable diseases are more prevalent than communicable diseases. Hypertension is very common among men than women though not significant, which can be associated with alcohol intake, central obesity and sedentary lifestyle. They suffer from both communicable and non-communicable diseases in all parts of India. Poverty, poor sanitation, lack of health care facilities, malnutrition, social barriers and taboos, lack of awareness are some of the contributors for increased health risk of tribes in India.

The poor health condition of people affects their livelihood and sets off poverty and affects their education and their social and cultural factors affect the mortality rate. Through awareness health and nutritional status can be improved. Moreover there is a gap to implement interventions which are low cost, affordable and providing immediate results because the majority of the people live in remote areas. Hence it is evident to address the issue on issues related health to understand its causes and pattern. Multi-pronged approaches may be used to increase the effectiveness of the interventions, like improving their nutritional status, integrating the Scheduled Tribes in Public Health Interventions. A study done among the Kora Mudis in West Bengal found that the BMI (Body Mass Index) was significantly low among women than men when compared to other Tribes in India and hence immediate nutritional interventions need to be carried out for tribal community. More research has to be carried out among Tribal population as well as among the rural and urban poor who fall under the below Poverty Line (BPL) as they constitute a vast majority of the population in India.

This study attempts to understand the pattern of diseases existing among tribes in Pandalur taluk, Gudalur taluk and Kotagiri block of Nilgiris District. This district is situated in the north western part of Tamilnadu, Southern India and it is also known as the “Queen of Hills”. There are about 6 different tribes Todas, Kotas, Kurumbas, Irulas, Paniyas and Katunayakas in this district with unique cultural traits. This study attempts to find out the pattern of diseases, their perception towards the disease, food pattern, the accessibility of health care services and the traditional method of treating the diseases among the tribes in Nilgiri district.

Materials and Method

This study emphasizes on Quantitative research and Survey Research Design has been employed to understand health care practices and pattern of disease among Nilgiri tribes. Non-probability sampling is employed in which convenient sampling is used to select the respondents from Pandalur Taluk, Gudalur Taluk and Kotagiri Block of Nilgiris district, Tamilnadu. The data was collected using semi-structured interview schedule and 94 respondents were studied in this research.

Findings

The research aims to understand the pattern of diseases among the Nilgiri tribes and the data was collected from 94 respondents and analysed. The findings of this study show that more than half 55.5% of the respondents are affected by life style diseases and 44.5% are affected by the chronic diseases. The description of the prevalence of the life style and chronic diseases is given in the table number 1.

47.9% of the respondent’s family history has similar health problems, 60.6% of the respondents responded there is no particular communicable diseases affecting their community at large, 90.4% of respondents seek doctors’ advice for treatment and only 7.4% respondents prefer herbal medicines. More than two third 71.3% of the respondents consume forest products as major food intake and majority 82% face economic problems because of which they are not getting nutritious food. More than half 56.4% of the respondents have no toilet facility at home and defecate in open space. The availability of traditional medical practitioners is only 20.2% and 28.7% preferring home deliveries. More than half 55.5% of the respondents have non-communicable diseases such as diabetes, hyper tension, asthma, arthritis and 44.5% of the respondents have chronic diseases such as cancer, sickle cell anaemia, TB and coronary heart diseases. Nearly half of the respondents 47.9% have similar family history of the particular disease. The sanitation facilities is not proper in most of the villages and the incidence of diseases is more during rainy season as nearly 56.4% defecate in open space and use water from river and well. Women are unaware of good menstrual practices and still they use clothes and leaves. Superstitious beliefs and taboos are prevailing in the community and so 28.7% prefer home deliveries and only 58.5% make use of mobile clinics. 40.5% of the respondents are found to be anaemic problems and among them it is mostly common in women which may be due to the insufficient consumption of nutritious food. More than half 58.5% of the respondents have immunity issues which causes further to be anaemic as well.

Discussion

Though tribes live in close harmony with nature, the Nilgiri tribes are found to be vulnerable to different communicable and non-communicable diseases which affect their development. It is found that 55.5% of the respondents have non-communicable diseases such as diabetes, hyper tension, asthma, arthritis and 44.5% of the respondents have chronic diseases such as cancer, sickle cell anaemia, TB and coronary heart diseases. Nearly half of the respondents 47.9% have similar family history of the particular disease. The sanitation facilities is not proper in most of the villages and the incidence of diseases is more during rainy season as nearly 56.4% defecate in open space and use water from river and well. Women are unaware of good menstrual practices and still they use clothes and leaves. Superstitious beliefs and taboos are prevailing in the community and so 28.7% prefer home deliveries and only 58.5% make use of mobile clinics. 40.5% of the respondents are found to be anaemic problems and among them it is mostly common in women which may be due to the insufficient consumption of nutritious food.

The major food items consumed by these people are mostly rice, dhal, spinach and tubers which may not be sufficient as a result of which they have tended to become anaemic. This affects their menstrual cycle, complications during pregnancy and also health complications during childbirth. It was found while interaction that there were child marriage incidents who have immunity issues which causes further to be anaemic as well.
Due to the social taboos and stigma the women are not ready to speak about their health issues. They prefer traditional health care practices but traditional medical practitioners are not always available now a day because of which they go for Allopathic Practitioners. Traditional health care practices are eroding at present as practitioners are not willing to teach the new generation since they do not show interest. 58.5% of the respondents have the accessibility to mobile medical unit once in every month in their village but they are not willing to come for check-up. It was inferred through the study that most of the people falls into the category of below poverty line and high incidence of health issues among them which indicates that they do not have resources to improve their nutrition due to poverty. Also it is observed that the respondents who take forest products such as spinach and honey etc., do not full fill the required nutrition which causes further health issues.

Around 71.3% of women prefer institutional delivery but most of the women hide their pregnancy during the visit of medical mobile unit. This may be due to fact that they have more faith and belief in their own god and are also willing to accept even when unfortunate events happen. 80.9% of the respondents have the support of NGO’s which help them in improving their health standards but the tribes are not make using of it.

**Conclusion**

The primary aim of this research is to understand the pattern of disease among the tribal in Nilgiri district. The dominant disease among the Nilgiri tribes is non-communicable life style diseases and 90% of the respondents seek doctors’ advice for treatment. Menstrual hygiene is not maintained properly and more interventions need to be given on that area. Anaemic problems are prevalent among women and economic status affect their health at large. Sanitation facilities need to be improved to prevent from water born diseases during rainy seasons. On the whole the tribals require additional support to fight against poverty such as organising them into self help groups, social mobilisation and eventually start income generating activity to improve the livelihood which in turn help them to resolve various health issues.

Abstract

Background: Acute Respiratory Infection (ARI) is a major cause of morbidity and mortality among young children. They account for nearly 3.9 million deaths every year globally. ARI accounts for 30-40% of the hospital outpatient visits by children under five years of age. About 156 million new episodes of childhood clinical pneumonia occurred globally in 2000, more than 95% of them in developing countries. Of all the pneumonia cases occurring in those countries, 8.7% are severe enough to be life-threatening and require hospital admission. Various risk factors have been identified across the globe such as low birth weight, lack of exclusive breastfeeding, crowding – more than seven persons per household, exposure to indoor air pollution, incomplete immunization, under-nutrition, and HIV infection.

Objective:

• To find out the association between socio-demographic variables and frequency of acute respiratory infections among under-five children.

• To find out the association between clinical variables and frequency of acute respiratory infections among under-five children.

Method: A cross sectional study was conducted among 400 under-five children admitted in various hospitals of northern part of Kerala, South India from January 2016- December 2016. Socio-demographic and clinical data was collected by using a Socio-Demographic and Clinical Variable Portfolio. One year follow up was done to identify the frequency of acute respiratory infections among the study participants.

Results: A significant association (p<0.05) was found between frequency of Acute Respiratory Infections (ARI) and age of children, domicile, method of waste disposal, smoking habits of parents, birth weight and nutritional status.

Keywords: Socio-Demographic and Clinical Variables, Acute Respiratory Infections, Under-five children.

Introduction

Acute Respiratory Infections (ARI) among children is one of the major threat to the health care systems of the developing countries¹. Acute Respiratory Infections are considered as a main cause of mortality and morbidity among the children under five years of age especially in Indian subcontinent. As per the recent data from Indian health statistics shows that nearly 19 % of mortality and 8.2 % of morbidity in under five children due to respiratory problems². A huge variety of factors were influencing the occurrence of Acute Respiratory Infections (ARI) among the children. That is why Acute Respiratory Infections (ARI) among children are one
the major public health problem in both developing and developed countries.

Acute Respiratory Infections (ARI) are the infections to any part of the respiratory tract, it may ranges from self-limiting disorders to life threatening ones. In India, about 26.3 million cases of ARI were reported in the year 2011, with an incidence rate of about 2,173 cases per one lakh population. In developing countries 70 % of the under-five mortality is due to respiratory problems. In pediatric patients, respiratory infections can be life threatening if not treated and resolved in time. Acute Respiratory infection (ARI) account for nearly 3.9 million deaths every year globally. ARI accounts for 30-40% of the hospital outpatient visits by children. About 156 million new episodes of childhood clinical pneumonia occurred globally in 2000, more than 95% of them in developing countries. Of all the pneumonia cases occurring in those countries, 8.7% are severe enough to be life-threatening and require hospital admission. About 2 million pneumonia deaths occur each year in children aged less than 5 years, mainly in the African and South-East Asia regions.

Various risk factors have been identified across the globe such as low birth weight, lack of exclusive breastfeeding, crowding – more than 7 persons per household, exposure to indoor air pollution, incomplete immunization, under-nutrition, and HIV infection etc. Emergence of more virulent and novel pathogenic organisms, recurrence of diseases previously controlled, insensible use antibiotics, and suboptimal immunization coverage are major factors that intensifying the incidence of ARI in the under five children apart from the commonly identified causes. Children aged 6-23 months were mostly affected with ARIs.

However most of the studies related to acute respiratory infections in under five children was trying to identify the prevalence and incidence of the problem. None of the studies addressed the actual impact of the contributory facts in the occurrence of acute respiratory infections among under five children. The present study was aimed to identify the impact of socio demographic and clinical variables in the incidence of acute respiratory infections in under five children because they are the most vulnerable group.

Method

A cross-sectional study with a descriptive survey design was used to identify the influence of socio-demographic and clinical variables on the frequency of acute respiratory infections among under five children, who were admitted in pediatric medical ward and pediatric intensive care units of selected hospitals at northern part of Kerala, South India. The target population of the study was assumed 2, 00000 based on the data gathered through the literature search. The sample size was calculated at 95% confidence interval and 5% margin of error. Finally, 400 Children in the age group of 0-5 years who were admitted in the selected pediatric units with Acute Respiratory Infections (ARI) during the time period between January 2016 to December 2016 with the attrition rate of 4% based on the inclusion criteria set by the investigators. Children with the history of chronic respiratory diseases were excluded from the study. A purposive sampling technique was used to recruit the samples for the present study.

A Socio-Demographic and Clinical Variable Portfolio was used to collect the data. The tool used in the present study was developed by the investigators based on the literature review, interactions with clinical experts, parents and professional experiences. The content validity of the tool was established with the help of the experts in the field of pediatrics, pediatric nursing and public health. The reliability of the tool was achieved by inter-rater reliability method and it seems to be reliable (Cohen’s Kappa= 0.88). The Socio-Demographic and Clinical Variable Portfolio having two sections: Section A- demographic profile of the child and Section B – Clinical profile with a respiratory status assessment scale.

After getting the permission from the institutional research and ethical committee, a formal permission from the authorities of the concerned hospitals, the investigators conducted a pilot study in order to find out the practicability of the study. Pilot study was conducted in 30 samples and it found to be feasible and those samples were excluded from the main study. An informed consent was obtained from the parents of all the subjects before data collection and the confidentiality of the data was ensured. After obtaining the written informed consent from the parents of the children was obtained, a semi structured interview was conducted among the parents (either mother or father) to obtain the demographic and clinical profile of the child. The investigators were collected some advanced information related to the child’s clinical profile through
the retrospective analysis of case files and by using biophysical measures. A one year follow up was done to identify the recurrence pattern of respiratory infections among the study participants.

Results

Among the recruited samples 64 % were males and majority of them (57%) belonged to the age group of 2-3 years. More than half (57%) of the samples were residing at corporation area. Majority of the samples (53.25%) belonged to nuclear family. Most of the subjects were residing in terraced houses and nearly half (48%) of the study participants were using gas and firewood as cooking fuel, whereas 13.75 % were using other combustion fuels for cooking. Most (50.75%) of the sample’s house having kitchen without proper chimney. More than (55%) half of the study participants were residing in the houses with less crossventilation.46% of the subjects family were using combustion with other methods as the waste disposal .Among the study participants (30%) of the parents having the habit of smoking.

More than half (52%) of the samples were the second child of their parents. 71.25 % of the participants having birth weight ≥ 3 kg.Majority (77%) of the samples had good nutritional status. Among the study participants 74% of the subjects had the history of inadequate breast feeding. All (100%) the study participants were completed their immunizations up to the age. Majority (84%) of the samples were no significant history of respiratory disorders in their family.

Figure – 1: Frequency of Acute Respiratory Infections (ARI) episodes among study participants

Most of the study participants (45.75%) having a recurrence of the Acute Respiratory Infections (ARI) in 9-11 months after the current infection (Figure-1).

Figure – 2: Monthly incidences of Acute Respiratory Infections (ARI) among study participants (Jan 2016-Dec 2016)

There is a steady increase in the incidence of acute respiratory infections among under five children is observed during the month of April (10.25%) to June (28%)(Figure-2).

Discussion

The present study revealed that there is an association between the age group of the under five children and the frequency of acute respiratory infections .The similar finding was reported by a study conducted in Haryana in 2012. There is a significant association between Domicile, Method of waste disposal, parent’s
smoking habits and frequency of respiratory infections. The finding is consistent with the study conducted by Sharma D, et al.\textsuperscript{3}\textsuperscript{,} frequency of the acute respiratory infections having a significant association between birth weight and nutritional status of the under-five children. The simile findings were reported by two studies from Tamilnadu, India (2009-2010) and Solapur, India (2000-2001)\textsuperscript{2-3}.

**Conclusion**

This study highlights the influence of the major socio-demographic and clinical variables in the development of acute respiratory infections and its repeated attacks in under-five children. Hospitalization for acute respiratory infections in young children poses a substantial burden on health services, especially in developing countries. However, since the majority of these risk factors are potentially preventable, governments should consider what action can be taken to decrease the prevalence of these risk factors. In addition, it emphasizes the need for further studies investigating other potential risk factors. Since these risk factors are potentially preventable, health policies targeted at reducing their prevalence provide a basis for decreasing the burden of acute respiratory infections (ARI).

Oral Mucosal Lesions and Conditions in Patients with Dermatologic Diseases: How Common is It?

Arjun Tallada, Junaid Ahmed, Nandita Shenoy, Kashinath Nayak, Nanditha Sujir

1 Post Graduate, 2 Professor and Head, 3 Associate Professor, 4 Reader, Department of Oral Medicine and Radiology, Manipal College of Dental Sciences, Mangalore, Affiliated to Manipal Academy of Higher Education, Manipal

Abstract

Background: Oral lesions are strongly associated with skin lesions and can be easily neglected by dermatologists. This study aimed to estimate the frequency of Oral Mucosal Lesions (OML) in skin disease patients attending the outpatient’s facility of Kasturba Medical College and Hospital (KMCH) in Mangalore city.

Method: Randomly selected 1254 dermatology outpatients were examined for dermatological diseases and Oral Mucosal Lesions (OML) of which 180(15%) are related to oral conditions. Systematic comprehensive extra-oral and intra-oral clinical examinations based on visual inspection and palpation following the World Health Organization (WHO) criteria for field surveys was carried out. All these patients were questioned about their tobacco usage also.

Results: The most frequently observed oral condition was Herpes zoster (10.34%), Lichen planus (9.20%), Pemphigus vulgaris (8.05%), Hand–foot–and mouth disease (8.05%), leukoplakia (6.90%) and Oral submucous fibrosis (6.90%).

Conclusions: Our findings revealed that OML were frequently diagnosed in skin disease patients attending KMCH. This data underlines the importance of the diagnosis of oral conditions in Dermatology because they are frequent and may provide guidelines for an appropriate comprehensive management of patients. Our results project the need for a thorough evaluation of all patients for OML and a multidisciplinary approach in the management of such patients.

Keywords: Oral Mucosa, Applied aspect, dermatology, Oral Lichen Planus, pemphigus

Introduction

The prevalence rates of oral lesions in different populations show a wide variability. Till date, epidemiologic researches have been performed in normal population and the dental outpatient. Global epidemiological studies of Oral mucosal lesions (OML) are rare in comparison with studies on caries and periodontal diseases.

Muco-cutaneous conditions are a group of disorders mainly observed in dermatology practice. Oral mucosal manifestations may be an initial feature, the most florid clinical feature, or the only sign of such diseases. In other cases, lesions occur in both the skin and mucosa, with severe clinical manifestations involving the oral tissues.

Focussing on patients referred to a dermatologic clinic, Ramirez-Amador et al. reported a prevalence...
of 35% OML in subjects affected with muco-cutaneous conditions. Pemphigus vulgaris, Lichen planus, candidiasis and recurrent aphthous ulcers were the most frequently diagnosed conditions.

Oral mucosal involvement of some of the dermatologic disorders such as lichen planus, Behcet’s disease, pemphigus is well known. OML in skin diseases deserve special attention, considering that some are life-threatening, while others have a great impact on individuals and society in terms of pain, discomfort, social and functional limitations.

In this study, we aimed to determine the frequency of OML in skin diseased patients attending the outpatient facilities of Kasturba Medical College and Hospital (KMCH) in Mangalore city.

**Materials and Method**

The study was approved by the Institutional Ethics Committee of Manipal College of Dental Sciences and informed consent was obtained from the patients selected for the study. The study was conducted on 1254 consecutive dermatology outpatients who attended dermatology clinic at Kasturba medical college and hospital (Mangalore).

A detailed history was taken including questions regarding the socio-demographics (gender, age, general health), oral health related characteristics and lifestyle characteristics including smoking and the consumption of smokeless forms of tobacco and alcohol.

**Clinical oral examination:**

Oral examination was carried out with the subject in a supine position. Systematic comprehensive extraoral and intra-oral clinical examinations based on visual inspection and palpatation following the World Health Organization (WHO) criteria for field surveys was carried out. Clinical parameters were recorded using a structured questionnaire modified from the (WHO) assessment form for oral mucosal diseases.

**Skin examination:**

An expert dermatologist evaluated the patient’s dermatological disease through information obtained in a structured interview conducted in the outpatient department of the dermatology clinic.

Elements which were evaluated during skin examination were chief complaint, duration and history of chief complains. Past history and family history was recorded.

**Data management and statistical analysis**

Data were analysed using the statistical packages for social sciences (SPSS, version 15.0). The level of statistical significance was set at 5%. Cross tabulation and Chi-square with Fishers exact test were used to test the statistical significance of the relationships between skin disease groups and types of OML.

**Results**

During the period of 3 months there were 1254 appointments in the dermatology clinic of which 180 (15%) are related to oral conditions. The median age of the patients was 42 years (range, 4-80 years). Twenty eight patients (32 %) were women. Fifty nine patients (68 %) were men.

*Include pseudomembranous candidiasis, Kaposi sarcoma, herpetic lesions, linear gingival erythema, and Oral hairy leukoplakia.

Pemphigus vulgaris (PV) was observed in 7 patients (8 %) with the age ranges (24-45 years). In two patients PV was confined to the oral mucosa, and in three patients PV involved oral mucosa and skin, and in two subjects PV involved oral mucosa, skin and conjunctiva.

Lichen planus (LP) was observed in 8 patients (9.2%) with the age ranges (10-67 years). In three patients (37.5%) LP involved the oral mucosa and skin. Oral involvement in LP mainly involved buccal mucosa, dorsum of the tongue, and lips. In the remaining 5 patients only skin involvement was present. In oral mucosal involvement, erosive and reticular forms of LP were most commonly observed. Two of the LP cases showed erosive component only and one case had papular and reticular type of LP.

*Includes drug induced pigmentation, anaemic stomatitis, linear gingival erythema, traumatic fibroma, lichenoid reaction, drug induced gingival enlargement.
The median age of the patients with herpetic lesions was 45 years (ranges 22-58 years). Most common sites of the lesions were tongue, hard palate and soft palate. 9 patients (10.34%) had oral manifestations of herpes zoster, out of which all were males. Most common presentation of these oral lesions was as multiple small oral ulcers.

The lesions of reactive muco-cutaneous disorders like (Erythema Multiforme, Steven Johnson’s Syndrome, and Toxic Epidermolysis Necrosis Syndrome) mainly involved several oral mucosal surfaces which include buccal mucosa, tongue, hard palate and soft palate. Two of the cases were drug related (Sulphonamides) and one case was associated with herpes simplex virus.

Hand-foot-and mouth disease (HFMD) was first described by Robinson and colleagues (1958) from an outbreak in Toronto caused by Coxsackie virus A16. The individuals range in the age group of 4-6 years. In the present study, 7 individuals (8.05%) were diagnosed with hand-foot-mouth disease. 6 individuals (85%) had oral lesions (papules, vesicles, ulcers) and the most common oral sites involved were the lips and the tongue.

Psoriasis was observed in 19 (10.5%) individuals in whom one individual had oral manifestation of geographic tongue.

Other conditions like leukoplakia and oral submucous fibrosis (OSMF) were also found in the study. 12 patients (13%) were found to be diagnosed with potential malignant disorders like leukoplakia and OSMF with a median age group of (range, 22-60 years) and nine individuals had the habit of chewing tobacco and the most common oral mucosal site involvement was buccal mucosa.

In the present study five individuals were diagnosed with Genodermatoses conditions like Hereditary Ectodermal dysplasia, Tuberous sclerosis, Neurofibromatosis.

**Discussion**

Variety of conditions can appear clinically as ulcers in the oral cavity. In our study diseases such as PV, Erythema multiforme, Hand-foot-and mouth disease, herpetic lesions were seen as ulcerations.

Oral mucosal lesions increase with age but in our study as many individuals were diagnosed with Hand-foot-and mouth disease that had oral manifestation of ulcers and papules in the oral cavity ranged in the age group of (4-6 years). In our series the most common infectious diseases were herpetic lesions 9 (10.94%).

Geographic tongue is fairly common in the general population, affecting 1% to 2% of normal persons, but is more frequently encountered in patients with psoriasis, particularly generalized pustular psoriasis. Studies report incidences of geographic tongue in patients with psoriasis to be anywhere from 5% to 10%10-13. Geographic tongue has also been noted in other dermatologic conditions, including atopic dermatitis, but its incidence is higher in pustular psoriasis than in those conditions 13. In our series 19 (10.5%) individuals were diagnosed with psoriasis, however only (5%) individual had oral manifestation of geographic tongue.

Oral lichen planus develops in women twice as often as in men, with a mean age of onset in the sixth decade of life. OLP is uncommon in children but when it develops in this age group, it is frequently erosive and painful. In our series five (18%) females and 3 (5%) males were diagnosed with lichen planus with mean age of onset in fifth decade of life. Children with OLP often have concomitant cutaneous disease14,15 and those of Asian descent may be predisposed to the development of the disease 16.

A remarkable finding in our study was two patients who were diagnosed with tuberous sclerosis; one patient had oral manifestation of fibroma on the buccal mucosa. One patient who was diagnosed with neurofibromatosis had oral manifestation of fibroma on ventral surface of the tongue.

Tuberous sclerosis complex (TSC) has been described and studied for more than 160 years17,18. Abnormalities of the skin, central nervous system, kidney, and heart are prominent features of this disorder. In our study two (1%) individuals were diagnosed with this disorder based on the diagnostic criteria. Oral fibromas in TSC have also been described on the buccal mucosa and dorsum of the tongue19. In our study one individual had shown fibroma on the buccal mucosa. In our study 5 individuals (3%) who were diagnosed with AIDS had oral manifestations like Pseudomembranous candidiasis, Oral hairy leukoplakia, Kaposi sarcoma and linear gingival erythema.
Conclusions

Our findings revealed that OML were frequently diagnosed in skin disease patients attending KMCH and underline the importance of the diagnosis of oral conditions in Dermatology because they are frequent and can provide guidelines for an appropriate management of patients. Our results project the need for a thorough evaluation of all patients and a multidisciplinary approach in the management of affected patients.

Impact of Vitamin D Supplementation on Anthropometric, Glycemic and Lipemic Profile in Subjects with Type 2 Diabetes: A Randomized Control Trial

Arti Muley¹, Uma Iyer²

¹Assistant Professor, Symbiosis School of Biological Sciences, Symbiosis International (Deemed) University, Symbiosis Knowledge Village, Lavale, Pune, Maharashtra, India, ²Professor, Department of Foods & Nutrition, Faculty of Family & Community Sciences, The Maharaja Sayajirao University of Baroda, Fatehgunj, Vadodara, Gujarat

Abstract

Background: Vitamin-D Deficiency is linked with pathogenesis and progression of diabetes, hypertension, and cardiovascular diseases through various vitamin-D receptors present on tissues and organs in the body. Literature suggests, vitamin-D replenishment improves concentration of lipids and insulin secretion in subjects with type-2 diabetes mellitus (T2DM) and established vitamin-D deficiency. This randomised control trial aimed to study the impact of vitamin-D3 granules on anthropometric measurements, glycemic and lipid parameters in T2DM subjects.

Method: 70 T2DM subjects of age 30-65y, having serum 25(OH)D levels <20ng/ml were randomly divided in two groups; supplementation group (n=40) receiving weekly 60,000 IU vitamin-D3 granules for 8 weeks and the control group (n=30). The anthropometric (waist & hip circumference, BMI) and blood pressure measurements were recorded. Fasting blood samples were taken for estimation of 25(OH)D, lipid profile and HbA1c, before and after supplementation period. Analysis was done using SPSS v20 by independent and paired t-test.

Results: The mean serum vitamin D levels of supplementation and control group were 12.1±3.3 and 10.9±3.3 respectively. After the supplementation significant rise in 25(OH)D levels was seen in supplemented group as compared to controls. A significant decrease in weight, waist-circumference, total cholesterol & LDL-C was observed in supplementation group, post intervention, while HbA1c levels decreased non-significantly.

Conclusion: Vitamin-D supplementation improved the anthropometric and lipid parameters among the subjects, thus suggesting a beneficial role on cardio-metabolic profile of the T2DM subjects.

Key words- 25(OH)D levels, type-2 diabetes mellitus, supplementation, adults, India

Introduction

Vitamin-D inadequacy is a worldwide problem with potential consequences for many chronic diseases, including obesity, cardiovascular disease and type 2 diabetes mellitus (T2DM). Evidence shows that vitamin-D status is important to regulate some pathways related to diabetes development, thus making vitamin-D deficiency (VDD) more evident in diabetic subjects. A
review indicated that VDD may predispose to glucose intolerance, altered insulin secretion and finally to T2DM, either through a direct action via vitamin-D receptor (VDR) activation or indirectly via calcemic hormones or through inflammation. Based on data from epidemiological studies, vitamin-D supplementation is considered to be a potential and inexpensive therapy to increase the serum 25-hydroxyvitamin-D [25(OH)D] levels not only to decrease the risk, but also to improve glycemic parameters in T2DM subjects. In a study among 100, T2DM subjects aged 30-70 years, significant improvements were seen in serum fasting plasma glucose, insulin and in HOMA-IR after treatment with 50,000 IU of vitamin-D3 orally per week for eight weeks. Beneficial effects of vitamin-D supplementation for lipemic parameters have also been reported among diabetics. In India, usually physicians prescribe a vitamin-D3 (cholecalciferol) sachet of 1500 µg (60,000 International Units [IU]) to be taken each week for 6–8 weeks for overt or occult VDD among the general population. However, the exact dose and duration for supplementation needs to be evaluated specifically for diabetic subjects. Also the impact of supplementation on cardio-metabolic profile requires further systematic research. Keeping this need in mind the present randomised control trial (RCT) was framed to study the impact of vitamin-D3 granules supplementation on the serum 25(OH)D levels, anthropometric measurements, glycosylated haemoglobin-A1c (HbA1c) and lipid parameters in adult subjects with T2DM.

### Material and Method

The RCT was conducted in an urban city of western India. A diabetic clinic was selected purposively for the enrolment of the subjects with T2DM (30-65 years). After screening, 94 subjects with serum vitamin-D levels <20ng/ml were randomly divided into two equal groups: supplementation group and control group using computer generated random number tables. 24 subjects (7 and 17 in supplementation and control group respectively) dropped out as were unable to continue or started vitamin-D supplementation in the coarse of time. Thus the intervention study was carried out on 70 subjects (40 in supplementation group and 30 controls). The intervention group received 60,000 IU cholecalciferol (D3) granules in a sachet, procured from USV Limited, Mumbai, once a week for tenure of eight weeks.

Information regarding socio-demographic characteristics and medical history was collected using a pre-tested semi-structured questionnaire. Weight was taken using calibrated Salter electronic bathroom scale. Height, waist and hip circumference were measured using non-stretchable fibre glass tape to the nearest 0.1cm. The waist was defined as the point midway between the iliac crest and coastal margin; while hip circumference as the widest circumference over the buttocks and below the iliac crest. Body mass index (BMI) was calculated by standard formula of weight in kg / height² in meters. Percentage body fat was calculated using the Omron body fat monitor (Model HBF-306). Blood pressure was measured by clinically validated digital BP meter (Omron HEM-7203 model).

For the biochemical profile, after an over-night fast, venous blood samples were collected by a trained technician. 25(OH)D for vitamin-D status was estimated by Chemiluminescence Immunoassay (CLIA) technique using kits by Simens – ADVIA Centaur. VDD was defined as serum 25(OH)D concentration of <20ng/ml and categorized as insufficiency (20-≤30 ng/ml) and sufficiency (>30 ng/ml). Lipid profile was analysed by Photometry using kits by Aggape and Rapid Diagnostics. HbA1c was estimated by HPLC technique. The biochemical analyses were done at an ISO 9001:2008, NABL (India) and College of American Pathologist certified laboratory.

Data was entered in Microsoft Excel 2007. SPSS version 20 was used for statistical analysis of the data. A two-tailed p<0.05 value was used for calculating statistical significance. For quantifiable variables, descriptive statistics were calculated. Comparison of means pre-post supplementation was done using independent t-test.

### Findings

The mean age of the subjects was 54.0±7.7 years. At baseline, all subjects were vitamin D-deficient with serum 25(OH)D levels <20 ng/ml. Change in serum 25(OH)D values performed at baseline and after supplementation at eight weeks are given in Table 1. Serum 25(OH)D significantly increased in supplementation-group (p<0.001). The levels also increased in the control-group significantly; however they still were in deficiency range (10.9±3.3 Vs 15.5±4.3ng/ml). After the supplementation eighty percent (32/40) of the subjects in the supplementation-group
achieved the sufficiency status for serum 25(OH)D, while for the controls nearly eighty percent (23/30) remained in the deficient range (Figure 1). Among the supplementation-group about twenty percent subjects remained in the insufficiency range.

A favourable trend was seen for the anthropometric measurements of the subjects taken at baseline and post supplementation (Table 2). It was observed that within the supplementation-group; weight (p=0.001), waist circumference (p=0.025), waist-stature ratio (p=0.031), systolic blood pressure (p=0.035) and diastolic blood pressure (p=0.010) significantly decreased. A significant decline in systolic blood pressure (p=0.036) was also observed among the controls. After the supplementation, between the groups almost all the anthropometric measurements were lower in the supplementation-group as compared to control-group with weight (p=0.027) and waist circumference (p=0.012) having decreased significantly.

Post supplementation there was a non-significant decline in the HbA1c levels for both the groups. It was positive to see that the supplementation-group had lower values as compared to control-group after eight weeks though the difference was not statistically significant (Table 3). Similarly lipid parameters of the subjects were studied to see the impact of supplementation on their lipemic profile (Table 4). It was observed that LDL-C decreased significantly (p<0.001) for the both the groups after eight weeks of supplementation. The control-group showed a significant decrease in total cholesterol (p=0.03) values as well, while for the supplementation-group lipid ratios TC/HDL-C (p=0.02) and LDL/HDL (p=0.001) decreased significantly. However between the groups post supplementation, the supplementation-group had significantly lower levels for total cholesterol (p=0.037), LDL-C (p=0.035) and the ratios TC/HDL-C (p=0.022) and LDL/HDL (p=0.021). The rest of the parameters also showed a favourable decreasing trend among the supplementation-group at eight weeks, though the difference was non-significant.

### Conclusion

In view of the Endocrine Society’s Practice Guidelines recommendation for treatment strategies a dose of 60,000 IU oral vitamin-D3 was given weekly for eight weeks. The guidelines are for patients with vitamin D deficiency depending on age and underlying medical conditions. After eight weeks of supplementation, mean serum 25(OH)D levels increased to the range currently considered adequate or sufficient for bone health & extra skeletal functions in about eighty percent of the supplemented subjects thus indicating that supplementation to achieve higher levels of vitamin D remains a promising adjuvant therapy for T2DM patients. Similar significant increase in serum 25(OH)D levels after supplementation have been reported among T2DM subjects by various authors with different baseline serum 25(OH)D levels, cholecalciferol doses used, duration of study, and response to supplementation. There are several reports that have shown an inverse relationship between vitamin D levels and obesity, even in different definition of obesity according to weight, BMI and waist circumference and this correlation...
was not dependent on dose of vitamin D supplements provided to the subjects. Our study also reported a significant decrease in weight and waist circumference post supplementation thus indicating that vitamin-D3 supplementation can alter the risk of abdominal obesity which is determined as one of the proven risk factors for T2DM. However the results differed to other studies which reported no significant changes in BMI & WC after vitamin D supplementation. Ethnicity of the subjects and duration of diabetes may be one of the possible reasons for these differences.

Vitamin D supplementation is considered as one of the novel strategies toward prevention and control of T2DM. However in the present study vitamin-D supplementation did not significantly lower the HbA1c levels among the subjects. This might be due to shorter study period which was unable to trace profound changes in the parameter. Witham also reported that vitamin D intake (at different dosage) had no effects on insulin resistance or on HbA1c values. A systematic review of fifteen trials also reported no significant improvement in fasting glucose, HbA1c or insulin resistance in those treated with vitamin D compared to placebo. Similarly there is enough evidence to support that vitamin D supplementation can independently improve cardiovascular risk. One mechanism may involve direct promotion of large HDL particle formation, via elevations in serum apolipoprotein A1 (ApoA1) concentrations, a process that increases reverse cholesterol transport.

Furthermore, the improved lipid profile of the T2DM subjects can also be attributed to lipid-lowering drugs, which are administered in the population with altered lipid profile. In the present study 32.5% (13/40) of supplementation-group and 14.4% (4/30) in control-group reported consumption of cholesterol lowering drugs. Our study also reported a significant decrease in total cholesterol and LDL-C and lipid ratios, while a non-significant increase in HDL-C in the supplemented group. Alkharfy et al (2013) reported similar results at end of 12 months of vitamin-D supplementation with a significant decrease in endothelial and cardiovascular parameters among Saudi T2DM subjects on different therapeutic regimes. The circulating 25-hydroxyvitamin D levels remained below normal 18 months after the onset of treatment in this group yet it significantly improved lipid profile with a favourable change in HDL/LDL ratio.

Few limitations should be mentioned. Firstly, the duration of eight weeks was very small to observe prominent changes in many of the parameters. Secondly the differences in various parameters were not seen across the duration of disease and based on various medication regimes (though it was not changed during the study period), which may interfere with the vitamin-D metabolism. However the findings have added to the existing knowledge of role of vitamin-D supplementation in improving anthropometric measurements and lipid profile in T2DM.

Thus to conclude, further long term research to see the effect of vitamin-D3 on the control of diabetes and to determine the sustainability of the serum 25(OH)D sufficiency status among diabetics after supplementation is needed. Also despite the close link of vitamin-D with human health, vitamin D inadequacy is not widely recognized as a problem by physicians, academicians and patients, which call for creating awareness among them.

Conflict of Interest: The authors declare no conflict of interest.

Source of Funding: The study was funded by University Grants Commission, New Delhi in the form of research fellowship to corresponding author.

Ethical Clearance: The study is approved by Institutional Ethics Committee for Human Research (No. IECRH/2013/04), the trial has been registered retrospectively in Clinical Trials Registry-India (No. CTRI/2016/08/007130).

Nutrigenomics: Gene-diet Interactions

Avineet Kaur¹, Malook Vir Singh²

¹Assistant Professor, Maharishi Markandeshwar College of Dental Sciences and Research, Mullana, Dept of Periodontology and Oral Implantology, ²Medical Officer, Govt of Punjab, National Health Mission, Civil Dispensary, Phase II, Mohali

Abstract

Nutrigenomics is a borderline discipline; it’s a branch of ecogenomics which deals with genetic factors that influence the biological response to diet and its influence on the expression on genes. This interaction has lead to a new scientific field leading to the interaction of genetic variation which the role of genetics with nutritional requirements have to lead to reducing susceptibility to chronic diseases.

Key words: Ecogenomics, gene, nutrigenomics.

Introduction

Nutrigenomics, otherwise known as ‘nutritional genomics’, is a branch of science which attends to all the genetic factors that influence the biological response to diet as well as the impact of diet on gene expression. It is a branch of a broader domain, called ecogenomics that addresses the role of genetic polymorphisms which results in the variability of organisms’ that responds to environmental factors.

The term genomics describes the process by which all genes present in the genome of a given species can be mapped, sequenced and characterized.¹

Other Terminologies

Transcriptomics describes the approach in which mRNA, and consequently gene expression, are analyzed in a biological sample under certain conditions at a given point in time.

Proteomics is the term that further aims to characterize all proteins in a biological sample at the functional level.

Metabolomics is used to describe the quantitative analysis of all metabolites in a biological system such as the cell, tissue or biological fluid (blood, plasma, and saliva).²

Ecogenetical diseases are produced after interaction of genetic vulnerability and environment aggression³

Environmental agents involved are as follows

• infectious ecogenomics
• nutritional ecogenomics (nutrigenomics)
• physical ecogenomics
• chemical ecogenomics (including toxicogenomics and the most developed branch of pharmacogenomics).¹

Aim of nutrigenomics

Nutrigenomics aims to reveal the relationship between nutrition and the genome, thus providing the scientific basis to improve public health through dietary means. Interactions between genotype and diet are important in determining the risk for most common complex diseases, including periodontal disease.

Numerous nutritional genetic studies were documented and markers of disease risk were found, most notably cardiovascular disease and cancer⁴-¹¹ thus providing proof of principle. Recently meta-analysis data was collected which compared Western and Asian populations that estimated a reduction in prostate
cancer risk of approximately 30% for men consuming high soy isoflavone diets. It has also been estimated that high intake of food rich in soy can be related to a reduction of approximately 15% in breast cancer risk for premenopausal women.\(^{13,14}\)

**Nutrigenomic segmentation**

Nutrigenomic segmentation means the limits of ‘personal nutrition’ into business models which are being exploited, but it may be needed in the future, consumers should get the value-added proposition for ingredients and products that are delivered by the food industry.\(^{15}\)

Up till now, taste, cultural norms and various stages of life dominate the consumer-centric model of personal nutrition. Prevalence of gingivitis and periodontitis as forms of periodontal disease in humans\(^{16}\) are caused as a result of inflammatory and immune responses to bacterial infections of the gingival tissues. Risk factors that are host-based such as the genetic background of an individual, socio-economic status, smoking and dietary habits lead to alteration of the innate susceptibility of the host to periodontal disease.\(^{17,18}\)

Recently it has been documented that nutrition is important in maintaining the balance between microbial challenges and host response as it has been implicated in a number of inflammatory diseases and conditions, including type 2 diabetes, cardiovascular disease, rheumatoid arthritis and inflammatory bowel disease, which are related to periodontal disease.\(^{19}\) Diet with high saturation of fats and sugar while maintaining low levels of fruit, vegetables, and fibers are common risk factors which leads to chronic diseases.\(^{20}\)

Prospective, observational study carried out over 14 years revealed that men with a high consumption of whole grain were in fact 23% less likely to develop periodontitis than those who had the lowest consumption of wholegrain.\(^{21}\) Furthermore, three separate analyses of the US Third National Health and Nutrition Examination Survey (NHANES III) produced statistically significant associations between periodontitis and markers of increased body mass, thus leading the authors to conclude that obesity has an association with periodontal disease, especially in younger subjects.\(^{22,23,24}\) The evidence for a direct link between periodontal disease and nutrition comes mainly from observational cross-sectional studies, with a large proportion finding that there was no significant association between the nutrient being analyzed and indicators on status of periodontal disease.\(^{25}\)

**Periodontal Disease and Reactive Oxygen Species**

Increase in production of reactive oxygen species in body raises requirements for the antioxidant nutrients involved in defense thus, it modulates periodontal health. Various antioxidant vitamins (vitamins A, C, and E) and trace elements (selenium, copper and zinc), are depleted during periods of inflammation, which counteract reactive oxygen species therefore it will lead to damage of cellular tissues therefore modulating immune-cell function through the regulation of redox-regulated transcription factors which affects the production of cytokines and prostaglandins.\(^{26}\)

Fish oil is the main source of intake of n-3 polyunsaturated fatty acids, that increase the tissue concentrations of eicosapentaenoic acid and docosahexaenoic acid, which in turn down regulate inflammation.\(^{27}\)

Additionally in a longitudinal study for periodontal disease markers in elderly patients revealed that those who consumed the low level of n-3 fatty acids have a high incidence of periodontal disease, thus suggesting an inverse relationship between dietary n-3 fatty acid intake and the progression of periodontal disease in older people.\(^{28}\)

**Gene and Diet Interactions**

Most of the emphasis on gene-environment interactions is on gene-diet interactions. Studies included both observational and intervention studies show major concern about dietary intake from observational studies and it was found that dietary intake assessments don’t accurately reflect true intake of the individual.

It is important to underscore the consolidation of certain genes regarding their role in lipid metabolism and modulation by dietary factors. This is the case of the APOA5 gene, involving the long-known but cryptic APOA2, suggesting potential roles of this apolipoprotein on dietary intake, body mass index, and postprandial lipemia.

Although most of the gene-diet interactions are mainly focusing on dietary fats, other habits like coffee drinking have been studied and observed interactions between the adenosine A2A receptor (ADOR2A), the
CYP1A2 genes and caffeine intake. A modulation was reported of caffeine intake with a genetic variability at the place of ADORA2A gene. Researchers in UK and New Zealand, tested whether children’s intellectual development was influenced either with genetics and early nutrition – i.e. breastfeeding versus formula feeding. It showed that the associates between breast feeding and IQ is moderated by genetic variant in FADS2, a gene involved in the genetic control of fatty acid pathways. T2Rs, receptors as many as 60 are involved in bitter-taste detection, are one of several families of G-protein-coupled receptors, selectively expressed in subsets of taste receptor cells. A wide range of structurally unrelated compounds, such as peptides, amino acids, ureas, thioureas, terpenoids, phenols, and polyphenols, give rise to a uniform bitter taste, these are a large number of distinct bitter taste receptors.

Phenylthiocarbamide (PTC) and 6-n-propylthiouracil (PROP), are two compounds that taste bitter to some individuals but are tasteless to others, used in genetic linkage studies. Women are identified as medium and supertasters they have lower acceptance scores for grapefruit juice, green tea, Brussels sprouts, and soybean curd (tofu) as compared to nontasters of PROP.

Food Allergies

Food allergies are characterized by and dependent on the induction of an immune response of one or more proteins. Although a variety of factors, such as timing, duration, and extent of exposure are key determinants, genetic predisposition also plays a key role.

Celiac Disease

Celiac disease otherwise known as celiac sprue and gluten-sensitive enteropathy, it is a multifactorial disorder of the small intestine. The clinical manifestation results from inflammatory injury to the mucosa of the small intestine after the ingestion of wheat gluten or related rye and barley proteins. The specific protein subunits which cause the damage are gliadins and phylogenetically-related rye secalins and barley hordeins. Celiac disease has a strong genetic association with human leukocyte antigen (HLA) class II antigens among which 95% of celiac disease patients are HLA-DQ2 carriers, the rest of them are HLA-DQ8 carriers.

Celiac disease can be treated with strict adherence to a gluten-free diet, omitting wheat, rye, barley, and possibly oats.

Polymorphism in Lipid Metabolism

Dietary fats absorbed into the intestine are packaged into large triacylglycerol-rich chylomicrons which are delivered to sites of lipid metabolism or storage. Lipoprotein lipase (LPL) thus causes lipolysis that forms chylomicron remnants. The remnants pick up the apolipoprotein E (apoE) and cholesteryl ester from high-density lipoproteins (HDLs) endogenous metabolism is required to handle the lipoproteins. In the liver, hepatocytes synthesize and secrete triacylglycerol-rich, very low-density lipoprotein (VLDL), which can be converted to intermediate-density and low-density lipoprotein (LDL) through lipolysis. Polymorphisms in lipoprotein pathways influence the efficiency of transport and handling of lipids and which alter the risk for cardiovascular disease.

Polymorphism in Biotransformation Enzymes and Its Effects in Cooked Meat

Cooked meat generates many compounds which are mutagenic in bacterial assays, and others are carcinogenic in animal models. The heterocyclic amines (HA) 2-amino-3,8-dimethylimidazo[4,5-f] quinoxaline (MeIQx), 2-amino-3,4,8-trimethylimidazo[4,5-f] quinoxaline (DiMeIQx), and 2-amino-1-methyl-6-phenylimidazo[4,5-b] pyridine (PhIP) are formed when food, particularly is cooked at high temperatures. Exposure to these cooking methods are readily absorbed and bioavailable. Metabolic activation of HA involves primarily CYP1-mediated-hydroxylation, followed by esterification by conjugating enzymes.

Personalized Nutrition and Consumer

The tracking of research on gene-environment interactions has the primary goal of gaining a better interpretation of the impact of nature and care for an individual’s metabolism. Some consumers are interested in the health benefits of personalized nutrition and other interventions, and this has resulted in some genetic testing products being offered to provide ‘personal dietary advice’ for them.

The Future of Nutrigenomics

Nutrigenomics is a profession with significant
challenges and hurdles to overcome, in the academic and the industrial world so the use of genetics is guiding dietary and lifestyle choices.

Pre-market review and post-market controls, genetic testing and laboratory registries, intensify involvement for third parties; and buyer education. Some nutrigenetic tests have been restricted by government bodies, scientists, doctors and purchaser organizations in the UK and the USA.  

The Footprints of Genomics on Creation in Foods and Drugs

Genomics is moving upheaval in food science and as well as pharmaceutical drug research and development. However, before new food products or drugs derived from these scientific advances will be able to enter the arena of commercial dealings. The desire that biotechnology would impact health in new ways has been at the cornerstone of the human Genome Project.

The blooming of New Food Products

A biomedical definition of food consists of essential nutrients in which both foods and drugs are recent innovations in foods. Foods that quell or prevent chronic diseases potentially depict the next trend in ‘added-value foods’. Fortification of foods could be achieved through attaching certain ingredients such as minerals and vitamins, so the emphasis is on alleviating the risk of chronic disease by removing ingredients such as fats, salt, and sugars. These blueprints in addition to advances in nutritional genomics, novel companies should be able to offer foods that enable consumers to live healthier and potentially longer lives simply by changing and surveilling their diets.

Conclusion

Various genetic variations are essential for estimating risk from all kinds of environmental agents thus more of efficient and cost-effective risk reduction approaches need to be designed. These approaches are mainly focusing on gene-diet synergism. So it’s quite difficult to standardize the environment than to as compared to clinical or biochemical traits. Major health problems can be addressed using molecular and more individually targeted approaches through nutrition genetic collaborations.

Rh factor and Autonomic Function Test in Normal and Deep Breathing

Chaitra Uppangala¹, Bhagyalakshmi Kodavanji², Vinodini NA³, Rekha D Kini³,
Nayanatara Arunkumar³, Anupama Noojibail³, Sneha Shetty³

¹Assistant Professor, Department of Physiology, Srinivas Institute of Medical Sciences and Research Center, Mukka, Surathkal, ²Professor and Head Department of Physiology, ³Associate Professor Department of Physiology, Kasturba Medical College, Mangalore. Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Background and Aim: Studies have revealed a relationship between erythrocytic antigens of the ABO and Rh blood systems and cardiovascular pathology. Reduced heart rate variability (HRV) indicates an increased risk factor for the development of cardiovascular diseases. The present study was aimed to do correlative analysis of Rh blood groups and HRV in normal individuals.

Materials and Method: This cross sectional study includes 120 healthy medical students (18-22 years) of both sexes, from Kasturba Medical College, Mangalore. The study was approved by institutional ethical committee and study was carried out with written informed consent of students. All the subjects were grouped in to Rh positive blood group and Rh negative blood groups based on the result of standard slide haem agglutination technique. ECG of all the subjects was recorded in lead II for a period of five minutes and HRV was analysed by measuring the R-R intervals using a software “HRV soft 1.1 Version” software package. The HRV was analyzed both by the time domain method and frequency domain analysis during normal breathing. HRV is also analysed by deep breathing test for one minute and analyzed by the time domain method. In the time domain method, RMSSD- the square root of the mean squared differences of successive RR intervals (in milliseconds) SDNN-Standard deviation of RR intervals (in milliseconds), pNN50 - percentage of differences between adjacent normal RR intervals exceeding 50 milliseconds were analyzed. In frequency domain method LF nu - Low frequency in normalized units, HF nu - High frequency in normalized units, LF/HF - Ratio between low frequency and high frequency was measured. Statistical tests included in this study were ANOVA and student’s unpaired t-test. P-value was taken as statistically significant at 5 percent confidence level (P<0.05).

Results: The time domain analysis and the frequency domain analysis of HRV among Rh positive blood group and Rh negative blood group subjects during normal breathing did not show any statistically significant changes. Further, comparison of HRV between Rh positive blood group and Rh negative blood groups during deep breathing using time domain method did not show any statistically significant results.

Conclusions: The present study, concludes that there were no significant change in the heart rate variability of Rh positive blood group and Rh negative blood groups subjects. Further research is needed including in a larger sample size to confirm these findings and to show the correlation of Rh groups and heart rate variability.

Keywords: Heart rate Variability, Time domain method, Frequency domain method, Rh blood group, deep breathing.

Introduction

The extraordinary complexity of the blood groups in association with human disease is a fascinating area in research. Currently there are about 285 blood group antigens according to International Society for Blood Transfusion. The Rh system, stands second most important blood group system in human blood and
it comprises about 50 antigens. Apart from the ABO antigens and Rh antigens, there are many other antigens, expressed on the RBC membrane. Heart rate variability (HRV) is considered a physiological occurrence. It can be measured by variation in heart beat to beat interval. HRV measurement can be used to assess the role of autonomic nervous function. Previous research also focus on the changes in the heart rate variability in healthy and non-healthy individuals. Incidence of various severe cardiac dysfunction has given scope for the emergence of the HRV as an important marker of cardiac abnormality. This current study aims to find out the relation between Rh blood groups and Heart rate variability (HRV) during normal and deep breathing, in normal individuals.

**Material and Method**

[120 volunteered healthy medical students, of age group 18–22 years, of both sexes, from Kasturba Medical College, Mangalore were participated in this study. The study was approved, and the procedures were followed in accordance with the institutional ethical standards. At orientation, each subject was explained the purpose, procedures and confidentiality of this study prior to their written informed consent. A detailed history was taken. They were subjected to preliminary medical check-up. A general physical examination was done for all the subjects and the height (in meters), weight (in kilograms), blood pressure (mmHg) and pulse rate (per minute) were noted. Body Mass Index (BMI) was calculated as the weight in kilograms divided by the square of the height in meters. Pulse rate and blood pressure were measured in sitting position after five minutes of rest. The basal recording of blood pressure was done using sphygmomanometer by standard Riva Rocci method. A systemic examination was also carried out for each subject. The following exclusion criteria were accepted for the investigation: presence of any serious cardiovascular disease, including arterial hypertension, metabolic, neurological, respiratory disorders, and history of smoking and alcohol intake that could influence heart rate variability.

**Rh group determination:** Rh blood group was determined by slide haemagglutination technique. 2.5% suspension of red blood cells was prepared in normal saline (0.85g/dl sodium chloride in distilled water) Rh factor determined using same procedure on a clean glass slide by placing one drop of Anti-D serum is placed by using Pasteur pipette and then one drop of whole blood is added to Anti-D sera and with the help of applicator stick cell serum mixture was finally mixed well. Then the slide was tilted back and forth and observed for agglutination. Then the tests that showed no agglutination within two minutes were considered negative.

**Assessment of HRV:** All the subjects were asked to abstain from consuming caffeinated beverages and undertaking excessive physical activity, including gymnastics, for 12 hrs preceding the data collection. They were also requested not to eat and drink on the morning of the experiment and not to take a shower. The subjects were fully habituated to the equipment, the protocols and the experimenters. Our investigation was performed in a semidarkened, temperature controlled, quiet laboratory which was at room temperature. Before the experiment, the participants rested in a laboratory room in a sitting posture for about 20 min. The records were taken between 09.00AM -10.00AM. The Autonomic activity was assessed by recording the electrocardiogram (ECG) from the limb lead II from all the subjects by using a BPL ECG machine. The analogue output from the machine was digitized by using an A/D converter from National Instruments, Bangalore. The HRV was analyzed by measuring the R-R intervals using a software “HRV soft 1.1 Version” software package (built by using the LabView software from Texas Instruments, USA) which was provided by the All India Institute of Medical Sciences (AIIMS), New Delhi. The ECG was recorded from all the subjects while they were in a supine position, fully relaxed and breathing normally for a period of five minutes, which gave the “Short term HRV”. After this, a he HRV was analyzed by measuring the R-R intervals using a software “HRV soft 1.1 Version” software package (built by using the LabView software from Texas Instruments, USA) which was provided by the All India Institute of Medical Sciences (AIIMS), New Delhi. The ECG was recorded from all the subjects while they were in a supine position, fully relaxed and breathing normally for a period of five minutes, which gave the “Short term HRV”. After this, a break of 2 minutes was given. HRV is also analyzed by deep breathing HR test[10] recorded during deep breathing for one minute. Before beginning the deep breathing test, the subject were taught to breath at a rate of 6 respiratory cycles per min, 5 seconds for each inhalation and 5
seconds for each exhalation. Lead II was then recorded continuously at a speed of 25 mm/seconds for 60 seconds while the subjects were deep breathing as instructed. The HRV was analyzed both by the time domain method and frequency domain analysis both during normal and deep breathing. In the time domain method, root of the mean of the squared successive R-R interval differences (RMSSD) and standard deviation of normal RR intervals in milliseconds (SDNN) were analyzed. The two main frequency components, i.e. the low frequency (LFnu) components (0.04 to 0.15Hz), and the high frequency (HFnu) components (0.15 to 0.4 Hz) in normalized units, was measured.

**Statistical analysis of data:** Statistical analysis of the data was done by SPSS (Statistical Package for Social Sciences) version 11.5. Statistical tests included in this study were ANOVA (analysis of variance), Kluskalwallis test, student’s unpaired t-test and Mann Whitney U test. P-value was taken as statistically significant at 5 percent confidence level (P<0.05).

**Results:** The time domain analysis and the frequency domain analysis of HRV among Rh positive and Rh negative subjects during normal breathing did not show any statistically significant changes. Further, comparison of HRV between Rh positive and Rh negative blood groups during deep breathing using time domain method did not show any statistically significant results.

**Discussion**

The ABO and the Rhesus are the most prominent type of blood groups in humans due to their importance and association with blood transfusional reactions and diseases. Currently, increased incidence of cardiovascular disease is observed to be one of the major reasons of sudden death. Various intimidating factors have been associated with CVD. Our previous results showed O blood group individuals had better HRV during deep breathing. HRV has become a method for the studies of physiological mechanisms responsible for the control of heart rate fluctuations.

Rh positive and Rh negative individuals did not show any statistical significance in time domain analysis of HRV during normal breathing and deep breathing. In other words no statistically significant change was seen in RMSSD, SDNN and pNN50 values as well as in frequency domain measures of HRV. To our knowledge this is the first study analyzing the correlation of Rh factor and heart rate variability. This negative correlation may be due to the smaller sample size included in this study. An extensive research is required including follow-up studies with substantial samples to confirm these findings.

Impact on Mental Health of Women Victims of Cyber Violence: A Case Analysis

Deepanjali Mishra
Associate Professor, School of Humanities, KIIT, Bhubaneswar

Abstract

In one of the shocking and bizarre incident recently a eight year girl, Asifa was gang-raped by a group of men before she was killed in Kathua, located in Jammu and Kashmir. This incidence created huge protest in the social media and many celebrities as well as common people took to social media to display their anger and disgust. Violence against women takes place in various forms which cannot be confined to one state or a nation. It is not bound by any religion, caste or social status. Abusing Woman is a regular phenomenon which occurs in many homes which many choosing to ignore considering it to be a trivial matter. “Without anyone’s knowledge she gets heartbroken and falls mentally sick sometimes leading to suicides or even murder thereby affecting her physical and mental health which ultimately leads to disastrous consequences on children and family. Rights of a woman are restricted and she is confined within the vicious circle of blames, humiliation and segregation. Various studies, research and surveys are being conducted on regular basis on gender violence”1. With the advancement of technology and development of the smart phones, women are falling prey to online violence at an alarming rate. The studies show women are victims of various types of violence and social media contributes to an increasing rate of violence against women falling prey to trolling, body shaming etc. This paper would aim at making a theoretical study from the following angles: An Introduction of the Social Networking sites and Gender Based Violence, An analysis of some shocking incidents of Gender Violence that made it to the headlines, How do women fall prey to social networking sites, remedial actions to be taking for preventing such measures and a conclusion.

Keywords: violence, Women, Social Networking sites, social media, harassment, mental health

Introduction

It is a well known concept that women and girls face violence during every stage of their life cycle. The statistical data shows that there have been maximum cases where women experience violence during the adulthood and lowest when they are children. This data has helped to understand the impact of violence that is inflicted on them in different stages of their life. No doubt it has drastic consequences on their issues related to their physical health as well as mental traumas. Twitter conducted a study on the Gender Based Violence in the year 2014 in order to make an extensive analysis of the use of misogynistic language in developed countries. It was found that the UK and US has maximum number of users who use misogynistic language. Though some conclusion yield same outcome as another survey which focused only on United Kingdom, the specification methods used by them is not satisfactory and are full of shortcomings with regard to location, identification of gender and the language features. In the year 2014, a survey was conducted to analyse the relationship between a misogynistic language and the statistics of rape in the US. This study was carried out through collection of a broader data like the harmful effects of sexual violence etc not just the type of misogynist language used by the users. They established a close connection between the violence and the growth of cell phones. It was found out that the growth in mobile phone use has provided the opportunity for increased access to the internet as a result of which one can easily get access to social media. It is not unknown that social media is a platform of sharing and exchange of useful information on one hand and at the same time it gives rise to drastic situation. As per the study conducted through search in internet through Google Search engine as well as and Google Scholar along with the

DOI Number: 10.5958/0976-5506.2019.02409.4
information that is accessible online to the users who are writers, media persons too were involved in the study. Out of which five cases were selected that were reported and was found that in those five cases, the victims had primary contact with their attackers on Facebook which means they knew each other well. In all the cases the attackers were men who were senior to the victims who were in the age group 17 to 20 compared to 24-34 years. The victims witnessed violence of all kinds of physical abuse, mental traumas, isolation, and also economic violence. In one case, the victim gave up and she died, whereas in the other two cases victims were hospitalised because of acute psychological torture. In the first three cases, they were constantly raped where as in the other two cases, they were molested and the attackers tried to rape them. Gender Based Violence have resulted in many cases where the victim as well as the attackers are known to each other and the education of the victim is the only necessity in order to improve their situation.

Objective

The objectives of the paper is to make a study about the impact of mental health of women of all ages due to cyber violence.

Review of Literature

“The usefulness of new media and the transformative potential of social media in the post-Facebook world, the nature of involvement and engagement of people have undergone remarkable changes.” The freedom and independence of social media has provided ample opportunity to stage and bring forth the various contemporary women issues and women movement dealing with gender issues like women atrocities and injustice.

Social Networking Sites have grown and developed rampantly over the years and presently these Social Networking Sites as well as sites have an eye on some countries, people who are members of those groups which are targeted and some professionals belonging to a specific profession. Though there are also instances of some Social Networking Sites which are very successful and mushrooming their business, but they have a very small number of members which may range from some hundreds. The size of members in a Social Networking Sites depend the frequency of group member’s interaction, finance and even the strategies these sites employ to retain their members. “Social Networking Sites as those web sites which permit their users to create a public profile or even a customised profile that professionally coherent the relationship with other members in such a way that the profile can be accessible by any other user who search their file”.

The Indian scenario is no different. A majority of adolescents in the age group 12-19 in India regularly uses digital technologies like smart mobile phones with internet. Various service providers like Jio, Airtel have slashed the data rates which makes the users to have at least one phone with them. By just pressing a fingertip they go to the virtual world. No doubt they use internet to work for their project or search and access study materials, it also facilitates them to create an identity of their own in the virtual media. They open account on these Social Networking sites without being fully aware about its impact. They try to develop friendship and build relationship with whom they know and also sometimes with whom they do not know. It was predicted that internet would internet may be used as an aid to beat the un economic, social equality but now the situation has become such that the adolescents are fast becoming victims due to the internet use. Sometimes the service providers of social networking services lure the users with a promise of lucrative rewards by providing their real identities which includes gender correctly. These users fall prey easily to this trap.

Methodology

The study population is proposed to be girls of various under graduate colleges, post graduate colleges, and those women who are in profession in software companies and in other groups. They were grouped according to their age, types of profession and their education.

The survey that was conducted on Social Media showed that a vast number of respondents have knowledge about the Sexual Violence and also know the association between Social Media and Sexual Violence. It was found that all the respondents were acquainted with Facebook and did not have much idea about the other social networking sites and nearly half of them said it is Facebook is a hub of abuse and harassment. Though some of them said they knew Twitter, Turnbir, Instagram and opined that sexual violence can take place in the form of texting abusive messages or harassing online to the victims.
It depicts the breakdown of awareness of sexual violence related to social media:

75% of respondents knew that social media can be used as a tool which would control, trolling, stalking, with the existing or past boyfriend

74% were of the view that they knew that users share others posts or even personal pictures without their consent

63% had knowledge that users post or share sexually violent texts or pictures

52% had knowledge that social networking sites are used for exploiting and finally it was 10% respondents who claimed that they did not know that harassment, trolling and humiliation take place on Social Networking Sites

A survey was carried out with a group of youngsters in USA consisting of a group of educators, lawyers dealing with cyber violence and workers between June and July 2013. The objectives of the study was

a) collecting data related to gender violence and social networking sites

b) identifying the prevailing strategies of prevention

c) Finding the steps for improvisation for prevention programming.

Findings

Then the online programmes that prevented sexual violence were and integrated and it was put in Appendices A and B.

The survey was conducted online where a link and letter of invitation was sent via email to a group of respondents in USA, comprising of various organisations, various educators, lawyers dealing with cyber crime, internet service providers. Individuals were encouraged to forward the information to community networks with the aim of increasing the survey’s reach and to allow individuals to identify relevant local partners and 25 contacts. 10 questions were given to them. It should be noted that many respondents fit into multiple categories (for example, a community health centre may also provide sexual assault support services) so this represents an approximate breakdown only. In the survey, approximately 25% of respondents directly noted that they work with children, adolescents/teens, and/or youth. Many other respondents did not directly refer to youth, but indicated indirect youth-serving roles (for example, working with parents, university students, and/or noting that they have seen bullying and/or cyber-bullying occurring among those they serve).

How do women fall prey on Social Media:

“Social Media has become more vulnerable and accessible due to smart phones, laptops and low cost service providers of internet, messages could now travel so fast and multidimensional. People have taken it to be one of the most reliable methods of communication. The users know very well that one can maintain anonymity and the message can reach a larger number of audience” 

Therefore users try to post rumours, and criticise someone whom they know or not because they want a very vast audience without just confining to their contacts thereby creating a new level of torture to the victim. Liou (2013) states that “social media campaigns are less effective when conducted as standalone activities, compared to when integrated with face to face and on the ground activities”

Digital Education: a Remedy to Combat Gender Violence:
“it is important to know that media can never take the place of human interactions” 6. He further emphasises that campaigns carried out on social media have less effect when they are conducted on standalone basis and its impact is huge when campaigns are combined with face-to-face interactions. Education can be imparted to the students regarding social media. In the schools, and colleges, Teachers should involve the students while talking about the social networking sites. Similarly, various NGOs and other non-profit organizations should conduct various training camps, workshops and educate the local people and create awareness about the social networking sites and social media. In order to make comfortable and easy reporting, lots of social platforms are being introduced which ensure prospective evidences and prevent unnecessary and irrelevant communications. For example:

A report link can be initiated where any particular as well as numerous communication can be reported directly without any interface. After that Social Networking sites can take a decision whether to discard the content or disable the account of any offender. Even though the platform cannot guarantee that the offender will not return if his account is suspended or disabled, yet it can provide some consolation to the victims and if such a case is reported in the police station, investigation would be much easier because the data of the offender as well as his offensive content of his message is already present in the report link platform and the police could easily access the data. One can take the screen shots of the abusive content of the texts and can be saved. There should a too that blocks or mute the user who has uploaded the offensive content so that the victim cannot see the post or the attacker will not be able to text her. There are tools that unsubscribe or unfollow users that post offensive content. Privacy settings need to be very strong so that the used could control who should see her posts, personal profile and details like the contact number, mailing id etc. Facebook and Google have developed a new strategy which immediately informs if an account is logged in from another device which makes the user alert and can immediately take action if she has not logged in from there.

Young has emphasised that the human service organization needs to view strategically about the social media for being successful. He goes on to further suggest to set objectives, make plans, implement it and evaluate its outcomes regarding the process of using a social media 10. There are many companies which do not use social media effectively because they are not aware about the process of using it. They need to be more concise and the messages need to have clarity regarding the strategy its using and how it is using the social media. Social media can be extensively used and blogs could be written in order to create awareness among the young people. Adequate reporting mechanisms should also be created which are easy to use and safe for the victims. There should be enhancement of services that are related to preventive measures and counselling to victims should always be available which would use healthcare and legal services and there should be immediate follow up system by the counsellors with their clients. These follow up systems should be done either by the educational institutions or through the professional counselling portals.

**Conclusion**

“No doubt report links are developed and common platforms are formed to combat the violence against women due to social networking sites, yet it would continue posing challenges to the victims and explore new opportunities for the officials of cyber crime as it is conventionally perceived that social media is dangerous for women giving rise to an increased number of crime” 8. “Victims not only face humiliation, torture but also it has drastic effects on mental health. Developed, no doubt common platforms are formed to combat the violence against women due to social networking sites, yet it would continue posing challenges to the victims and explore new opportunities for the officials of cyber crime as it is conventionally perceived that social media is dangerous for women giving rise to an increased number of crime”. 9 Therefore it needs to be seen that the government norms are seriously implemented and the victims needs to be more careful and aware about the latest technologies in order to safeguard themselves from being victimised.

¹Ph.D Scholar, ²Professor and Head, Krishna Institute of Medical Sciences Deemed University, Dept of Physiology, Karad, Maharashtra, India, ³Scientist and Head, ICMR-National Institute of Traditional Medicine, Dept of Phytochemistry, Nehru Nagar, Belagavi, Karnataka, India, ⁴Professor and Head, Gujarat Adani Institute of Medical Sciences, Dept of Physiology, Bhuj, Gujarat, India

Abstract

Introduction: Oral squamous cell carcinoma encompasses at least 90% of all oral malignancies. It is sixth most common malignancy and the major cause of cancer morbidity and mortality worldwide. Early detection of a premalignant oral lesion would improve the survival to a greater extent. Tobacco lays an enormous effect of disease for health, economic, social and environment issues. Cross sectional study was done at tertiary care hospital to find association between urinary cotinine levels and buccal mucosal micronuclei cells of smokeless tobacco chewers.

Method: Study comprised of 300 Smokeless Tobacco chewers (STC) and 300 Non tobacco chewers (NTC). Physical examination and Anthropometric parameters were recorded. Fasting urine samples collected for extraction of cotinine. Buccal smears were prepared for exfoliated cells. Slides were stained by Papanicolaou stain and micronuclei (MN) cells was examined by using 100X, 400X magnification as per the Tolbert et al criteria.

Results: Mean Urinary Cotinine in STC was enhanced as compared to NTC. The MN cells were also increased in STC as compared to NTC and statistically highly significant (Mean SD of STC 21.30±10.55, 95% CI ; 20.11 to 22.49 , NTC Mean SD 3.74±3.43, 95 % CI ; 3.35 to 4.12). The MN cells of STC showed strong positive association and statistically highly significant correlation with urinary cotinine levels (r=0.692, p=<0.0001).

Conclusions: The present study establishes link between rise in exfoliated buccal MN and determination of urinary cotinine levels which is a biomarker of genotoxicity and epithelial carcinogenic progression.

Key words: Smokeless tobacco chewers, Non tobacco chewers, Micronuclei, Cotinine

Introduction

Oral cancer is one of the commonest causes of disease and death rate nowadays. In developing countries, both smokeless tobacco chewing and smoking have cancerous causing behavior that contributes to increasing global burden of oral cancer. The World Health Organization figured out that proportion of deaths that result due to tobacco-related diseases would rise in India from 1.4% of all in 1990 to 13.3% of all deaths in 2020².

Tobacco lays an enormous effect of disease for contrary health, economic, social and environment issues. The tobacco epidemic is among the largest public health threat at present situation which almost kills six million peoples per year. Among mortality of ten adults
in every six seconds, one death is reported due to habitual tobacco. Use of tobacco is an indicative public health problem on earth and the only cause for preventable hazard for human health.\(^3\)

As per latest report intimated by Global Adult Tobacco Survey 2, (GATS-2) 2016-17 in India affirm that 28.6% of adults aged >15 (26.7 crore) use tobacco in various forms. Smokeless tobacco usage is marked in every 5\(^{th}\) adult (19.9 crore) and (10.0 crore) in every 10\(^{th}\) adult in smokers.\(^4\) The frequency of tobacco usage is around 37.97% in men 12.5% in female in Belgaum region and the commonest form of tobacco use is smokeless tobacco (ST).\(^5\)

Biological consequences of Nicotine are widespread and lengthened to all systems of the body including cardiovascular, respiratory, renal and reproductive systems.\(^6\) Smokeless tobacco is thought to be highly addictive due to their high nicotine content. The ST also contain carcinogenic substances like tobacco-specific N-nitrosamines (TSNAs) leading to an increased risk of cancers of oral cavity, pharynx and esophagus. Depending on the type of ST products, nicotine content may vary, and therefore, measurement of nicotine and its metabolites among ST users is important to understand the addictive potential of ST products. The half life of nicotine is very less and its metabolites especially cotinine has a long half life, which is good biomarker of nicotine in urine (urinary cotinine level).\(^7,8\)

Estimation of cotinine concentration levels from urine sample of Smokeless tobacco chewers (STC) and Non tobacco chewers (NTC) by High performance liquid chromatography- Diode array (HPLC-DA) and conformation of cotinine metabolite by Gas Chromatography-Mass spectrometry (GC-MS) serves as useful marker to determine the effects of different forms of tobacco consumption. Studies on nicotine and Cotinine levels in smokers and non-smokers in other ethnic groups are well documented but very few studies are found in STC. This may be fact because of the cultivation of the tobacco crops in specific parts of that region only.\(^9\)

Multiple studies have reported that all forms of tobacco use are highly prevalent in both men and women in India. The prevalence of ST use is estimated 33% and 18% for men and women respectively in India.\(^10\) The risk of oral cancer associated with those who use chewing tobacco is approximately 50 times higher than that of non-tobacco users. Nearly 90% of oral neoplasms are caused by smokeless chewing tobacco. Chewing tobacco also results in lesions like leukoplakia caused due to chronic irritation. Many tumors are likely to be known to arise from these lesions.

Globally, about 5,00,000 new oral and pharyngeal cancers are diagnosed annually and three-quarters of these are seen in the developing countries, including about 65,000 cases being reported from India.\(^11\) The micronuclei (MN) assay in exfoliated buccal epithelial cells is potentially an excellent candidate to serve as a biomarker. If not precise, but an arbitrary prediction about the molecular changes that take place in the buccal mucosal cells of tobacco users in individuals without any lesion can hint towards the occurrence of any lesion in those individuals in future.\(^12\) The biomarkers most widely used to quantify exposure to tobacco include nicotine, and their metabolites are cotinine, carbon monoxide, and thiocyanate. Recent investigation has focused on various hemoglobin and DNA (deoxyribonucleic acid) adducts and excretion of nitrosamines in the urine samples.\(^13\)

The literature review revealed that there is a paucity of literature regarding the association among smokeless tobacco chewers in Belagavi region. Therefore, the study aimed to study the cytomorphological changes in the buccal mucosa of smokeless tobacco chewers and normal subjects.

**Material and Method**

This Cross sectional study was conducted in Belagavi region of Karnataka state in India. The study groups were divided as Smokeless tobacco chewers (STC) and Non tobacco chewers (NTC). Ethical clearance was obtained from the Ethical Committee of the Institution and University. A total of 600 participants were studied in this study. The study population comprised from Belagavi Institute of Medical Sciences (BIMS), Belagavi, Karnataka, India. Written informed consent was explained and taken from the participants in English and local languages (Kannada and Marathi). Study was done in the month of April 2013 to December 2016.

Inclusion criteria for age were 300 smokeless tobacco chewers and 300 Non tobacco chewers between 18 to 65 years. Subjects with pre-existing oral cavity lesions, alcoholics and having recent viral infections and who
had received radiotherapy or chemotherapy in last month were excluded from the study. The study included 183 cases based on the prevalence of 13.9 % in Karnataka.

Physical examinations of the subjects were done to record Respiratory rate (cycles/minute) Heart rate (Beats/minute). Anthropometric parameters was recorded for (Height (in cms), Weight (in kgs), Body Surface Area (Square meters), Body Mass Index (Kilogram/meter²),

Collection and chromatographic analysis of the urine samples for cotinine has been already reported by the same group.

Each individual was asked to rinse his mouth neatly by tap water. The exfoliated cells were taken by scrapping the buccal mucosa by using wooden/steel spatula and the scraped cells were taken on lean grease free glass slide and smears were prepared. All smears were stained by Papanicolaou technique using commercially available staining kit Rapid Pap. From each slide, minimum 100 cells were examined in high power magnification (400X) and location of micronuclei (MN) cells was examined by using 100X, 400X magnification. As per the Tolbert et al criteria identifying of micronucleus cells were done.

The completed questionnaires were entered into a database using MS Excel 2000. Frequency distributions and percentages were examined for each answer. Descriptive statistics, comparison among NTC and STC groups using Mann-Whitney U test and Spearman non-parametric correlation analysis was used to indicate a measure of the correlation and the strength of the relationship. The statistical significance level was set at P < 0.05. The statistical analysis was conducted using SPSS version 26.

**Results**

The mean age of participants for NTC was (37.00±16.05) whereas for STC was (37.10±15.99). Distribution of sex for male and female for NTC was 222 (74%) and 78 (26%) respectively, and for STC male and female it was 214 (71.33%) and 86 (28.66%) respectively. The anthropometric data for height (cm) and weight (kg) mean ± SD in case of NTC and STC was 157.85±5.19 and 158.93±6.42 for height (cm) and 59.49±7.24 and 52.00±4.96 for weight (kg). The difference between mean values was statistically highly significant (<0.001). Heart rate in Beats/minute (HR) and Respiratory rate in cycles/minute (RR) on comparison with NTC and STC groups was statistically highly significant. Mean Urinary cotinine value in STC was enhanced as compared to NTC group (NTC, Mean SD, 23.48±11.08 and STC, Mean SD, 1563.68±1198.97) and were statistically highly significant (<0.001) (Figure 1). The comparison of buccal mucosal micronuclei cells by using Mann-Whitney U test was increased in case of STC (Mean SD of STC 21.30±10.55, 95% CI ; 20.11 to 22.49 as compared to NTC Mean SD 3.74±3.43, 95% CI ; 3.35 to 4.12) and was also statistically highly significant (<0.001) (Figure 2). The buccal mucosal micronuclei cells in case of STC showed strong positive association and statistically highly significant correlation with urinary cotinine levels (r= 0.692, p=<0.0001) by using spearman non parametric correlation analysis (Figure 3).

Discussion

The present study was aimed to assess and compare micronuclei cells of buccal mucosa in STC and NTC and to establish the correlation between urinary cotinine levels of STC with above findings. Previous researchers\(^8,13,15,16\) found a wide range of urinary cotinine levels which is also seen in the present study in STC and NTC 100.84 -5810 and 10.01- 59.02 ng/mL respectively. Several studies showed that urinary cotinine levels in nonsmokers are always less than 100 ng/ml\(^17,18\). The variation in range of cotinine depends on the tobacco chewer’s dietary intake of nicotine, cotinine excretion, metabolic activity, passive smoking and environmental smoke\(^8\).

From the present study highly statistically significant difference was found between STC and NTC group. Similar findings were also found among previous reports\(^19,20,21\). The potential of carcinogenic and genotoxicants effect is very high among tobacco chewers. Habituated chewing tobacco users are the likely odds estimated for oral cancer development\(^19\). Micronuclei in oral exfoliated cells are the biomarkers of chromosomal damage caused by genotoxic agents from the tobacco and tobacco related substances\(^20\). Tobacco-specific nitrosamines present in the smokeless tobacco forms also play a significant role in causing the damage\(^19\).

Urinary cotinine levels of STC statistically correlates with micronuclei of buccal mucosa cells (STC MN cells, \(r = 0.692, p <0.0001\)) in present study. This was similar to the findings of Poppel GV\(^22\) who studied the serum cotinine levels in tobacco users. Oral carcinogenesis is a multistep process of accumulated genetic damage leading to cell dysregulation with disruption in cell-signaling, DNA repair and cell cycle events, which are fundamental to hemostasis. MN in oral exfoliated cells is a biomarker of chromosomal damage caused by genotoxic agents from tobacco related substances\(^20\).

Conclusion

Early detection of a premalignant or cancerous oral lesion would improve the survival to a greater extent and also will reduce the morbidity associated with the treatment to a considerable extent. There is strong correlation between urinary cotinine levels of smokeless tobacco chewers and exfoliated buccal mucosal micronuclei cells. Thus the present study elucidates the link between rise in exfoliated buccal micronuclei...
and determination of urinary cotinine levels, whichisan important biomarker and is valuable measure for diagnosis of health risk.

For definitive and sound results, still larger samples should be studied for longer duration. The buccal exfoliated cells should also be collected after cessation of habit to confirm the prognostic value of MN cells and level of genotoxicity. The cause of micronuclei formation due to tobacco use, different forms tobacco products, difference in the degree and mechanism of action of smokeless variants of tobacco and also the effects of cotinine levels in relation to occurrence of MN should be studied in detailed for strategic tobacco control program.

Effects of Steroid Eye Drops on Intraocular Pressure in Post Operative Cataract Patients in a Tertiary Center

Hemalatha Mohan¹, M. Meera Alias Devasena²
¹Consultant in Radhatri Nethralaya, Chennai, ²Assistant Professor, Department of Ophthalmology, Sri Ramachandra Medical College & Research Institute, Porur, Chennai

Abstract

Background: Steroids are known to cause elevation of IOP when used topical, periocular or systemic routes. IOP rise is said to be maximum with periocular use and minimum with systemic use. The degree of IOP elevation depends on the specific drug, the dose, the frequency of administration, and the individual patient. Aim: To study the rise in IOP on using dexamethasone and prednisolone eye drops on postoperative cataract patients in a tertiary center. Settings and Design: It is a prospective hospital based follow up study done in 300 patients, their IOP were evaluated pre operatively and post operatively at 1 and 6 weeks. Material and Method: In this study dexamethasone eye drops and prednisolone eye drops are used along with antibiotic eye drops for a period of 6 weeks in tapering schedule. The patients were examined pre operatively for cataract, IOP measured using Applanation tonometry and fundus examination. Patients were operated by standard SICS or phacoemulsification technique. Patients with uneventful post operative period were examined for IOP using Applanation tonometry at the end of 1st week and 6 weeks. This study was approved by local Institutional Ethics Committee. Statistical Analysis: Data entry and analysis was done using SPSS-16.0 for windows software. Analytical type of analysis were done. Percentages and p values were estimated and paried T test were done to find out significance. Results: Mean value of IOP in patients at the end of 1st week using eye drops dexamethasone was 14.63 and in patients using prednisolone was 14.31 and this found to be statistically insignificant, but at the end of 6th week mean value of IOP in patients using dexamethasone was 14.29 and prednisolone was 13.11 with p value of <0.005. Conclusion: From this study it was found that there was no significant increase in IOP at the end of 1 week and 6 weeks in both groups. however dexamethasone group had significant IOP rise than on prednisolone group at the end of 6 week

Key Words: - Dexamethasone eye drops, Prednisolone eye drops, Cataract, applanation tonometer.

Background

Steroids are known to cause elevation of IOP when used topical, periocular or systemic routes. IOP rise is said to be maximum with periocular use and minimum with systemic use. The degree of IOP elevation depends on the specific drug, the dose, the frequency of administration, and the individual patient. Evidence suppot three independent potential mechanisms of increased resistance to the outflow of aqueous humor that can act synergistically to produce corticosteroid-induced ocular hypertension.

1. Structural changes of the trabecular meshwork
2. A mechanical obstruction of the trabecular meshwork by steroid particles
3. The inhibition of phagocytosis by trabecular meshwork cells
Glucocorticoids exert their effect by increased expression of myociline gene (MYOC) located on locus GLC1A on 1q25.5 chromosome.

Trabecular cells exposed to glucocorticoids increase production of elastin, fibronectin and laminin and decrease production of tissue plasminogen activator, collagenase IV and stromelysin, which causes an accumulation of extracellular matrix (ECM) and increases resistance to aqueous outflow.

Cross-linked actin networks form within the trabecular cells treated with glucocorticoids, which inhibit their proliferation, migration and phagocytic activity and cause accumulation of cellular debris and clogging of the aqueous outflow channels.

Objectives

To study the rise in IOP on using Dexamethasone and Prednisolone eye drops on postoperative cataract patients in a tertiary center.

Material and Method

This study was carried from January 2017 to November 2017. Out of 500 patients operated for cataract surgery during this period 300 patients were followed up to 6 weeks after surgery were selected. Patients selected for this study underwent cataract surgery by routine SICS or Phacoemulsification with uneventful post operative period. Exclusion criteria were history/ family history of glaucoma, high myopia, complicated cataract, intra- op complications, h/o ocular trauma, patients with systemic illness like diabetes, collagen vascular diseases and pediatric patients. Detailed history of all patients was taken including complaints, family history, ocular history and systemic history. Patients were then examined in detail which included Best Corrected Visual Acuity with Snellen’s chart, Slit-lamp examination, Fundus examination and intraocular pressure measurement with Goldmannn Applanation tonometer after anesthetizing the eye with paracaine eyedrops under sterile conditions. Patients underwent either SICS or phacoemulsification surgeries and were followed up. 150 Patients were given 0.1% dexamethasone eye drops and 150 patients were given 1% prednisolone eye drops 6 times a day for 1 week and tapering schedule is followed upto 6 weeks.

Intraocular pressure measurement with Applanation tonometry under sterile conditions were measured at one week after surgery and at the end of six weeks after surgery and were analyzed.

Results

The study results were analysed among 300 patients selected for Cataract surgery in a Tertiary care Hospital. Among them, 165 were Males and the remaining were Females. Intra Ocular Pressure was measured and documented Preoperatively. All patients in the study underwent uncomplicated Cataract extraction by either SICS or Phacoemulsification with posterior chamber IntraOcular Lens implantation. Post operative Intra Ocular Pressure (IOP) was measured at the end of 1 week and 6 weeks. From this study it is found that mean pre op Intra Ocular Pressure between the two groups was 14.87 mm Hg and 13.75 mm Hg respectively. On Statistical Analysis, the postop Intra Ocular Pressure at 1 week between the 2 groups is found to be not statistically significant where as post op Intra Ocular Pressure measured at 6 weeks showed significant statistical difference between the 2 groups with 14.29 mm Hg and 13.11 mm Hg in Dexamethasone and Prednisolone groups respectively with p value <0.005. Detail is given in Table no 1. In Dexamethasone group the standard deviation is 2.178 with standard error of 0.178 and SD of 2.105 with standard error of 0.172 in Prednisolone group was found. Details given in TABLE 2.

Discussion

Following cataract surgery raised intraocular pressure is one of the most common problem and most of it is transient rise in intraocular pressure is more marked and is the most frequent postoperative complication requiring specific treatment. From then on numerous studies have evaluated the risks of an increase in IOP following cataract surgery. Individuals with IOP spikes usually have ocular pain, corneal edema and even sight-threatening complications such as retinal vascular occlusion, progressive field loss in advanced glaucoma, and anterior ischemic optic neuropathy (AION) in prone patients. Around to 35 percent of people have rise in intraocular pressure with topical steroid use which was studied by Mansour F. Armaly, MD, in 1960s. In the study steroid drops were given to one eye of normal volunteers thrice a day for one month. He identified that there were 3 levels of responders: in 66 percent IOP went up to less than 5 mmHg, 30 percent of the subjects IOP increased up to 6 - 15 mmHg and in 5 percent it increased more than 15 mmHg. These suggest one out of every three people in the healthy population have a steroid response. Normally patients have transient increase in IOP following postoperative cataract surgery. Aproximately 25% of patients experience an IOP rise of >30 mmHg within 4 to 6 hours following uncomplicated phacoemulsification according to a recent study. But in our study there was no significant increase in postoperative IOP at the end 1st and 6th week. As clinical data suggests that as a general rule, patients with healthy eyes can tolerate a transient postoperative rise in IOP with no detectable effect on visual function. Steroid-induced IOP elevation normally occurs within a few weeks of steroid therapy and the IOP lowers spontaneously to the baseline within a few weeks to months on stopping the drug.

Saari et al. compared the anti-inflammatory effects of 0.7% dexamethasone-cyclodextrin aqueous solution used once daily and 0.1% dexamethasone sodium phosphate used thrice a day in 20 postoperative cataract patients. They were randomized to receive treatment and were assessed on 1, 3, 7, and 21 postoperative days.

They found that there was no significant differences in the mean [standard deviation (SD) IOP between the two treatment groups [14.0 (3.1) vs. 14.3 (2.1) mmHg at final visit]. Lorenz et al. studied the effects of prednisolone acetate 0.5% on intraocular inflammation following phacoemulsification. Prednisolone acetate 0.5% or placebo was instilled in 62 patients QID until day 2 post-operatively. Later patients were then treated with open-label prednisolone acetate 0.5% was given QID until day 14.

Increased IOP observed in 3 patients (4.8%), although mean IOP was normal (<21 mmHg) in both groups at the end of the study period.
Smerdon et al.\textsuperscript{15} compared the efficacy and safety of prednisolone 0.5\% with placebo in the control of inflammation post cataract surgery and found that 7 patients (24\%) had IOP elevated to >22 mmHg during the trial. Akingbehin et al.\textsuperscript{16} compared the IOP effects of fluorometholone 0.1\% and dexamethasone 0.1\% administered QID for 6 weeks in 15 patients with ocular hypertension or glaucoma by using provocative testing. 13 patients (22 eyes) were first provoked with dexamethasone and 6 months after, with fluorometholone. The remaining 2 patients underwent simultaneous testing with dexamethasone (right eye) and fluorometholone (left eye). Drops were discontinued if their was an IOP of >15 mmHg over baseline. The mean increase in IOP was 8.58 mmHg with dexamethasone treatment as compared to 2.96 mmHg with fluorometholone treatment (P < 0.001) was found. Post-treatment IOP elevations of ≥10 mmHg were observed in 45.8\% and 4.2\% of the dexamethasone- and fluorometholone-treated eyes. Stewart et al.\textsuperscript{17} also compared the IOP effects of fluorometholone 0.1\% and dexamethasone 0.1\% in patients who had previously experienced an IOP increase of ≥10 mmHg with dexamethasone. This was a double-masked, crossover study, with 17 patients dosed sequentially with each of the treatments, with a 1-month between-treatment washout period. Dosing consisted of one drop instilled four-times daily for 6 weeks or until there was an IOP elevation of ≥10 mmHg. The mean (SE) duration necessary to effect an elevation of 10 mmHg as compared to baseline was 29.5 (3.9) days in the fluorometholone group when compared with 22.7 (3.5) days in the dexamethasone group (P = 0.015). The authors subsequently proposed that an increase in IOP of ≥10 mmHg over baseline should be considered clinically significant. The same was considered in this study too. Though there was no significant rise in IOP with both types of steroid eye drops, there was a statistically significant difference between mean IOP at the end of 6 weeks in both groups, with dexamethasone group having higher mean value.

**Conclusion**

There was no significant rise in IOP measured at 1\textsuperscript{st} week and 6\textsuperscript{th} week in patients using dexamethasone and prednisolone eye drops along with antibiotic eye drops. Mean value of IOP at the end of 1\textsuperscript{st} week using dexamethasone eye drops was 14.63 and in patients using prednisolone eye drops was 14.31 and this found to statically insignificant. But at the end of 6\textsuperscript{th} week mean value of IOP in patients using dexamethasone eye drops was 14.29 and prednisolone eye drops was 13.11 with p value of <0.005. Thus it is seen that at the end of 6 weeks the IOP in patients using dexamethasone eye drops was higher than in patients using prednisolone eye drops.

Study of Family History and Environmental Risk Factors Associated with Refractive Errors in Urban School Children Aged Between 10 to 17 Years

K.E. Asvini Sugumaran¹, M.Meera Alias Devasena²
¹Final Year Post Graduate, ²Assistant Professor, Department of Ophthalmology, SriRamachandra Medical College & Research Institute, Porur, Chennai

Abstract

Purpose: The main aim of this study was to collect information regarding the family history and environmental risk factors associated with refractive error and the prevalence of refractive error in urban school children aged between 10 to 17 years.

Study Design: Cross Sectional Study

Method: After getting permission from school Principal and consent from parents, children from class 5 to 12 were included in this study. The unaided visual acuity of each child is assessed with snellen’s number. Visual acuity less than 6/9 in one or both eyes was classified as visually impaired. Cycloplegic refraction and subjective refraction was done to all visually impaired children. Details about environmental factors, time spent to reading, watching television, using electronic gadgets and outdoor sports were collected by questionnaire. Data entry and analysis were done by SPSS-16.0 for windows software.

Results: This cross sectional study was done among 1680 school children aged between 10 to 18 years. Among that 407 children had refractive error. The prevalence of refractive error was 24.2%. The prevalence of refractive error in males was 58.7% and in females was 41.2%. Among the type of refractive error, the commonest was myopia (261) followed by astigmatism (126) and Hypermetropia (20). Among the risk factors studied, reading books, viewing television, electronic gadgets had a statistically significant association to the prevalence of refractive error.

Conclusions: Awareness has to be created among the children, parents and school teachers about the signs and symptoms and the risk factors involved in the development of refractive error. Regular school eye screening programme should be conducted to identify and correct the refractive error and to emphasize the importance of wearing correcting spectacles for refractive error regularly to prevent and avoid childhood blindness

Key-words: Prevalence, Refractive errors, Urban School Children, Myopia, Risk Factors

Introduction

In 2010, 285 million people around the world were disabled visually, 39 million people were blind and 246 million people were with decreased vision. The major cause of blindness was uncorrected refractive error. Visual impairment was 19 million among children, out of these 12 million children were visually impaired
due to uncorrected refractive error which can be easily diagnosed and can be treated. The prevalence of blindness in India was estimated to be 11.2 per 1000 population for the year 2004, out of these 0.1 per 1000 population belong to the age group of 0-14 years. National prevalence of childhood blindness and low vision was estimated to be about 0.8 per 1000. The national survey on blindness conducted in India in 2006-2007 recognized that the second main cause for visual impairment and blindness is uncorrected refractive error (19.7). The blind patients in India was estimated to be 30 % and they lose their vision before 20 years of age and many before 5 years of age. The important cause for blindness among children and in younger age group is uncorrected refractive error. Family history and refractive error play a major role in the development of refractive error in children. Vision is important for children for learning. Defective vision due to uncorrected refractive error in children affects their learning. To eliminate the avoidable blindness, the world health organization launched vision 2020, uncorrected refractive error is one of the important cause of avoidable blindness. School eye screening program is a part of district blindness control society since 1996 which is an important program for blindness control.

**Aim**

The main aim of this study was to collect information regarding the family history and environmental risk factors associated with refractive error and the prevalence of refractive error in urban school children aged between 10 to 17 years.

**Materials and Method**

This cross sectional study was done in urban school children aged between 10 to 17 years in 2016 in Chennai. Permission from school principal and consent from the parents were obtained. All the school children from class 5 to 12 were included in this study. The unaided visual acuity of each child is assessed with snellen’s number and alphabet chart at 6 meters distance by ophthalmic assistants. Visual acuity less than 6/9 in one or both eyes was classified as visually impaired and referred to ophthalmologist in our institution. Cycloplegic refraction and subjective refraction was done to all visually impaired children. Anterior segment examination was done using slit lamp and fundus examination was done with direct ophthalmoscopes. Questionnaires were asked to all the visually impaired children regarding family history and environmental factors, time spent to reading, watching television, using electronic gadgets and outdoor sports.

Data entry and analysis was done using SPSS 16.0 for windows software. Percentages and p values were estimated. Chi-square test was done to find out the association.

**Results**

This cross sectional study was done among 1680 school children aged between 10 to 18 years. Among that 407 children had refractive error. The prevalence of refractive error was 24.2%. The prevalence of refractive error in males was 58.7% and in females was 41.2%. The prevalence of refractive error was higher in males than in females. Among the males, the prevalence of refractive error was highest in the age group of 13 to 15 years which was 23.3% and lowest in the age group of 16 to 18 years which was 15.7%. Among the females, the prevalence of refractive error was highest in the age group of 13 to 15 years which was 15.9% and lowest in the age group of 10 to 12 years which was 9.8%. The prevalence of refractive error was highest in 13 to 15 years of age group in both males and females. Details were given in Table No:1.

Among the type of refractive error, the commonest was myopia (261) followed by astigmatism (126) and Hypermetropia (20). About 145 males and 116 females were myopic. About 80 males and 46 females were astigmatic. 14 males and 6 females were hypermetropic. Myopia was common in 13 to 15 years of age. Hypermetropia was common in 10 to 12 years of age. Astigmatism was common in 16 to 18 years of age. Details were given in Figure No: 1 &Table No:2.

Among the risk factors studied, reading books, viewing television, electronic gadgets had a statistically significant association to the prevalence of refractive error. Children who spent time outdoor playing sport had statistically lower prevalence of refractive error.

**Discussion**

The prevalence of refractive error in our study was 24.2%. In other study where school going children aged between 5 to 15 years of age, screened for refractive error in rural Delhi showed prevalence of 7.4% \(^1\). In a study conducted in Hyderabad to assess the prevalence of refractive error in urban school children showed prevalence of 9.8% \(^2\). The prevalence of refractive error in a study conducted in New Delhi by GVS Murthy et al was 6.4% \(^3\), in Lucknow by Kumar et al was 7.4% \(^4\) and in Haryana by Sharma S et al was 13.65% \(^5\). Studies conducted in different other parts of the world showed the prevalence of refractive error of 8.2% in Baltimore, USA \(^6\), 12.8% in Shunyi district in China \(^7\) and 15.8% in Chile \(^8\). Our study showed a higher prevalence when compared to all the above mentioned similar studies. But a study conducted in a school at Chennai, the prevalence of refractive error was found to be 37.39% \(^9\) which is higher than our study.

In our study, the prevalence of refractive error in males was 58.7% and in females was 41.2%. In a study conducted by Battacharya RN et al \(^10\) found that refractive error was more in males (21.3%) than in females (1.52%). In a study conducted by Niroula DR et al \(^11\) among the school going children in Pokhara City of Nepal on refractive error, found that refractive errors more in boys (7.59%) than in girls (5.31%). The prevalence of refractive error was higher in males when compared to females in our study and in similar other studies.

In our study, the prevalence of refractive error was higher in 13 to 15 years of age group in both male and females. They found that refractive error is increasing with increasing age in the age group of 10 to 14 years among the adolescent age group attending ophthalmology OPD in a study conducted by S.Matta et al \(^12\).

In our study, myopia is the most common refractive error followed by astigmatism and Hypermetropia. Das et al observed that among the school going children aged between 5 to 10 years in Kolkata, 25.11% had refractive error, myopia being the most common 14.02%
followed by astigmatism 3.93% \(^1\). In a study conducted by Rose K et al. they found that the prevalence of myopia, hypermetropia and astigmatism in urban school children was 3.16%, 1.06% and 0.16% \(^1\). In another community based study conducted by Murthy GVS, et al on refractive error in children aged between 5-15 years in the urban population in New Delhi reported the prevalence of myopia as 7.4% and hypermetropia as 7.7% and astigmatism was seen in 5.4% of the cases \(^4\).

In our study, risk factors like reading books, viewing television, electronic gadgets had a significant association to the prevalence of refractive error. In our study, children who spent time outdoor playing sport had lower prevalence of refractive error. Uzma et al. have observed that children with high myopia spent more time studying, reading, and less time playing sports \(^2\) which was similar to our study.

**Conclusion**

The prevalence of refractive error in this study was found to be 24.2%. The prevalence of refractive error was common in males, common in the age group of 13 to 15 years and myopia being the most common refractive error. The risk factors, reading, watching television, using electronic gadgets had a significant association with the development of refractive error. Awareness has to be created among the children, parents and school teachers about the signs and symptoms and the risk factors involved in the development of refractive error. Regular school eye screening programme should be conducted to identify and correct the refractive error and to emphasize the importance of wearing correcting spectacles for refractive error regularly to prevent and avoid childhood blindness.

Comparative Assessment of and Self-Perceived and Normative Orthodontic Treatment Need and Its Effect on the Self-Esteem of Students of a Prominent Indian Dental School – A Cross Sectional Survey

Madhura Rao¹, Yash Singh¹, Asavari Desai²

¹Undergraduate Student, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, India, ²Reader, Dept of Orthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, India

Abstract

Objective - To assess and compare the normative and self-perceived need for orthodontic treatment and its effect on self-esteem in a sample of undergraduate dental students.

Methodology – This cross sectional study was conducted on a pool of 102 dental students after obtaining the required approval from the Institutional Ethics Committee. Students of either gender, between the ages of 18-22 yrs and with a similar socio-economic background were selected for the study. Those who were undergoing or had previously undergone orthodontic treatment were not considered.

Self perceived need of orthodontic treatment was assessed by using the Aesthetic Component (AC) of the Index of Orthodontic Treatment Needs (IOTN). The AC assesses the perception of an individual on the attractiveness of his/her dentition through a 10-point photographical scale showing different levels of dental attractiveness, with photo 1 representing the most attractive and photo 10 the least attractive.

Clinical intraoral examination was done to assess the normative treatment need by using the modified Dental Health Component (m DHC) of the IOTN.

Questionnaires were distributed to the participants to evaluate the psychological impact of the malocclusion. The Global Negative Self Evaluation Scale (GSE), which is an adaptation of the self-esteem scale of Rosenberg (1965), was used.

Results: According to the AC scores only 3% of the study subjects felt a need to seek orthodontic treatment, whereas 58.8% of them fell into the “definite need for treatment” category as evaluated by the orthodontist using the mDHC. There was a negative correlation between perceived treatment need and self-esteem. Female students had a higher self esteem than their male counterparts.

Conclusion: There was a marked difference between the students' and investigator’s opinion in the need for orthodontic treatment. This stresses the importance of taking into account the patient’s need and expectations and avoiding the traditional paternal approach in treatment planning.

Key words: index of orthodontic treatment need, self esteem, perceived malocclusion.

Introduction

The physical appearance of an individual significantly affects his/her self-esteem and social acceptance as evidenced by several studies in social psychology¹-³, leading to the assumption that improved dental aesthetics would lead to a sense of well being.
However, perception of dental aesthetics is subjective in nature and often idiosyncratic and varies widely, as societal expectations are not equal in all countries and economic subsets.

Orthodontics in the 21st century differs from the past with more emphasis being placed on dental and facial appearance, with patients playing a bigger role in treatment planning than before. Although the demand for treatment may be greatly driven by the desire for improved aesthetics, one should not detract from the prevalence of normative need. A high level of education and exposure to orthodontics has been shown to increase the level of awareness of dentofacial deformities and have a positive impact on attitude towards dental treatment in general.1-5

Dental students in India have training in orthodontics for a total duration of 3 years of which 2 years are in the clinical setting. As future practitioners and clinicians, they should be able to diagnose malocclusion accurately as well as assess its potential detrimental impact on the patient’s oral health and self-esteem. Therefore, it is important to understand how they perceive malocclusion and the need for orthodontic treatment not only as dental professionals but also as consumers of orthodontic care.

Keeping this in mind, this study was designed to assess self-perceived and normative orthodontic treatment needs of Indian dental students and evaluate its effect on their self-esteem.

**Materials and Method**

Approval for this cross-sectional and interview based study was granted by the Institutional Ethics Committee of Manipal College of Dental Sciences, Manipal University, Mangalore.

The study sample consisted of 102 dental students of either gender between 18-22 years of age. Students who were undergoing or have already undergone orthodontic treatment were excluded from the study. Informed consent was obtained from each student prior to study commencement.

Interviews were conducted in a room adjacent to the orthodontic clinic and took approximately 20 minutes to complete. Each student was given a questionnaire to fill out in the presence of the investigator, in case of any clarifications. In addition to demographic data as well as socio-economic status, this questionnaire sought to assess the perceived and normative need for orthodontic treatment; and impact of perceived malocclusion on their self-esteem.

Self perceived aesthetics was assessed using the Aesthetic Component (AC) of the Index of Orthodontic Treatment Needs (IOTN)6. Each student was shown the 10 photographs, which were not in the order that they appear in the original AC scale, and was asked to select the one that he/she felt best represented his/her dental appearance. For the purpose of this research project, it was necessary to distinguish individuals who had a definite normative need for treatment from those who had borderline or no need for treatment. As this was the goal, the use of the modified DHC as described by Burden et al (2001)7 fulfilled the requirements of a normative needs assessment index. Each participant was assessed for the specific conditions mentioned in the index and if any one of these was found, he/she was given a score of “1” and no further conditions were sought. The study population therefore fell into one of the two groups based on this modified DHC, either ‘no definite need for treatment’ or ‘definite need for treatment’.

Twenty participants were randomly selected one month after the initial assessment and the AC and DHC were recorded again, in order to minimize inter-examiner bias.

Questionnaires were distributed to the participants to evaluate the psychological impact of the malocclusion. The Global Negative Self Evaluation Scale (GSE), which is an adaptation of the self-esteem scale of Rosenberg (1965), was used.

It consisted of each question with six response options scored from 1 to 6 and the scores were summed to obtain the average self-esteem of each student.

Subsequently, focus group discussions consisting of 6-8 students were carried out in which participants were asked open ended questions about the impact of malocclusion on their self-esteem.

**Statistical Analysis**

The data obtained was analysed with the help of the Statistical Package for Social Sciences (version 20.0, SPSS Inc., Chicago, Illinois, USA).

Perceived treatment need, normative treatment need and the association between the two was assessed by Chi
square tests. Independent t test was used to check whether there was any correlation between the AC and the gender and year.

Results

A total of 102 students (50 females, 52 males) participated in the study, out of which 54 were from 2nd and 3rd year and 48 were final year students/interns. The subjects were categorized into 2 groups,

Group A – consisting of 2nd and 3rd year students, with very little/preliminary knowledge of orthodontics, and

Group B – consisting of final year students and interns, with considerably more training and understanding of orthodontics.

This was done with the intention of assessing whether the amount of training received by the students affected their perception of malocclusion and need for treatment.

The students’ perceived need for treatment according to the AC of the IOTN is presented in Table 1. The results showed that only 1% felt they definitely needed treatment (photos 8-10), 2% in the borderline need for treatment (photos 5-7) and 97% felt they do not need treatment (photos 1-4).

However, the normative treatment need as assessed by the investigator according to the modified DHC (Table 2) showed that only 41.2% of the participants fell into the “no need for treatment” category whereas 58.8% had a definite need for treatment. There was a marked difference between the students’ and investigator’s opinion in assessing treatment need (Table 3).

Comparison of the AC scores with self-esteem and gender revealed that female students had higher self-esteem than their male counterparts inspite of having higher AC scores, but the difference was statistically insignificant with a p value of 0.798 (Table 4).

Discussion

In the present study, we attempted to evaluate the correlation between perceived and normative orthodontic treatment needs using the AC and modified DHC of the IOTN, on a patient pool of 102 dental students. These students were selected for their higher capability for expressing opinions on dental appearance compared to younger age groups, as well as for accessibility as they regularly attend university. Most importantly, it was assumed that as upcoming dental graduates these students would be more cognizant of their own malocclusion.

The validity of using the photographs of the AC to represent one’s dental attractiveness has been previously reported. The impact of perceived malocclusion on students’ self-esteem was also assessed using the Global Self-Esteem (GSE) scale.

The results of this study indicate that there was a marked difference between the normative need for treatment and the students’ self-perceived need.

According to the modified DHC assessment done by the investigator, 58.8% of the students had a definite need for treatment. Findings of previous studies on young adults show that normative treatment need ranged from 1.4% to 71.6%, however these studies used different indices to ascertain treatment need. Different ethnicities as well as age of the selected sample size also could have contributed to the varying outcomes.

Self perceived need for orthodontic care was found to be very low in this study with only 1% of the students falling into the “definite need for treatment” category (photos 8-10) and 2% falling in the “borderline need for treatment” category (photos 5-7), as evaluated by...
the AC of the IOTN. Out of the remaining students, 56.9% deemed their dental attractiveness to be similar to photograph 1 of the AC. This contradicts the findings of a study by Ravindranath S et al reported a much higher self perceived need for treatment as compared to the examiner assessed need. This corroborates the findings of several previous studies which shows that there is an uneven distribution towards the attractive end of the scale.

Both the index determined occlusal traits as well as self perceived need for treatment was higher in females and was statistically insignificant. Inspe of this, females recorded higher self-esteem scores than their male counterparts in this study. This can be attributed to the fact that self esteem of a person is affected by several factors like societal and economic background, parental and peer influence, attitude and mental make up of the individual. Physical appearance and malocclusion, though contributing factors, do not solely determine an individual’s self-esteem. This contradicts the findings of studies done by Barani K et al and Birkeland et al.

**Conclusion**

There was a very significant difference between the orthodontic treatment need evaluated by an orthodontist and dental students. The presence of malocclusion appeared to have no impact on the self-esteem. This study reinforces the fact that perception of treatment need and treatment uptake does not solely depend on the knowledge thereof and may be influenced by other psychological, economic or social factors.

Non-Invasive Diabetes Diagnosis with Pancreas Bio-Magnetism

P.Sankari¹, N.Prabhavathi²

¹Assistant Professor; ²Head and Associate Professor, Government Arts College for Women, Sri Sarada College for Women, Salem-8, Salem

Abstract

Obese patients are at a higher risk of being affected by diabetes. Diabetic patients often use invasive blood sample collecting devices to measure glycemic level. The method discourages patients to use these invasive devices. The glycemic level measure after each meal to keep track of blood glucose level. This analysis helps diabetic patients to maintain glycemic level at normal levels. In this paper, we propose a novel non-invasive method to measure pancreas insulin secretion activity. This helps to analyze glycemic level in body.

Keywords: Pancreas, Bio magnetism, insulin, Diabetes

Introduction

The autoimmune disease is caused due to the effect of self-immune system detects its own proteins as antigens and performs an attack over its own tissues. These are caused due to the genetic proneness over the stimulus of prior environmental disease commencement. Diabetes is a chronic disease caused due to the swelling of T-cells, which causes autoimmune disorder that destroys the β-cells in the pancreas. These are the base cells for producing insulin for regulating the blood glucose level.

This develops the impairment in maintaining glucose level in the blood. The insulin helps the cells to consume glucose from the blood stream. Nearly 70 to 80% of β-cells are present in the islet of pancreas and it covers 1 to 2% of pancreas total size. The islet is covered by glucagon, somatostatin and pancreatic polypeptide. These are responsible for generation of α-cells, δ-cells and ε-cells. The pancreas acts as a digestive organ that generates lytic enzymes for the catabolism of nutrients. Type 1 diabetes was detectable only after the loss of 80 to 90% of β-cell.

The several researches and development in the knowledge about the pancreatic impairments leads to the study of different types in the diabetic syndrome. Three type are categorized they are Type 1, Type 2 and Type 3 diabetes syndrome. Along with this category, gestational diabetes is also classified as individual type.

The classification was generated clinically and analysis performed based on etiologies over the molecular level generates individual classifications of diabetes mellitus.

The patients with Type 1 diabetes depend on external insulin source. This is the only way to treat the Type 1 diabetes since the insulin was invented by Banting, Macleod and Collip (1920). Normal pancreas maintains the blood glucose level around 5.5mmol/L but the patients with Type 1 diabetes have fluctuated concentration of blood glucose at before and after fasting. Frequent increase in concentration of blood glucose in Type 1 diabetes patients will lead to diseases like neuropathy, retinopathy, nephropathy and cardiovascular problems.

Patients with Type 2 diabetes are not dependent on external insulin injection. This is caused due to the insulin resistance or failure of β-cells to overcome the resistance. To improve the glucose homeostasis few patients are allowed to intake insulin. The development of Type 2 diabetes may or may not lead to Type 1 diabetes condition. The patients with Type 1 diabetes can posses’ symptoms of Type 2 diabetes. This leads to the difficulty in categorizing the patients. The patients not responding to oral therapy of Type 2 diabetes treatment may lead to Type 1 diabetes.

The third type of diabetes is also referred as secondary diabetes, which may be caused due to the malnutrition. This type of diabetes can be seen in infants due to the delay in development of β-cells in the pancreas. Due to
the lack of alternative way to generate insulin and the severity of type 1 diabetes, there is a need to develop the options for diagnosis and treatment. Several methods are introduced to monitor the functions of pancreatic cells and many new technologies are introduced to classify the type of diabetes present in the patients. The methods and technologies to identify and diagnose diabetes mellitus was presented as literature review.

**Literature Survey:**

Diabetes, for the early diagnosis and daily monitoring, acetone existing in human breath is an effective biomarker of diabetes. Breathe analysis of acetone such as non-invasive, accurate, and its merits, comparing to the other methods diabetes diagnosis and monitoring based on analyzing blood glucose level. For acetone detection, a novel nanostructured $K_2W_7O_{22}$ was tested and recently developed. The trace amount of acetone at room temperature shows that $K_2W_7O_{22}$. The fast response time of 12s is achieved with the lowest detection limit of 2.0 ppm (parts per million). $K_2W_7O_{22}$ and modifying the design of device circuit to realize weak signal detection, further improvement of sensing performance with the detection limit down to 25ppb. Strong charge transfer between acetone and $K_2W_7O_{22}$ and the result is the effective interaction of unique properties of $K_2W_7O_{22}$ and ferroelectric and semiconducting.

Acetone gas in breath has a good correlation to blood glucose levels its suggested by the researches, its reliable non-invasive diabetes prediction system. Acetone levels are measured using quartz crystal microbalance sensor that application has biosensor; acetone is promising biomarker in diabetes prediction system. To detect the quantity mass variations piezoelectric sensor, we can use. When there is a deposition of mass on the surface of the crystal, the resonant frequency of the sensor changed. Need to understand the sensors electrical characteristics such as its conductance gain and admittance, to evaluate the performance of this sensor, the shift in resonant frequency is directly proportional to the change in the mass concentration. Characteristics and calculate the Presence of different acetone absorption in for normal type 1 and type 2 diabetic topics.

Diabetes mellitus (DM) is gradually becoming an epidemic. Sparse representation classifier (SRC) its features to detect DM based on facial block color using the non-invasive method. It’s used to capture a facial image of four facial blocks strategically placed around the block, of non-invasive capture device with image correction. To calculate the facial color features of each block six centroids from a facial color gamut are applied. Facial color features represented the facial block. For SRC, Healthy facial color features sub dictionary and DM facial color features sub dictionary, two sub-dictionaries, are employed in the SRC operation. The SRC can difference Healthy and DM classes an average accuracy of 97.54% by using the combination of facial blocks.

Diabetic Retinopathy (DR) becomes one of the 21st century’s major health problems; the non-invasive method to detect Non-proliferative Diabetic Retinopathy (NPDR) and DM, three groups of features extracted from tongue images of the initial stage. Twelve colors representing the tongue color features, a color tongue gamut is established. The texture values nine-tongue texture features, eight blocks strategically located on the tongue surface, with additional of all eight blocks is used to characterize. From tongue images, 13 features extracted based on measurements, areas distances, and ratios, geometry features. Tongues using from each of the three groups with average accuracies of 80.52% and 80.33% applied 34 combinations of features, Healthy/DM tongues same as NPDR/DM sand NPDR (DM samples without NPDR).

Screening system has two parts, the first analyses the signal obtained from the pulse oximeter, and the second consists of a machine-learning module. Pulse oximeter signal consists of a front end that extracts a set of features. This features the input of the machine-learning algorithm determined the class of the input sample, whether the subject had diabetes or not, based on the physiological considerations. Machine-learning algorithm was gradient boosting, random forests, and linear discriminate analysis as the benchmark. Collected from five community health centers the system was tested on a database 1,157 subjects (two samples per subject). Receiver operating characteristic area found 69.4% and range [75.4% - 61.1%], specificity=64%, threshold gave a sensitivity=5%. Screening method for detecting diabetes comparable to the glycated hemoglobin test results in less than five minutes does not require blood extraction.

Diabetes is a disease affects many people. Here by the analysis of Heart Rate Variability (HRV) signals...
acquired from the ECG signals, diabetes is diagnosed. The deep learning networks of Convolutional Neural Network (CNN) and Convolutional Neural Network Long Short-Term Memory (CNN-LSTM) combination to detect the abnormality automatically. Feature extraction is not needed for these deep learning techniques. The maximum accuracy sing CNN-LSTM for test data is 90.9%. With 5-fold cross-validation, the accuracy by CNN is 93.6% and the accuracy by CNN-LSTM is 95.1%.

Here to carry out an early detection of Diabetes Mellitus, an application of computational intelligence with the help of fuzzy hierarchical model. The concept of the proposed method is designed based on how a doctor finalized in relation to the indication that someone has the power against Diabetes Mellitus, which is the model that has been coincided with the data that have been obtained in a medical laboratory. A comparison of the data has obtained from the laboratory with the decision of the doctor and the result is 87.46% of the 311 relevant data is same with the doctor’s statement.

Persons with the elevated risk of diabetes mellitus developing with the early detection are not possible to prevent the disease. Here the objective is that in electronic medical records, to apply association rule to discover sets of risk factors and their subsequent subpopulations that show patients especially at high risk of developing diabetes.

**Methodology**

Here the early detection of diabetes is by analyzing the function of pancreas. If the pancreas of a patient is functioning normally then the patient has no symptoms of diabetes. To detect the diabetes in a patient, the primary step is to analyze the functioning of pancreas. The pancreas is a glandular organ located in the digestive system and endocrine system in vertebrates. In humans it is in the abdominal cavity behind the stomach. It produces several important hormones such as insulin, glucagon and pancreatic polypeptide. The proposed method of detecting diabetes by the pancreas by capturing the magnetic emissions from pancreas is shown in the figure 1.

**Figure 1: Detection of Diabetes using Pancreas**

**Data Acquisition:**

The figure 2 shows the pancreas bio-magnetic signal emission. A spintronic sensor captures these magnetic emissions. Spintronic sensor working principle is based on the magneto resistive effect. It converts the magnetic field directly into voltage or resistance with a DC bias current supply. Spintronic sensor is based on the concept of spintronics that describes the intrinsic spin of electron and its associated magnetic moment. The principle of spintronic is based on the fundamental physical principles such as anisotropic magneto resistance, giant magneto resistance and tunneling magneto resistance. The output from the spintronic sensor is a voltage signal. Figure 2 shows the signal acquired from pancreas using spintronic sensor.

**Figure 2: Spintronic sensor placement above pancreas.**

The obtained signal from the spintronic sensor is denoised by applying the stationary wavelet transform. In discrete wavelet transform there is a lack of translation invariance. To overcome this stationary wavelet transform is used. The Stationary Wavelet Transform
has many applications such as signal de-noising, pattern recognition, brain image classification and pathological brain detection. After the signal is de-noised using the stationary wavelet transform, the signal is processed with the HAAR wavelet analysis. HAAR wavelet is nothing but a continuous sequence of rescaled square mapped functions. The HAAR wavelet’s mother wavelet function can be described as

$$\psi(t) = \begin{cases} 
1 & 0 \leq t < \frac{1}{2}, \\
-1 & \frac{1}{2} \leq t < 1, \\
0 & \text{otherwise}.
\end{cases}$$

Its scaling function can be expressed as

$$\varphi(t) = \begin{cases} 
1 & 0 \leq t < 1, \\
0 & \text{otherwise}.
\end{cases}$$

Finally, the processed signal from the HAAR wavelet analysis and the glucometer correlation processed for validation.

Results & Discussion

The blood sample acquire from two people with non-diabetic and other with diabetic condition to check glycemic level. For both people the magnetic signal from pancreas acquires and process with stationary wavelet transform and Haar wavelet analysis to detect pancreas magnetic activity. The sprintronic sensor placed above pancreas region of non-diabetic person. The pancreas magnetic signal acquires from person before meal and signal processed with stationary and Haar wavelet analysis. The processed signal shows pancreas insulin secretion inactivity. The pancreas does not secrete insulin due to no food ingestion.

For study, the blood sample acquires from a diabetic person before meal and check for glycemic level. The glycemic level was abnormal. The magnetic signal from pancreas acquired before food intake and processed with wavelet analysis. The wavelet features show lower pancreas activity than normal person due to lower beta cell content in pancreas. The lower beta cell produces less insulin, resulting in minimal pancreas activity as shown in figure 3 and 4.
The diabetic person feed with meal and the glycemic level check with glucometer. The glucometer shows increased glycemic level. The bio-magnetic signal analyses with wavelet transform. The wavelet analysis shows slender pancreas activity compared to before meal consumption. However, the pancreas magnetic activity for diabetic person is low as in figure 5 compared to pancreas magnetic activity for non-diabetic person after meal scenario. Table 1 gives the signal parameter comparison for diabetic and non-diabetic person bio-magnetic signal.
Table 1: Signal parameter comparison for diabetic & Non-diabetic patients.

Conclusion

The performance of spintronic sensor to detect bio magnetic signal from pancreas before and after meal is presented. The spintronic sensor absorbs magnetic signal emitted by pancreas. The magnetic signal process with stationary and Haar wavelet to extract magnetic features in pancreas. The magnetic features provide a non-invasive way to detect pancreas insulin secretion activity to determine glycemic level in body. Experimental results show the proposed method analyses magnetic property of pancreas effectively before and after meal.

A Study to Assess the Effectiveness of Educational Package Regarding Life Style and Behavior Modification Practices on Body Mass Index (BMI) of Adolescents from Selected Colleges of Greater Noida

Pauline Sharmila¹, Revathi²
¹Dean Cum Principal, School of Nursing Science and Research, Sharda University, Greater Noida, U.P; ²Research Director, Maher, Chennai, Tamilnadu

Abstract

It is essential to maintain an adequate nutrition, physical activity and sound body weight for overall wellbeing of an individual. These measures could reduce the risk of the development of serious health effects such as hypertension, diabetes mellitus, high blood cholesterol, stroke, cancer and cardiac disorders. According to Office of disease prevention and health promotion (2015); to achieve and maintain a healthy weight; balanced diet, regular exercises and activities and keeping up a healthy weight are essential to manage these health conditions, so that they will not worsen the eventually.

On the background of prevalence pattern of overweight and obesity in late adolescents, there is a need for educating and counselling, for at least 30 to 45 minutes of cumulative moderate physical activity at least 5 days in a week. Multi-sectoral approach of different sectors like education department, food industry, media and people will contribute in halting this problem of childhood obesity.

Objectives:

1. To assess the level of knowledge regarding the efficacy of dietary practices, physical activities and behavioural modification practices on effective management of body mass index among adolescents.
2. To find out the effectiveness of educational package regarding life style and behavior modification practices on body mass index (BMI) of adolescents.
3. To assess the life style and behavior modification practices by the adolescents for maintaining adequate body mass index (BMI).
4. To correlate the knowledge and practice regarding life style and behavior modification interventions by the adolescents.
5. To describe the frequency of dietary consumption among the adolescents with a view to identify possible dietary factors regulating the BMI.
6. To develop and distribute an educational booklet regarding life style and behavior modification practices on body mass index among the adolescents.

Key words: Effectiveness, Educational package, Lifestyle practices, Behavioral modification practices, Body Mass Index, Adolescents

Background of the Study

If someone wishes for a good health, one must first ask oneself if he is ready to do away with the reasons for his illness; only then it is possible to help him.
Once it was thought that the high prevalence of overweight and obesity is an issue only faced by the developed countries. But the obesity is found to be increasing even in developing and underdeveloped nations, especially urban areas. According to various studies the prevalence of obesity has doubled since 1980. According to WHO, more than 340 million children and adolescents up to the age 19 years were in the category of overweight or obesity in 2016. As per a recent study published in The New England Journal of Medicine, in the world, after China, India has got highest number of the adolescents (14.4 million cases) who are reported to be obese.

A significant change responsible for obesity is the lack of exercise that the older adolescents nowadays get. Earlier, they had more time to play, run about or work out, compared to the adolescents of this generation. Long school hours, the ordeal of getting ready for college and tuitions increases inactivity. Most of the adolescents are physically inactive as they have limited play areas and open spaces around their schools and homes. Another reason for lack of exercise, sports and physical activities are high level of academic competitiveness, homework and parent’s academic expectation about their children.

Even, recommended daily calorie requirement would lead to excessive energy balance due to lack of activity. This makes the fat accumulated in the body and leads to overweight and obesity. Especially, this pattern is frequent when the older adolescents spend excessive time on watching TV, play video games and work on computers. The problems of late adolescent obesity and sedentary lifestyle are interrelated leading to a vicious cycle. Many studies have shown a significant association between physical activity and obesity.

Goyal et al. (2010) suggested that prevention of obesity in adulthood requires the prevention and management of childhood overweight and obesity. In late adolescents, it leads to the health issues during adulthood by means of development of chronic diseases such as adult-onset diabetes mellitus, coronary heart disease, orthopedic and respiratory diseases.

Childhood and adolescence obesity is today a global health problem. Concerted efforts by health care providers, parents and the children themselves are needed to control and prevent the problem from escalating. So, the researcher felt the need to conduct this study to understand their level of knowledge and practice and increase the awareness about BMI, overweight and obesity management among the late adolescents with the help of an educational package.

Methodology

Research Approach

In this study Quantitative research approach is used.

Research Design

True Experimental Pretest posttest design (Randomised pre-test post-test control group design) was adopted for this study.

Variables Under The Study:

Independent variables: In this study, independent variable refers to the intervention, which is Educational Package.

Dependent variables: Dependent variables are Level of knowledge and practice regarding diet, physical activities and behavioral modification, which helps in weight management strategies of obesity.
Demographic variables: It includes the variables including age, gender, grade/class, height, weight, BMI, parent’s education, parent’s occupation, parent’s income, religion, type of family, area of residence, obesity level of parents and type of diet.

Setting:

Pilot study was conducted in Noida International University, Greater Noida.

Population

Target population: All the overweight or obese bachelor degree students of age 18-19 years, from Greater Noida, Uttar Pradesh

Accessible population: All the overweight or obese bachelor degree students of age 18-19 years, who meets the inclusion criteria.

Sample

The sample comprises of 40 bachelor degree students who were overweight or obese, of age 18-19 years from selected colleges, Greater Noida; who fulfilled the inclusion criteria were selected for pilot study and the samples were excluded from original sample that is samples for pilot study were selected from Noida International University, Greater Noida.

Sampling Technique

Simple random technique (Lottery method) was used to allocate the participants into experimental and control group.

Criteria for sample selection

Inclusion Criteria: - The study participants include

- those who are bachelor degree students, aged 18-19 years
- who are overweight or obese
- those who knows to read, write and interact in English
- who are available and willing to participate in the study.

Exclusion Criteria: - The study will exclude the participants, who had endocrine/medical problems which led to obesity.

DESCRIPTION OF THE TOOL: The instrument consists of following parts.

Part I – Demographic Data: It includes the variables including age, gender, grade/class, height, weight, BMI, parent’s education, parent’s occupation, parent’s income, religion, type of family, area of residence, obesity level of parents and type of diet.

Part II – Knowledge questionnaire regarding the lifestyle and behavioral modification: This part consists of 40 items to assess the level of knowledge regarding the lifestyle and behavioral modification in the management of overweight and obesity.

Part III- Practice questionnaire regarding the lifestyle and behavioral modification: This part consists of 32 items to assess the lifestyle and behavioral modification practices in the management of overweight and obesity. It also contained a FFQ.

Part IV: Educational package: Educational package regarding the diet, activity and behavioral modification which helped the adolescents to enhance their knowledge and manage their weight.

Scoring and interpretation:

Questionnaire for Assessing Knowledge

The questionnaire consists of 40 questions. Score of 1 was given for each single correct answer, and 0 score for wrong answer. Hence, the maximum score calculated for each adolescent was 40 and a minimum of 0.

Table No:- 2 showing the interpretation of the knowledge score

<tr>
<td>0 - 50 %</td>
<td>Inadequate Knowledge</td>
</tr>
</tbody>
</table>

Questionnaire for Assessing Practice

This consists of 32 items to assess the practice of the adolescents in the management of overweight and obesity. Each correct answer carried 1-5 marks based on the level of practice in the scale. Hence, the maximum
score calculated for each adolescent was 160.

Table No :-3 Table showing the interpretation of the practice score

</tbody>
</table>

Results of the pilot study:-

The pilot study was conducted with 40 (10% sample size of the main study) samples, allotted using randomization with 20 to study group and 20 to control group. These participants were excluded from the main study. Reliability of the tool was assessed by using Cronbach Alpha and was found to be $r' = 0.92$ ($p<0.001$) for knowledge questionnaire and $r' = 0.95$ ($p<0.001$) for practice questionnaire. The reliability was found to be highly significant. Pilot study was conducted after obtaining permission, from 01.06.2017 to 30.06.2017 with a total of 40 samples, 20 in each group. A miniature study of pre-test post-test knowledge and practice assessment was performed to find out the effectiveness of the tool, and obtained t-value was extremely statistically significant, which shown that, the study is feasible and tool is effective for administration.

Summary and Implications

Overweight and obesity are the significant long-term health problems that are common among the late adolescents in India. Being overweight or obese can contribute to type 2 diabetes in childhood and increase the risk of secondary effects in adulthood. Primary prevention of obesity prevents the development of serious secondary complications in adulthood too. Nurses can help adolescents by providing nutritional advice and, through weight management programs, offer strategies for decreasing caloric intake and increasing physical activity. Nurses’ actions should always take a family and community level approach including schools because it is challenging for obese adolescents to alter their dietary or physical habits if not supported by their families, friends and the teachers, who helps in their behavioral modification. Nurses should work with all members of the multidisciplinary team in addressing adolescent obesity as it is a major health issue with long-term complications.

Impact of Market Economic Principles on Workplace Anxiety and Stress

Pradeep Menon P, Priya V
1Research Scholar, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India, 2Assistant Professor, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Synopsis

The mainstream economic policies that have almost become a global narrative post the World War II have been that of the Free Market Economy. The key principles of this narrative include free labour market, free trade and the self-regulating market mechanisms. These principles essentially stem from the formalist economic principles that found its manifestation as classical and neo classical economic theories.

While “Maximization of Social Welfare” has been professed as the ultimate goal of this principle, there are incriminating instances and evidences where adoption of these principles has led to conflicts at micro (individual) and macro (societal) levels in society through increase in workplace anxiety consumerism, inequalities, poverty, identity conflicts, reduction in social capital, social cohesion etc.

This paper attempts to establish the how the outcome of market economic principle led policies such as inequality, individualism, social capital and globalized workplace contributes to workplace anxiety and stress.

Keywords: Market Economy, Formalist Economy, Globalisation, Inequalities, Social Capital, Identity Conflict, Decision Latitude, Social Welfare

Introduction

The Market Economic policies pushed to the centre stage by the International Monetary Fund, World Bank and the US Department of treasury which is otherwise known as Washington consensus has come to dominate the current economic world view. The market economic world view professes greatest good for the greatest number. However, increasing number of studies have pointed to incriminating evidences that the application of Market Economic principles have actually led to increase in conflicts in societies affecting the mental and social welfare of human beings.

Market economic policies put “Market” which was hitherto functioning on the periphery of society as the only institution of economic activity. In order for effective functioning of the market as the central place in society, it was necessary to commoditize factors of production, strip away the non-mechanistic characteristics of the labour and shape a new human and social reality where production and acquisition of wealth was the main purpose of life. The market economic characterization of human being (homo economicus) thus became the de facto expectation of the individual in the society.

The adoption of market economic principles paved the way for introduction of multitude of policy changes in adopting countries including Globalization, Liberalization and Privatisation. While the impact on GDP has been encouraging for many of the countries which adopted these changes, it was not without significant social ramifications including widening of income inequality, lack of social capital and cohesion, individuality, job instability, pollution, job insecurity among others.

Research studies on workplace stress indicates that the above listed factors which are outcome of market economic policies are primarily reasons for workplace stress and anxiety. Termed as the twenty first century
health epidemic, workplace anxiety and stress is said to cause significant global economic losses up to the tune of US Dollars one trillion per year in lost productivity (5).

Materials and Method

There is very little direct research on the effects of market economic principles on workplace anxiety and stress. The focus of this paper will be on potent risks of anxiety and stress in workplace that are central outcomes of market economic principles. This paper tends to review the research articles and chapters from books focusing causative factors for workplace anxiety and stress. More than 40 research articles and chapters from books published by Scopus, Pub Med and Sage were reviewed and the following factors concomitant to economic principles were recognized as leading to workplace anxiety and stress.

Findings

The findings from the reviews are categorised into four major factors and the evidences pertaining to these causes are discussed below.

- Wealth and Income Inequality
- Social Capital
- Individualism
- Globalized Workplace

Wealth and Income Inequality

Since the adoption of Washington consensus driven deregulation policies, the gap between the world’s rich and poor has only widened. In varying data levels across the years, Naomi Klein in her book Capitalism vs Climate Change claims that the top three percent of the wealthy, held fifty five percent of all wealth while the bottom ninety nine percent controlled only around twenty five percent of wealth (6). The data on wealth inequality in recent years in 2018 shows that the world’s richest which constitute nearly one percent of the population owns a staggering forty five percent of global wealth (7).

Inequality in societies leads to trust erosion, increased anxiety levels and excessive consumption. When economic inequality is more pronounced it has been found to have adverse impact such as physical health and mental health degradation, drug abuse, increase in imprisonment, decreased social mobility, trust and community life, increase in violence and child well-being (8). Inequality in economic status creates adverse view of one’s self worth and loss of control over work and life leading to deterioration in mental health.

The homo economicus characterization has set the default expectation of an individual in modern society as the one who not only constantly strives to create wealth but also has made it the main purpose in life. A dominant global narrative such as this in societies lead to Status Anxiety, a constant fear among individuals of not being perceived as successful if they don’t end up in the top of the economic income or wealth ladder (9). In workplace this translates to increase in competition, trying to outsmart his/her colleagues at whatever cost leading to constant state of anxiety and fear at the workplace. A vast disparity in wealth and income in societies thus leads to a constant stress and anxiety in the workplace.

Social Capital

Workplace is a social setting where individuals develop important friendships among co-workers. Elements of trust in workplace enables individuals to discuss individual problems which can have a positive effect on well-being of workers (10). Social capital is defined as features of social structure (such as trust, norms, sanctions, informal social control), appropriable social institutions, and channels that benefit groups or societies, which fosters mutual trust and reciprocity (11) (12) (13).

Market economic principles made Markets as the sole institution handling economic activity and subjugated other social institutions such as kinship, religious and political institutions which were also involved in production and distribution of goods (14). The hegemony of market as the sole institution handling economic activity in societies have thus paved the way for weakening of other traditional social institutions, traditions and norms. By appropriating and subjugating the functions of these social institutions market economic principles eroded the central social mechanisms governing human relations and thereby reducing the social cohesion in society (15) (16).

Wide range of studies conducted in United States, Finland and Iran have indicated that decrease in social cohesiveness and social capital results in weakened social support and increased psychosocial morbidity (17) (18). World Health Organization studies on Social
Determinants of Health further establishes that Social Capital and Social Cohesion is one of the key factors affecting individual health (20). Social capital in workplace has been identified to reduce stress and anxiety through various means including stress-buffering, availability of social support and exerting individuals to act in accordance with the established norms within the workplace (19)(21).

**Individualism**

Individualism is a set of principles that advocates that the interests of the individual should achieve precedence over the state or a social group. The political and economic system based on the principles of individualism value independence and self-reliance and limit the control of the government (22). Under individualism, individuals are considered as the basic building block of society and emphasises more on personal achievement with the person being the focus of attention (23). Relations with others are shallow and of limited emotive intensity (24).

The market economic principles for optimal functioning of the market are firmly anchored on economic individualism which considers individuals consistently make rational decisions and are narrowly self-interested and pursue their individual goals. Driven by American and European nations with its political and economic strength, globalization has not just exported products, technologies and economic systems but also the western culture, values, ideas and beliefs anchored on individualism (25).

Thus, individualism has become an essential characteristic of the developed market economy countries. Market economy through its emphasis and focus on individual achievement and competition have made individualistic values more desirable than collectivistic ones in these societies (26). Various studies indicate that job dissatisfaction, turnover intentions, common mental disorders, crime and divorce increases when societies become more individualistic (27)(28).

In today’s social setting workplace makes up significant time of an individual’s life catering to the need of the social self. Driven by the individualistic requirement of the market economic society, workplace of today is thus characterized by individuals who focuses only on personal gains. Continuous competition to succeed, one up-manship, winning at other’s cost and thereby creating a climate of distrust, continuous stress and anxiety at workplace.

**Globalized Workplace**

The market economy adoption have significantly changed the work environment, which is now characterised by boundary less outsourcing of business, increase in identity conflicts and reduction in decision latitude at work (29).

Globalization provides an avenue for organization to increase profits through outsourcing it to geographies, where the cost of production is less (30). However, the strategy has created a core set of fulltime workforce which focuses on the organization’s critical work and another set of nonstandard workers in periphery which is outsourced for cost advantages.

There are compelling evidences from studies that majority of the new jobs created post 1990s are informal and temporary in nature (31) and the erstwhile jobs characterized by reliable and stable employment has given way to new changing workplace experience characterised by informal and temporary arrangements (8) Studies conducted by (Kivimäki et al., 2001) (32) and (Virtanen et al., 2005) (33) have found that informal temporary employment is associated with higher psychological morbidity.

The globalized work environment has also contributed to the change in decision latitude which is defined as the extent to which one can make decisions and exercise control over his/her work. The globalized work environment is characterised by business and operational decisions being made at a global scale without leaving enough room for individual decision making in workplace (34). The new form of globalized workplace has also increased the level of job demands from the workers. Many a times workers have realized that the autonomy of work in globalized setting is only illusory (35). Numerous studies conducted over the years provide consistent findings that that low decision latitude combined with heavy job demands is associated with mental strain in workplace (36)(37)(38).
Market economic principles led globalization are characterized by rapid expansion of multinational corporations, dominance of global brands and pervasiveness of global media, which penetrate the local experience and provide a gateway to information and people in other geographies. Exposed to the global media, young people from non-market economic societies end up forging identities with the westernized global views and culture. This has led to an identity confusion among individuals outside the west, with a sense of delocalization resulting in significant sense of alienation, temporariness and lack of cultural identity. Lack of cultural identity leaves the population in these countries without clear guidelines on how life is to be interpreted and how lives have to be lived (39).

Influenced by globalized work environment, individuals in these newly adopted societies thus ends up possessing simultaneous identities, a globalized one at the workplace and a localized one outside the workplace. Multiple possession of identities leads to confusion and distress as individuals struggle to make priority of one over another while encountering conflicting situations. There have been growing evidence that multinational organization setting has actually led to increase in domestic problems, substance abuse, depression and anxiety (40) (41).

Conclusion

Market economic principles were the outcome of situations prevailing in sections of Europe post Second World War. The resurgence of these principles as Neo classical economics and Washington consensus has been applied worldwide in form of globalization, deregulation and privatization. These form of uniform policy application without due consideration of traditional culture, societal and religious norms prevalent in countries have developed conflicts in both at the level of the individual and the society. We have seen that the market economic principle implications include wealth and income inequality, reduction in social capital, rise in individualism and changing workplace among others. These factors are seen to increase mental stress and depression at the workplace.

A multipronged intervention is urgently required in order to mitigate this growing epidemic. The approach should include positive intervention from government, employers and NGOs. All interventions should take a comprehensive view of the social, cultural and economic context. Holistic interventions at workplace such as Yoga, Tai-Chi may also be explored.

Further ongoing research is needed to fully understand the fault lines created by blind application of market economic policies without due consideration to the social and anthropological factors, so that the community and society is saved from the rising requirements for operating at the margins of Supply Demand Curves.

Physiologic and Psychologic Understanding and Consideration in the Treatment of Geriatric Edentolous Patients – A Review

Pradeep. S

1Additional Professor, Dept. of Prosthodontics, Manipal College of Dental Sciences, Manipal

Abstract

Perfect health has been the goal of mankind throughout all ages. It must be understood that there can be no separation between good bodily health and good dental health. A diseased body often produces a diseased mouth intum, a diseased mouth may often lead to a diseased body. Great majority of people have a heritage of good health, many destroy this priceless possession by failure to properly care for their bodies. Much of this neglect is due to a lack of knowledge of the best way to care for this complicated and wonderful machine. This is more so amongst the older age group of individuals. The care of dental problems of the senior citizens assumes an increasing proportion of the time of health care-takers. Dentistry for elderly must be practiced with increased awareness of the biologic factors, since the adaptive mechanism and tissue regenerative potentials of the elderly patients are usually significantly lowered

Keywords – Geriatrics, old age, senile

Introduction

Perfect health is a prize that has been the goal of mankind throughout all ages. It must be understood that there can be no separation between good bodily health and good dental health. A diseased body often produces a diseased mouth intum, a diseased mouth may often lead to a diseased body.

The care of dental problems of the senior citizens assumes an increasing proportion of the time of health care-takers. Dentistry for elderly must be practiced with increased awareness of the biologic factors, since the adaptive mechanism and tissue regenerative potentials of the elderly patients are usually significantly lowered. The elderly are not merely older ordinary patients because they require a different approach, modified treatment planning and a knowledge of how the tissue changes associated with senescence affect oral health services.

The subject of geriatrics is increasing in its importance because of great age shift in the living population of the world. Statistical data from United States, published in 1964, indicated that approximately 50% of the American population over 45 years of age was edentulous. This percentage was estimated to be 75% for those over 70 years of age. In spite of the profound changes, which can be anticipated in these statistics in future, owing to the remarkable advancements in the scientific disciplines of pedodontia, periodontia and restorative dental procedure, the potential number of geriatric patients seeking prosthodontic services in the immediate and predictable future stagger the imagination.

Geriatrics refers to the study of aged. Dr. S. Silverman views age as a three dimensional phenomenon; wherein, there is a constant interaction between chronologic age, physiologic age and psychologic age. The average life expectancy in 1789 was 35 ½ years. Today, it is one hundred years. The man has altered his average life span, but not his maximum potential. It seems obvious that whatever the troubles man’s mass longevity may cause, they make him no less eager to survive as an individual. His dream of continuing life and vigor and his corresponding terror of impotent old age are obsessive themes in his literature and now-a-days in his psychiatry.

The process of aging begins at birth. Thereafter, two phases of aging must be considered. The chronologic age and the physiologic age. The former denotes the time of existence of the individual and the later, the resultant effect of the passage of time on the functional elements of the body. Much of the life span is controlled...
by heredity, but a degree of modification may be made by environment, diet, emotional status and medical care. A person at the age of 60 years may have a gastrointestinal tract comparable to that of a 40-year-old, a nervous system of a 30 year old, a cardiovascular system comparable to that of a 50 year old person and the dental apparatus of an 80 years old, biologically.

From this we come to understand that the degree of a person i.e. chronologic, physiologic and psychologic, if plotted on a graph, may invariably stand at different levels in terms of years. This is a matter of increasing concern in the practice of dentistry, because of the number of elderly people who require denture service. The validity of this statement can be understood. If one maintains the records of problems posed by aged denture patients as against the young. The dental practitioner, who follows a stereo-typed treatment plan, without giving any consideration to the age and the problem, which are specific of each individual, certainly faces more number of failures in case of elderly patients. This can be attributed to different oral and general disorders of the aging persons, which, most of the practitioners fail to realize. These patients need to be treated by nutrotherapy as well as psychotherapy. Also the treatment procedures need to be altered according to the requirements of individual patient.

The effectiveness of execution and application of nutrotherapy, psychotherapy and modified clinical procedures in the success of the treatment, greatly depends upon the thorough understanding of changes that may take place in different systems of the body as well as in different organs, tissues and cells.

The prosthodontist can play a key role in reducing the number of prosthetic failures by a careful understanding of the physical, mental and metabolic changes that occur during senescence. The oral changes that occur during aging should be recognized, understood and treated before prosthetic restorations are prescribed for these individuals.

This article has been aimed at reviewing the available literature pertaining to “The problems and management of geriatric patients” and suggest methodology which will help the prosthodontists as well as general practitioners of dentistry, to considerably reduce the number of prosthetic failures through a proper understanding of the pitfalls and suggest ways and means to overcome these difficulties.

**Effect of aging on organ systems**

No organ and tissue of the body is spared from physio-anatomic changes, which can be called, senescent degenerations. These changes occur to a variable extent in different organs. To make a generalized statement, the essential changes is dehydration and waste of tissue. This wasted tissue is either not replaced at all or is replaced by a tissue of a different variety. Those changes in cellular function and growth are manifested by different organs, in different ways.

**Gastrointestinal system**

There are dilatations of the intestine and stomach accompanied by progressive atrophy of the glands. This probably causes irregularities of absorption and bowel. There is a diminished secretion of hydrochloric acid resulting in impaired absorption of dietary elements such as calcium, iron and vitamin C. Secretion of proteolytic enzymes, pepsin, trypsin chymotrypsin, is markedly reduced, consequently causing incomplete protein digestion.

**Glandular system**

There may be progressive atrophy, fibrosis, sclerosis and fatty degeneration in different glands of the body. As a result, there is marked degree of reduction in function which adversely affects metabolism, nutrition, enzymatic and hormonal relationships. This will be evident from the fact that the patient may suffer from moderate to severe deficiency diseases, inspite of consuming a balanced diet. Diminution of sexual power, diabetes, kidney dysfunction due to altered acid-base balance, are some of the manifestations of diminished glandular activity.

**Cardiovascular system**

Blood volume and haemoglobin content of blood, are reduced, cardiac insufficiency along with vascular changes – which reduce the optimal blood supply to tissues are common findings. The result is less oxygen supply to the tissues. According to many Geriatricians, this fact is the basis of senescence. Hypochromic anaemia is commonly seen in aged patients, which can probably be attributed to achlorhydria and deficiency of ascorbic acid, which affects absorption of iron. Sastry et al are of the opinion that 60% of the patients seeking
complete denture treatment are anaemic.

**Respiratory system**

Lungs show gradual fibrosis, which decreases respiratory efficiency leading to problem of oxygen exchange. This may be manifested as breathlessness after a little physical strain.

**Musculo-skeletal systems**

Generalized dehydration results in loss of elasticity and resiliency of the muscles. Notable skeletal changes also take place. Organic matrix of the bone is reduced which makes the bones brittle and prone to easy fractures, which heal with difficulty. This impaired healing tendency can probably be attributed to the deficiency states of vitamin C, calcium, which are important in healing of wounds. Bone marrow becomes gelations and contains relatively more fat that younger bones. There is also reduced osteoclastic activity. As a result, osteoclastic activity is apparently increased. This causes continuous resorption of the bones. This fact also, can probably be attributed to impaired healing of the fractures bones.

**Skin**

Thin, dry, and inelastic skin is characteristic of an aged. There may be atrophy of sebaceous and sweat glands. This makes the skin prone to injuries. The subcutaneous fat disappears and hyperkeratotic areas become apparent. There may be sparse and discoloured hair.

**Nervous system**

These cells reach the highest degree of specialization, undergo senescence and die without being able to divide and produce new cells. They lose the capacity to reproduce about the end of first year of life. Aging changes are most evident in such tissues and cells.

**Psychologic aspects of aging**

In addition to the physiologic evaluation of the geriatric patient who is to undergo prosthodontic treatment, a psychologic preparation is most important, which plays an important role in the success of the treatment. It is important to have some understanding of the psychology of human aging, to be able to appreciate the difference between behavioral disorders associated with organic brain disease and those which are not. According to Dr. Donald B. Giddon, this differentiation is necessary, as it would decide the need of measures to be followed in psychological conditioning of the patients.

Among the psychologic disorders which are associated with any organic brain damage, hypochondriasis (morbid anxiety about one’s own health, with complaint of imaginary disorders) is the common behavioral disturbance. In the older people this is basically withdrawal phenomenon where the individual substitutes his body for his previous concern for the world about him.

Organic brain damage presents difficult problems in the dental treatment. For example, in senile dementia, an irreversible deterioration of intellectual faculties develops and the patient is frequently withdrawn and incapable of adjusting to any prosthesis. Such patients are probably best treated by the eradication of oral disease and dietary changes to accommodate to their modified dentition or their non-existent prosthesis.

Geriatric patients show high incidence of depression and feelings of insecurity and experience vague pains and fears. Nervous habits like tooth clenching may develop and this places extra stress on tissues that already have lowered load bearing capacity.

Older patients are also likely to be using drugs and care must be taken to understand the clinical dental implications of such drug use. Tissue distortion can result from medication taken for oedema caused by kidney or cardiac dysfunction, from fatigue or changes in fluid intake. Tissue distortion can seriously affect impression making and it is recommended that morning appointments be organized to ensure minimum tissue distortion from oedema.

Reassurance, tolerance and a patient clinical approach can usually help the elderly obtain satisfactory prosthodontic results.

**Discussion**

General health and oro-dental health, are interdependent. In other words, one must have good bodily health, if he is to have a healthy oral cavity. Similarly, an unhealthy oral cavity and stomatognathic system adversely affect the general health of the individual. Again, the general as well as oral health depend upon the age of the person and his dietary habits.
As for any construction to be successful, a strong and stable foundation is the basic requirement, similarly for the artificial dentures to function successfully, healthy foundation tissues are necessary. No prosthesis, even if it is fabricated by a highly skilled and well experienced clinician using latest materials and techniques, can be and should not be expected to function satisfactorily, if it is to rest on poor and weak foundation. Moreover, psychological constitution of the patient also plays an important role in the success of treatment procedures and hence this aspect of patient evaluation cannot be overlooked.

Human body as a whole undergoes degenerative changes during the declining years of life. Stomatognathic system manifests these senile changes in different ways depending upon nutritional status of the patient. The alterations seen in the oral cavity during the old age should be considered to be physiologic. We, as dental professionals, should be able to appreciate these physiologic aging manifestations and should also be in a position to treat these conditions, so as to improve the individual’s oral health, thereby uplifting the stress bearing capacity of the denture supporting and denture bearing elements of the orofacial complex. The treatment procedures aimed at betterment of the oral and dental health status, should include the recognition of the dietary inadequacies and psychological setbacks and their treatment by proper dietary and psychologic counseling. This make evident the necessity of the knowledge of aging changes in different tissue of the body, particularly, those in the province of the prosthodontist

Summary

Knowledge of the senile changes that take place in different tissues, is important for the prosthodontists, to be able to appreciate and treat these conditions. Psychologic evaluation and counseling plays and important role in the treatment success

Post Stroke Pain in Patients from Eastern Uttar Pradesh: A Prospective Study from a Tertiary Care Centre

Rameshwar Nath Chaurasia¹, Jitendra Sharma², Abhishek Pathak³, Deepika Joshi¹, Vijay Nath Mishra¹

¹Professor, Department of Neurology, Institute of Medical Sciences, Banaras Hindu University, India,
²Senior Resident, Department of Neurology, Banaras Hindu University, India, ³Assistant Professor, Department of Neurology, Institute of Medical Sciences, Banaras Hindu University, India

Abstract

Background: Post stroke pain (PSP) is one of the most common but understudied consequence of stroke along with depression, cognitive impairment and poor quality of life. The aim of current study is to see the prevalence and intensity of post stroke pain after 03 months.

Method: The present study was a hospital based prospective study. For this study data was collected from stroke patients admitted in Neurology ward during Oct, 2015 to April, 2017. Total 200 patients were included in this study. VAS scale was used for measurement of intensity of post stroke pain after 03 months. Chi-square test was used to see independence between two variables.

Results: The prevalence of pain among stroke survivors is 25% at 03 months after onset of stroke. Average VAS score was 6.12 and standard deviation 1.76. Majority of the patients reported moderate to severe pain. Association between age, gender, type of stroke, territory of lesion are not significant predictors of pain intensity.

Conclusion: Post stroke pain is still an underestimated consequence of stroke which results in impairment of daily activities of life and further deteriorates quality of life, which affects restoration process negatively. Stroke patients having lesion in the thalamic region are more prone to develop post stroke pain. Therefore, pain management should be integrated with stroke treatment of patients.

Keywords: VAS Score, Central Post Stroke Pain, Thalamus.

Introduction

Stroke is a global health problem and is a leading cause of adult disability.¹ Of 35 million deaths attributable to Chronic Non-communicable diseases that occurred worldwide in 2005, stroke was responsible for 5.7 million (16.6%) deaths, and 87% of these deaths occurred in low-income and middle-income countries.² The earliest studies conducted in late sixties and early seventies in the Vellore in South India³ and Rohtak in the North India⁴, demonstrated prevalence rates of 57 and 44 per 100,000 persons, respectively.

Post stroke pain is characterized by constant or intermittent pain and is associated with sensory abnormalities, particularly of thermal sensation.⁵ Central Post Stroke Pain (CPSP) which was formerly known as thalamic pain syndrome, is a central neuropathic pain occurring in patients affected by stroke.⁶

CPSP has been a neglected consequence of cerebral stroke which has a negative impact on the quality of life. Since it has negative impact on quality of life and

Professor, Department of Neurology, Institute of Medical Science, Banaras Hindu University, Varanasi-221005, U.P. (INDIA).
E_mail: goforrameshwar@gmail.com
rehabilitation therefore, pain is an important topic to be studied among stroke survivors.

**Material and Method**

The present study is a hospital based prospective study. Patients were enrolled in this study from Oct, 2015 to April, 2017. Total 200 patients were included in this study from stroke registry. A valid informed consent was taken from all of them. All the patients were subjected to a detailed clinical history, physical, neurological and radiological examination as per the standard protocol prepared by us. The past history of any illness, history of chronic illness, personal history of addiction, occupational, dietary habits and family history were taken in detail.

**Stroke Registration**

Stroke is defined as rapidly developing clinical signs of local or global loss of cerebral function that lasted for more than 24 hours or led to death within 24 hours. Subtypes of stroke were coded according to the *International Classification of Diseases (ICD), 10th Revision*. Events were classified as cerebral infarction (ischemic; ICD 434), Intracerebral hemorrhage (ICD 431), and subarachnoid hemorrhage (ICD 430). Patients with transient ischemic attacks were excluded. The subtype of stroke was verified by computed tomography (BRAIN), MRI (BRAIN). Stroke was further sub classified as unspecified stroke (ICD 436) if CT or MRI does not reveal any abnormality. VAS score was used to measure pain intensity and it defines pain intensity as mild (1–3), moderate (4–6), or severe (>6). We used SPSS 16.0 for analysis purpose. Chi-square Test was used to see relationship between two variables. Probability (p) values less than 0.05 were considered significant.

**Inclusion Criteria**

All Stroke patients admitted in neurology ward of Sir Sundar Lal Hospital from Oct 2015 to April 2017 were included.

Visual analog scale (VAS) was used for pain intensity measurement defining pain intensity as mild (1–3), moderate (4–6), or severe (>7).

WHO guidelines were used for all blood parameters.

Hypertension was classified as per Joint National Committee (JNC) 8.

**Exclusion Criteria**

Patients of Transient Ischemic Attacks (TIA) and Cerebral Venous Thrombosis (CVT).

Pediatric Age Groups were excluded (upto 14 yrs).

**Results**

Majority (33.0%) of the patients belong to age group 61-70 years, followed by 26.5% between 71-80 years and 23.0% between 51-60 years. In this study we see that more than 80.0% of patients are in the age range 51-80 years. Mean age of patients is 64 years with a standard deviation of 12 years. Further, sex- wise distribution of stroke patients shows three fourth of the patients were male (73.5%) and 26.5% patients were female. Majority (70.5%) of the patients were educated upto primary level, 13.5% upto high school and only 7.0% upto graduation level or above while 9.0% patients were illiterate. In our data economic status of the patients was measured by Kuppuswamy’s socio-economic scale. According to this 24.0% patients belonged to lower class followed by 29.0% from lower middle class, 34.5% belonged to upper middle class and 11.0 % belonged to upper class.

In our data 140 (70%) had left infarction/ bleed and 60 (30%) had right side injury in brain. Out of these 39 had lesion in thalamic region and 25 patients had bleed while only 4 patients had infarction. Further it is evident that majority of the strokes are Ischemic 113 (56.5%) as compared to Haemorrhagic 79 (39.5%). Subarachnoid haemorrhage constituted only 4% of total stroke. According to the TOAST classification of ischemic stroke majority of the patients had SVD (65) followed by LVD (28) and cardio embolic (20). In our study group around one third (31.5%) patients had hypertension. Also 97.0% of the patients had first ever stroke and only 3% patients had experienced stroke prior in the past. Pain intensity was measured by VAS score. The mean VAS score was 6.12 and the standard deviation was 1.76. In the present study Post stroke pain was found in 50 (25.0%) cases out of 200 stroke patients. Among all stroke patients, 12.0% patients reported moderate pain followed by 10.5% with severe pain and only 2.5% had mild pain.(Table 1)

Table 1 presents the association between different background characteristics and pain intensity. We used chi square test to check the significance of association between two characteristics. From table 2 it is clear that
age, sex, education, economic status and hypertension has insignificant association with pain intensity. Further we see that association between pain intensity and type of stroke was also not significant at 03 months. In our data out of 39 patients whose territory of lesion was thalamic region, left sided lesions (25) predominated. Among these 39 patients, 32(82%) patients developed post stroke pain within 03 months after onset of stroke. Out of these 32 patients, 15 (46%) patients had moderate pain and 16(50%) had severe pain intensity. The rest of the 18 patients with PSP had extra thalamic lesions. Among these 9(50%) patients had moderate and 5(27%) had severe intensity pain at 03 months after onset of stroke. Thus, we can say that stroke patients having thalamic lesion are more prone to develop PSP but this result was not statistically significant.

* insignificant at 95%
Discussion

The results of our study showed that the prevalence of PSP is 25%, which is in the range cited in previous studies. In many previous studies prevalence of PSP is reported in the range of 1%-12%. However, in a study 21% had pain related to stroke at 03 months. In Hansen et al. (2012) study 55.3% had post stroke pain at 03 months. In Kong et al. (2004) study 42% of the patients had post stroke pain. The time for onset of PSP has not yet been established. It may start immediately after onset of stroke up to 10 years but usually PSP starts between 03 to 06 months after onset of stroke. Therefore, the timing of clinical investigations must be considered carefully. In a study by Bashir et al. half of the patients reported onset of pain within first three months after stroke. While in present study one fourth of the patients had pain after three months of onset of stroke.

In our study average VAS score were 6.12 which shows higher proportion of patients belonged to moderate to severe pain category. In our study one fourth patients reported moderate to severe pain intensity. While in a study by Jonson found that one third of patients had moderate to severe pain at 04 months after stroke onset, and at one year follow up 20% were still experiencing moderate to severe pain with increased intensity. Also, they found that women had significantly lower Barthel Index than men. In a study by Klint and colleagues patients with CPSP often reported moderate pain intensities and CPSP generally only interfered little with daily activities, mood, sleep, and enjoyment of life. In present study we found CPSP was more prevalent in men than women. Similar results were obtained in study by Bashir also but they did not test the significance of results. However in our study we used chi square test to check the association between two and found insignificant association. Previous studies have shown that age, gender and location of lesion in the CNS could not be considered as predictors of CPSP. In present study also we have seen age, sex, education and economic status have shown insignificant association with the type of stroke.

Further in subgroup analysis between type of stroke and pain intensity at 03 months we found in ischemic stroke subgroup, three fourth of the patients had moderate pain and around one fifth had severe pain. Here again we see that majority of the patients had moderate to severe pain. In hemorrhagic stroke subgroup we found equal ratio between moderate and severe pain intensity and there was no patient with mild pain. While in subarachnoid haemorrhage subgroup 100% patients had moderate pain. The distribution of pain can range from a small area (e.g., the hand) to large areas (e.g., to one side of the body). Place of the pain varies, but hemi syndrome or lower limb involvement was frequent, which results in motor impairment and disability. In present study the cerebrovascular lesions were located in the lower brain-stem in 10 patients, involved the thalamus in 30 and in 6 were supra-thalamic. In 4 patients the location of the cerebrovascular lesion (CVL) could not be determined.

Here we seen that prevalence of CPSP vary widely from study to study and the possible reasons are non-uniformity in the selection criteria and the different ethnic populations being studied. Some studies are population based whereas some studies are hospital based and the duration of study also varies from one study to the other.

As per pain intensity is considered we can say that majority of the patients had moderate to severe pain at first follow up or baseline and over the time of second follow up at 06 months or one year or after that we found decreased percentage of patients reporting moderate to severe pain. Here again we see that there is discrepancy between timing of second follow up. Thus, different methods of study adopted and time points at which pain is measured makes comparison between two studies difficult. Therefore, some standard guidelines must be prepared by higher authorities and should be strictly followed by researchers. Then only we would be able to compare two studies scientifically and can come up with some crucial and relevant investigations which will ultimately help in further policy making.

In our study we found that age, sex, education and economic status are not significant predictors of CPSP. Though we have seen majority (96%) of patients having lesion in thalamic region had experienced pain intensity as moderate to severe while only 77% patients experienced moderate to severe pain intensity whose lesion site was extra-thalamic. Type of stroke, territory of lesion and physical activity are also not significant predictors for CPSP and this result is in accordance by the previous studies. But we recommend that pain therapies should be integrated with treatment of stroke.
patients having lesion in thalamic region because if affects motor activities of patients.

Surgical Management of Radicular Cyst of Deciduous Tooth – A Case Report

Rathanakumar Vigil Dev Asir¹, Banu Sargunar², Rakesh Mohan¹, Wasim Ahamed¹, Shanmugapriyan², Swarna Priya²
¹Senior Lecturer, ²Reader, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospitals, Chennai

Abstract

Radicular cyst is the most common inflammatory odontogenic cystic lesion of the jaws. They arise from the epithelial remnants of the periodontal ligament as a sequel to the periapical inflammatory process, following chemical, physical or bacterial injury. The radicular cysts most commonly involves the maxillary anterior region and are managed by surgical enucleation and marsupialization. This article deals with the pathogenesis, clinical features, and treatment options present thereby discussing the successful management of the radicular cyst by surgical method.

Keywords: radicular cyst, odontogenic cyst, enucleation, deciduous tooth

Introduction

The term, ‘cyst’ is derived from a Greek word, meaning, ‘sac or bladder’ (1). Cyst is defined as a pathological cavity that is usually lined by epithelium and which has a centrifugal, expansive mode of growth (2). Of all the cysts that occur in the jaw, radicular cysts occurs the most and comprise about 52% to 68% of all the cysts(3–5)oral medicine, oral & maxillofacial surgery and radiology. This fourth edition reflects advances in immunohistochemistry, molecular biology and human genetics, which have contributed to the understanding of the etiology, pathogenesis, pathology and treatment of these lesions. This book is a comprehensive treatise on cysts occurring in the oral and maxillofacial regions, covering clinical features, epidemiology, radiology, pathogenesis and pathology. Classification and frequency of cysts of the oral and maxillofacial tissues -- Gingival cyst and midpalatal raphé cyst of infants -- Odontogenic keratocyst -- Dentigerous cyst -- Eruption cyst -- Gingival cyst of adults, lateral periodontal cyst, botryoid odontogenic cyst -- Glandular odontogenic cyst (sialo-odontogenic cyst, mucoepidermoid odontogenic cyst. Radicular cysts are rare in the primary dentition, representing only 0.5–3.3% of the total number in both primary and permanent dentitions (6). The male preponderance occurs essentially in the fourth and fifth decades(1). They originate from epithelial remnants of the periodontal ligament as a result of inflammation that is generally a consequence of pulp necrosis (7). Commonly found at the apices of the involved teeth(8) but may also occur in the lateral aspects of the roots in relation to lateral accessory canals(9). These cysts are slow growing and asymptomatic unless secondarily infected and usually an accidental finding

Trauma or dental caries are the common etiological factors. Dental caries cause inflammation of the pulp cavity, leading to pulp necrosis (10). The infection then spreads to the tooth apex of the root, causing periapical periodontitis, which leads to either an acute abscess or a chronic granuloma. Persistent chronic infection can lead to formation of a periapical cyst(11). Cortical expansion and root resorption of the affected tooth and displacement of the adjacent teeth are common features of radicular cysts(11). The treatment for radicular cysts includes conventional nonsurgical root canal therapy when lesion is localized or surgical treatment like enucleation, marsupialization or decompression when...
the lesion is large \(^{12}\)

**Case Report:**

An eight year old female patient reported to the Department of Oral and Maxillofacial surgery, with a chief complaint of swelling and pain in the left lower back tooth region for the past 15 days.

History revealed pulpectomy procedure followed by stainless steel crowns placement in 74,75,64,65 a year ago. On Extraoral examination a swelling measuring 2 x 1.5cm, was present in the left body of the mandible. On palpation, it was tender and hard in consistency. Intraoral examination revealed a swelling extending from 73 to the mesial aspect of 36. Radiographic examination revealed periapical radiolucency involving 73,74,75 and the tooth buds of 33(Nolla’s stage VI)\(^{13}\), 34(Nolla’s stage V)\(^{13}\) and 35(Nolla’s stage IV)\(^{13}\) and mesial root of 36. (FIGURE 1)

Based on history and clinical findings a provisional diagnosis of Radicular cyst involving the primary molars was made.

FNAC was performed with an 18 gauge sterile needle. 1cc of dirty white turbid fluid which was aspirated was sent for histopathological examination. Incisional biopsy was done under LA and a specimen of 0.5cm soft tissue with extracted 74 was sent for histopathologic examination. It confirmed the provisional diagnosis of Radicular cyst.

The patient was planned for surgery under general anesthesia. Routine blood investigations and chest X-Ray was taken. Pre-anesthetic consent was obtained. Medical history and investigation did not reveal anything that could oppose or influence the proposed treatment plan.

The patient was posted for surgery. Under general anesthesia nasotracheal intubation was done. Local anaesthesia administered in surgical site. Crevicular incision extending from 72 to 36 was made with relieving incision anteriorly. Mucoperiosteal flap was elevated. For entry into the cystic cavity, cortical bone window was created until the underlying pathology was adequately exposed and sufficient space was available for thorough enucleation and bone curettage and surgical removal of tooth buds of 33, 34 and 35. A careful enucleation was carried out along with the careful removal of the tooth buds which were embedded and loosely hanging inside the sac. Extreme care was taken not to injure the inferior alveolar nerve. After thorough enucleation, sharp bony margins were trimmed. Metronidazole and betadine wash was given. Careful examination of the area ensured that no residual infected tissues were left behind. The flap was repositioned and the flap margin was ensured to rest on the sound bone. Wound closure done with 3.0 vicryl. Post-operative oral antibiotics and analgesics were advised for 10 days and the patient was advised to be on soft diet for 1 week. (FIGURE 2,3)

**Followup:**

The patient was periodically followed on the third day, one week, three weeks, two months, three months and six months post operatively. (Figure 4,4)

**FIGURE 1** pre operative Orthopantomogram

**FIGURE 2** Intra operative – cystic cavity after thorough enucleation

**FIGURE 3** cystic content with removed tooth buds
Discussion

Radicular cysts originating from the deciduous teeth are quite rare. The low frequency maybe because the pulpal and periapical infections in deciduous teeth tend to drain more readily than those of permanent teeth and different antigenic stimuli may evoke the changes responsible for the formation of radicular cyst\(^6\). However, Mass et al\(^1\) reported that the prevalence rate of radicular cysts associated with primary molars is probably higher compared with that in the reported literature. It may be attributed to the fact that, unlike cysts of permanent dentition, primary teeth are extracted but not submitted for pathological examination, which may account for the low estimation of the real frequency of cysts associated with primary teeth\(^6\). Owing to the fact that these cysts are asymptomatic until they are secondarily infected, they are usually diagnosed during routine radiographs. The sequelae of an untreated or undiagnosed radicular cyst are swelling, tenderness, tooth mobility, and a bluish tinge caused by buccal expansion of the cortical plate. Furthermore, displacement of the successor tooth or, even more unforgiving, the loss of its vitality may result\(^9\).

The radicular cyst of the primary dentition most commonly occur in the mandibular molars\(^1\). In the present case pulpectomy procedure was undertaken for treatment of apical periodontitis in the primary mandibular molars, a year before. However, the side effects of the pulp therapy procedures may include cyst formation, delayed eruption or enamel defects in successor teeth\(^1\). The growth rate of radicular cyst in primary dentition was estimated to be 4-5 mm annually\(^2\). Rare cases of rapidly growing cyst similar to the present case has been reported\(^1\).

Owing to the large size of the lesion, conservative surgical approach was planned which involved the removal of the infected tissues. Marsupialization or enucleation are the common surgical approach to treating cysts of the jaws. The treatment of choice is dependent on the size and localization of the lesion, the bone integrity of the cystic wall and its proximity to vital structures\(^1\). Thorough examination after enucleation was done to prevent any possible recurrence. Post-surgical period was uneventful. The histopathological features of the submitted lesion were consistent with the clinical diagnosis of infected radicular cyst.

Conclusion

The present case is one of the rare occurrences of radicular cyst occurring in the primary dentition. Early diagnosis proves very important, and regular clinical and radiographic follow up for pulp treated primary teeth is strongly recommended.

Comparison of Perceptions Towards Modified PBL and Didactic Lecture among First Year Medical Students in India

Ravindra Maradi¹, Chandana Bhargavi², Kishan K³, Krishnananda Prabhuvi¹, Vaideki Bvi⁵, Prashanth N Dixitvi⁶

¹Associate Professor, Department of Biochemistry, ²Assistant Professor, Department of Anatomy, ³Assistant Professor, Department of Physiology, ⁴Professor, Department of Biochemistry, ⁵Post graduate, Department of Biochemistry, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Karnataka, India, ⁶Associate Professor, Department of Physiology, KIMS, Koppal, Karnataka, India

Abstract

Background: Most of the Western Medical schools have implemented Problem Based Learning (PBL) for many years and found that it facilitates deeper learning and longer retention of knowledge required for the patient care. But in India, because of the high ratio of students to faculty and lack of resources, it is very difficult to implement proper PBL. The present study is done to know the perceptions of medical students towards MPBL (Modified problem based learning) and didactic lecture.

Materials and Method: 165 students who have completed I MBBS and undergone MPBL and didactic lecture at Kasturba Medical College, Manipal were involved in the study. Informed consent and feedback was taken through a validated questionnaire. A descriptive analysis was done.

Results: Our study showed didactic lecture is better suited for understanding of medical concepts (58%), examination performance (77%), focus on important issues (59%), understanding and longer retention (57%), coverage of syllabus (82%), learning of new information and clarification of existing information (47%). For motivation, self-directed learning and use of additional learning resources (55%), active involvement (48%), fun and enjoyable (52%), improvement in confidence, communication and presentation skills (75%), critical thinking (51%), leadership qualities and team work (76%), application of basic science knowledge to diagnose the diseases (51%) and integration of preclinical subjects (61%) modified PBL is the preferred method.

Conclusions: The present study shows that a hybrid model of teaching and learning method (MPBL + Didactic Lectures) is more suitable for Indian Medical Schools than MPBL alone as our students have not been exposed to such Teaching and Learning methods in their pre-professional years. Also our assessment methods are not suitable for evaluation of MPBL.

Keywords: Modified Problem Based Learning, didactic lecture, PBL, Active learning

Introduction

Most of the Western Medical schools have implemented Problem Based Learning (PBL) for many years and found that it facilitates deeper learning and longer retention of knowledge required for the patient care. It should motivate students toward active, self-directed learning, rather than just being passive recipients of information in the classrooms. In 1997
recommendation of Medical Council of India has suggested the introduction of problem-based learning (PBL) in teaching. In PBL, a clinical problem is given to students without prior reading or lecture. The student analyses the problem through self-directed efforts, solves the given problem by applying his knowledge and skills followed later by group discussions. The student not only acquires knowledge but also develops skills. An adequate infrastructure, trained faculty, well-equipped library and internet facility is required for PBL. A tutor is present throughout the session to facilitate the learning process. Work by Papinczak T et al concludes that PBL will be beneficial to both teachers and students in terms of early availability of notes and easy, quicker assessment process. They also concluded it improves interaction among students and also with teacher. It also improved student’s perception to problem solving and their motivation to perform better. But in India, because of the high ratio of students to faculty and lack of resources, it is very difficult to implement proper PBL. A mixture of modified PBL (MPBL) and didactic lecture will be better suited for enhanced student learning in medical schools of India. Objective of our study is to compare the perception of first year medical students towards modified PBL and didactic lectures.

Material and Method

Institutional Ethical Committee clearance was taken Institutional Ethics Committee of Kasturba Medical College, Manipal. Informed consent was taken from 165 students who have completed I MBBS and undergone MPBL and didactic lecture at Kasturba Medical College, Manipal.

Unlike classical PBL which requires at least one facilitator for each small group, in modified PBL all 250 students were divided into 4 groups of 62-63 students each. Four different halls were allotted for each group of students and one facilitator from each preclinical subjects namely anatomy/physiology/biochemistry were facilitating the sessions. Each hall students were sub grouped into 6 small groups with 10-11 students. Each sub group was asked to write one objective on the board after discussing the key words of the case, which was debated by all other groups with active interaction. Likewise, all groups were asked to write one or two objectives each. Subject experts from each department finalized and shortlisted the objectives. All group members were asked to discuss all the objectives. Then one-week time was given for the students to prepare for their presentation. The presenter from each group was decided by lots. This activity was simultaneously happening in all the 4 halls in the presence of facilitators. This approach enforced all students to prepare for all the objectives and was conducted efficiently with minimum number of facilitators. Data were collected using an author designed questionnaire which was pilot tested on few students and was further modified based on their inputs. A descriptive analysis was done.

Our study showed didactic lecture is better suited for understanding of medical concepts (58%), examination performance (77%), focus on important issues (59%), understanding and longer retention (57%), coverage of syllabus (82%), learning of new information and clarification of existing information (47%). For motivation, self-directed learning and use of additional learning resources (55%), active involvement (48%), fun and enjoyable (52%), improvement in confidence, communication and presentation skills (75%), critical thinking (51%), leadership qualities and team work (76%), application of basic science knowledge to diagnose the diseases (51%) and integration of preclinical subjects (61%) modified PBL is the preferred method.

**Discussion**

In this questionnaire based study, students had more inclination towards MPBL than didactic lectures in many questions which were answered. In this study group students felt PBL is a better method of teaching learning method when compared to didactic lectures in terms of motivation for self-directed learning using different resources. PBL is more enjoyable, helps in critical thinking, integration of topics between different subjects and helps in application of basic science knowledge to understanding diseases and its process.

Students agreed to the point that PBL help to improve immensely the confidence, leadership qualities and presentation skills. PBL helped them to improves the inter personal relationship and improves the team work capacity. Many papers have showed similar results in their study.

In Sanson-Fisher RW at al study almost same type of results in their study where PBL was rated higher by the students when compared to lecture based learning (LBL). They agreed that PBL stimulated their interest, improved retention of knowledge, stimulates interest, helps students to apply their knowledge thus integrating basic with clinical science4. In study by Ibrahim NK et al PBL was preferred over didactic lectures by their study group. This was mainly seen in learning skills and attitudes4. In Indian Scenario, effective implementation of PBL is difficult as student faculty ratio is more and lack of resources. Work by Ibrahim ME et al suggested that for Effectiveness of PBL will be high after taking a series of PBLs and intended program outcome should be determined to assess the effects of PBL6.

In many studies faculty prefer PBL over didactic lectures, studies done in Bangladesh7, Hong Kong,8 and in Canada9 faculty rated PBL high over traditional methods and supported inclusion of PBL in their teaching. In a study done in Pakistan10, 46.22% of the faculties were in favor of the implementation of PBL. Study done in Chennai half of the study group agreed that the PBL will help them to understand concepts and improves their communication skills11. Similar observations were made in studies from Iran12, Malaysia13, and Pakistan14.

In our study students were of the opinion that didactic lectures are better in understanding medical concepts, focuses on the important concepts and helps in long retention of concepts learned. Students felt that didactic lecture role is maximum in completing the syllabus and facilitates exam performance. Tisonova J et al. study concludes that students felt that lectures were more useful than PBL in solving multiple choice questions (MCQs) and essays questions. This is possible as most of the MCQs in examinations is not based on clinical case, but related to knowledge acquired following LBL15.

Further improvements are needed to provide students with an effective favorable learning environment and to take the students recommendations into consideration16. Even though lectures are being considered passive type of learning, for many complicated topics in medical education, well organized lectures will be a good teaching and learning tool17.
Intense efforts are being made to implement PBL extensively in the medical curricula. It is seen as a method to acquire knowledge, skills, and attitude. To implement PBL, sufficient number of trained staff and adequate time is required. In some medical schools, education is implemented entirely through PBL, whereas in others it is combined with lectures and other methods of teaching-learning depending on the structure of the curriculum. Finally, whichever method is selected for teaching pharmacology, it should be student centered and integrate theoretical knowledge with practical skills\(^1\).

These results suggest that PBL is a useful strategy in the teaching and learning process and it is clear that the pedagogical process and other variables can potentially influence the results obtained\(^18\). Many of the previous studies have shown PBL is better suited for student learning. But from our study it’s found that both MPBL & didactic lectures have their own advantages and disadvantages.

**Conclusions**

The present study shows that a hybrid model of Teaching and Learning method (MPBL + Didactic Lectures) is more suitable for Indian Medical Schools than MPBL alone as our students have not been exposed to such Teaching and Learning methods in their pre-professional years. Also our assessment methods are not suitable for evaluation of MPBL.

Teenager Response to the Conditions of Basic Level Emergency: A Phenomenology Study

Ronal Surya Aditya¹, Fitriana Kurniasari Solikhah², Setyo Budi Kurniawan³
¹Kepanjen College of Health Sciences, ²Polytechnic of Health, Ministry of Health, Malang, ³Shipbuilding Institute of Polytechnic Surabaya

Abstract

Emergency events are occurred quickly, suddenly, impacting anyone and difficult to be predicted. The ability of basic emergency services is an obligation that must be skilled by everyone, not only health workers. Teenagers are the frontline in handling emergencies among society. This research was conducted to qualitatively analyze the understanding of basic level emergency action among teenagers. The descriptive phenomenology design was used in this study to obtain data via in-depth interviews conducted to 15 participants that have experiences in handling emergency events in their past. The Interpretative Phenomenological Analysis (IPA) was chosen to analyze the result of obtained data. Result showed that there were four identified thematic areas in the understanding basic emergency action namely the knowledge of emergency handling, the experience in handling emergency situations, the feelings when handling emergency situations and the meaning of handling emergency situations. Specific themes indicating that teenagers obtain their knowledge in handling emergency situation from various methods. The thematic area of teenagers feeling suggested that they are feeling happy while helping others.

Keywords: Action, Adolescence, Emergency situation, Experience, Interpretative Phenomenological Analysis.

Introduction

Emergency events are serious condition that occurred rapidly, suddenly and unpredictable. Emergency can occur at any time and generally involves serious condition that threatens the life and the standard actions are needed for immediate action to handle the victim. Emergency conditions like cardiac arrest and loss of breath are life-threatening problems and can result in death. The most effective way to handle emergency condition is by knowing the response to anticipate a worse situation. Basic Life Support (BLS) is important because it is showing basic techniques about how to save victims from various accidents or everyday calamities that are commonly encountered.

An assistance for the victims from the beginning of the events until the trip to the health facility must be considered and prioritized. Achieving the quality of victim’s life must be the goal of the accompaniment. In order to achieve to carry a proper response to the emergency situations, a basic level understanding of emergency conditions become the basis of first aid procedure. This ability is usually skilled by only health workers while actually, this ability is also expected to be skilled by general public.

Teenagers are currently becoming the largest population (23%) among Indonesian society. Since the number of teenagers is very high, it should be the focus of attention and strategic intervention points for the development of human resources. Study related to the depth of understanding of teenagers to the basic level emergency situation is very interesting to be conducted, but still have not been widely studied. This can be the basis for determining future strategies in educating the younger generation to be more responsive to emergency conditions. Related to this condition, the experience of teenagers in facing the emergency conditions become a very important information for understanding their knowledge about proper responses (Califf et al, 2016). This research was aimed to deeply analyze the understanding of teenagers to the response of basic level emergency conditions by determining thematic area and specific themes to describe the phenomena of the response of basic level emergency by teenagers.
presented result may highlight the depth of teenagers understanding in terms of basic level emergency condition, especially in Indonesian society.

**Materials and Method**

This research was carried out in a descriptive qualitative study using phenomenological approach. By using this method, researchers want to explore or reveal the meaning of a concept or phenomenon of experience based on the awareness that occurs in some individuals. This research was conducted on November 19 to November 26, 2018. The method of selecting participants was carried out using a non-probability sampling basis with a purposive sampling technique, which was considered to be suitable for our certain criteria.

A total of fifteen participants who interviewed in this study were teenagers aged 18-20 years old (coded as P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15). All participants reside in Kebon Agung Sub-district, Malang District, Indonesia and had experienced a basic emergency toward their friends of the same age. All participants were declaring their willingness to provide information needed by researchers to achieve the goal of this study. Data collection in this study was carried out by in-depth interviews using voice recorder and direct observation techniques. Interviews were conducted structurally using interview guidelines prepared by researchers based on response theory and phycology theory. All obtained data from in-depth interviews were then analyzed using Interpretative Phenomenological Analysis (IPA).

The sample studied for this investigation consisted of fifteen Indonesian women and men aged 18-20 years. This range and demographic is a representation of community members interested in emergency response in Malang (total population of 861,414 at the 2017 census) where the developer first introduced the practice at the community level. Table 1 provides a brief description of the sample, including the number given to each participant (in lieu of the name) to protect their identity. Various activities are represented in the core sample of this participant (college, personal work, home, and others). The youngest participant identified as a student.

**Results**

The educational background of all participants were homogenous since most they are all senior high school graduates with 20% of them were Health Vocational School graduates. The level of education is highly related to the knowledge they have. The higher the education, the better knowledge in terms of health education they have such as the provision and delivery of Methadone (as legal drugs. The result of in-depth interview analysis was presented in 4 themes as described below.

**Theme 1: Knowledge of emergency handling**

Teenager achieved their knowledge about basic emergency actions derived from their subject matter at school, school health unit, online information and sharing with health worker. Based on the opinions expressed by participants, 4 groups of sub-themes for the source of the knowledge, namely subject matter at school, school health unit, online information and sharing with health worker can be created. The expressed statements by participants were listed below:

“From biology subject matter at school”, stated by P1, P2, P3, P7 and P9;

“There are first aid lessons at school”, stated by P4, P5, P6, P8, P11 and P15;

“I have had school health unit training”, stated by P1, P2, P3, P10, P12 and P14;

“I asked the health center employee, but I was confused about the treatment”, stated by P4, P10 and P13;

“I search and browse on the internet”, stated by all participants.

**Theme 2: Experience on handling emergency conditions**

Teenagers have many experiences on basic emergency handling during their daily activities. Five sub-theme groups of experience on emergency conditions namely taking care of dysmenorrhea, treating wounds, caring for nosebleeds, handling fainting during ceremonies and helping road accidents were divided based on the expressed opinions. The expressed opinions were mentioned below:

“Take care of my friend who was having dysmenorrhea”, stated by P1, P2, P3, P4, P6, P11;

“I have treated wounds during exercise”, stated by P4, P5, P10, P13;

“When my friend got a nosebleed I immediately looked for cotton to stop the blood”, stated by P1, P7, P15;

“I often help friends that are faint during school ceremony”, stated by P5, P8, and P14;

“People fall, then I help and accompany them to the hospital”, stated by P2 P9 and P12;

**Theme 3: Feelings while handling emergency conditions**

There are so many feelings when handling basic emergency situations during daily activities. The opinions expressed by participants about feelings while handling emergency situations can be grouped into 5 sub-themes i.e., fear, anxiety, confusion, calm, shock. The feeling expressions while handling basic emergency conditions were mentioned below:

“First time doing it, I’m afraid”, stated by all participants;

“My friend fell from bicycle, I was confused about what to do first”, stated by P5 and P14;

“After routine Red Cross Youth Volunteer exercises and facing the case more often, I started to calm down a bit”, stated by P1, P2, P11;

“I often see my friends fainted during nose bleeding, so I’m shocked”, stated by P3, P13.
Theme 4: Personal view on the meaning of handling emergency situations

Teenagers have a various personal sight on the meaning of handling emergency situations. The opinions expressed by participants about their personal view on the meaning of handling emergency conditions can be grouped into 3 sub-themes i.e., happy, proud, and curious about advance emergency situations handling. The stated opinions indicating the sub-themes were listed below:

“I am happy to be able to help others”, stated by all participants;

“With me being able to treat it like this, I am proud and I can also make my parents proud”, stated by P3, P4, P5, P13 and P14;

“I am happy when I see someone whom I care for is getting normal again”, stated by P1, P2 and P3;

“If there is an opportunity, I want to increase knowledge about advance handling methods on emergency situations”, stated by all participants.

Discussion

The results of research on knowledge about emergency action indicating sources of Red Cross Youth Volunteer training, school subject lessons, online information and sharing with health workers. This was in line with. Support from their close friends can help someone to better adapt and accept their success in life, which stated that one factors that influence knowledge was the level of education. Person who is highly educated will find it easier to receive information. The participants experience in daily emergency situations are quite varied. They have experience in caring for dysmenorrhea, treating wounds, taking care of nosebleeds, handling fainting during ceremonies and helping on road accidents. This result was in accordance with research conducted by, which stated that personal experience was gained from practicing the obtained knowledge so that it can provide benefits to others. the opportunity for someone to live independently, work for themselves and others can be given a strong community.

Participants were expressing the feeling of scared, nervous, confused, calm, and shocked. The obtained expressions were in match with such as the provision and delivery of Methadone (as legal drugs which reported that attitudes have three elements, namely cognitive (knowledge), affective (emotions, feelings) and active (actions). Confusion about handling victims, affects emotionally and develops emotionally. From these elements of emotion or feeling, teenagers can be triggered to have negative or positive expression based on personal role model on their daily live. Participants have various personal meaning of handling emergency situations. They interpreted it happily, proudly, and curious in learning advance response to the emergency conditions. The importance of moral values easily understood by children when they can discuss their understanding with their peers rather than just being heard lectures from teachers or parents. regulating the behavior of individuals in their immediate community environment has a slim relevance to cultural values. Previous research shows the need for a public education strategy to improve community preparedness in emergency conditions.

This research is very important because it is the basis of further research on the provision of basic life aid materials. the success of Basic life support training needs to be explored by the experience of handling daily emergencies and the response experience of someone handling the emergency so that the important results of this study are to become a reference material. so that the training does not increase knowledge but is able to practice it in daily life. BLS done to patients is of course an important step before definitive care is planned. Government policies support related to the distribution of expert health workers who are fair so that the community is able to maximize prevent emergency conditions.

Conclusion

Teenagers gain knowledge related to the response to emergency condition from various method and medium, especially from additional health-related activity during their formal education period, the online information, and a lot of information from the media will enrich life support knowledge. Teenagers were also concluded to be proud and happy by doing social activity in helping others during the emergency situation. So they will look for life support and be a motivation for themselves.

Abstract

**Background:** Total laryngectomy (TL) is necessary for patients with malignant tumor on the larynx. This could however cause a devastating situation affecting patients’ quality of life. A comprehensive pre-operative counselling could reduce their anxiety and prepare them for TL. Laryngectomy rehabilitation requires a team approach and we aimed at developing (Phase 1) and validating (Phase 2) the pre-operative counselling module for TL, using an interprofessional (IP) approach.

**Material and Method:** Phase 1: Development of the pre-operative counselling module through the literature review and discussions among the IP team consisting of a speech-language pathologist, head neck surgeon, psychologist and physiotherapist.

**Phase 2:** Validation of the module by another IP team having a minimum of five years clinical experience in alaryngeal rehabilitation. The changes done to an item following specific “ratings” by at least two experts were as follows: “highly appropriate”- item exactly retained; “just appropriate” - minor modification; “inappropriate”- major modification, and “highly inappropriate” - excluded.

**Findings:** Phase 1 resulted in the module having six domains (D) focusing on speech subsystems, oncological aspects, physical limitations, respiratory, phonatory, swallowing changes and their management. Following phase 2, the items under all domains were retained as they were, except for D3.7 which was rated as “inappropriate”.

**Discussion and Conclusion:** The item D3.7 i.e., ‘progressive resistance strengthening with thera-bands’ was rated as ‘highly inappropriate’ by two experts, and ‘inappropriate’ by another two. Therefore, the item was excluded. However, as per the suggestion of two experts ‘post-isometric relaxation techniques’ and ‘myofascial release of cervical region’ were included as D3.7. The finalized module has four items each under D1, D2, D4, D5, and eight items under D3 beneficial in providing comprehensive information for patients undergoing TL. Future studies can focus on comparing anxiety levels of patients undergoing TL, before and after counselling using the module presented.

**Keywords:** Laryngeal Cancer, Total laryngectomy, Pre-op counselling, Anxiety, Interprofessional approach

**Background**

Laryngeal cancer is a type of head and neck cancer (HNC) characterized by malignant tumor on the vocal cords.
folds and/or other parts of the larynx. The patient who has been diagnosed with advanced laryngeal cancer -stage 3 or 4 will be undergoing devastating situation as there will be a need to undergo major surgery. Total laryngectomy (TL) is a surgical procedure which involves the surgical removal of larynx.

Increased anxiety prior to surgery is reported in patients recommended for TL\(^1\) and this also affects their quality of life (QOL). Therefore, comprehensive counselling of such patients who are candidates for TL should be considered\(^2\). There are studies in which laryngectomees have post-operatively reported that they wished for a more detailed pre-operative counselling\(^3\,-\,6\). Providing good pre-operative counselling to patients posted for surgery will provide an opportunity to discuss their concerns, reduce their anxiety and help them recover better\(^7\,-\,9\). A systematic review of the need for appropriate information with particular reference to patients with head and neck cancer suggested that, providing detailed information increases patient’s knowledge, overall satisfaction, and decreases emotional distress\(^10\). Another systematic review on pre-operative counselling, suggested that the studies done on pre-operative counselling for laryngectomees are flawed in design and represent weak levels of evidence\(^11\). Therefore, a well designed pre-operative counselling module is the need of the hour.

Laryngectomees undergo a lot of biological, psychological, and social changes post. Lack of proper prior information on such aspects naturally increases anxiety levels in patients. Inadequate counselling might make them refuse surgery, increase the risk associated with surgery or make them anxious about life after surgery. So, providing them comprehensive information through pre-operative counselling could help in reducing their anxiety. However, no pre-operative counselling can fully prepare a patient for the consequences of such a major surgery. Yet, the role of a comprehensive counselling to assist the patient to accept the condition and be prepared for the surgery with as lesser anxiety as possible cannot be refuted. Such counselling, will also provide opportunities to the patient to clarify their expectations and accept the ‘ground reality’ and facilitates an improved long-term quality of life following surgery. Total laryngectomy rehabilitation requires a team approach. Therefore, a comprehensive pre-operative counselling protocol for individuals with advanced laryngeal cancer developed with Interprofessional (IP) team approach is warranted. IP team approach refers to the cooperation, coordination, and collaboration among members of different professions in delivering patient-centered care collectively. The study was aimed to develop and validate the pre-operative counselling module using an IP approach for individuals undergoing total laryngectomy.

### Material and Method

The study was conducted in two phases. Phase 1 involved the development of pre-operative counselling module through the review of literature (ROL) and discussions among the IP team that consisted of a speech-language pathologist (SLP), head neck surgeon (HNS), psychologist (PL) and physiotherapist (PT). All had a minimum of five years experience in the rehabilitation of alaryngeal patients. In phase 2, validation of the module by another IP team of four subject experts (SLP, HNS, PL, & PT) again with a minimum of five years clinical experience in alaryngeal rehabilitation, was carried out. If ≥ 2 experts rated an item as ‘highly appropriate’, that item was exactly retained. If ≥ 2 experts rated an item as ‘just appropriate’, that item was retained after suitable minor modifications. Similarly, if ≥ 2 experts rated an item as ‘inappropriate’, such an item was subjected to major modification, and if ≥ 2 experts rated an item as ‘highly inappropriate’ then, such an item was excluded. Content validation ensured that the tool does not miss out any potentially relevant items.

### Findings

Phase 1 resulted in the development of a module consisting six domains namely: ‘awareness of speech subsystems and their function’, ‘oncological aspects’, ‘respiratory changes and treatment’, ‘phonatory changes and treatment’, ‘swallowing changes and diet recommendations’ and ‘physical limitations’. During Phase 2, for the validation of the module, ≥ 2 IP team experts rated as ‘highly appropriate’ for all the items under domains ‘awareness of speech subsystems and their function’, ‘oncological aspects’, ‘phonatory changes and treatment’, ‘swallowing changes and diet recommendations’ and ‘physical limitations’. During Phase 2, for the validation of the module, ≥ 2 IP team experts rated as ‘highly appropriate’ for all the items under domains ‘awareness of speech subsystems and their function’, ‘oncological aspects’, ‘phonatory changes and treatment’, ‘swallowing changes and diet recommendations’ and ‘physical limitations’. During Phase 2, for the validation of the module, ≥ 2 IP team experts rated as ‘highly appropriate’ for all the items under domains ‘awareness of speech subsystems and their function’, ‘oncological aspects’, ‘phonatory changes and treatment’, ‘swallowing changes and diet recommendations’ and ‘physical limitations’. But only one item (no. D3.7) under ‘respiratory changes and treatment’ domain, was rated as ‘highly inappropriate’ by two, and as ‘inappropriate’ by other two IP team experts.
Discussion and Conclusion

The current study aimed to develop and validate the pre-operative counselling module using an IP approach for individuals undergoing total laryngectomy. Phase 1 resulted in the development of a module with 6 domains (D) namely: D1-‘ awareness of speech subsystems and their function’, D2-‘oncological aspects’, D3-‘respiratory changes and treatment’, D4-‘phonatory changes and treatment’, D5-‘swallowing changes and diet recommendations’ and D6-‘physical limitations’.

Phase 2 involved four more IP team experts, rating the items for their appropriateness so as to be included/modified/excluded in the pre-operative counselling module. Items rated as ‘highly appropriate’ by at least two experts were retained without any changes. It was noted that a majority of the items across all the domains were rated as ‘highly appropriate’ by ≥ 2 experts. But, the item D3.7 i.e., ‘Progressive resistance strengthening with therabands’ was rated as ‘highly inappropriate’ by two experts, and as ‘inappropriate’ by other two experts. Therefore, the theraband exercise was excluded. However, as per the suggestion of two experts ‘relaxation exercises’ such as ‘post-isometric relaxation techniques’ and ‘myofascial release of cervical region’ were included as D3.7. This is relevant because patients after TL, with or without radiation therapy could experience restriction in the range of motion of the neck and shoulders. This decrease in flexibility could be treated using stretching techniques like post-isometric relaxation. On the other hand, the typical continuity of the fascial tissue could impact superior esophageal constrictor that forms the ‘mouth of esophagus’ and could thereby hinder the mastery of esophageal speech. Literature has report of average decrease in pressure from 37.9 to 26.6 mmHg in the cervical region using myofascial release therapy. This could help patient obtain faster esophageal speech.

Using an IP approach, the current study offers a validated pre-operative counselling module The finalized module has six domains out of which four domains (D1, D2, D4, and D5) has 4 each items and one domain (D3) has 8 items (See Appendix). As the module is developed and validated with IP approach and hence is comprehensive, each item is believed to have positive influence on the outcome of laryngectomy rehabilitation. Potential patients undergoing TL could benefit by the use of this pre-operative counselling module by SLPs. Future studies can focus on comparing the anxiety levels of patients undergoing TL, before and after counselling using the comprehensive module presented in this study.

Appendix

D1. Awareness of speech subsystems and their function

D1.1. Respiratory system

D1.2. Phonatory system

D1.3. Resonatory system

D1.4. Articulatory system

D2. Oncological aspects

D2.1. Diagnostic findings based on Biopsy/ CT/ PET/ TNM staging

D2.2. Need for the surgery

D2.3. Need for Radiation therapy (RT) / Chemotherapy (CT) and side effects

D2.4. Prognosis, local recurrence and metastasis

D3. Respiratory changes and treatment

D3.1. Transformation from nose to neck breathing

D3.2. Permanent tracheostoma care and maintenance

D3.3. When the patient coughs, the sputum will be expelled through the stoma

D3.4. Diaphragmatic breathing exercise - Take slow, big breath through the stoma; Try to hold the breath for 1 to 2 seconds by placing the finger over the end of the stoma; Relax and breath out

D3.5. Active cycle of breathing technique (ACBT) - It is a combination of deep breathing, relaxed breathing and huffing; It can be performed in high sitting or side lying

D3.6. Flexibility exercises - Neck and shoulder range of motion (One set of 5 repetitions per session)

D3.7. Relaxation exercises (Post-isometric relaxation technique-one set of 5 repetitions per session; Myofascial release for the cervical region for 10 -15
D3.8. Physical fitness exercise - Warm-up exercise (10-15 min); Aerobic exercise such as walking, jogging, cycling etc. (30-45 min); Cool down exercise (10-15 min)

D4. Phonatory changes and treatment

D4.1. Loss of voice

D4.2. Communication immediately after TL either through writing or gestures only until voice restoration is done

D4.3. Most commonly used voice restoration modes – EL speech, esophageal speech and TE speech

D4.4. Pros and cons of each mode in terms of time needed to learn, overall voice quality, cost, care and maintenance of the device

D5. Swallowing changes and diet recommendations

D5.1. Reduced sense of taste

D5.2. Reduced sense of smell

D5.3. Swallowing feels different and relatively more effort is required to clear food through the throat

D5.4. Post-surgery, need to begin with liquid and/or pureed and gradually shift to solid food intake

D6. Physical limitations

D6.1. Lifting heavy objects/weights in the early post-operative periods (lifting domestic LPG cylinders, putting two-wheeler on centre stand etc.)

D6.2. Bathing, swimming and aquatic exercises

D6.3. Walking in the rain

D6.4. Smoking is not possible through mouth. However, smoking through the stoma is not recommended

Comparative Evaluation of Gallium Aluminium Arsenide Laser in Disinfection of Root Canal System

Shruthi H Attavar¹, Mithra N Hegde², Veena Shetty³

¹Lecturer, ²Vice Principal /And Head of The Department, Department of Conservative Dentistry and Endodontics, A B Shetty Memorial, Institute of Dental Science, NIITE (deemed to be University) Mangalore, ³Additional Professor, Department of Microbiology, K S Hegde Medical College, NIITE (Deemed to be University) Mangalore

Abstract

Aim: To evaluate the bactericidal effect of 980 nm gallium aluminium arsenide laser and irrigating solutions such as 3% sodium hypochlorite and 2% chlorhexidine in E. faecalis infected root canals

Material Method: Thirtynoncarious mandibular premolar teeth were selected for the study. crowns of all the teeth were decoronated working length was determined followed by cleaning and shaping of the root canal was done using protaper size F 2. Pure bacterial culture of E faecalis (ATTC 29219) in BHI broth was obtained and inoculated into the root canal using insulin syringe and incubated for 48hrs. After 48 hrs root canal were disinfected using following irrigation protocol: Positive control group (n=5) – Tooth inoculated with E faecalis with no irrigation, negative control no bacterial inoculation. Experimental group (n=10) – group I -5% sodium hypochlorite as irrigant followed by laser irradiation .group II (n=10) -2% Chlorhexidine along with laser disinfection .After disinfection, the root samples were collected using the paper point and was placed in BHI broth incubated for 24hrs. The samples were then collected from the tube and streaked into brain heart infusion agar plates using a nichrome wire loop and incubated for 24 hrs. Bacterial colony counting and scanning electron microscopic analysis was done to evaluate the efficacy of irrigation protocol on disinfection of the root canal system.

Results: student t-test was done to assess the level of significance between the groups. The results showed no statistically significant results between the two groups. However, chlorhexidine with laser showed less no of bacterial colonies compared to sodium hypochlorite with the laser.

Conclusion: within the limitation of this study both chlorhexidine with laser and sodium hypochlorite with laser can be a promising treatment option for disinfection of the root canal system.

Key words: laser, E faecalis, brain heart infusion broth

Introduction

The success of root canal treatment depends on complete removal of microorganism from the root canal system. The removal of biofilm, necrotic tissue debris from the root canal space can be done using hand or rotary instruments under copious irrigation. Enterococcus faecalis is a gram-positive facultative anaerobic cocci which resist chemo mechanical instrumentation endures chemomechanical instrumentation as well asintracanalmedicaments. They release lytic enzymes, pheromones to proceed to remain viable within the dentinal tubules.

Sodium hypochlorite is the most commonly used straw colored nonspecific proteolytic root canal irrigant
with concentration ranging from 0.5-5.25%. The important property of sodium hypochlorite is that it has excellent antimicrobial property and tissue dissolving capacity.

Chlorhexidine gluconate solutions in varying concentrations of (0.2-2%) have been recommended as an endodontic irrigant. Its broad-spectrum activity against Gram-positive and Gram-negative bacteria, its ability to absorb to dental tissues and mucous membrane with prolonged gradual release at therapeutic levels, as well as its biocompatibility are some of the properties that justify its clinical use.

Lasers have become the latest choice to eradicate microorganisms in the root channel, especially in the lateral dentinal tubules. This has been achieved by the development of a fiber delivery system. It has been proved in numerous studies that an emission of laser light directly in the root canal does have a bactericidal effect. The antibacterial effect of a laser beam is based on thermal properties of laser-tissue interaction. The high-power diode laser has been used in several areas of dentistry, with promising results in relation to dentinal disinfection. Hence the aim of this study, is to evaluate the bactericidal effect of 980 nm diode laser and irrigating solutions such as 3% sodium hypochlorite and 2% chlorhexidine in *E. faecalis* infected root canals.

### Material and Method

Thirty noncarious mandibular premolar teeth extracted for orthodontic purpose, were collected from the department of oral and maxillofacial surgery ABSMIDS. The presence of a single canal was determined radiographically with digital radiographs taken at different angulations. The teeth with open and resorbed apices, grossly carious teeth, and teeth with fractured roots were excluded from the study. All the teeth were disinfected according to the Occupational Safety & Health Administration (OSHA) regulations, 2004. Crowns of all the teeth were transversally removed with a high-speed diamond disc. The working length was determined with the help of digital radiograph and chemomechanical preparation of the root canal sample was done using protaper file up to ISO 25 (DentsplySirona). Two coats of nail varnish were applied to seal the apex. Tooth was subjected to ethylene oxide sterilization at the center for sterilization services KSHEMA.

A pure bacterial culture of the Gram-positive cocci *Enterococcus faecalis* (ATCC 29212) [Hi Media Laboratories, Mumbai, India] were obtained. The grown bacterial colonies were then harvested and placed in BRAIN HEART INFUSION broth (Hi-Media Laboratories, Mumbai, India) and incubated for 24 hr at 37°C under aerobic conditions. The turbidity of BHI broth containing *E. faecalis* was adjusted to MacFarland and 0.5 standard which corresponds to $1.5 \times 10^8$ colonies. Then the 20 μL of the bacterial culture was transferred into the canal lumen of the mechanically enlarged root canals using a sterile insulin syringe and stored at 48 hrs at 37°C. After incubation, samples were retrieved from the incubator.

### Irrigation Protocol

#### Control Groups

- **Positive control group (N=5)** – Tooth inoculated with *E. faecalis*
- **Negative control group (N=5)** – Tooth containing only BHI Broth without organism

GROUP I (n=15) - 5 ml of 3% sodium hypochlorite (Vansons India) were irrigated for 2 mins followed by 2 ml of saline to remove any residual irrigant. The canals were dried using sterile paper points and followed by laser disinfection.

GROUP II (n=15) - 5 ml of 2% Chlorhexidine (DC CHLOR) will be irrigated for 2 mins followed by 2 ml of saline to remove any residual irrigant. The canals will be dried using sterile paper point followed by laser disinfection.

Irradiation of the root canal system was done using 980 nm diode laser and power of 2 w. A 200 μm fiber tip was placed 1 mm short of the working length and laser light was delivered 5 times for 5 sec, with a 15-s interval between irradiations at repeated pulse mode, using a pulse duration of 20 ms and a pulse interval of 40 ms.

### Bacterial Culture Method

After disinfection, the samples from the root canal were collected using paper point and placed in an Eppendorf tube containing 1 ml of brain heart infusion broth and incubated for 24 hr.

The samples were then collected from the tube and streaked into brain heart infusion agar plates using a
nichrome wire loop and incubated for 24 hrs.

Mean colony forming unit was calculated using the formula

\[ \text{Bacteria per ml} = \frac{\text{Number Of Colonies Present On The Plate}}{\text{Dilution Factor}} \]

The volume of culture plate

**Scanning electron microscopic analysis of samples**

The SEM was performed to visualize the remaining biofilm after disinfection procedure. Two grooves were placed on the tooth surface and with the help of a hammer and a sharp chisel, teeth were split into two halves along the longitudinal grooves cut previously. SEM images were taken at 1000 x magnification.

The total area of the image and the area occupied by the biofilm were scored.

Score 0 – No *E. faecalis* biofilm seen

Scores: 1. Few areas covered by *E. faecalis* biofilm colonizing root dentin surface without invasion of dentinal tubules

2. Few areas covered by *E. faecalis* biofilm colonizing root dentin surface with invasion on dentinal tubules

3. Most areas covered by *E. faecalis* biofilm colonizing root dentin surface and invading dentinal tubules

4. All areas covered by *E. faecalis* biofilm, no dentinal tubule openings

**Results**

**BACTERIAL COLONY COUNT** (figure 1a & b, 2, 3)

![Fig 1](image1)

Fig 1 : A) positive control group showing the growth of microorganism

B) Negative control group showing no growth of microorganism

![Fig 2](image2)

Fig 2: Sodium hypochlorite group along with laser disinfection

![Fig 3](image3)

Fig 3 : Chlorhexidine group along with laser disinfection

The mean standard deviation and standard error of all groups are shown in table 1. The mean colony counting of sodium hypochlorite in the combination of laser group (group I) was slightly more compared to chlorhexidine and laser group (group II). Further Independent sample t-test was done to check the level of significance between the groups. The results show no statistically significant difference between group I and II with the P-Value of 0.4050 which is >0.05, However when compared to the positive control group there was a significant difference (table 2).

Scanning Electron Microscopic Imaging (figure 4,5,6,7)

SEM analysis revealed the differences between the surface of root dentin and morphology of the microbial cells after treatments. Examination of the root canals after incubation with E. faecalis (control group) showed the formation of a thick biofilm on the surface of root dentin with bacteria penetrating the dentin tubules. In group I and II there was no biofilm formation seen. Table 3 shows the percentile difference between the two experimental groups however the p-value was P=0.3415,P=0.64,P=0.6147,P=0.16 which was > 0.05.

Table 3 denotes the independent sample t-test for two samples since the P-Value 0.4050 which is > 0.05 hence there was no statistically significant difference between the two experimental groups.

Discussion

Endodontic microorganism forms a complex biofilm or can penetrate into the dentinal tubules which resist removal by the chemomechanical technique of cleaning the infected root canals. The present treatment protocol includes mechanical treatment by instrumentation using the rotary file system followed by chemical cleaning by the irrigants\textsuperscript{11}.

Several studies have been documented to determine the role of E faecalis as a biological indicator. Adhesion of E faecalis into the root canal wall is the essential step which determines the pathogenicity of the microorganism. E faecalis has the capacity to adhere to the dentin because they contain collagen binding proteins, ace and gelatinase which are the virulence factors.

Sodium hypochlorite has the ability to remove most of the infected microorganism from root canal infection but due to the presence of smear layer that prevents the penetration of irrigants, there can be the possibility of reinfection\textsuperscript{12}.

Table 3 denotes the percentage difference between the two experimental groups

</table>
Chlorhexidine has the ability to bind to hydroxyapatite crystals on the tooth surface hence there is a sustained release of irrigants and prevent bacterial colonization on the root canal for a prolonged period of time.

Diode laser with the fiber optic tip can penetrate into unaccessible areas of the tubular walls resulting in greater bactericidal effects. This can be attributed to the fact that the laser can penetrate up to depth of 1000 micrometer into the dentinal tubules when compared to the conventional irrigation method which has been limited to a depth of 100 micro mt. Laser light has the property of light scattering, local intensity enhancement and attenuation which allows the greater depth of penetration contributing to superior antimicrobial efficacy.

In the present study, both sodium hypochlorite and chlorhexidine in combination with laser disinfection showed a better eradication of *E. faecalis* from the root canal wall with no statistical difference between the two groups (table 2 and 3). This may be due to the fact chlorhexidine has a unique property of antimicrobial substantivity. The positively charged molecules of chlorhexidine get absorbed on the dentin and prevent the microbial colonization on the dentinal wall. Similar studies were done by White et al to evaluate the antimicrobial property of 2% chlorhexidine as an endodontic irrigant and they found that the substantivity property lasted for up to 72 hrs. Leonardo et al conducted an in vivo study to evaluate the efficacy of 2% chlorhexidine when used as an irrigating solution in teeth with pulp necrosis and visible chronic periapical lesion and they found that chlorhexidine prevents microbial activity with residual effects in the root canal up to 48 hrs.

Hence within the limitation of this study combination of the laser along with chlorhexidine and sodium hypochlorite can be an irrigation regime to eradicate *E. faecalis* from the root canal system.

**Conclusion**

Combination therapy consisting of irrigation using chlorhexidine along with LASER irradiation, and sodium hypochlorite with laser especially at high output power was an effective treatment option for a reduction in *E. faecalis* as well as other bacterial flora from the root canal system.

³Assessing the Awareness of Type 2 Diabetes Mellitus from KAP (Knowledge, Attitude, Practice) Studies in West Bengal, India

Abstract

Type 2 Diabetes Mellitus (T2DM) is regarded as one of the major threat for mankind. A large number of people died or getting impaired due to it. Many life threatening complications are arising due to T2DM. The awareness level of T2DM is poor among general people of different countries. In India the public awareness regarding T2DM is also poor according to many researchers. In this research paper we were trying to find out the Knowledge level, attitude level and practice level (KAP) regarding T2DM in people of West Bengal, India. A cross sectional survey has been executed in selected Municipal and Gram-Panchayat areas in West Bengal through purposive sampling method. A structure questionnaire was prepared in three languages which covers knowledge, practice and attitude portion to access the awareness level among people. Independent t-test and ANOVA were executed with the help of Statistical Package for Social Science (SPSS) version 21.0. The study shows that the KAP level is poor among the people of West Bengal. There are verity levels of knowledge, practice and attitude score in different people from different demographic background. The paper suggests that extensive level of awareness program on diabetes is required which can minimize the effects of this dangerous issue.

Key Words: Type 2 Diabetes Mellitus (T2DM); Knowledge; Attitude; Practice; West Bengal.

Introduction

Diabetes is known as one of the most ghastly threat for mankind as 4.6 million people from all over the world, are dying due to diabetes in every year. Nearly about 8.5% of the total world populations are diabetic. Researchers have made estimation and it is saying that by the year 2030, diabetes will be the seventh major cause of death (Mathers, et al., 2006). Diabetes is preventable and controllable disease but still people are devastated by it, one of the major causes of failure is lack of participation in the treatment process by the patient (Jin, et al., 2008). Diabetes causes occurrence of many life threatening complications, like kidney failure, stroke, blindness, heart attacks, lower limb amputation, coronary heart disease, diabetic retinopathy and diabetic neuropathy and many more. In many developing countries, the diabetes is prevalent as there is existence of unhealthy lifestyle, rapid westernization, poor knowledge, negative attitude and poor practices (Lemes, et al., 2014). Major things associated with the management of the diabetes are the ability of following self care, development of awareness. Generally three ways are to be looked at to reduce the diabetes – growing knowledge, attitude and self management. Type 2 diabetes is preventable but still now, 90% of the diabetic patients are having type 2 diabetes. Most of the T2DM cases are remained undiagnosed. Health Education and awareness on diabetes has significant impact on the treatment process of diabetes as it helps to decrease the chances of complications. Indian people are still having lack of awareness, lack of knowledge and myths on
diabetes (Murugesan, et al., 2007; Sawant, 2016)8-9.

**Review of Literature**

There are lots of differences of opinions can be seen among researchers who are trying to find out and analyze the knowledge gap between genders in respect to diabetes. Most of the studies have showed that male populations have far better knowledge than female population regarding the complications and the preventive measures of diabetes. Some study identified that there are knowledge, attitude and practice gap existing between people of different ages, occupations and income groups. A study shows that only about 43.2% of the study population heard the term diabetes; 17% of the study population has poor knowledge and half of the study population believes that diabetes is communicable disease (Desai, et al., 2012)4. Some study shows though the people having knowledge of Diabetes Mellitus but they have poor knowledge on complication and self care practice, very few of them are taking diabetic medicine, 71% of the people believe that high sugar intake is the cause of diabetes (Singla, et al., 2017)10. Awareness is even more threatening as non diabetic patient are having poorer knowledge than those people who have diabetes. The overall knowledge of diabetes is lower in case of people who are not having diabetes than those populations who are self reported diabetic. Early prevention and control of the diabetes can be possible by implementing three positive elements - knowledge, attitude and practice (KAP) among the people. All three elements are related with each other. To prevent, to diagnose early, to control the risk factor, to do the management of disease; KAP study is playing an important role (Demaio, et al., 2013)3. There are lots of researches have done which were trying to find out the nature of existing knowledge gap among rural urban people in respect of diabetes, nearly all of them have agreed that urban people are way ahead of rural people in case of correct concept on diabetes. It is known that the level of educational qualification is more in case of urban than rural areas. Most of the study shows that the health care facilities are more accessible to them (Aung, et al., 2018)1. Apart from that, basic knowledge about diabetes, level of Knowledge of complication, level of Knowledge of way of prevention, level of Knowledge of involvement of gene in diabetes are far more in case of urban people (Deepa, et al., 2014)2. Higher educated people are showing better awareness of T2DM. Also the knowledge of diabetes differs according to marital status too (Sawant, 2016)9.

**Objective of the Study**

To determine the awareness level of Type 2 Diabetes Mellitus from KAP (Knowledge, Attitude and Practice) Studies in West Bengal, India

**Hypothesis Development**

Hypothesis (H1): There are statistically significant differences existing among different sexual category, age groups, educational qualifications, marital status, income groups, occupations and areas in respect to awareness level of Type 2 Diabetes Mellitus.

**Research Methodology**

A cross-sectional survey was executed from February 2019 to April 2019 among 1319 adult respondents. Here purposive sampling method was used to collect the responses from willing participants. Opinion and advice were taken from experts from related fields for preparing the questionnaire. The questionnaire was prepared in different languages i.e. Bengali, Hindi and English. For analysis, a total of 30 variables were incorporated with 10 variables each in knowledge, attitude and practice section. The maximum attainable score for knowledge related questions with 10 variables was ‘10’ and the minimum score was ‘0’. In case of attitude and practice, maximum and minimum attainable score were same. Here 3-point Likert scale (‘yes’, ‘no’ and ‘do not know’) was used to measure the awareness level of the respondents. The response ‘yes’ was assigned a score of ‘1’ and other responses as a score of ‘0’. Average scores of ‘below 5’ = poor, ‘5 – 7’ = normal and ‘above 7’ were scored as good awareness scores. Written informed consent was taken from the respondents after explaining them the purpose of this study. The statistical analysis was executed using Microsoft Excel and Statistical Package for Social Science (SPSS) version 21.0. Demographic profiles (age, gender, education, marital status, income, education and area) of the respondents were depicted through descriptive statistics such as frequency and percentages. Independent sample t-test and one-way ANOVA were executed to compare the mean awareness scores among different attributes of demographic profile. The P-Value of less than 0.01 and 0.05 were considered as statistically significant at 1% and 5% level.

</table>

The above chart shows different groups of population are formed according to gender, age group, level of education, marital status, income, occupation and urban and rural areas; they all are having poor score in knowledge, attitude and practice on diabetes. According to the result it can be seen that the knowledge score on T2DM is same in case of both the gender and the difference is insignificant but in case of attitude and
the practice the male population have scored higher. The male population is more serious regarding the diabetes because they are more cautious regarding the risk and characteristics of the diabetes but the female population is being ignorant on the practice and attitude towards the diabetes though the female populations have same knowledge score on diabetes. Health education and healthy life style in both the cases the female population is still lagging behind and diabetes is not an exception. The study also revealed that the knowledge score and the attitude score are not affected by different age group of people and the difference is insignificant but in case of practice, the younger populations are more serious than older population. It is seen that the older population is showing ignorance on diabetes and they are not at all serious about the modification of their life style which is able to minimize the risk of diabetes. Due to lack of awareness camp on diabetes and lack of provision of health education, the older groups are not following healthy practice to fight against diabetes. The younger populations are more aware and more knowledgeable regarding the utilities of diabetes so they are keen to follow the healthy practices. The younger population has better outer knowledge than old population; it may play a vital role in it. Our study shows that the knowledge and the practice score do not depend on the marital status of the population that is married, unmarried and the widow or widowers. The income level does not affect the knowledge score and the practice score on diabetes. This study reveals that the highest income group and the lowest income group have scored poor in attitude portion of diabetes. Both of them are ignorant on factors affecting the diabetes though they have same level of knowledge and follow same score of practice to reduce diabetes. The study shows that the knowledge level on diabetes does not depending upon the occupation of the respondent, people of all four kinds of professions have nearly same mean score on diabetes. Significant differences can be observed in rural and urban population in respect of knowledge on diabetes and attitude score. The urban people have better knowledge and have more correct attitude towards diabetes than rural population, but though urban people have slightly better attitude than rural people but the difference is insignificant. The number of awareness program on diabetes is more organized in urban area and also the health care institutions are more accessible to the urban people than the rural people but the attitude towards the diabetes in both the cases is poor. In both urban and the rural people are showing ignorance on the healthy attitude towards the process of controlling the diabetes, so more awareness programs are required in case of both urban and rural areas.

Implications of the study

This study will be helpful to understand the level of KAP among different people of West Bengal, India. The study reveals that different people from different demography have different level of KAP score but if we consider the overall KAP score, it is poor. There are disparities of KAP score among people from different demography in West Bengal. So it can be said that the extensive awareness camp is necessary to achieve the desired score. Social awareness camp is necessary to uplift the KAP score among different people of different demography. Education is playing a vital part in the diabetes management. Some trained counselors of diabetes who are entitled to educate the people on diabetes must be associated in every hospital. Access for health education on diabetes must be available for every people of different demography. Apart from that the study shows different people of different demography have some problems regarding score of knowledge, attitude and practice, so this should be considered and special emphasis on them are needed. In this regard different social awareness program which is specialized in creating awareness on diabetes of different people from different demography of West Bengal, are to be implemented.

Conclusion

The study shows the level of awareness among the people of West Bengal is poor. The disease T2DM is a life style disease it can be controlled by slight alteration of the lifestyle. The diabetes is worsening the health condition because in many cases they remained undetected. The awareness level on diabetes is useful to identify the existence of the disease in first instance. The KAP score reveals that the gender, age, educational status, marital status, income, level of education and the area of living are having different level of KAP score. Some are significantly different among each other and some are don’t, but overall study reveals the KAP score is poor in case of people of West Bengal. Many awareness programs on diabetes are carried out but they are not enough to cover all the people of West Bengal. So there is a huge need of extensive awareness program
on diabetes is required.

**Ethical Clearance**: Ethical approval for this study has been taken from selected Municipal Authorities and Gram-Panchayats of West Bengal for executing the data collection process smoothly. Also respondents have been assured for keeping complete confidentiality of their responses regarding our research topic.

Cost Effective Solution for Visually Impaired

Sudha Senthilkumar¹, Brindha K², Angulakshmi³, Kaaviya⁴

¹Associate Professor, ²Assistant Professor(SG), ³Assistant Professor(Senior), ⁴Student, School of Information Technology and Engineering, Vellore Institute of Technology, Vellore, Tamil Nadu, India

Abstract

The fundamental aim of this article is to show a developed framework that can help the visually impaired for dealing with their daily life activities such as navigation, reading, colour detection and currency detection using a very cost - effective model. 285 million human beings are estimated to be visually impaired globally: 39 million are visually impaired and 246 have problems like low vision. “About 90% of the sector’s visually impaired live in low-earnings settings.” Most of those can’t travel freely. There has been minimal carried out with appreciate to indoor navigation in cutting-edge answers, referred to as electronic Orientation Aids (EOA), owing to high cost for instrumentation and confined capacities. We will likely separate these boundaries by presenting a framework which is generally economical for both the visually impaired and the organizations that prepare their structures. Utilizing RFID labels to set up a location–tagging framework inside structures with the end goal that the visually impaired can utilize a RFIDs to find out their area and also for navigational purposes. The whole framework is actualized by utilizing Raspberry Pi Micro controller running in Universal Windows. Highlighting various technologies and methods with their effective usefulness, design and working challenges and requirements of blind people, we discuss on how this cost-effective solution can serve a great help in this undeniably essential social area.

Key Words: Blind Assist, RFID, Ultrasonic sensor, LDR, Microsoft Cognitive Services, Navigation

Introduction

Envision walking into an entirely new railway station. The spots we need to scan for, ticket counter, security registration, entryway, are difficult to find even with signs. Think about the amount of a difficulty this would be for a person who can’t even see the signs. Even some basic activities can be challenging for a visually impaired person. At the same time as shopping centers regularly have constructing maps, they’re commonly stationary shows which can be useful just while you could find and study them. For a visually impaired individual, the assignment of finding a route turns out to be almost impossible. This is where we need some advanced technologies that can help them in a cost-effective way as nearly 90% of the visually impaired people cannot afford the existing costly solutions.

Related Works

In previous approaches, only color identification module used to detect the colored object and then speaks it to the visually impaired people. Orcam is available, but is very costly and was not actually aimed for blind people. It just acts as a commercial product which can help people in reading articles and recognizing known faces. Finger Reader is currently only an idea with a prototype, however it is way more beyond the capabilities for the visually impaired for teaching children to examine or translation of languages. We already have a lot of apps in the market doing this on smartphones, and OCR is becoming more user friendly and popular but Finger Reader is more of a natural way. The Anagraphs assignment took the initiative and began planning for a tool that uses both thermos-hydraulic micro-actuation to infer Braille dots via infrared rays with the help of a micro-mirror scanning machine. It could be easily imagined as a type of fabric made of wax, which can transform from strong to warm liquid and easily made into Braille dots. Sadly, the EU funding have bankrupted and the assignment wishes greater coins to be found out. This idea first which began some years ago came back into action as Yanko layo idea. What if there is a device wherein blind humans can also digitally examine, similar to kindle? Braille education percentage
has been in regular decline because the Nineteen Sixties for diverse motives. There nonetheless exists a quandary concerning the significance of Braille and problems associated with talking computers followed through the outcomes of a research revealing that there’s a hyperlink between Braille literacy and employment. RFID based manual perusing framework which offers specialized solution for the outwardly weakened to undergo open regions efficaciously making use of RFID label matrix, RFID stick Reader, Bluetooth interface and person computerized assist. But, its beginning advancement fee may be very excessive and odds of impedance in big hobby. \[1\]

**Different Technique Results and Discussion**

**Navigation Assist**

A speakme help place discovering framework is proposed for each indoor and outdoor path. Framework incorporates of walking stick having GSM module to ship message to accredited man or woman at the season of emergency, sonar sensors and RF transmitter and recipient. For indoor locality reference RFID is used and GPS for outdoors. in this way, this GPS framework applied as a part of on foot stick decreases the price of introducing numerous RFID labels in outdoors to understand the region. This GPS based strategy is “Drishiti” which can switch the framework from an indoor to an outdoor. To give finish route framework, creators augment indoor variant of Drishiti to the outdoor variants for visually impaired people on foot by including just two ultrasonic handsets that are littler than a Master card and are labelled to the client’s shoulder.

For the approach that include in reality crossing down the passageway and stepping into every other, best crucial headings are given. On the factor while the customer involves the vacation spot wherein the room is observed, headings are detailed in minute element of ways away to move based totally on entryways they need to skip to their left aspect or right facet. Those instructions are without difficulty understandable to a blind person as they’re normally educated to path the partitions on both side and their stick permit them sense for entrance.

**Currency Detection**

The trouble of identifying forex paper money with appreciate to adjustments in length, route, torn and worn of tidy hobby in the discipline of pc vision. Takeda et al. \[3\] proposed foreign paper money identification approach by means of victimization neural community for improvement of recent shape of foreign paper money reputation machines. They projected 3 center techniques using semantic network. The little size semantic-identification machine is hired due to the fact the first approach. The second approach is the mask dedication approach victimization inheritable set of rules. The semantic-engine method, that uses virtual sign
The notion approach is based on an occasional price opt-digital device, which outputs a symbol related to the sunshine refracted via forex paper money. Takeda et al. [3] projected a manner for identification of forex paper money. The implemented math properties corresponding with the feel of the foreign paper money are identified in their paintings. The feel of the forex word photographs are characterized by assembling a co-occurrence matrix. The received co-occurrence matrix is then gained to extricate the alternatives. [11]

Pattern popularity algorithms normally intention to offer an lower priced solution for all possible combinations of inputs and to carry out “most probable” matching of the inputs, deliberating their statistical variation. That is against sample similarity algorithms, which searches for specific matches inside the input with pre-gift styles. A commonplace instance of a sample-similarity set of guidelines is overseas money notes shaping, which seems for types of a given type in textual photo and is included inside are searching for skills of many rupees notice values in intensities. [6]

Techniques to convert the uncooked function vectors (trait extraction) are occasionally used prior to software of the pattern-similarity set of guidelines. for example, function extraction algorithms try and reduce a large-amplitude trait vector into a smaller-amplitude vector that is easier to art work with and encodes a whole lot less duplicity, the usage of mathematical strategies which includes fundamental components assessment (PCA).The difference between function choice and trait extraction is that the ensuing trait after trait extraction has taken location are of a distinct kind than the authentic functions and won’t easily be interpretable, whilst the functions left after trait selection are clearly a subset of the original capabilities. [13]

Techniques to convert the raw trait component (function extraction) are from time to time utilized prior to application of the template-matching set of rules. as an instance, trait extraction algorithms try and reduce a huge-amplitude characteristic vector into a smaller-amplitude vector that is simpler to paintings with and encrypts into much less duplication, the use of mathematical techniques which includes fundamental additives evaluation (PCA). The distinction between trait selection and trait extraction is that the resulting trait after trait extraction has taken place are of a different sort than the original traits and may not easily be interpretable, while the traits left after traits selection are simply a subset of the original traits.

The paper money are different in texture, size and color. The trait values of each paper money extracted by our proposed approach do not have any overlapping with respect to the other paper money. Therefore, the removed trait are good enough to segregate different paper money based on PCA Algorithm Using Local Binary Pattern Analysis.
Obstacle Detection

Wearable and compact assistive advances are likewise utilized for supporting individuals with incapacities, for example, the visually impaired. Wearable gadgets are permitting without hands cooperation, or at slightest limiting the utilization of hands when utilizing the gadget, while versatile assistive gadgets required a consistent hand collaboration. A wearable impediment evasion hardware gadget intended to serve the route arrangement of outwardly debilitated individual. The system accentuates its qualities like free hands, free ears, wearable and easy to work.

![Ultra-sonic sensor](image)

**Figure 4. Ultra-sonic sensor**

An ultrasonic sensor based route framework for visually impaired individuals depends on microcontroller with manufactured discourse yield and convenient gadget to manage the client about urban strolling ways to call attention to what choices to make. This gadget utilizes the rule of impression of high recurrence ultrasonic pillar to identify impediments in the way. This versatility bolster guidelines are given by vibro-material shape keeping in mind the end goal to decrease route troubles. [14]

![LDR resistance vs light intensity](image)

**Figure 5. LDR resistance vs light intensity**

Considering an electrical cutting-edge would encompass motion of electrons, it drifts according to the distinction in the potential on both ends. An LDR or picture-resistor is made out of a semi-conductor cloth which has an excessive resistance, supplying much less variety of loose electrons for conduction. As mild is incident upon the semiconductor, photons are ate up with the aid of the lattice of it. a part of this energy receives exchanged to the electrons within the lattice which might then have ok power to interrupt free from the lattice and take an interest in conduction. Therefore, the resistance of the photograph resistor lessens with fluctuating strength of incidence mild.

\[
it \text{Intensity} = \frac{500}{\left(\frac{10.72}{\text{voltage}}\right) \cdot \text{volt}}
\]

Image to Speech conversion

Optical Character Recognition (Microsoft Cognitive Services), OCR distinguishes contextual information in a picture and in this way, removes the recognized content into a machine-readable character stream utilized for search and various different purposes ranging from medicinal records to security. It also supports various languages. OCR spares time and gives comfort to customers by means of enabling them to just take photographs of content in place of translating direct textual content. Right now, 21 languages are being supported by OCR. If vital, OCR rotates the photo throughout the horizontal axis. OCR offers the frame coordinates of each phrase as seen inside the determine 1.[5]

- Blurry images
- Handwritten or cursive content
- artistic textual patterns
- Small content material length
- complex backgrounds, shadows or glare over text or angle distortion
- out sized letters at the beginnings of words
- Subscript, strikethrough and superscript textual content

![OCR image correction](image)

**Figure 6. OCR image correction**

The pc imaginative and prescient set of rules extracts colors from an image. the colors are analyzed in three precise contexts, foreground, historical, past, and whole, and colors are grouped into twelve 12 dominant accessory hues (black, blue, brown, gray, inexperienced, orange, pink, red, red, teal, white, and yellow). Relying
on the colors in an photograph, smooth black and white or accent colors can be again in hexadecimal shade codes. \[12\]

**Conclusion**

Using all the effective methods stated in this paper, we can come up with a cost-effective solution for blind which is also highly efficient. Half of the work of finding the obstacle in front can be done by the LDR and the rest can be done by the Cognitive services API. However, this is limited just to indoor environments, as the distances between the VIP and the nearest obstacle in front will be high. However, this isn’t a great fall-back as the obstacle isn’t near the VIP and in a general context a person would be wanting to know only about the things that are nearer to him/her. All the previous solutions didn’t take the advantage of the new emerging cloud platforms, like Microsoft cognitive services. These platforms are highly effective and also the burden of creating all the image processing techniques can be left out by using these and more concentration can be kept on user experience.

Abstract

Background: The displacement of tooth completely from its socket, in the alveolar bone following trauma is known as Avulsion. It leads to periodontal damage and pulp necrosis. The consequences of tooth avulsion are less if the remaining viable periodontal ligament (PDL) does not get dehydrated. Various types of storage medium have been mentioned in literature and reviews. An acceptable storage medium should possess certain properties to enable its use in the clinical scenario. An appropriate storage media keeps the PDL cells in hydrated form, thus preserving the vitality of PDL fibroblasts in situations where an immediate replantation is not possible. The current review highlights the histological changes and the management of avulsion.

Keywords: Avulsion, traumatic injury, Storage media

Introduction

The displacement of tooth completely from its socket in the alveolar bone following trauma is known as Avulsion (Andreasen, et al., 2003). It is a relatively uncommon type of traumatic injury to the permanent dentition.¹ Following the International Association of Dental Traumatology guidelines or Andreasen’s Dental Trauma Guide it is essential to offer optimal treatment to such patients in a timely manner.

The frequency of tooth avulsions following traumatic injuries ranges from 0.5% to 16% in permanent dentition and from 7% to 13% in primary dentition. It takes place most commonly in the age of 7–14 years with the highest incidence in maxillary central incisors.²

When a tooth is avulsed, periodontal damage and pulpal necrosis occurs. Due to the tearing of the periodontal ligament (PDL), the tooth gets detached from the socket leaving viable cells on the root cementum surface. Also, small localized cemental damage occurs due to the crushing of the tooth against the socket. If the remaining viable PDL does not get dehydrated, they will maintain their viability, allowing healing along with regeneration of new cells when replanted without causing destructive inflammation.³

Pulpal necrosis occurs after an avulsion injury. A tooth with pulpal necrosis will not continue its normal
development and is prone to bacterial contamination. The pulp space becomes infected if revascularization does not occur or effective endodontic therapy is not performed. The treatment plan is directed to limit root canal infection and peri-radicular inflammation, thus inclining the balance towards favourable (cemental) rather than unfavourable (osseous replacement or inflammatory resorption) healing.4

History

The first reported case of avulsed teeth being replanted was by Pare in 1593. In 1966 Andresen in a retrospective study, hypothesised that if the avulsed teeth were replanted within the first 30 minutes of the accident, 90% is successfully retained.5 In 1974, Cvek hypothesized that to prevent root resorption of the replanted teeth, extirpation of the pulp was necessary.6 In 1992, Trope et al reported that delayed replantation of avulsed mature teeth with calcium hydroxide treatment leads to a stable, functional position with absence of clinical ankylosis or replacement resorption.8 In 2000, Mehmet Kemal Caliskan et al reported that delayed replantation of avulsed mature teeth with calcium hydroxide treatment leads to a stable, functional position with absence of clinical ankylosis or replacement resorption.8 In 2016 Demirel S et al found that adipose tissue stem cells and fibrin sealant treatment improves PDL healing after tooth replantation.9 In 2018, Adnan S et al in a systematic review stated that milk was the most recommended medium followed by Hank’s balanced salt solution.10 Among natural products other than milk, propolis and coconut water were most frequently recommended.

Histological Changes

The physiological status of PDL, the stage of root development and the extra-oral time period predicts the prognosis of replantation of an avulsed tooth. The best prognosis is achieved with replantation within 5 minutes after avulsion. Such teeth are functional for an average of 5 years. But majority of them undergo progressive replacement root resorption or external inflammatory root resorption. Andreason reported that if the extra-oral time for an avulsed tooth is more than 2 hours, there is a 95% chance of external resorption.5 However, if treated properly, replanted avulsed teeth with a vital periodontal ligament will remain functional for some years.11

The inflammatory response increases as the extra-oral dry time prolongs. The PDL cells need to be repaired by new tissues as a large area of root surface is affected. The cementoblast cells cannot cover the entire root surface in time as they are slow moving and the bone cells come in direct contact with the root surface which leads to ankylosis. Osteoclastic activity may also be initiated, leading to resorption.

The complicating sequelae following avulsion injury is damage to the PDL resulting in root resorption with the denuded root surface being chemotactic to hard tissue resorbing cells leading to loss of pre-cementum, cementoblasts and epithelial rests of Mallassez. However the damaged PDL and cementum gets subsequently resorbed by macrophages and osteoclasts.

The combination of the above mentioned factors may lead to external root resorption at the site of injury. The damage of the periodontium at the time of trauma and the presence of bacteria within the root canal and dentinal tubules leads to the development of inflammatory root resorption. Root resorption is common, with a reported prevalence of 57-80%.12 Pre-treatment of a tooth prior to its replantation with stannous fluoride has recently been described appears to offer more encouraging results and make it more resistant to resorption.13

EFFECT OF STORAGE MEDIA ON PERIODONTAL HEALING

Teeth are usually dehydrated in the time interval between the avulsion and the replantation period. As dry storage is unfavourable for the preservation of the PDL, avulsed tooth must be prevented from drying by the use of storage media for ideal osmolality and pH. Healing of periodontal and pulpal tissues is dependent on the storage time and storage media as confirmed by various clinical studies.14

VARIous TYPES OF STORAGE MEDIA USED FOR AVULSED TEETH

There are various solutions that are used as storage medium based on properties possessed by the material. They are as follows:-

HANK’S BALANCED SALT SOLUTION (HBSS):

This is a sterile, physiologically balanced isotonic standard salt solution that is widely used in biomedical research to support the growth of many cell types.14 This solution is nontoxic, biocompatible with PDL cells. It has pH of 7.2 and osmolality of 320 mOsm/kg.
It is composed of: 8 g/L of sodium chloride, 0.14 g/L of calcium chloride, 0.1 g/L of magnesium chloride, 0.4 g/L of potassium chloride, 0.14 g/L of potassium phosphate, 0.35 g/L of sodium bicarbonate, 0.1 g/L of magnesium sulphate and 0.4 g/L of D-glucose. These ingredients endure and reconstitute the depleted cellular components of the PDL cells. HBSS is recommended by the American Association of Endodontists as the storage medium of choice for management of avulsed teeth because of its ability to provide maximum preservation of PDL cell viability in the long term.

2. VIASPAN

Basically it is a cold transplant organ storage medium. It has an osmolality of 320 mOsm/kg and pH of around 7.4 at room temperature, ideal for the growth of cells. Ashkenazi et al has evaluated the effectiveness of different storage media such as culture medium, milk, HBSS, ViaSpan and conditioned medium for the observing the viability of fibroblasts of the PDL for avulsed teeth. It was found that the stored cells kept in ViaSpan for 8 hours have high clonogenic capacity that was comparable to HBSS and superior to milk.

3. TOOTH RESCUE BOX (DENTOSAFE)

The Dentosafe is a culture medium that consists of salts, amino acids, glucose, and vitamins, similar to the medium used during pancreatic islet cell transplantation. The vitality of PDL cells are maintained for upto 48 hours at room temperature in vitro.

4. EAGLE’S MEDIUM

Eagle’s medium (EM) contains: 4 mL L-glutamine, 105 IU/L penicillin,100 μg/mL streptomycin, 10 μg/mL nystatin and calf serum (10% v/v). EM possess high viability, mitogenic and clonogenic capacity for upto 8 hours when stored at 4°C in a study conducted by Ashkenazi et al. However it was less effective than milk or HBSS when the storage time was extended to 24 hours. Temperature of 37°C helps in preserving the PDL for prolonged periods, within the recommended storage time prior to replantation.

5. PASTEURIZED MILK

Milk has a pH of 6.5-7.2 and osmolality of 270 mOsm/kg are compatible with PDL cells. However, it should be used in the first 20 minutes following avulsion. Milk contains epithelial growth factor, enhances exocrine gland secretion which stimulates the proliferation and regeneration of epithelial cell rests of Malassez and activates the alveolar bone resorption. This ultimately decreases the chances of ankylosis.

6. PROPOLIS

Margaret and Pileggi reported that there was highest viability of PDL cells in the avulsed teeth that were stored in propolis when compared to HBSS, milk and saline. Its composition includes: resins rich in flavonoids, 45-55% of resin, 23-35% waxes, fatty acids, 10% of essential oils, 5% of pollen proteins, other organic compounds and minerals.

7. GREEN TEA EXTRACT (GTE)

Hwang and Park in their study stated that there was no difference in the PDL cell viability between GTE and HBSS when used as a storage medium for avulsed teeth. However, GTE showed higher viability than milk, water and commercial green tea.

8. EGG WHITE

Egg white or egg albumin consists of high protein, vitamins, water and due to the lack of microbial contamination and easy accessibility it is a good choice for storage medium. It has a pH of 8.6 to 9.3 and its osmolality is 258 mOsm/kg. Khademi et al compared milk and egg white as storage media for avulsed teeth and found that the teeth stored in egg white for 6 to 10 hours had better repair than those stored in milk for the same amount of time.

9. COCONUT WATER

It is liquid endosperm of coconut which is rich in amino acids, proteins, vitamins, and minerals. Gopikrishna et al stated that coconut water is superior than HBSS, milk or propolis in maintaining the viability of PDL cells. However, an acidic pH of 4.1 was observed by Moreira-Neto et al in coconut water which is harmful for cell metabolism.

10. ASCORBIC ACID

Ishikawa et al studied the effect of ascorbic acid on PDL cells and observed it to increase the alkaline phosphatase activity which is required for the binding of PDL cells to type I collagen through 2 β 1 integrin were ascorbic acid again increases their expression. As
the production of type I collagen is considered to be an initial process in differentiation of PDL cells, it is considered as a potential storage medium.\(^\text{17}\)

**11. SALIVA**

According to Weine, patient’s own saliva is the best immediate transport medium for an avulsed tooth. However, more recent studies have indicated that saliva is not the most appropriate medium if storage time is greater than 1 hour.\(^\text{14}\)

**SPLINTING OF AVULSED TEETH**

Splinting is the repositioning of teeth to stabilize it that enhances healing outcomes for the pulp and PDL. A splint is defined as a tool which is used to support, protect or immobilize teeth that have been loosened, replanted, fractured or exposed to certain endodontic or surgical procedures.\(^\text{22}\)

Flexible splints became popular in the clinical scenario when a lower incidence of ankylosis was reported in animal experimentation when tooth were subjected to masticatory forces, which suggested that some functional movement was provided by the flexible splints in the traumatized teeth which a rigid splint could not during immobilization of injured teeth.

A recent systematic review and meta-analysis on auto transplanted teeth reported that the rate of ankylosis was three times higher with wire and composite resin splinting when compared with suture splinting, suggesting the importance of physiological movement on outcomes of healing.\(^\text{23}\) The International Association of Dental Traumatology (IADT) guidelines recommend flexible splinting rather than rigid splinting.

**Currently Employed Types Of Splints:**

- Composite splints
- Fiber splints
- Composite and fishing line splints
- Titanium trauma splints
- Composite and wire splints
- Orthodontic wire and bracket splints
- Arch bar splints
- Wire ligature splints

**DURATION OF SPLINTING**

Splinting duration time as advocated in the IADT guidelines for Avulsion is 2 weeks and for avulsed tooth with extra-oral dry time greater than 60 minutes, it is 4 weeks. However, a systematic analysis of splinting duration and periodontal outcomes for replanted avulsed teeth found that periodontal outcomes were not affected by splinting duration when comparing short-term splinting (14 days or less) and long-term splinting (over 14 days).\(^\text{23}\)

**Conclusion**

An appropriate storage media is recommended for protection and maintenance of the viability of PDL cells following trauma. A number of storage media have been proposed, HBSS being the best. The use of tooth rescue box, Via Span and Eagles’s Medium is not practical as it is expensive and not readily available. The use of pasteurized milk, egg white, propolis and coconut water have shown promising results and are readily available. According to IADT guideline, for avulsion injuries, a flexible splint for 2 weeks is recommended. For teeth that have been avulsed and the extra oral dry time is more than 60 minutes, the recommendation duration of splinting is 4 weeks.

Cost of Primary Care during Episodes of Child Diarrhoea in Uttar Pradesh

Surya AV¹, Rahul Sharma²
¹South Asia CEO, Kantar Public, ²Associate Professor - Jaypee Business School

Abstract

Treatment of diseases entails different costs; both direct and indirect. These costs can be a deterrent to healthcare seeking leading to increased disease morbidity and mortality. This is especially so for diseases like diarrhea which is more prevalent among children from the lower economic strata. This can cause huge economic burden to a nation like India where a significant portion of the population is economically weak. Thus it is imperative that each element of the healthcare cost is well investigated and understood to formulate pragmatic health policies aimed at reducing the disease burden. This study is an attempt to quantify the treatment cost per episode of under 5 diarrhoea, one of the leading cause of childhood morbidity and mortality in India, by accounting for all direct and indirect elements in the household expenses incurred in treating an episode of the same.

Keywords: childhood diarrhea, child mortality, child morbidity, direct and indirect costs, private and government health facility.

Introduction

Diarrhoea continues to be a major cause of child morbidity and mortality in India and many other developing countries. In India diarrhoea kills more than 3 lakh children every year and accounts for 15% of all under 5 child deaths (Lakshminarayanan and Jayalakshmy 2015)¹. The total Disability Adjusted Life Years (DALYs) loss due to under 5 diarrhoea was calculated at 23.17 billion USD (Townsend, Greenland and Curtis 2017)². The average cost of a diarrhoeal episode in India was calculated at 3.33 USD or about 235 rupees (Rheingans, et al. 2012)³. Such high cost burden for an easily preventable disease can be attributed to various factors. Despite reasonably well-established health infrastructure, both private and public, we still find significant proportion of parents/ primary caretakers who do not access health services as much as they should for the economic reasons. Five countries - India, Ethiopia, Nigeria, Pakistan and Afghanistan- contribute to more than 50% of the diarrheal deaths; which otherwise is preventable as well as treatable (Unicef 2018)⁴.

Literature Review

Economic variables have a significant impact on the overall health seeking behaviour within the family (Savitha and Kiran 2013)⁵. There are various variables that impact the economics of a household – urbanization, regularity of the income, number of earning members of the family etcetera. The rapid speed at which the urbanization has happened has significant impact on the diversity across the families within the urban areas. Many of the urban slums have not kept pace with the rapid urbanization. Poor access to water and sanitation and higher rate of diarrhoea has resulted in higher cost of health seeking for the urban poor living in slums. The cost to the household if one person is affected of diarrhoea is around Rs.205 (Patel, et al. 2013)⁶ which can go up to Rs.400 in an urban slum and accounts for 7-8% of the total monthly income spent. Other studies have indicated to an expenditure of 10% of monthly income on single episode of diarrhoea depending on the demography and geography of the household (Dongre and Garg 2010)⁷.

The paper also finds that private medical providers are
the preferred source of treatment for acute illnesses and in such cases the direct and indirect costs are likely to go up significantly compared to public health providers. The cost escalation is also compounded by delay in health seeking and home remedies; which contribute to complications and further hospitalization. As child hospitalization needs attendants it will add up significantly to the indirect costs incurred; like lost wages of the attendant.

Though diarrhoeal treatment is usually not expensive, across the world, for a single episode; it is the frequency of the episodes/ recurrences sometimes that increases the overall economic burden of the family (S. D. Shillcutt, et al. 2017). Some research has also indicated that the introduction of zinc along with the increased promotion of ORS was associated with the decrease in the economic burden of diarrhea among children. Caregivers, who could execute the medication including Zinc with the help of medical service providers, have reported significant reduction in medical expenses in their households (S. D. Shillcutt, et al. 2016). The use of ors and Zinc also significantly reduced the use of antibiotics and adjuvant treatments bringing down the overall cost of diarrhoeal treatment. However the awareness levels about their usage is still low despite government interventions and shows a varying trend across the geographies. Successive governments have ensured continuous programs to promote the prevention and timely treatment of child diseases like diarrhoea. Despite this, various unhealthy behaviours like open defecation etc lead to significant increase in the prevalence of child diarrhoea (Surya, Vyas et al 2016). Governments along with multi-lateral agencies also have started vaccination schemes to prevent Rotavirus induced diarrhoea in children – a very common form of diarrhoea among the Indian children (Rashmi and Soumya 2016). All this has lead to increased utilization of public health facilities, especially among the poor, leading to reduction in direct costs associated with diarrhoeal treatment. The rotavirus vaccination is also expected to reduce the outpatient visit and hospitalization of patients by 28.1% and avert the cost per disability-adjusted life year (DALY) by 3429 rupees (about USD 50) per patient (Rose, et al. 2017).

The economic burden of diarrhoea is affected by various factors which may include the education of parents/ primary care givers (P/PCG), their access to health care (geographic access), their economic status, their attitude towards healthcare, prior experience in handling diarrhoea and other social influence (Surya, Sanjeev and Rahul 2019). The burden of treatment seems to be unusually high on the families from lower wealth quintiles – mainly due to their lower economic status and lower access to the private healthcare system, which still dominates the healthcare provision in India. This also means more complications and longer treatment for children from economically weaker sections. However, all studies seem to have primarily included only the direct expenses and not the indirect expenses that also need to be considered while calculating the economic burden of the disease.

**Research Objectives**

This study is an attempt to comprehensively assess the economic burden of under 5 diarrhoea to households considering the direct and indirect costs incurred in the treatment. The two critical objectives of the study are

Firstly, the study aims to identify the various direct and indirect costs involved in treating childhood diarrhoea not needing hospitalization.

The secondary objective was to calculate the overall cost of treatment for the diarrhoeal episode based separately for urban and rural patients.

**Research scope & methodology:**

The study was conducted in select geographies in the state of Uttar Pradesh. Two districts which high incidence of diarrhoea and two districts with the lowest incidence of diarrhoea have been selected for the study using National Family Health Survey (NFHS) data to generate the sampling frames. With that, Jalaun, Hardoi, Barelliey & Rai Bareli were chosen as districts for the coverage. A total of 960 parents/ primary care givers (P/PCG) of the children who were affected of diarrhoea have been identified through random sampling methods. A detailed interview which captures their demographics, family wealth status and treatment methods adopted has been captured along with the variables that capture the economic burden of the last episode of child being affected with diarrhoea. Both direct and indirect expenses born by the P/PCG in providing treatment to the child was captured in a structured manner using quantitative research tool. Wherever possible, the information provided by the parents has been validated through reviewing the prescriptions and bills. A detailed...
analysis has been conducted of these variables. The distribution of the sample has been proportionate to the population distribution in each of these districts, making it self-weighted.

**Analysis & Discussion**

The data has been analysed using SPSS version 23.0 © Copyright SPSS Inc. 1989, 2010). This particular paper focuses primarily on the expenditure on the last diarrhoeal episode. The purpose of the discussion is to compare the economic burden on the families due to diarrhoea and how it impacts the overall treatment seeking behaviour including provision of timely treatment to the child. The paper focuses only on the burden of the primary care.

**Descriptive:**

More than 95% of the responded to the survey as either the parent of the child or a primary care giver is a female. 56% of the respondents who participated in the survey are literates (50% of them can write whereas 6% of them can only read). Out of those who said they can read/ write, more than 85% of them have only studied up to class X. In 3.6% of the cases neither parents were working and in rest either or both were working and the same can have a significant impact on the health seeking behaviour.

**Types of treatment sought for diarrhoeal episode**

As per the survey only in 1.3% of the cases the parents had to seek secondary treatment (hospitalization) and in 82.7% of the cases primary treatment was sought and in 16.1% of the cases no treatment was sought.

Only in 75.7% of the cases timely treatment was provided (treatment from a medical facility within one day of observing the symptoms); rest of the cases either there has been a delay in seeking treatment or no treatment was sought. The delay in providing immediate medical treatment always results in the loss of fluids from the body and the child ends up with secondary care.

**Type of medical facility used**

It is important to understand the types of medical facilities from where the treatment is sought as it affects the expenditure. It was observed that in 51.16% of cases (out of those who sought primary treatment for the child) the P/PCG opted for government hospital and the rest private medical-providers. The private medical providers include both formal and informal (qualified and unqualified) medical service providers. It is important to note that the proportion of respondents who reported to have sought treatment from a government facility is significantly higher in the rural areas (58.9%) as compared to the urban areas (34.7%).

**Expenditure by the type of treatment facility:**

The expenditure for each diarrhoeal episode has been captured as a part of the study to understand the burden of the expenditure on the families. It has been observed that the overall cost for each diarrhoeal episode per child is roughly Rs. 319.5 at an aggregate level. This is significantly higher in case of urban areas where the total expenditure can reach up to Rs. 383 as compared to Rs. 289.3 in the rural areas; which is 32% higher. The proportion of direct cost reported was 68% of the total cost of the treatment and the rest 32% was indirect cost (Figure. 1). It is interesting to note that the family has some rough idea of the total direct costs (the accurate costs have been obtained through a head-by-head probing by the researcher) whereas the family could not report the total indirect costs readily. However, they do understand that there is a wage loss in case where both parents or the primary care giver is employed and had to skip work to take the child to a medical service center.

**Expenditure by the type of facility:**

There was no significant difference in the cost of treatment by the type of health facility providing treatment and the government facility was just 8% economical in comparison to the private health facility. However, the primary difference is in the direct expenses. Those who seek treatment from the private hospitals spend 50% more on the direct expenses. However, the parents who visit the primary facilities are likely to save almost half of their indirect expenses (Rs.69.4 to Rs.113.9) (Figure. 2).

A detailed review of expenditures, both- direct and indirect, between rural/ urban geographies and government/ private hospitals paint an interesting picture (Table. 1). The main component of the increased direct expense between government and private hospitals, both urban and rural, is due to the consultation fees charged by private hospital which is done for free in government institutions, though they charge a nominal registration fee. The difference in medicine cost is a mere 5-10%
which indicates that even patients seeking government hospital treatment also end up paying a similar amount. This might be due to the non-availability of free medicines in the hospital pharmacy or lack of trust in the government distributed medicines or a nexus between the consultant and the pharmaceutical company.

</tbody>
</table>

However, the indirect costs associated with seeking treatment in government facilities are more and expresses itself in higher wage loss (due to longer waiting times at hospitals) and transportation costs (poor access due to lesser number of facilities). The total cost of treatment is similar in rural areas and a tad higher (5%) in urban areas between private and government facilities (Table.1).

**Conclusions**

The study quantifies the economic burden of the child diarrhoeal episode can be at an average of Rs. 319.5 on the families. This can range significantly anywhere from Rs. 289.8 in the rural areas where the treatment is sought from the government facilities to Rs. 391.1 in the urban areas where the treatment is sought from the private facilities. This is the primary reason for P/PCGs not seeking treatment or timely treatment in case of childhood diarrhoea which further increases the morbidity and mortality. The government can improve the primary healthcare facilities so as to ensure timely treatment of childhood diarrhea reducing its morbidity and mortality. In case of government inability in doing so a private-public partnership can be thought of through direct cost transfers to private healthcare providers for treating childhood diarrheal episodes. Technology like tele-medicine also can be roped in to ensure quick treatment of the same.

**Limitation of the survey:**

The distances from the home to hospital have not been normalized. Most P/PCGs have relied on their recall on the quantum of expenses on various elements of the cost. Though the researcher could verify the costs wherever there is a record available at the household, in a significant proportion of cases the reliance is only on the reported data. The survey is limited in its geographic scope and the costs may differ in other geography with difference in healthcare infrastructure and policy.
Funding: The study was self-funded.

Abstract

Background: Unfavorable attitude towards mental health disorders are prevalent in the general population. Since teachers are considered as key resources in the promotion of adolescent’s mental health, assessing their attitudes and beliefs are crucial.

Materials and Method: A descriptive cross-sectional study was conducted in Udupi Taluk. A semi-structured questionnaire was used to assess their perceptions of regarding mental health disorders. A total of 93 high school teachers were included in the preliminary study.

Results: Out of 93 respondents, 45(48.4%) were in the age group 30-39 years and 38 (40.9%) of the respondents had 5-9 years’ teaching experience. About (58.1%) of the respondents indicated that mental health problems were not a real medical illness and 80.6% of the respondents stated that mental health disorders were signs of personal weaknesses. About 53.8% cited that people with mental health problems were not dangerous to others and 55.9% of them reported that it is easier to give advice to someone else to seek help than for themselves in relation to mental health.

Conclusion: Preliminary findings indicated that teachers were willing to participate in the study. There is a need to provide interventions to teachers to develop a positive attitude towards mental illnesses, which is very much essential in the promotion of mental health of the adolescents

Keywords: attitude, teachers, mental health problems

Introduction

According to WHO, mental health is “a state of well-being in which the individual realizes his or her own abilities can cope with the normal stresses of life, can work productively and fruitfully and is able to make a contribution to his or her community”. Mental health disorders are a state of dysfunction in the psychological, biological or developmental aspects fundamental to mental functioning, which results in a serious disturbance of a person’s cognitive, emotional or behavioral functioning². Mental health disorders are generally considered as one of the major contributors to the overall burden of disease among the adolescents and the prevalence among them is increasing ³,⁴ including suicides which are highly correlated with mental illnesses ⁵,⁶ and can appear as early as 14 years of age ⁷.

There are numerous studies conducted globally to assess the prevalence of mental illness among children and adolescents. The lifetime prevalence of mental illnesses among American adolescents ranged ⁸ from 11-32% while in India it ranged ⁹ from 3.2-36.5% with depression, anxiety, schizophrenia and substance
abuse contributing majorly to the burden of disease. Globally, the prevalence of mental health disorders are increasing among adolescents and only 18-34% seek professional help. In India, there is a paucity of literature on help-seeking behavior for mental illnesses augmented by the stigma surrounding mental health. Mental health disorders are associated with labeling as a psychiatric patient which usually results in delayed diagnosis and treatment initiation, poor prognosis and adverse outcomes including risky behavior and suicide which could be prevented if timely treatment were instituted.

Untreated mental illness can negatively influence academics including increased absenteeism rates and school dropouts. Since most of the teens are students and spend half of their waking time every day interacting with their peers and teachers in the school setting, teachers play a vital role in the recognition of behavioral changes and the promotion of mental health of their wards in schools and providing timely referral. However, their perception of mental ill-health may influence their attitude toward adolescent mental health.

Given the prevalent negative attitudes towards mental health disorders in all sections of society and teachers being an integral part of society, understanding their perspectives towards mental health is of importance. So, this study was undertaken to understand teachers’ attitudes and beliefs towards mental health disorders as well as to assess the feasibility of conducting a prospective study among teachers in the school setting.

**Materials and Method**

Based on educational blocks of Udupi, Taluk, schools were sampled from Udupi and Brahmavar blocks. The data collection was conducted from March-August, 2017. Ethical clearance was obtained from the Manipal University ethics committee. Permission was obtained from Deputy Director of Public Instruction (DDPI) and Block education officer (BEO) Udupi and Brahmavar to conduct the study.

This pilot study was designed as a descriptive cross-sectional study. The sampling frame included high school teachers who had five years and above teaching experience and taught at least six hours in a week were included from the schools of Udupi Taluk. A total of 93 consenting high school teachers from English medium and Kannada medium schools were assessed using a pre-tested, self-administered questionnaire. The tool was developed from “Australian National Mental Health Literacy and Stigma Youth Survey”. Permission has been obtained from the author for the use of the questionnaire.

Data analysis: The data was analyzed using SPSS version 15. The data was presented in the form of percentages and frequency tables. Chi-square test was used to find the association. The p-value of less than 0.05 was considered statistically significant.

**Findings**

Socio-demographic details of the respondents have shown that, out of the 93 respondents, 45(48.4%) were in the age group 30-39 years and were largely females (71 and 76.3%). A larger proportion of the teachers (45 and 48.4%) had completed post-graduation and 40.9% had 5-9 years’ teaching experience. The majority (82 and 88.2%) of them taught in private schools with English as the medium of instruction in urban areas.

**Teachers’ beliefs about mental health conditions:**

Regarding beliefs related to mental disorders, more than half (58.1%) of the respondents opined that mental health disorders were not real medical illnesses. Nearly half (49.5%) of the respondents reported that women suffered from mental illnesses as compared to men. Nearly 48.4% cited that people with lower socio-economic background were less likely to suffer from mental illnesses but largely, they indicated that young people (71%) and the unemployed (76.3%) were more likely to suffer from these problems (Table 1).

Teachers’ attitudes towards mental health conditions:

Regarding attitudes on people with mental disorders, the majority (80.6%) of the respondents felt that mental health issues were signs of personal weaknesses. More than half (53.8%), opined that people with mental health problems were not dangerous to others. It is of importance to note that 62.4% of the respondents were willing to be neighbors to people with mental health issues with 71% willing to work closely on school duties with them. Interestingly 55.9% of them reported that it was easier to give advice to someone else than to seek help than for themselves in relation to mental health (Table 2).

<td>40(43)</td>
<td>-</td>
</tr>
</tbody>
</table>
Association between socio-demographic details with beliefs and attitudes of the teachers:

The attitude among respondents that mental health problems were signs of personal weaknesses (p = 0.001) and that they were dangerous to others were associated (p = 0.04) with the location of the school. The attitude of respondents that people with mental illness were unpredictable (p = 0.04) was associated with the religion of the respondents. The respondents’ belief that mental illnesses were not real medical illnesses were associated with gender (p = 0.04) and the location of the school (p = 0.001). The belief among respondents that poor people were more likely to suffer from mental illnesses was associated with age (p = 0.004), level of education (p = 0.01) and location of the school (p = 0.009).

Discussion

Teachers’ attitudes and beliefs towards mental illness plays an important role in early identification and referral. In this regard, this preliminary study was conducted to investigate attitudes and beliefs among high school teachers towards mental illnesses and to assess the feasibility of conducting a study with the goal of providing interventions based on the findings.

The study showed that the respondents showed that the majority of them believed that mental illnesses were not real medical illnesses. Similar findings were reported in a study conducted by Ogorchukwu et al. among male adolescents. The belief that women had a higher likelihood of becoming mentally ill was not supported by existing literature in the Indian context on mental health disorders as observed by Malhotra and Shah et al., in their study on women and mental health where internalizing disorders were higher in women while externalizing disorders were higher in men. Majority of the respondents believed that unemployed people had a higher chance of becoming mentally ill and this was supported by the literature as well. The impact of unemployment has been studied by Batic-Mujanovic et al. among the working population of Herzegovina and Bosnia and found that unemployment had a negative influence on mental health.

Regarding attitude towards mental illness, the present study reveals that the majority (80.6%) of the teachers indicated mental illnesses were signs of personal weaknesses. In comparison, the survey conducted by Coppens et al. in Portugal, Germany, Ireland, and Hungary stated that 31%, of the respondents, reported depression as a sign of personal weakness. The respondents’ beliefs that people from lower socioeconomic background had a lesser possibility of becoming mentally ill was in contrast to the statement that mental illnesses were closely linked with poverty as reported in the WHO mind project. In this study, most of the respondents opined that people with mental illnesses were not dangerous to others but this was in contrast to the study from Lahore conducted by Javed et al., where more than 70% indicated that people with mental illnesses such as depression, drug abuse, and schizophrenia were thought to be dangerous. The majority of the teachers in this study reported that people with mental illnesses were generally predictable, which is a positive attitude towards mental health disorders. In contrast, in the survey conducted by Coppens et al., where about half of the respondents (48%) felt that people with depression were unpredictable. Similarly in the study by Javed et al., more than three-fourths of the participants including University teachers and students felt that people with mental illnesses such as depression, drug abuse, and schizophrenia, were unpredictable. In the current study, more than half of the respondents indicated a willingness to be neighbors to people with mental illnesses and were willing to work closely on school duties with them, which are signs of positive attitudes towards people having mental health issues. Teachers’ attitude toward providing advice to someone else to seek help than for themselves in relation to mental health was supported by the literature. According to the systematic review conducted by Gulliver et al., stigma, embarrassment and poor literacy related to mental health and preference on self-reliance were the barriers for seeking help with regard to mental health.

Conclusion

Positive aspects related to people with mental illness as not posing a danger and not being unpredictable were gleaned from the study. The findings of the study indicated both positive and negative attitudes and beliefs among high school teachers. The findings of this preliminary study also indicate the feasibility of conducting a larger school-based study with the development of an interventional module.

Conflict of Interest: Nil

Relationship between Service Quality Dimensions and its Impact on Patients’ Satisfaction: A Case Study of Jawaharlal Nehru Medical College

Yogendra Pal Bharadwaj

Assistant Professor, IBM, GLA University, Mathura and PDF Fellow, ICSSR, Ministry of HRD, New Delhi & Department of Commerce, AMU, Aligarh (U.P)-India

Abstract

Purpose: The purpose of this paper is to identify the relationship between service quality dimensions and their impact on patients’ satisfaction and that improves the organizational image of Jawaharlal Nehru Medical College (JNMC).

Design/Methodology/Approach: Data was collected from 2,900 patients visiting JNMC through self-administered questionnaire on five point Likert scale and convenient sampling approach. A descriptive and inferential statistical technique was adopted while structural equation model also used to examine the relevance of proposed model.

Findings: The results showed that empathy is the most paramount determinant of patients’ satisfaction, followed by reliability, responsiveness, security, tangibles and assurance. They almost share the same relationships in terms of strengthen of patients’ satisfaction. However, patients’ satisfaction laid down the greatest impact on the organizational image of JNMC. While, responsiveness emphasized greatly on organizational image of JNMC and the least on patients’ satisfaction among all the six dimensions of service quality.

Practical Implications: It will greatly help both JNMC officials and health care industry experts in developing appropriate strategies to increase the propensity of patients’ satisfaction for an effective cum desired services for a better health policy.

Originality/Value: The study is pioneering in the sense that the construct patients’ satisfaction had relatively been less explored in the Indian context of JNMC and it is acting like a source that provides regular stuff for effective medical service to the patients.

Keywords: Service Quality Dimensions, Patients’ Satisfaction, Organizational Image and Jawaharlal Nehru Medical College (JNMC).

Introduction

In the modern dynamic environment, service sector has been challenging aspect for continuous performance and quality improvement and in the last few years, it has become extremely multifaceted in the health care industry. It is true to sustain in the health care industry but it requires both technical and functional aspect of ingredient to make it success. Technical aspect deals with the technical accuracy and diagnosis of a medical concern, while functional aspect talks about the manner of delivery of required health care services to cover up that problem. The basic objective of any medical college or institution is to provide basic medical aid with proper treatment and availability of services...
and to satisfy patients became a paramount concern for medical organization\textsuperscript{2, 6, 8}. This study is motivated to identify the relationship between dimensions of service quality and patients satisfaction with respective to Jawaharlal Nehru Medical College, which is in Aligarh. It is one of the leading government medical college that provides medical education in terms of theoretical as well as practical aspects for treatment of medical patients\textsuperscript{7}. In this study, six dimensions of SERVQUAL method (tangibles, reliability, responsiveness, assurance, empathy and security) are used to evaluate the relationship between perceptions of patients towards these dimensions in Jawaharlal Nehru Medical College cum hospital\textsuperscript{6, 8, 9}. After a brief outlining of service quality dimensions, patients’ satisfaction and organizational image of JNMC, the research hypotheses are proposed with a conceptual model of the research and proved with certain inferential remark and a path diagram\textsuperscript{11, 12}. 

In the last few years, service quality has considered pivotal in terms of retaining and satisfaction of customer and that proves to be more significant especially in core service industries\textsuperscript{12, 13}. Previous studies have primarily focused upon service performance methodologies in healthcare industry but that have not analyzed in such a manner, where, a best practice could be developed to alter the perception of patients for better delivery of services\textsuperscript{2, 6, 8}. A patient feels more contented, once, he is technically look after and functionally controlled, then only, he expects his matching desire with the required one and there the relationship seems to be positively enlarge\textsuperscript{1, 2}. The Indian healthcare system is mainly public oriented, where, most of the services are being characterised for different society people and this phenomena led to the birth of Jawaharlal Nehru Medical College cum hospital in 1962 which is running under the monitoring of Medical Council of India and Aligarh Muslim University, Aligarh- Uttar Pradesh\textsuperscript{7}. Several studies were conducted on the thrusting area of service quality between patients’ satisfaction and organizational image but we could not come across any study that specifically identified the relationship between patients’ satisfaction and service quality that affects organizational image of JNMC\textsuperscript{8, 9, 11}. Thus, authors chose six different dimensions of service quality (tangibles, reliability, responsiveness, assurance, empathy and security) that directly affects the organizational image and a model of relationship framework is formulated, that clearly explains the nature of this study\textsuperscript{8, 12}. 

![Figure I shows conceptual model of the study](image)

Source: Prepared by the researcher

The following hypotheses, based on different studies, provide the scope and depth of the study:-

\begin{itemize}
  \item H1: Tangible has a significantly positive influence on patient satisfaction in JNMC.
  \item H2: Reliability has a significantly positive influence on patient satisfaction in JNMC.
  \item H3: Assurance has a significantly positive influence on patient satisfaction in JNMC.
  \item H4: Responsiveness has a significantly positive influence on patient satisfaction in JNMC.
  \item H5: Empathy has a significantly positive influence on patient satisfaction in JNMC.
  \item H6: Security has a significantly positive influence on patient satisfaction in JNMC.
  \item H7: Patient satisfaction has a significant impact on organizational image of JNMC.
  \item H8: Tangible has a significantly positive influence on organizational image of JNMC.
  \item H9: Reliability has a significantly positive influence on organizational image of JNMC.
  \item H10: Assurance has a significantly positive influence on organizational image of JNMC.
  \item H11: Responsiveness has a significantly positive influence on organizational image of JNMC.
  \item H12: Empathy has a significantly positive influence on organizational image of JNMC.
  \item H13: Security has a significantly positive influence on organizational image of JNMC.
\end{itemize}
Materials and Method

Research Design

It is based on a conclusive research, where, the dependent variable is organizational image (OI) and independent variables are dimensions of service quality. Patients’ satisfaction (PS) plays a mediating role between organizational image and dimensions of service quality\textsuperscript{13}. The items of tangible, reliability, responsiveness, and assurance were derived from the studies of Parasuraman et al.,\textsuperscript{11} (1988), Maxwell\textsuperscript{10} (1984). The studies exercised by Andaleeb\textsuperscript{1} (2001), Duggirala et al.,\textsuperscript{6} (2008), have identified for empathy and security for the evaluative purpose of patient satisfaction. While, the studies of S.M. Irfan et al.,\textsuperscript{13} (2012), and Ramaiah Itumalla\textsuperscript{12} (2012) have adopted for patient satisfaction. Moreover, for the purpose of organizational image, few studies conducted by Kazemi et al.,\textsuperscript{8} (2013), Alhashem et al.,\textsuperscript{2} (2011), and Ladhari et al.,\textsuperscript{9} (2008) have adopted to select the relative items.

Sample Design and Procedure

Bilingual questionnaire based on a five-point Likert scale was used through convenience sampling approach. The first part comprised of demographic profiles (age, occupation, education level, treatment availing period and gender) of the patients, while, the second section dealt with the independent variables, mediate variable and the dependent variable. The data were collected in two stages from September 2018 to December 2018. In the first stage, data was generated from 500 respondents for the purpose of pilot study. In the second stage, data was generated from larger sample size of 2900 respondents. According to the annual reports published by central record section of JNMC, an average 2350 patients are being treated daily in the hospital\textsuperscript{7}. Considering this, we had distributed 3500 questionnaires as previous studies have observed a degree of non-response\textsuperscript{7}. Out of 3500, only 2900 respondents returned the questionnaires. This indicates 82 percent of response rate which is higher than the average of response rates reported in such type of studies\textsuperscript{12, 13}. The overall reliability of the scale was .701 which is considered to be acceptable\textsuperscript{5}.

Dimensions of service quality\(^6,^8\). In terms of occupation, majority of the patients belonged to business class (56.9 per cent) and service class (43.1 per cent), as far as education profile, 48.6 per cent were literate, 30.7 per cent were graduate, and 19.0 percent were post graduate and above, while 1.7 per cent were illiterate\(^8,^9\). It means majority of patients know the paradigm approach to judge judiciously. As far as treatment availability duration is concerned, 34.1 per cent patients were of more than ten months period, 26.2 per cent were of 6 to 10 months duration, 22.1 per cent were of 1 to 2 months period, and 17.6 per cent were of 3 to 5 months duration which means still patients are reluctant enough to follow the service quality procedure of JNMC\(^2,^5,^8\).

Analysis of Model and Findings

In terms of hypotheses testing, the results proved positively significant influence of service quality dimensions such as tangible on patient satisfaction (\(\beta = .56\)) which shows 56 per cent tangible dimension motivate patient to opt for services, while the critical ratio (CR=6.647) intensifies it as an important determinant of patient satisfaction\(^2,^6,^8\). Other dimensions like reliability (\(\beta = .61\)), responsiveness (\(\beta = .51\)), assurance (\(\beta = .59\)), empathy (\(\beta = .64\)), and security (\(\beta = .57\)) positively influenced patient satisfaction that motivate them to choose better services\(^1,^2\). While, patient satisfaction (\(\beta = .76\)) is positively influenced towards organizational image, where, patients are more reluctant to avail JNMC services on a regular basis\(^12,^13\). It also stated that the hospital workforce is more concerned about patient’s issues to build good rapport. In order to test the relationship between dimensions of service quality and organizational image, all dimensions were found having significantly influence on OI\(^8,^8,^10\). Hence, the analysis further stated tangible (\(\beta = .42\)), reliability (\(\beta = .56\)), assurance (\(\beta = .44\)), responsiveness (\(\beta = .64\)), empathy (\(\beta = .57\)), and security (\(\beta = .49\)) also have significant impact on organizational image of JNMC\(^12,^13\).

Data Analysis and results

Descriptive Analysis of Demographic Factors

As per the respondents profile based on gender, 2,030 were males and 870 were females. While, 42.8 per cent were aged 30 to 39 years, 41.4 per cent were aged 40 years and above, and 15.9 per cent were aged 20 to 29 years that means most of the patients are matured enough to understand the parameter of medical care and

**Source:** Survey data and prepared by the researcher

After extracting the entire model concurrently, empathy ($\beta = 0.64$) is one of the most paramount determinant of patient satisfaction, while reliability ($\beta = 0.61$), assurance ($\beta = 0.59$), security ($\beta = 0.56$), and responsiveness ($\beta = 0.51$) trying hard to share the same relationship between patients satisfaction and service quality$^{10,12,13}$. However, patients satisfaction identified the greatest influence on organizational image ($\beta = 0.76$) to develop positive proximity of relationship between these two variables$^{8,9,10}$. The subsequent factors of organizational image are also influenced by dimensions viz., responsiveness ($\beta = 0.64$), empathy ($\beta = 0.57$), reliability ($\beta = 0.56$), security ($\beta = 0.49$), assurance ($\beta = 0.44$) and tangible ($\beta = 0.42$). It shows responsiveness signifies the most influencing factor for organizational image and the least associated factor for patients’ satisfaction$^{10,12,13}$.

**Source:** Survey data and prepared by the researcher
RMSEA scores below 0.10 are generally considered to signal good fit, and our value is 0.08, which is a good fit of the model\(^1\)\(^4\). Considering this, it is proved all hypotheses are significantly influencing the relationship between dimensions of service quality and patient satisfaction that improve the organizational image of JNMC\(^10, 12\).

Discussion and Implications

This study identified the relationship between the dimensions of service quality and patients’ satisfaction, and examined the impact of these dimensions on organizational image of JNMC involving a sample of 2900 participants to whom structured questionnaire was administered. The results highlighted the empirical evidence for the identification of statistically significant and positive influence of these dimensions on patients’ satisfaction and improvisation of organizational image of JNMC\(^10, 11, 12\). Empathy is considered to be the most paramount factor among all the dimensions for patients’ satisfaction. The notion is that higher empathetic consideration leads to improvised organizational image, so it could be another strategic factor that acts as a source of differentiator in the medical industry\(^11, 12, 13\).

In addition, patient satisfaction exerts the greatest impact on organizational image which means the service parameters are properly implemented with due care of patients and by providing effective and efficient medical treatment\(^6, 8\). On the other hand, in terms of organizational image, responsiveness proved to be the highest exerting factor among all the dimensions that means the willingness and responsible behaviour of the employees are much effective in the minds of targeted patients, while, as far as patient satisfaction is concerned, responsiveness seems to be the least dominating factor among all the dimensions in JNMC\(^2, 11, 13\). All these findings could serve as suggestions for JNMC officials to evaluate their relationship and its outcomes for patients’ so that it can provide practical output for the medical care industry\(^9, 12\).

Limitations and future research directions

The study was limited to investigating the relationship of dimensions of service quality on patients’ satisfaction in JNMC. Further investigation in other types of institutions may provide different insight into the findings of this study. According to the requirement of the respective industry, these dimensions could be added or modified to fit the organization specific attributes and extra research is suggested to be done longitudinally in order to assess the relationship over time, nature and region wise\(^12\). The sample consisted of patients availing medical care only and it may be further conducted among categorical of patients\(^8, 9, 10\). Further research can be conducted in terms of government and private medical organizations and other countries medical organizations could be added for a comparative purpose\(^5, 6\).

Oral Health Considerations in an Achondroplastic Child: A Case Report

Yogesh Chhaparwal¹, Vineetha R², Keerthilatha M Pai³, Shubha Chhaparwal⁴

¹Associate Professor, ²Professor and Head, ³Dean and Professor, Department of Oral Medicine and Radiology, Manipal College of Dental Sciences, Manipal (Karnataka), ⁴Department of Conservative Dentistry and Endodontics, Manipal College of Dental Sciences, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Achondroplasia is the most common form of skeletal dysplasia and is typically characterized by short stature and disproportional limb shortening. It is inherited as an autosomal dominant trait with full penetrance and consistent expression. Here we report general and dental findings in a 12 year old boy with achondroplasia with emphasis on special considerations during dental treatment.

Key Words: stature, dwarfism, malocclusion.

Introduction

Achondroplasia is the most common form of short-limb dwarfism, which is reported to occur in 1 of 25,000 births.¹ It is caused by mutation in fibroblast growth factor 3 (FGFR3) on chromosome 4, causing a defect in the maturation of chondrocytes in the cartilage growth plate which results in defective bone formation.² The complications of achondroplasia often involve multiple organs, and are secondary to atypical bone growth. The diagnosis is essentially based on clinical and radiographic features which are specific to this genetic disorder. General features of this disorder include short stature, lumbar lordosis, shortening of limbs, short stubby trident hands, prominent buttocks and protuberant abdomen.³ The most common skull changes include prognathic mandible, macrocephaly, prominent forehead, depressed nasal bridge, hypoplasia of maxillae, otolaryngeal system dysfunction, and stenosis of foramen magnum.³ The most common dental manifestation is malocclusion. Fortunately individuals with achondroplasia have normal intelligence quotient and are able to lead normal productive life.⁴

Case Report

A 14 year old boy presented with a complaint of maligned upper and lower front teeth which interfered with normal chewing and caused esthetic concern. He also reported of difficulty in speaking. He was diagnosed with achondroplasia at three months of age and advised bilateral limb lengthening procedure at six years of age which was not done because of financial constraints.

General examination revealed short stature with long narrow trunk and short limbs, short stubby trident hands, bow legs and lumbar lordosis (Figure 1). His height was 115cm and average normal height of his age is 147cm. Examination of face revealed brachycephalic skull, bossing of the frontal region, depressed nasal bridge and ocular hypertelorism. There was a typical underdevelopment (hypoplasia) of the midface with cheek bones that lacked prominence. A concave facial profile with prognathic mandible was noted.

Figure 1: Achondroplastic boy with short stature

Intraoral examination showed poor oral hygiene and generalized marginal gingivitis. Full complement of teeth were present with clinically absent third molars which was in accordance to his age. Maxillary arch was constricted with blocked out lateral incisors and highly placed right canine. Lower arch showed severe crowding. There was posterior cross bite and anterior open bite relation (Figure 2a, 2b). Panoramic radiograph showed developing third molars. Lateral cephalogram revealed prognathic mandible and retruded maxilla and a skeletal class III jaw relation (Figure 3). Treatment plan was formulated which involved fixed orthodontic therapy to correct the dental malocclusion. Due to severe mandibular prognathism orthognathic surgery was planned after correction of dental malocclusion.

Discussion

Achondroplasia is a genetic disorder of cartilaginous bone formation, often inherited as an autosomal dominant trait. This genetic defect results in a reduction in functional fibroblast growth factor receptor-3 (FGFR-3). Most of the cases (80%) arise due to spontaneous mutation of this gene whereas remaining arise denovo. It is reported that approximately 2, 50,000 individuals globally have achondroplasia and is the most common form of dwarfism.1,2

Our case showed typical general and oral features of achondroplasia. The short stature with long narrow trunk and short limbs were attributed to the defect in the endochondral bone formation particularly at epiphysis of long bones. The digits were broad and stubby giving the appearance of trident hand which is considered to be a diagnostic sign.3,4 The patient complained of difficulty in speaking which was due to severe malocclusion.
There is no data available about the prevalence of this disorder in Indian population and not many reports of Indian patients with achondroplasia.\(^5\)\(^6\).

The delayed eruption of teeth due to defective endochondral bone formation has been reported in children with achondroplasia but our case did not show this feature\(^6\). There was midface hypoplasia with prognathic mandible with skeletal and dental class ii, posterior crossbite and anterior open bite which are consistent features of achondroplasia\(^7\). The American Academy of Paediatrics recommends review of orthodontic problems in achondroplastic children after 5 years of age.\(^8\) However early orthodontic evaluation and subsequent intervention with interceptive orthodontics is the most desired management approach\(^9\).

One of the common medical complications associated with short stature is stenosis of spinal cord. The spinal stenosis occurring in late childhood or early adolescence can result in chronic backache. The position of dental chair during dental treatment may be modified by lowering the height. Furthermore, special consideration should be taken to stabilize the head during dental procedures, as poor head control can lead to cranio-cervical instability, foramen magnum stenosis and restricted neck movement which can lead to respiratory complications\(^10\). In addition, macroglossia and large mandible may lead to the increased difficulty of airway management in case of emergency. Treatment under general anaesthesia poses certain complications due to small pharynx and larynx, lumbar lordosis, narrowing of spinal cord and small chest.\(^11\) This holds importance for general dental practitioners treating these patients to recognize potential risk factors and complications when procedures under anesthesia are required.

**Conclusion**

The dental care in patients with achondroplasia requires special considerations. The presence of disproportionate short stature causes societal problems and can result in treatment delay. Acondroplastic children require restoration of emotional and social care apart from regular treatment needs. The present case signifies the need for the dental clinician to be versed with oral manifestations and be competent enough to manage any potential complications and thereby provide a comprehensive dental care.

Study of Menstrual Hygiene among Adolescent Girls in a Rural Area

Aakruti Ganla1, Patil Supriya Satish2, Patil Satish R3, Durgawale PM4
1MBBS Student, 2 Associate Professor, Department of Community Medicine, Dean Academics, 3 Prof, Dept of Microbiology, 4 Professor & Head, Department of Community Medicine, Krishna Institute of Medical Sciences, (KIMS), Karad

Abstract

Background: Adolescence in girls is marked by menstruation. The lack of mention of the topic leads to unawareness about the basic physiological phenomenon that occurs in every woman's life on a monthly basis. Good hygienic practices are essential during menstruation.

Aims and Objectives: To assess the knowledge, sources of information and beliefs regarding menstruation among adolescent girls and identify hygiene practices and restrictions that are followed by adolescent girls during menstruation.

Materials and Method: School based cross-sectional study was carried out in a rural school in Malkapur. Data was collected using a pre-designed questionnaire from 107 adolescent girls.

Results: Among the 107 girls, maximum 56(52.34%) were 14 years old. Maximum number of girls had menarche at 13 years – 42(39.25%). 52(48.60%) girls had no knowledge of menses prior to menarche. Source of information for the remaining 55(51.40%) was mother for 40(72.73%) of the girls. 72(67.29%) girls commented that bleeding occurs from the uterus. 58(54.21%) used sanitary pads while 18(16.82%) used old cloth pieces. Absorbents were wrapped in newspaper and disposed by 88(82.24%) girls. Multiple restrictions were practiced and only 22.43% girls did not have any restrictions.

Conclusion: There is an urgent need for spread of awareness regarding menstrual hygiene practices especially in the rural area as it can play a major contributory role in uplifting overall health of adolescent girls and women in the region.

Keywords: Menstrual, hygiene, adolescents, rural

Introduction

Adolescence is an important stage of development that occurs from puberty to legal adulthood. In girls, it is marked by menstruation. Menarche marks the onset of this period in which she becomes reproductively active.

Menstruation is generally considered as unclean in the Indian society. The lack of mention of the topic leads to unawareness about the basic physiological phenomenon. Girls are not educated regarding menstruation so most don’t know how to respond to the first incident. Isolation of the menstruating girls and restrictions being imposed on them in the family, have reinforced a negative attitude towards menstruation(1).

Adolescent girls often have incomplete and inaccurate information about the menstrual physiology and hygiene. Mothers, television, friends, teachers and relatives are the main sources of information on menstruation to the adolescent girls which without proper guidance may be misleading and inadequate.

With this backdrop a study was conducted among adolescent girls in a school in the rural area of Karad, Maharashtra to assess the knowledge, beliefs, sources of information, practices of menstrual hygiene, patterns and problems and also to identify restrictions practiced...
by adolescent girls during menstruation.

Materials and Method

A school based cross-sectional study was carried out in a rural school in Malkapur area, Karad Taluka in Satara district in the state of Maharashtra. The study was undertaken among 107 adolescent girls aged between 13-16 years. According to a study, out of 190 respondents, 80(42%) girls were aware about menstruation prior to attainment of menarche. Consequently, the sample size is calculated using the formula:

\[ N = \frac{4pq}{l^2} \]

Where, \( p \) = the proportion of girls who are aware about menstruation prior to menarche,

\( q \) = the proportion of girls who are unaware about menstruation prior to menarche,

\( l \) = allowable error (10). According to data collected from above mentioned study, minimum sample size is 97. The data was collected in two months from March 2018-April 2018. Report writing was done in 1 month i.e. July 2018.

A list of schools in rural area of Karad Taluka was prepared which formed the sampling frame from which one school was randomly selected. The purpose and the process of the study were explained to the school principal and teachers. Among all the girls in the school who have attained menarche, 107 randomly selected girls made up the study population after acquiring informed consent from the parents or guardians and assent from the girls and assuring them regarding confidentiality of their information.

Data was collected using a pre-designed questionnaire. It consisted of socio-demographic details, knowledge about menstruation, menstrual patterns and practices, hygiene followed and lastly, any restrictions followed during menstruation. At the end of the interview the girls were educated about facts relating to menstruation and the importance of hygiene during menses.

Statistical analysis: Data was fed to Microsoft excel 2007 and was analyzed in the form of proportions and percentage.

Results

Distribution of the girls according to socio-demographic factors is given in Table 1. Among the 107 girls, maximum 56(52.34%) were in 14 year age group. 90(84.11%) were Hindu. 44(41.12%) girls’ fathers were found to be educated upto higher secondary. 50(46.72%) girls’ mothers were educated till higher secondary (11th-12th std.) while only 1(0.94%) of the mothers was illiterate. Majority, that is, 57(55.88%) fathers were semi-skilled workers while 84(78.51%) mothers were home-makers.

52(48.60%) girls had no knowledge of menses prior to menarche. Source of information for the remaining 55(51%) was mother for most, 40(72.73%) of the girls. Only 72(67.29%) commented that bleeding occurs from the uterus. 3(2.81%) girls thought it was a ‘god-given gift.’

![FIGURE 1: Absorbent used during Menstruation](image)

Figure 1 shows that 58(54.21%) girls used sanitary pads while 18(16.82%) used old cloth pieces. 30(28.04%) bought new cloth every 3 months and only 1(0.93%) used both cloth and pads.
Table 4 shows that of the girls who used cloth pieces as absorbent 32(29.91%) stored the same with their routine clothes. 40(83.33%) girls dried the cloth outside the house in sunlight. 91(85.05%) did not feel the need to change absorbent in school. 94(87.85%) changed the absorbent multiple times daily. An unusual practice of burying used absorbents in the mud by 2(1.87%) girls was observed in our study.

Majority, 77(71%) girls attended school even during menses despite the dysmenorrhoea experienced by them as seen in Table 2.

Only 24(22.43%) girls did not practice any restrictions while the remaining practiced or were subjected to one/multiple restrictions such as not visiting temples during menses was seen in 83(77.57%) girls. Not touching stored food was observed in 18(16.82%) girls while some, 3(2.80%) were isolated and not allowed to sleep on their routine bed during menstruation.

**Discussion**

Among the 107 girls, maximum 56(52.34%) were in 14 year age group. Maximum number of girls were found to have menarche at 13 years – 42(39.25%) followed by 34(31.78%) at 12 years of age. A study by Thakre

reveals that the age of the menstruating girls ranged from 12-17 years, with the maximum number of girls being between 13-14 years of age.\[3\] In our study 84.11% girls are Hindus whereas in a study done in South India 90.2% girls were Hindus.\[4\]

The education of the parents, especially mothers, played an important role in knowledge and hygiene practices followed by the girls. We found that maximum, 44(41.12%) fathers and 50(46.73%) mothers were educated till higher secondary (11th-12th std.). According to a study carried out in an urban slum area,\[5\] a majority of 47% of the mothers were illiterate which had a direct relationship with the hygiene practices of girls in the area. In another study, 14% of fathers and 12% of mothers had no education.\[6\]

Here, most fathers 57(55.88%) were semi-skilled workers while mothers 84(78.51%) were home-makers whereas in a study done in Nigeria\[7\] indicated that employment of mothers showed significant statistical association with respect to the practice of good menstrual hygiene. Mothers are primary source of such knowledge for daughters and having a job that provides exposure and access to information can increase awareness about the importance of menstrual hygiene.

The duration of blood flow was found to be between 4-5 days in 89(83.18%) followed by 1-3 days in 11(10.28%) girls. Studies have indicated differences in duration of flow, the mean duration being 5.3±1.32 days and stretched to more than 7 days for Indians. Long duration of flow has been reported ranging from 1 to 4 % of women.\[8\]

The amount of blood flow was scanty in majority, 62(57.94%) girls while 26(24.30%) had moderate blood flow. The menses were irregular in 95(88.78%) in our study. Further studies have also found the irregular and excessive flow as the two most common menstrual disorder.\[9\] Only 1(0.93%) girl had menorrhagia. Studies indicated large variations in menstrual blood loss (excessive flow) among adolescent population, 23.5% from West Bengal; some encountering moderate while other having heavy discharge.\[10\]

Most of the girls, 82(76.64%) had dysmenorrhea however 77(71.96%) attended school despite the same. A study in Delhi\[11\] reported that among adolescent girls, dysmenorrhea was the most common problem followed by pre-menstrual syndrome. This affects the daily routines of majority of the girls leading to absenteeism from school/college and work.

In our study, 52(48.60%) girls had no knowledge of menses prior to menarche. A study conducted by Verma et al. in Gujarat indicated that 88.1% girls had knowledge regarding menstruation.\[12\] We found the source of information for the remaining 55(51.40%) was mother for 40(72.73%) of the girls. In a study conducted by Dudeja et al. 60.7% girls revealed mother as their source of information while 31.8% declared that they obtained information from their friends.\[13\] Only 72(67.29%) girls commented that bleeding occurs from the uterus. 92(85.98%) knew that menstruation is a physiological phenomenon. In a study by Juyal et al., 29.1% of the girls were having knowledge about the reproductive system as the source of bleeding, 20% of girls believed it to be a physiological process and 76% were unaware of the reasons for menstruation.\[14\]

As per our data, 58(54.21%) girls used sanitary pads while 18(16.82%) used old cloth pieces. Studies by Dasgupta and Sarkar\[15\] showed the usage of sanitary pads to be 40% and 32.2% respectively. Of the girls who used cloth pieces as absorbent 32(29.91%) stored the same with their routine clothes. 40(83.33%) girls dried the cloth outside the house in sunlight while 4(8.33%) dried it inside their houses. In another interventional study, reusing of cloth declined from 84.8% to 57.1% and among the reusers of cloth, the practices of washing it with soap and water and sun drying increased from 86.2% to 94.2% and 78.4% to 90.0% respectively.\[16\]

An unusual practice of burying used pads or cloths in the mud by 2(1.87%) girls was observed in our study. According to a study by Despannde,\[5\] 51.67% of the girls used proper disposal technique of wrapping the sanitary pad with paper and then throwing it into a dustbin as was followed by a majority of 76(71%) girls in our study while others 17(15.89%) burned it.

Only 24(22.43%) girls did not practice any restrictions while the remaining were subjected to one/multiple restrictions such as, not visiting temples during menses was seen in 83(77.57%) girls and not touching stored food was observed in 18(16.82%). A study in Delhi, India shows that 92% girls were restricted in religious and social activities.\[17\] Studies show a rather harsh situation for girls and women who are considered untouchable while menstruating and as a consequence
kept away from normal activities of life by not leaving the home, presumably missing work and school, or being unable to attend places of worship or to swim or exercise.

**Conclusion**

Overall knowledge regarding menstruation was comparatively less as compared to other studies carried out in various places. The usage of sanitary pads was lower than seen in other studies mainly due to lack of access and also cost efficiency. Hygiene practices to wash, dry and store the cloth, regularity of changing was poorer than seen in more developed parts of the country. Restrictions practiced during menstruation were not as widespread as in some other parts of the country but certain religious and social restrictions were imposed nonetheless.

There is an urgent need for spread of awareness regarding menstrual hygiene practices especially in the rural area as it can play a major contributory role in uplifting overall health of adolescent girls and women in the region.

Firmicutes – The Lesser Known Flora Playing Greater Roles in Periodontitis

Anitha Balaji1, K.Mahalakshmi2, Mohan Valiathan3, Krishna Prasanth4

1Professor, Department of Periodontics, 2Professor & HOD, Department of Microbiology, 3Professor, Department of Periodontics, 4Assistant Professor, Department of Epidemiology

Abstract

Background: In the complex issue of oral microbiome, the clear floral recipe for periodontitis is yet a unachieved milestone. Lesser known species are being associated with periodontal lesions. The role of Firmicutes is still not completely described.

Aim: To identify and explore the role of clinically significant Firmicutes in chronic and aggressive presentations of periodontal lesions.

Methodology: Subgingival plaque samples were isolated from six patients (three chronic and three aggressive lesions) and metagenomics was performed. Those Firmicutes that differed significantly were identified and discussed.

Conclusions: Firmicutes as thought earlier are not insignificant and have great potential in periodontal dysbiota. Molecular pathways have to be determined to aid in arriving at a floral recipe for periodontitis.

Keywords: Firmicutes, Metagenomics, Periodontitis

Introduction

Oral microbiome is a complex study issue, owing to its great and unpredictable diversity. Its variation has been uncharted till date and is impossible to do so. The oral cavity is predominated by two major infectious diseases viz., Caries and periodontitis, of which periodontal diseases dominate the human race. In case of periodontitis, associating a particular species to disease and attributing a causal relationship has always been a difficult problem. In the past, many researchers have tried to associate single species to periodontal pathology in vain.1 Subsequently, the concept of grouping bacteria for associating them to respective pathologic lesions was proposed and accepted, such as red complex bacteria and so on. As evidences began to grow, the rationale of such grouping is now questioned. This is due to introduction of newer methods to identify un-cultivable flora and possible relations to previously identified lesions.

Recent classification of periodontal diseases has attempted to eliminate these confusions around the etiology and management of such lesions. This classification is supported by ubiquitous presence of previously declared pathogens in all kinds of infectious periodontal lesions. As defined by Hill et al., (1965) the disparity between causal and casual relation is still a major issue in periodontal microbiology.2 Hence, etiology is now considered to be of polymicrobial synergism rather than keystone pathogen concept.3

Hence, rather that arriving at a causal relationship of a pathogen to disease, the contribution of the flora to dysbiota provides a picture of evolution of the microbial ecosystem. This will yield valuable information on stages of disease and prognosis. If there is a significant difference in the prevalence of a species in various manifestations of periodontitis, then detecting the levels of such species might predict not only the risk, but also the possible course of the disease. This can offer better control to the clinician in treating such patients.

However, the definition of pathologic dysbiota, which will give the actual floral recipe for periodontal disease, is not completely arrived at. This is a huge and complex problem, varying with ethnicity, diet and
other variations. Hence, it requires various investigators around the world to conduct studies and report it. For arriving at such results, metagenomics paves clear way to identify the microbiota in various samples. Firmicutes are a group of bacteria that are present in oral cavity in lesser numbers and have been known for long time. But their small numbers did not attract considerable attention of clinicians and researchers. But, recent improvements in metagenomics have paved way to elucidate the role of these flora. In this direction, this study is conducted to identify the contribution of Firmicutes group of bacteria in the various presentations of periodontitis.

**Materials and Method**

This study was conducted in Sree Balaji Dental College and Hospital, with approval of institutional human ethics committee and with informed consent of the subjects involved in the study. Samples of subgingival plaque were obtained from 6 periodontitis patients, who were grouped into chronic and aggressive presentations of the same disease. The samples were collected using absorbant paper tips and metagenomic analysis was conducted using standard protocol.

Of the bacterial species noted in every sample, difference in prevalence between group A and B was analysed using independent student t-test. Only those Firmicutes, which showed statistically significant difference in prevalence between the groups, were included in this analysis. Further, only those Firmicutes that showed prevalence above 10 (arbitrary value) were considered for discussion.

**Results and Discussion**

Out of 1,534 species found, only 40 species showed statistically significant difference in prevalence, of which 27 were Firmicutes. Of these species, only 7 bacteria showed prevalence above 10. Hence, their presence is discussed below.

</tbody>
</table>

Finegoldia magna is a well-known pathogen in polymicrobial orthopedic and soft tissue infections. It is insensitive to common antibiotics and hence is a threat to periodontium. It is a common pathogen of bone infection and is frequently found after injury. These facts suggest that this bacteria may be an opportunistic pathogen exploiting the disintegrity of periodontium. Nevertheless, it can precipitate further damage and worsen the prognosis. Further, it is also associated with prosthetic joint infections. Implication of this fact in periodontology is still unclear, but, since periodontium is also related to implants and other reconstructive materials, it can be expected that this bacteria can play a major role. In this study it is seen that its count was higher in aggressive presentation of periodontitis.

Mitsuokella multacida has been seen as adjunct pathogen in lower respiratory tract infections. It is not much reported in systemic microbiology. But, as a pathogen, it can play a small but definitive role in periodontal disintegration. Further, it is not clear on how these bacteria enter the oral cavity. It may find its way from the respiratory tract or from gastric reflux. In this study, it shows higher presence in chronic presentation of
periodontitis. However, since its actual role is uncertain, in future, studies have focus on presence and molecular role this species in periodontium.

*Megasphaera elsdenii* is a known lactose fermenting ruminal bacteria present in cattle. Since its role in fermentation is known, one should foresee that it will make the environment acidic, favouring inflammation. This is contributory to progression of preexisting periodontal destruction. Its presence normal flora may be significant, but only after a destruction occurs, this shows its role. Further, it can be augmented by other lactose fermenting bacteria to worsen the prognosis. In this study, this bacteria was abundant in chronic presentation.

*Megasphaera micronuciformis* is seen in healthy individuals and is found to exhibit commensal lifestyle in the human oral cavity. It is reported to be reduced in pregnancy. Hence, its level in periodontium is influenced by numerous systemic factors. In this study, its level was found to be different in various presentations of periodontal diseases. This means that they take up an opportunistic role in the process and hence should be included in the “Recipe” for periodontal destruction. In this study, this bacterium was also abundant in chronic presentation.

*Streptococcus parasanguinis* is seen in periodontitis in association with *A. actinimycetemcomitans*. It is found in good concentrations before bone loss happens. Hence, its role in slow destruction of bone support can be explored in future. Its level in aggressive presentation was very less in this study. Though it cannot take up a “Keystone pathogen” status, it contributes significantly to slow and definitive destruction of periodontal apparatus.

*Selenomonas ruminantium* is a sugar fermenting bacteria found widely in cattle. Given its strictly anaerobic nature, its presence in periodontium implies that it the inflammation has progressed to a level, where the environment can provide strict anaerobic niche. Hence, more than its pathogenicity, its presence indicates worsened periodontal prognosis. In addition, its fermenting action will not only promote inflammation, but also signal other fermentors to take-up the niche. In current study, its presence is seen in chronic presentation of periodontitis.

Parvimonas micra is known to be associated with periodontitis. Though it is a commensal, it is frequently isolated in periodontal destruction. It is a known pathogen in other mixed anerobic infections like tonsillitis and endodontic abscess. That being said, its presence offers a negative shift to periodontal prognosis.

**Conclusion**

Irrespective of their presence in healthy individuals, their presence is significantly variable in chronic and aggressive presentations. In summary, these are known commensals in either human or animal ecosystems. Their role in pathogenesis seems to be opportunistic. Arora et al., have remarked that a lion’s share of literature is devoted to red complex bacteria, but little has been spoken about these minor, nevertheless significant groups of species. In future, metagenomic results have to be combined with biochemical pathways to aid periodontologists in arriving at a recipe of dysbiota.

Parents Perception on General Anaesthesia in Paediatric Dentistry: A Questionnaire Study

Anupama Nayak P1, Srikant N2, Karuna YM3, Kiran N Baliga4, Ashwin Rao5

1Assistant Professor, Department of Paedodontics and Preventive Dentistry, 2Professor and Head of the Department, Department of Oral Pathology and Microbiology, 3Assistant Professor, Department of Paedodontics and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India, 4Associate Professor, Department of Paediatrics, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India, 5Associate Professor, Department of Paedodontics and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Managing an uncooperative child is the major issue in paediatric dentistry. In such cases general anaesthesia provides safe and effective dental treatment. Thus this study aims to elucidate the knowledge gaps and preconceived ideas that parent brings into a discussion with a paediatric dentist about GA through a questionnaire given to parents.

Material and Method: A 17- question questionnaire, administered to parents of children presenting for care in paediatric dental practices, collected demographic information, media exposure, and parental knowledge/opinions regarding GA procedures, and parental acceptance of treatment scenarios.

Results: Maximum respondents were not aware (56.3%) and only few were aware (43.7%) that dental treatments for children is sometimes carried out under GA; 68% of respondents think that GA is safe and 32% think it’s not safe; 52.5% respondent said GA and conscious sedation are not same, 24.1% said yes and 23.4% said they don’t know. Cross tabulations and Pearson’s chi-square statistics were used to examine relationships between categorical variables.

Conclusion: Previous GA experience in the family or child had improved parents knowledge on GA but education level of the parents had no influence. Father feels GA is safe. Parents are generally unaware of news coverage pertaining to GA use in Paediatric Dentistry.

Key-Words: General anaesthesia (GA), Paediatric dentistry, child, Questionnaire, Paediatrician.

Introduction

Many children due to lack of co-operation for dental treatment, their treatments are postponed and ultimately lead to severe pain and affects quality of both oral and general health. To avoid these undesirable consequences, behaviour management becomes an important part of the paediatric dental practice.1,2

Behaviour management of children in paediatric dental clinic, consist of two techniques- non pharmacological and pharmacological.3 While majority of the children can be treated with non-pharmacological techniques, treatment of few children with definitely negative behaviour demands pharmacological behaviour management techniques.4
General anaesthesia (GA) is one of the pharmacological behaviour management techniques and can be beneficial for paediatric patients who are unable to cooperate; experience ineffective local anaesthesia; are extremely fearful, anxious, or uncommunicative; requiring significant surgical procedures thus protecting them from psychological trauma and/or reducing medical risks; and requiring immediate, comprehensive oral care. The easy accessibility and availability of the internet sources, and the news allows parents to know all kinds of uncommon adverse events occurred during the course of a dental treatment under GA. Though these unwanted events do not always occur, it’s not unusual for parents to become anxious. Thus, proper communication and the ability to address the concerns/ misconceptions of the parent become an integral part of the informed consent process.

Thus, this study was conducted to elucidate the knowledge gaps and preconceived ideas that parent brings into a discussion with a paediatric dentist about GA through a questionnaire given to parents.

Materials and Method

This was a cohort questionnaire study initiated after approval from the institutional ethics committee with the protocol reference number 16124 and conducted on the outpatient in the Department of Paedodontic and Preventive Dentistry and to the outpatient of the paediatrician clinic at Mangalore.

398 samples were taken to achieve 80% power to detect a difference of 0.2 using a two-sided binomial test. The target significance level was 0.05. The actual significance level achieved by this test was 0.049.

Primary caregiver of the children who are indicated for the dental treatment under GA were included and respondents who could not speak and read English and incompletely filled questionnaire were excluded. Informed consent was obtained from Caregivers who met the above criteria.

The questionnaire was constructed both in English and Kannada (local language) and consisted of 17 pretested questions or statements. Basic socioeconomic and demographic information (age, education level, type of insurance) was collected along with past GA experience with categorical response types. Some of the questions allowed for a “yes” or “no” response.

Questions regarding media coverage of GA events asked parents if they had seen/ heard coverage of dental general anaesthesia and, if so, through which media and how this coverage would influence their decision. Few questions like reasons and advantages to undergo GA allowed multiple choices. Respondents were not given any information or knowledge regarding GA prior to the administration of the questionnaire.

The collected data were entered into a Microsoft Excel. Percentage statistics were calculated for all categorical variables by Cross tabulations and Pearson’s chi-square statistics.

Results

Out of 398 respondents, 316 (79.4%) were females and 82 (20.6%) were males. Among females, 0.8% were guardians and 77.9% were mothers. Among males, 19.8% were fathers and 1.5% were guardians. Level of education of the parents/ guardians showed that, 26.6% had studied up to 10th standard, 15.3% up to PUC, 47.5% up to degree/ diploma and 10.6% had obtained post-graduation. 29.9% of the respondents had previous experience and 70.1% had no previous GA experience. While more than half of the respondents had no insurance (69.3%), among the ones who had, the government/public and private insurance type were almost equally divided (13.3% and 17.3% respectively).

When parents were evaluated to know their awareness on GA, maximum respondents were not aware (56.3%) and only few were aware (43.7%). When awareness of the parents regarding needs of the child to be on empty stomach before GA was assessed, majority of them were not aware (54%) and few had known about this (46%). When respondents were asked if GA and conscious sedation are the same, maximum respondent said no (52.5), few said yes (24.1) and some said they don’t know (23.4%). When previous experience of any treatment done under GA was co related with their awareness about the GA as an option for dental treatments of uncooperative children, there was a statistically significant association (p=0.048). When association of the same was assessed with their knowledge on GA and conscious sedation, respondents with previous experience said that they are not same with a statistically significant (p= 0.01). When parents were asked about preconceived ideas on GA use for children dental treatment, 68% of respondents said GA is safe and majority of them were either fathers (72.2%) or mothers (67.5%). On the other hand among those who felt GA to be unsafe, majority of them were guardians (77.3%).

Only 25% of respondents had seen negative episodes in news coverage from television and/or internet. However, news exposure did not influence the likelihood of choosing GA as a treatment modality. When this was co-related with the education level of the respondents, there were no differences seen but when co-related with respondents relation to the child, it was seen that fathers were less likely to undergo GA (48.8%). This correlation was seen to be statistically significant (p=0.03). (Table 2)

When parents were asked about their opinion regarding justification on the need for undergoing dental treatment under GA in paediatric dentistry, out of 398 parents, 140 of them responded that, GA for dental emergency in uncooperative child, like severe pain or swellings justified. Others reported GA is justified in children having recurring pain in an unco-operative child ultimately resulting missing school hours, special children, children having extensive treatment requiring multiple visits and in very young children less than 2 years. (GRAPH 1)
However when respondents were asked about advantages, 67.8% did not agree that under GA all dental procedures can be done in a single visit, 53% of the respondents disagreed GA increases patient comfort level. On the whole, Majority of the respondents (85.1%) agreed that GA is justified. (GRAPH 2)

When it came to convincing parents on subjecting their child for treatment under GA, it was seen that paediatrician had major role (57%), followed by dentist (32%) and least by other parents who had previously experienced GA (11%). 64.9% respondents preferred day care anaesthesia and 35.1% preferred GA after administration.

Discussion

The relationship between the child–parent–dentist is very important in paediatric dentistry. Parents play an important role in deciding treatment choices, for their child and also the methods of delivering it. Hence, recognizing the acceptable treatment techniques to the parents is critical for a paediatric dentist. In spite of the availability of multiple efficient behavioural management options, there exists a need to carry out the treatment under GA for a small group of children.

Modern parents are willing to abdicate disciplinary actions and opt for pharmacological techniques. Parental acceptance is impressively increased for pharmacological behaviour management techniques and similar result was seen in a study conducted in Kuwait by Muhammad S et al.

The result in our study showed that maximum respondents were not aware and very few respondents had awareness that dental treatments for children are sometimes carried out under GA and also level of education of the respondents had no influence on the awareness of the respondents. This is in contrast to the findings of the study conducted in Kuwait by Alkandari et al., where, parental education had a significant direct association with their acceptance of nitrous oxide sedation technique.

The knowledge on GA is not constant and needs to be updated. Nonetheless, media also influences parental views on dental care as doe’s internet. Eaton et al., proposed that an increased exposure to GA on television could be contributing to the increase in acceptability toward GA and conscious sedation. However, results of our study showed that maximum respondents had not seen or were not exposed to news coverage. Present study showed that previous GA experience by respondents on themselves or on child improved their knowledge.

In the present study, it was also seen that parents were more convinced for getting treatment under GA when paediatricians told them. The reason for the same could be that, Paediatricians are the primary care providers who usually see children during the first 3 years of life. Paediatricians help the children and their families during challenging and stressful times like when a child is unwell. Thus, the parents are comfortable
and confident that the paediatrician will identify and treat conditions appropriately that affect their children. Parents also tend to share a bond of trust with their paediatricians’ guidance and referral tooth sources of improving the health and parents view paediatricians as respected advisors and counsellors.

The limitation of this study was that few questions did not include details, such as; “How long ago did your child experience GA?” “Did your child have all of his/her dental needs completed?” “Did your child receive local anaesthesia?” Hence, a positive response to previous experience did not guarantee that participants underwent a homogenous experience. Thus, in future probably a focus group discussion with the parents on their knowledge and perceptions about their children undergoing dental treatment under GA would be more appropriate.

**Conclusion**

Parents were not aware that the dental treatments for children is sometimes carried out under GA. Previous GA experience in the family or child had improved parents knowledge on use of GA in Paediatric Dentistry. Education level of the parents had no influence on their knowledge on GA. Parents, mainly father feels GA is safe. Parents are generally unaware of news coverage pertaining to unwanted events occurred during use of GA in Paediatric Dentistry.

Correlation Between Autistic Endophenotypes and Associated Risk Factors

Chandrakala E1, Nagaraj K1

1Molecular Genetics Laboratory, Department of Applied Zoology, Kuvempu University, Jnana Sahyadri, Shankaraghatta, Shivamogga, Karnataka, India

Abstract

Background: Autism is a neurodevelopmental disorder, it is a widely diagnosed in nowadays all worldwide. In India, its prevalence is not precisely known and research on autism has not been reported in central Karnataka region, India. Moreover, correlation between autistic endophenotypes has not been reported earlier. Hence, this made us take a step towards this work.

Aims: To analyse the correlation between autistic endophenotypes, and to assess the teaching and caretaking/treatment methods adopted for autistic children in this region.

Method: Autistic children were identified by using questionnaires and interview was carried out personally with parents/caretakers. The data was analyzed for correlation of autistic endophenotypes. Endophenotypic impairment varies among autistic patients, and it is classified into seven groups. SPSS-21 was used for statistical analysis.

Results and Conclusion: 43 autistic patients were identified from 532 developmentally challenged children, and categorised into seven groups. This data reveals that incidence of autism is three times more in males. Special teaching and individual caring for autistic patients has been found to be implemented to overcome the autistic symptoms.

Keywords: Autism, associated risk factors, treatment programs, and correlation of endophenotypes.

Introduction

Autism is the neurodevelopmental disorder and the symptoms of this disorder can occur in any combination with varying degrees of severity, and affect three distinct areas of child life; a) Social interaction, b) Communication (both verbal and non-verbal), and c) Behaviours and interests[1]. Autistic children pay out their time-bound in puzzling and disturbing behaviours that are obviously different from those of typically developed children. These behaviours make them to pursue some repetitive activities with no apparent purpose and do not like to mingle with other people even also with their parents. Autism affects children differently and different children can meet different combinations of diagnostic criteria. It manifests in the first few years of life usually around three to four years[2,3] and occurs three to four times more in males than that of females[4,5]. The prevalence of autism has increased noticeably in recent years and the earlier investigations reveal a drastic increase in the incidence of autism[6,7]. Although autism is prevalent in all over the world, there is no prominent study reported in India.

Caring an autistic child is different from caring a normal child. Autistic children require special and individual care[9], and cannot be normalized completely, but the symptoms can be overcome by various therapies as the age rolls on. The family and caretaker play a crucial role to minimize the severity of autism. In Indian scenario, many of the parents don’t keep their mentally challenged children with them in home, so they admit those children to the special schools. Our study describes the Correlation between autistic endophenotypes, age and gender. The present study also reveals the caretaking or treatment programs adopted by family and caretakers to overcome the autistic features.

Material and Method

Diagnosis and identification of autistic children: Participants were selected from some special schools of few places of Central Karnataka region, India. A total of 532 mentally challenged individuals were examined for autism. Autistic patients were diagnosed by following Diagnostic and Statistical Manual of mental disorder-IV (DSM-IV) criteria. According to this criterion questionnaires were prepared and detailed interview was carried out personally with parents/caretakers of the patients with the help of doctors.

Endophenotypes: The collected data of participants were analysed and categorised. Autistic endophenotypes were grouped into seven different groups on the basis of affected region such as motor, behaviour, physical/medical, sensory, social interaction and speech (Table-1).

Associated risk factors: As there are lot of risk factors involved in autism, the present study also accomplished for associated risk factors. During interview, parents/caretakers were asked for all kinds of incidence taken place during their developmental stage. Autistic children’s medical certificate was verified for associated diseases.

Caretaking: Parents/caretakers and management of special schools were interviewed for kind of caretaking methods they have adopted and its significance. Different kinds of methods were followed by different schools. Parents/caretakers were inspected in this aspect to check the method which is more effective to overcome the autism.

Data analysis: Statistically data was analysed using Statistical Package for the Social Sciences (SPSS) version 21, to examine the relationship between endophenotypic features, age and gender.

Results

Total 532 mentally challenged children were examined and 43 were diagnosed as autistic. In 43 autistic children, 76.74% (33) of them are males and remaining 23.25% (10) are females. This reveals that males are utmost affected than females (Fig.1).

Endophenotypes

In the present study, we found variation in the expression of autistic endophenotypes, which were different from one individual to another. Table-1 represents the categorization of different endophenotypic groups based on features such as motor, behaviour, physical/medical, sensory, social interaction and speech. This categorization was made on the basis of impairments of endophenotypic features, and individuals are represented in table-1. Majority of the autistic children were belonged to the group-1 and followed by group-3, 4,2,5,6,7. This proves that autism shows dreadful impairment in the development of a person.

Age of the patients during the study

In all cases, autism was onset in early infancy. During the study, age of the patients was considered and categorized into seven groups, such as 1-5, 6-10, 11-15, 16-20, 21-25, 26-30, and 31-35 years (Fig.2). Among these 11–15 years were predominant and there were no evident in the group of 26-30 years.

Relationship between endophenotypic features, age, and gender

In the present study population, among all endophenotypes, autistic children with speech and language are found to be in the higher degree of impairments. In some cases, the autistic children showed complete mutism. Motor, behaviour and physical/medical endophenotypes were found to be high in the age group of 0-5 years, followed by sensory, and social is moderate in all the age groups (Fig.3). The level of impairments is represented in terms of scoring (1-Not affected; 2-Less affected; 3-Moderately affected and 4-Severely affected).

The relationship between age, gender, and endophenotypic features was analysed by Pearson
correlation (SPSS version 21). There is a strong positive correlation between behaviour and sensory (P < 0.01), social and sensory (P < 0.001), social and speech (P < 0.01), motor and physical (P < 0.05), behaviour and physical (P < 0.05). It suggests that when the impairment in behaviour is increased sensory impairment also increases. However, there is a significant negative correlation between age and motor in which, age and the motor is indirectly proportional to each other (P < 0.05), i.e., in the higher age group motor impairment is less when compared to lower age group. As the age increases autistic children improve in functioning due to treatment and therapies. Further, it is revealed that there is no correlation between gender and any specific endophenotype group (Table-2).

Risk factors associated with autism

This present study reveals different kinds of factors associated with autism. There are both genetic as well as environmental factors. 19 children showed to have been associated with the other monogenic conditions, which are in the proportion of 14 children with epilepsy, one with epilepsy and ADHD, one with epilepsy and physically challenged, two with downs syndrome and 1 with physically challenged.

Consanguineous marriages were identified in parents of seven autistic children. In addition, there are some factors which influence the foetal development including both prenatal and postnatal condition. In one of the cases of the present study mother was found to have mental stress during gestation, and in two other cases, severe maternal ill-health was found to be reported. Maternal age is also one of the colossal factors. In one case, maternal age was 35 years and in another it was 40 years. One of the mother had attempted to have abortion during gestation, and the drug taken to abort the foetus might have caused the child to develop autism. In addition, the time of parturition also influences the risk factor. In this aspect three preterm births and one post-term birth were found. As a postnatal factor, in two cases the child with brain fever was reported after a few days of birth. All of these suggest that environmental factors play a huge role in the cause of autism.

Treatment programs

In the present study, two forms of teaching namely, creative teaching and regular teaching have been found to be implemented in special schools of study region. Creative form of teaching involves use of objects, pictures painted on the walls of classrooms, charts, toys, puzzles of alphabets and numbers etc. to improve the cognition. Some of the schools have implemented special and individual caring for autistic children. These schools have implemented Mental retardation Development Program System (MDPS) for the improvement of autistic children. In the MDPS they train the children step wise manner making them to lead life comfortably. By this system the autistic children develop self-help skill. Depending on IQ, teachers train the children about self-life improvement. For instance, they train the children for working in book-binding shop, stitching cloths etc. In addition to teaching adaptations and caring methodologies implemented, some of the important therapeutic measures have been found to be adopted. In these schools they have adopted some sort of exercise, physical therapy, speech therapy, dance, playing activities to improve the motor and speech impairments of children. They examine each child’s skills and depending on IQ, percentage affected they edify each child.

The results presented here are based on study carried out in special schools. Data reveals that autism was observed in 8.08% of the studied group. We have identified 76.74% of autistic males and only 23.25% of females, indicating that males are 3 times at higher risk to autism which is correlated with the earlier reports [4,5,9,10,11].

Statistical analysis reveals both positive and negative significance between the endophenotypes.

Discussion

The results presented here are based on study carried out in special schools. Data reveals that autism was observed in 8.08% of the studied group. We have identified 76.74% of autistic males and only 23.25% of females, indicating that males are 3 times at higher risk to autism which is correlated with the earlier reports [4,5,9,10,11].

Statistical analysis reveals both positive and negative significance between the endophenotypes.
In the present study, the age of onset was found to be at early infancy which is within three to four years of life and this is in congruence with the earlier studies\textsuperscript{[2]}.

As the age increases, the impairment of motor was decreased, whereas in speech and language impairment was more with increase in age. Correlation between age and motor showed negative significance at $P < 0.05$ level which represents impairment of motor was subordinate in higher age group. A strong positive association was found between behaviour and sensory, social and sensory, speech and social at $P < 0.01$ level, which follows motor and physical, behaviour and physical at $P < 0.05$ level. However, awful impairments were seen in speech and language when compared to other endophenotypic features, which clearly indicates as one of the defining features of autism.

Earlier research has revealed that causes of autism may be due to genetics or environmental factor\textsuperscript{[2,12]}. An environmental factor includes exposure to alcohol or medications such as sodium valproate during pregnancy, premature birth, gestational age, maternal illness, etc\textsuperscript{[13]}.

There is no permanent cure for autism. But significant improvements can be made in several aspects of the lives of autistic children, especially in social interaction, behavior, physical activities etc. All teachers in special schools are specially trained for taking care of disabled children. In some schools separate classroom for children was setup based on severity, and each class will be monitored by individual teachers. In order to avoid the loneliness and make autistic children active, caretakers pay special attention towards them. This was very effective and is clearly evidenced in one of the autistic child who was severely affected in the beginning stage, but in the later years he was recovered so that he could perceive and live better.

One particular school has followed the method of MDPS, in which they teach self-help skills for 6-16 years old children. Teachers edify the children stepwise like custodial, trainable and educable steps. In custodial step, they first take the child into their control, and trainable step includes self-help skills like taking food, wearing dress, toilet training etc. In educable step they provide education according to child’s perception. To reduce the child’s hyperactivity and to improve the concentration, child will be kept engaged in different activities such as arranging beads to join them in the thread, arranging puzzles, playing with them, etc. They teach only for 10-15 minutes, after that they allow the children to be free and again teach other topics for 15 minutes.

**Conclusion**

The present study has revealed the both positive and negative correlation between endophenotypes, age and gender. There are many associated risk factors for autism. Not only etiology of autism, but understanding the clinical manifestation of other associated disorders helps to treat the autistic children. Early identification of autism, proper caring and treatment help the autistic children to cope up with autism and to live a comfortable life.

Femoral Tunnel and Lateral Femoral Condyle Measurements in Anterior Cruciate Ligament Reconstruction

Divya Sethi¹, Surendra U Kamath²
¹Final MBBS Student, ²Professor and Head, Department of Orthopaedics, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, India

Abstract

Anterior Cruciate Ligament footprint size is normally correlated with the height and area of the lateral wall of femoral inter condylar notch. Pre-operative anthropometric parameters are also helpful in predicting length and thickness of quadrupled hamstring graft for reconstruction in adults.

In our study, aim was to determine the average length of a femoral tunnel along with lateral femoral condyle measurement and to correlate this with patient gender, height and Body Mass Index. Also, another aim was to measure the value of some anthropometric measurements to predict the length of hamstring graft diameter before surgery.

A total of 91 patients were analysed during the study period. The length of Femoral Tunnel varied from 29 mm to 41 mm (Range 12 mm). The mean length is 35.08 mm, with a Standard Deviation of 2.557 mm. This is a low standard deviation which implies that the length of femoral tunnel would generally be close to the mean value of 40.08 mm. The Lateral Femoral Condyle measurements vary from 35 mm to 67 mm (Range 32 mm). The mean value is 43.22 mm with a Standard Deviation of 4.002 mm. The Hamstring graft diameter varies from 6 mm to 10 mm (Range 5 mm). The mean is 7.86 mm with a Standard Deviation of 0.811 mm. This is a very low standard deviation indicating that the in most cases the Hamstring Graft Diameter is likely to be close to the mean value of 7.86 mm.

Keywords: Anterior Cruciate Ligament Reconstruction, Femoral Tunnel, Hamstring Graft Diameter, Lateral Femoral Condyle Measurements

Introduction

Surgical treatment with reconstruction has now become common in management of Anterior Cruciate Ligament injuries. The main aim in this surgery is to reproduce the normal kinematics of the knee and provide stability in the sagittal and coronal plane. There is better patient satisfaction associated with better stability and kinematics.

In most cases, the surgical technique is still a matter of preference of the surgeon. In the last few years, the most important innovation is to create the femoral tunnel through the antero medial portal. This technique allows an independent creation of the femoral tunnel and a more anatomic placement. The available studies on this subject have analysed the tunnel length with respect to knee flexion during femoral tunnel drilling or axial angle of guide wire. However, there is no study objectively analysing the three dimensional relationship between tunnel orientation and length.

ACL footprint size is normally correlated with the height and areas of the lateral wall of femoral inter condylar notch. Pre-operative anthropometric parameters are also helpful in predicting length and thickness of quadrupled hamstring graft for reconstruction in adults. Studies have also been conducted to determine...
the average length of a femoral tunnel created using a medial portal technique and to correlate this with patient gender, height and Body mass index\textsuperscript{3,4}.

In our study, aim was to determine the average length of a femoral tunnel created using a medial portal technique and to correlate this with patient gender, height and Body mass index. Also, another aim was to measure the value of some anthropometric measurements to predict the length of hamstring graft diameter before surgery.

**Patients and Method**

Between July 2016 and December 2016, a total of 91 patients, including 68 male and 23 female Indian patients, who underwent ACL reconstruction by a single surgeon using the hamstrings tendon auto graft, were studied. All those patients who were not willing to participate in the study and patients with associated major ligament injuries were excluded from the study.

The length of femoral tunnel was measured during the surgery. Other clinical information was collected including gender, age, body mass index, method of tibial fixation and so on. Lateral femoral condyle length measured on a standardized radiograph of knee. A standard arthroscopic antero lateral portal and a far medial portal were used. A spinal needle number 18 was used to identify the position of the far medial portal from where visualisation of the Anterior Cruciate Ligament footprint was optimal. Delineation of the anatomic landmarks of the lateral condylar ridge and bifurcate ridge was facilitated by electrothermal ablation. With the knee in maximal hyperflexion, a guide pin was introduced into the femur and a 4.5 mm cannulated drill bit was used to create the femoral tunnel. The femoral tunnel length was measured with a depth gauge. The femoral tunnel was then reamed with a femoral reamer.

All data was entered into the computerized relational database to analyze and compare using correlation analysis. Correlations of femoral tunnel length with gender, body height, and Body Mass Index were determined. Femoral tunnel lengths were compared using the 2-sided independent t-test. A p value of <0.05 was considered statistically significant. Analysis of Variance (ANOVA) was used to compare means between 3 or more groups. This test for homogeneity of variance provides an F-statistic and a significance value (p-value). We are primarily concerned with the significance value – if it is greater than 0.05 (i.e., p > .05), our group variances can be treated as equal. However, if p < 0.05, we have unequal variances and we have violated the assumption of homogeneity of variances.

**Results**

A total of 91 patients were analysed who had undergone surgery for ACL Reconstruction in the study period. Out of these, 68 were males (74.7%) and 23 females (25.3%). Also, injuries to the right knee were 53 (58.2%) and to the left knee were 38 (41.8%). Maximum injuries were sustained in road traffic accidents (37 patients) followed by fall and twisting injuries.

The length of femoral tunnel varies from 29 mm to 41 mm (Range 12 mm). The mean length is 35.08 mm, with a Standard Deviation of 2.557 mm. This is a low standard deviation which implies that the length of femoral tunnel would generally be close to the mean value of 40.08 mm. The Lateral femoral condyle measurements vary from 35 mm to 67 mm (Range 32 mm). The mean value is 43.22 mm with a Standard Deviation of 4.002 mm. The Hamstring graft (semitendinosus) diameter varies from 6 mm to 10 mm (Range 5 mm). The mean is 7.86 mm with a Standard Deviation of 0.811 mm. This is a very low standard deviation indicating that the in most cases the Hamstring Graft Diameter is likely to be close to the mean value of 7.86 mm (Table 1)

ANOVA: In this case the Significance Value was 0.169 which is greater than 0.05, which implies that the group variances (male / female, Right knee / left knee, modes of injury), will be equal and hence a reasonably accurate estimation of Femoral Tunnel And Lateral Femoral Condyle Measurements can be made based on the above group data.

Discussion

Major injuries of the ligamentous structures of the knee joint are being increasingly reported. Advances in imaging modalities and arthroscopy have contributed to better understanding of the derangement patterns and in diagnosis of associated intra articular injuries. Surgical treatment with reconstruction has now become gold standard in management of Anterior Cruciate Ligament injury. Young active individuals should be offered early surgical intervention to minimize the progressive damage to intra articular structures and prevent arthrosis.

In a study by Wang et al, the incidence and extent of bone tunnel expansion in arthroscopic ACL reconstruction with hamstring tendon autograft are more significant in femoral tunnel than in tibial tunnel. Bone tunnel expansion is correlated to patients’ age, height, BMI and location of the tunnel. The main factors related to bone tunnel expansion are the location and angle of the tunnel.

Body height positively correlates with femoral tunnel length. As height varies in different races so should femoral tunnel length. Preoperative assessment of femoral tunnel length can determine the success of Anterior Cruciate Ligament reconstruction with femoral fixation by endobutton.

The graft length within the tunnel should be at least 15 mm with a 10- or 15-mm endobutton loop, the femoral tunnel length should be at least 25 mm or 30 mm, respectively. If the femoral tunnel length falls short of the sum of the graft length in the tunnel and the endobutton loop length, the graft can be fixed with a tight rope.

van Eck and others did arthroscopic evaluation which included establishing a classification for notch shapes, identifying the shape frequency, measuring notch dimensions, and determining correlation between notch shape, notch dimensions, and demographic patient data.

In a cadaveric study by van Zyl R assessed that individual’s Femoral Epicondylar Width can be used to predict Anterior Cruciate Ligament length preoperatively. These results could improve pre-operative planning of Anterior Cruciate Ligament reconstruction.

Our study determines the relationship between height and area of lateral wall of inter condylar notch and native Anterior Cruciate Ligament size prior to surgery. Also, it has showed that anthropometric parameters can serve as a guide to plan hamstring graft diameter and length before reconstruction. Patient height may be a useful clinical tool to indicate the potential for a short femoral tunnel. The statistical data has brought out clearly that the variances in the mean for different groups would tend to be equal, thus enabling a reasonable estimation of Length of Femoral Tunnel and Hamstring Graft Diameter, prior to surgery.

Conclusion

Anthropometric parameters, especially height and thigh length, can serve as a guide to plan hamstring graft diameter and length before ACL reconstruction. Also, it has been well established that patient parameters like height, gender, age and demographic pattern can assist in
ascertaining the length of femoral tunnel before surgery.

Avocado Consumption and Immune Response: A Review on Ethiopian Context

Dhar Gargi

1 Assistant Professor, Department of Reproductive Health and Nutrition, Wolaita Sodo University, Ethiopia,
2 Academic Counsellor, IGNOU, India

Abstract

This article is talking about avocado in terms of varieties, nutritional fact, scientific evidences of immune response of avocado and its nutrients with special emphasis on Ethiopian situation. According to the United States Department of Agriculture National Nutrient Database; avocados contain carbohydrate, protein, mono-unsaturated fatty acids, dietary fiber, minerals and vitamins. Early published literature showed that avocado can boost up immune systems, having antioxidant and anti-inflammatory potency. Avocados are available throughout the year in Ethiopia, but price, quality and accessibility may vary. Ethiopians, irrespective of age, sex and social class are fond of eating avocados. Based on Institute for Health Metrics and Evaluation, USA data; immuno-deficiency diseases have been enlisted within the top five leading causes of death in Ethiopia, 2017. Malnutrition and dietary practice have been identified within top five mortality related behavioural risk list. Considering this information, Ethiopia has to search any low cost food based dietary approach, which can support to handle immunity mediated disease burden with the limited resources and health service implementation challenges. In this respect, avocado can be considered for its nutritional value and It’s availability, accessibility and affordability issue. Unfortunately, there is no published data available related to avocado consumption and health benefits specially immune response in Ethiopian context. Along with in depth research on nutritional characteristics of avocado; exploration and attention are required on avocado farming and processing technology, awareness creation on “what-when-how” to consume food and multi-sectoral coordination between Government, Non-Governmental organisation and other stakeholders.

Keywords: Avocado, Immune response, Ethiopia

Introduction

The avocado (Persea americana) is a tree, are cultivated in tropical and Mediterranean climates throughout the world but long thought to have originated in South Central Mexico. It is often called “alligator pear,” as it tends to be pear-shaped and has green, bumpy skin like an alligator. Based on Food and Agriculture Organization of United Nations Database of avocado production in 2016-2017, top five producers are Mexico, Dominican Republic, Peru, Indonesia and Colombia. Ethiopia stands at 20th position in terms of production [1]. According to United States Department of Agriculture (USDA) nutrient database, a typical serving of avocado (100 g) is moderate to rich in carbohydrate, protein, mono-unsaturated fatty acids, dietary fiber, minerals and vitamins, phytochemicals (carotenoids, phytosterols etc) [2]. It is well documented by the researchers that incorporating avocado into daily diet can strengthen immune system, lower cholesterol, reduce risk of heart disease and help to manage weight, skin health, cancer, eye health, osteoarthritis [3].

According to Institute for Health Metrics and Evaluation, USA; the top five leading causes of death in Ethiopia (2017) are Neonatal disorders; Diarrhoeal diseases; Lower respiratory infection; Tuberculosis; Ischaemic heart disease; mostly body immunity response...
related diseases. Among the identified mortality related behavioural risk; malnutrition and dietary practice are within top five list [4]. Considering this information, Ethiopia has to think about any low cost food based dietary approach, which can support existing double burden of disease in long run. In this regard, avocado is an unique in terms of nutritional value and already been accepted in Ethiopian diet. Moreover, it is available, accessible and affordable almost all over the country throughout the year. Unfortunately, there is no published information available related to avocado consumption and health benefits specially immune response in Ethiopian context. Along with researchers, policy makers also did not pay more attention on organized and improved avocado farming, processing and marketing in the country.

This article is going to highlight on avocado varieties, nutritional fact, scientific evidences of immune response of avocado and its nutrients with special emphasis on Ethiopian situation. The information and analysis of this review may guide the country to combat disease burden even with the limited resources and health service implementation challenges.

Cultivation of Different Varieties of Avocado in Ethiopia

Avocado was first introduced to Ethiopia in 1938 by private orchardists in Hirna and Wondo-genet and production gradually spread into the countryside where the crop was adapted to different agro-ecologies [5]. The first governmental orchards were formed at Tepi and Gera, bypass of the Great Rift Valley by the year 1979. To date, the avocado commands 75 percent of the total fruit acreage in these areas. Principally, Hass (clean texture, and deep purple skin upon ripening), the most important avocado variety in the southwest part of Ethiopia; season May to October. It is characterized by a darkish purple hue and has a sumptuous flavour that belies its smooth external skin. Next is Fuerte (nutty flavour, notably creamy texture, and maintains green colour while ripening), which is also available between May and October. The other variety is Ettinger (green smooth-skinned), which looks exactly like Fuerte, only that it is available for April to August. Nabal (exceptionally creamy flesh and a gentle coconut flavour), is not easy to spot in many orchards, is accessible between May and October. The only variety that is outside the prime season is Pinkerton, visually closest to Hass. It bears a simple fruit with plenty of pulp and tiny stone. It is available between December to April. So in Ethiopia, avocados are available throughout the year ignoring the varieties. Avocado farming till not yet fully organised in most part of Ethiopia, mostly small-scale production, somewhere as a house-plant, some where it is cultivated alongside other crops, including tea/coffee [6].

Nutritional Facts of Avocado

Amount of nutrients present in 100gm of raw avocado has been compared from two sources: one from USDA Database [2] and another from Ethiopian Food Composition Table [7]. Nutrients like protein, carbohydrate, dietary fibre, fat, energy, calcium, iron, phosphorus, Vitamin C, thiamine, riboflavin, and niacin values are available in both the cases with small difference. These differences may be due to techniques used for analysis; irrigation and soil type, time of harvest, degree of ripening, lack of access to improved varieties those are prone to attacked by pests and diseases; poor post-harvesting techniques etc. Micro-nutrient like Vitamin A, E, K, B6, folic acid, magnesium, potassium, sodium, zinc, copper, selenium values are not available in case of Ethiopian Data.

Immune Response of Avocado in terms of Nutrient Content

Immune System: An Overview

The immune system protects the body against infections and other external and internal threats by utilizing three distinct layers, depending on the nature of the threat: physical (e.g., skin, epithelial lining of the gastrointestinal and respiratory tracts) and biochemical barriers (e.g., secretions, mucus, and gastric acid), numerous different immune cells (e.g., granulocytes, CD4 or CD8 T and B cells), and antibodies (i.e., immunoglobulins).

The first line of defense is innate immunity, which combines physical and biochemical barriers with a non-specific, leukocyte-mediated cellular response to defend against pathogens. The adaptive immune system involves an antigen-specific response mediated by T and B lymphocytes that is activated by exposure to pathogens; this works with the innate immune system to reduce the severity of infection. The complement system can work with both the innate and adaptive immune systems (Figure 1) [8].
Life-style factors affecting immune function: An overview

Immunological maturity is achieved by adolescence, and young adults should be well fortified against attack by pathogens [9]. Nevertheless, several lifestyle-related factors affect immune competence in healthy adults and increase their risk of infection (Figure 2). In particular, energy-dense, micronutrient-poor food combined with a sedentary lifestyle, make less bioavailable the immune-competent nutrients, increased risk of infection [10]. However, prolonged and excessive exercise, over-training are also thought to impair immune function [11-13]. Pollution and cigarette smoking with poor nutrition compromise immune function [14]. Chronic, psychological stress is another factor that can impact immune function [15]. Alcohol consumption has variable effects on immunity; moderate amounts of polyphenol-rich alcoholic beverages potentially provide some immune protection, but excessive consumption can suppress many aspects of immune function [16]. Sleep is an important homeostatic regulator of immune function [17]. It is clear that optimal immuno-competence depends upon nutritional status [18]. The risk of infection is also influenced by gender, age, genetics, early programming, vaccination history, pathogen exposure, specific health conditions, and diseases [19].

Nutrients have vital roles throughout the immune system that are independent of life stage. The nutrients are essential to sustain an immune-competent include protein, fat, vitamins A, C, D, E, B6 and B12, folic acid, iron, selenium, copper and zinc and the literature suggested that avocado comprised of all above mentioned immuno nutritional elements except Vitamin D, B12 [20].

Avocado and Immune Response: Scientific Evidences

Avocado contains substantial amounts of bioactive compounds such as phytosterols, β-sitosterol. The β-sitosterol in avocado also has a special effect on immunity, contributing to the treatment of diseases such as cancer, HIV and infections. In relation to cancer, it works by suppressing carcinogenesis and in HIV by strengthening the immune system [21]. This compound enhances lymphocytes proliferation and natural killer cell activity, which inactivates invading microorganisms [22].
Avocado can help in absorption antioxidants. It has been documented that eating carotenoids (antioxidants including lycopene and beta-carotene) with avocado or avocado oil increased their absorption, which is attributed primarily to the lipids present in avocado [23]. The critical review results indicated that compounds in avocado are unique antioxidants, by suppressing radical generation, acting as effective neuroprotective agents [24].

Jaquelin and his colleagues (2013) reported that antimicrobial activity of avocado with the help of antimicrobial peptides (AMP) to control of pathogens [25]. Researches indicated that 300 mg of avocado and soybean unsaponifiables (ASU; an extract prepared from avocado and soybean oil) per day (with or without glucosamine and chondroitin sulfate) appears to be beneficial for patients with hip or knee Osteoarthritis. This is indicating anti-inflammatory function of avocado [26].

California Hass avocados have the highest content of lutein among commonly eaten fruits, lipophilic extract of avocado can inhibit the growth of both androgen-dependent (LNCaP) and androgen-independent (PC-3) human prostate cancer cell lines in vitro [27]. Avocado extract selectively induced apoptosis in human oral cancer cell lines by modulation of reactive oxygen species [28]. In the same year, Castillo-Juarez et al. concluded that antibacterial activity of a methanolic avocado extract against Helicobacter pylori, a cause of gastritis implicated in the etiology of gastric cancer [29].

**Ethiopian Context**

In Ethiopia, avocados is very popular to everybody irrespective of age, sex, socio-economic class. Ethiopians are preparing juice by mixing avocado with sugar and milk or water, frequently served with “Vimto” (locally called, brand name may be different, made up of grapes juice mostly). Avocados are also used to make salads and sandwiches as well as consumed raw. But avocado farming and marketing is not that much organised. Even, there is no specific database available related to avocado consumption in any part of Ethiopia. According to Ethiopia National Food Consumption Survey (2013), overall Vitamin A rich fruits and vegetables consumption is very low throughout the country [30]. The researchers have already documented that tobacco use, physical inactivity, unhealthy diet (low dietary diversity and faulty dietary practices), excessive alcohol use, as well as “Khat” consumption are widely prevalent in Ethiopia [31], those behaviours are antagonist for bioavailability of immune-competent nutrients.

**Conclusion**

It can be concluded that Ethiopia is lacking in Immune-competent individuals and malnutrition-dietary practice have been identified under the top five mortality related behavioural risk list. This is the prime time, when nutritionist and food scientist of Ethiopia have to consider any low cost, culturally accepted food based dietary approach to handle the immunity related disease burden from infant to adult. Another interesting point to be noted that researchers have suggested avocado as a complementary and transitional food for infants and toddlers in terms of its taste, consistency and nutritional value to ensure their optimal health [32]. Considering nutritional potential and existing scientific evidences, avocado can be warranted for further exploration in terms of immune response and related health benefits over the life course in Ethipians. A number of actions need to be undertaken in order to promote the health benefits of avocado with special emphasis on immune response. These includes:

- Capacity building, plant breeding-protection activities, implementing improved varieties, post-harvest technology, standardized packaging, organised marketing etc.
- Establishment of local processing industry, especially for avocado pulp processing or oil extraction, considering its composition and the health benefits, which can be used for manufacturing new food products/supplements.
- There is a need to revise existing food composition tables for Ethiopia by using the more sensitive technology, because existing one is very old.
- Development of dietary awareness program based not only what to be consumed, how and when to be consumed. Faulty dietary practices making nutrients not bioavailable for physiological and biochemical functions in the body, so deficiency symptoms will come up even after adequate consumption of nutrients.
- Finally, suggested collaboration from Government sectors like health, agriculture, trade and industry, education, urban planning, and transportation along with
Non-government organizations and other stakeholders.

Evaluation of Immunostimulant and Chemprotective Activity of *Chicoreus Ramosus* against Cisplatin Induced Toxicity in Balb/C Mice

J. Bindhu¹, Arunava Das²

¹Research Associate cum Assistant Professor, ²Associate Professor, Molecular Diagnostics and Bacterial Pathogenomics Research Laboratory, Department of Biotechnology, Bannari Amman Institute Technology, Sathyamangalam, Erode District, Tamil Nadu, India

Abstract

Traditional plant medicines are used for a range of cancer displays. The *Chicoreus ramosus* is an enormous proteinaceous gastropod for human consumption. In this research evaluation of chemoprotective activities *Chicoreus ramosus* (CR) in cisplatin-triggered immunosuppressed mice was studied. Cisplatin (100mg/kg, intraperitoneally [IP]) brought on immunosuppressed mice changed into treated with *Chicoreus ramosus* (150 mg/dose/animal/IP) for a duration of 10-day. The influence of the extract on lymphoid organ weight, bone marrow cellularity, alpha esterase hobby and on enzyme degrees such as SGOT,SGPT, Urea, Creatinine changed into estimated to choose out the chemoprotective impact of CR. Administration of CR in cisplatin treated mice, found to enhance bone marrow cellularity and α- esterase exquisite cells, which were appreciably decreased in cisplatin best handled control animals indicates that cisplatin brought on myelosuppression changed into reversed or inhibited by CR management probably via its chemoprotective activity. Cisplatin binds to DNA and reasons damages ensuing in chromosome breaks,micronucleus formation and cell loss of life.CR contains several center-chain aliphatic alcohols, aldehydes and ketones, which can be believed to be the quit yields of fatty acids. Administration of CR in cisplatin handled mice, boosts the bone marrow cellularity and α- esterase advantageous cells, which have been notably reduced in cisplatin best indicates that cisplatin caused myelosuppression was reversed or inhibited via *Chicoreus ramosus*.

Keywords: *Chicoreus ramosus*; Chemoprotective; Cisplatin; Alpha Esterase, SGOT,SGPT

Introduction

Cancer isn’t one unwellness, however several diseases that occur in several areas of the body. every variety of cancer is characterised by the uncontrolled growth of cells. below traditional conditions, cell replica is rigorously controlled by the body. However, these controls will malfunction, leading to abnormal cell growth and therefore the development of a lump, mass, or tumor. Some cancers involving the blood and blood-forming organs don’t type tumors however flow into through alternative tissues wherever they grow. [¹] [²] Common locations of metastasis are the bones, lungs, liver, and central system nervosum. All cancers begin in cells, the body’s basic unit of life. The body is formed from many sorts of cells. These cells grow and divide during a controlled thanks to turn out additional cells as they’re required to stay the body healthy. once cells grow up or broken, they die and are replaced with new cells. However, generally this orderly method goes wrong. The genetic material (DNA) of a cell will become broken or modified, manufacturing mutations that have an effect on traditional cell growth and division. once this happens, cells don’t die after they ought to and new cells type once the body doesn’t want them. the additional cells could type a mass of tissue referred to as a tumour. [³⁻⁶]
Materials and Method

IDENTIFICATION AND PURIFICATION OF BIOACTIVE COMPOUNDS

Animals:

Inbred BALB/C (6-8 weeks) mice, consideration 23-28g, were obtained from biologist Institute, breeding section, Coonoor. The animals were housed in airy plastic cages at thirty seven ± 1°C, 40±10% humidity and 12/12-hrs light/dark cycles throughout for night period of time period of adaptation to laboratory conditions and throughout the whole experimental period. The animals were fed with traditional mouse chow (Sai Feeds, Mumbai, India) and given water ad libitum.

Preperation and administration of Extract

Chicoreus ramosus (Gastropod) were collected from native shell meat dealers Tuticorin, South East Coast of India. The mollusc meat was washed in water and dried during a hot air kitchen appliance at 50°C. The dried meat was small-grained and extracted long by stirring with ten volumes of 75 % methyl alcohol. Supernatant was collected when centrifuging at 3000 rpm for ten minutes. The yield of the extract was 35%.

For animal administration the extract was dissolved in minimum amount of methyl alcohol, then resuspended in gum acacia in phosphate buffered saline and given at a degree of 25 mg /dose/animal intraperitoneally.

Experimental Design:

The animals were divided into three groups of six animals each as follows:

Group 1: Normal animals, without any treatment.

Group 2: Treated animals received cisplatin alone dissolved in 1% gum acacia intraperitoneally for 10 continous days.

Group 3: Treated animals received Chicoreus ramosus (0.5mg) methanolic extracts dissolved in 1% gum acacia intraperitoneally for 10 consecutive days.

Determination of the consequences of Chicoreus ramosus on relative organ weight in Cisplatin treated animals

Eighteen animals were indiscriminately divided into 3 teams, containing six animals in each tea, the primary cluster had traditional animals, that failed to receive any treatment. The second cluster had animals, treated with cisplatin alone. The third cluster had animals treated with cisplatin and Chicoreus ramosus.3 animals from every cluster were sacrificed at 2 totally different time intervals (7th and eleventh day) by cervical dislocation. weight of every animal was taken before sacrifice and organs like lungs, liver, kidney, thymus and spleen were excised, weighed and expressed as relative organ weight.

Determination of the influence of Chicoreus ramosus on alpha esterase activity in Cisplatin treated animals (Azodye coupling method, Bancroft and Cook, 1984)

Femurs was separated to PBS, washed thrice and smeared over the slides. Slides were fixed after air drying in freshly prepared fixative 30 sec at 4°C and dipped in double distilled water thrice. After that the fixed slides were incubated in freshly prepared filtered solution, 1.2 ml solution. After hematoxylin staining slides were washed in water for long time and viewed using microscope (100x, oil immersion) for scoring positive and negative alpha esterase cells out of 4000 cells.

Determination of the consequences of Chicoreus ramosus on Bone marrow physiological state (BMC) in cisplatin treated animals

Bone marrow physiological state was done in line with the strategy of Sredni et al (1992). Bone marrow was collected from the femur into the medium containing a pair of liquid body substance and created into single cell suspension. the amount of cells was firm employing a haemocytometer and expressed as total cells determined by trypan blue (1% in saline) exclusion methodology per femur.

Determination of alpha-esterase activity in Cisplatin treated animals (Azodye coupling method) (Bancroft and Cook, 1984)

Bone marrow from femurs of mice was collected in PBS, washed thrice and dirty over the slides. Air dried slides were fastened in freshly ready fixative for thirty seconds at 4°C and swayback in double water thrice. During incubation slides were washed in double water for ten min and counter stained with haematoxylin for one min. when staining slides were washed in water for a while and discovered below magnifier (100X, oil
immersion) for evaluation positive and negative alpha esterase cells out of 4000 cells.

**Estimation of SGPT (Span medical specialty Ltd., Surat, India)**

Alanine aminotransferase (ALT) catalyses the transamination of L-Alanine and α- Ketoglutarate to form pyruvate and L- Glutamate. Pyruvate so formed is coupled with 2,4- Dinitrophenyl hydrazine (2,4- DNPH) to form a corresponding hydrazone, a brown coloured complex in alkaline medium and this can be measured colorimetrically.

**Estimation of SGOT (Span Diagionostics Ltd., Surat, India)**

Aspartate aminotransferase (AST) catalyses the transamination of L-Aspartate and α-ketoglutarate to make L- salt and salt. salt thus shaped is not to mention a pair of,4- Dinitrophenyl reducing agent (2,4- DNPH) to make a corresponding hydrazone, a brown colored complicated in base-forming medium and this will be measured colorimetrically.

**Statistical Analysis:**

The results are expressed in mean ± standard deviation (SD). Statistical analysis were performed by using Students ’ t ’ test. p Values < 0.05 were considered to be statistically significant.

**Result & Discussion**

**Chemoprotective activity of Chicoreus ramosus:**

**Impact of Chicoreus ramosus on Relative Organ Weights in Cisplatin treated Animals:** The Cisplatin treated animals showed high reduction within the weight of all the organs like zero.2848± 0.04772g/100g weight of spleen, 0.0455± 0.0733 g/100 g weight of thymus, 4.6081± 0.402g/100g weight of liver, 0.98873± 0.04351g/100g weight of excretory organ, 0.5385± 0.03630g weight of lungs. The Chicoreus ramosus treated together with cisplatin mice showed a major increase (p < zero.001) within the weight of all the organs in treated cluster as zero.3995± 0.1355g / a hundred g weight of spleen, 0.1435± 0.02192g/100g weight of thymus, 5.5575± 0.3104g /100g weight of liver, 1.1095± 0.2171g / 100g weight of excretory organ, 0.6885± 0.06859g /100g weight of lungs (Table:1).

**Impact of Chicoreus ramosus on bone marrow physiological state and α-esterase activity on Cisplatin administration:**

Impact of Chicoreus ramosus on bone marrow physiological state and α-esterase activity is given in the Table 2: The amount of bone marrow cells similarly as α-esterase positive cells was shrieved drastically in Cisplatin alone treated management animals, however this was considerably reversed (p < zero.001) by administration of Chicoreus ramosus. In Cisplatin alone treated management animals, on the seventh day there was a forceful reduction within the variety of bonemarrow cells(25.5 × one zero five ± one five.414cells / femur) and α – esterase positive cells (63.4.5± 4.95 positive cells / 4000 cells) compared to Chicoreus ramosus treated together with cisplatin animals. Treatment with Chicoreus ramosus may elevate the bone marrow physiological state and variety of α-esterase positive cells. In treated cluster of animals, bonemarrow physiological state and α- esterase positive cells was found to be sixty seven.6 ×105± 18.385cells / femoris and 1208.5± 101.12cells / 4000 bone marrow cells on 11t h day severally compare to the Cisplatin alone treated animals twenty.93 ×105± 3.055cells / femur and 620.66± 3.055cells/4000 bone marrow cells). The results are given in table 2. The impact of Biophytum sensitivum on the bone marrow physiological state and α-esterase positive cells when the administration of the methanolic extract of Biophytum sensitivum showed a major (p<0.001) sweetening within the bone marrow physiological state (28.3 x 106 cells/femur) compared to the traditional management (17.3 x 106 cells/femur) animals. In Cisplatin alone treated animals, on the seventh day there was a forceful reduction within the variety of bonemarrow cells(25.5 × one zero five ± one five.414cells / femur) and α – esterase positive cells (63.4.5± 4.95 positive cells / 4000 cells) compared to Chicoreus ramosus treated together with cisplatin animals. Treatment with Chicoreus ramosus may elevate the bone marrow physiological state and variety of α-esterase positive cells. In treated cluster of animals, bonemarrow physiological state and α- esterase positive cells was found to be sixty seven.6 ×105± 18.385cells / femoris and 1208.5± 101.12cells / 4000 bone marrow cells on 11t h day severally compare to the Cisplatin alone treated animals twenty.93 ×105± 3.055cells / femur and 620.66± 3.055cells/4000 bone marrow cells). The results are given in Table 2. The impact of Biophytum sensitivum on the bone marrow physiological state and α-esterase positive cells when the administration of the methanolic extract of Biophytum sensitivum showed a major (p<0.001) sweetening within the bone marrow physiological state (28.3 x 106 cells/femur) compared to the traditional management (17.3 x 106 cells/femur) animals. In Cisplatin alone treated animals, on the seventh day there was a forceful reduction within the variety of bonemarrow cells(25.5 × one zero five ± one five.414cells / femur) and α – esterase positive cells (63.4.5± 4.95 positive cells / 4000 cells) compared to Chicoreus ramosus treated together with cisplatin animals. Treatment with Chicoreus ramosus may elevate the bone marrow physiological state and variety of α-esterase positive cells. In treated cluster of animals, bonemarrow physiological state and α- esterase positive cells was found to be sixty seven.6 ×105± 18.385cells / femoris and 1208.5± 101.12cells / 4000 bone marrow cells on 11t h day severally compare to the Cisplatin alone treated animals twenty.93 ×105± 3.055cells / femur and 620.66± 3.055cells/4000 bone marrow cells). The results are given in table 2. The impact of Biophytum sensitivum on the bone marrow physiological state and α-esterase positive cells when the administration of the methanolic extract of Biophytum sensitivum showed a major (p<0.001) sweetening within the bone marrow physiological state (28.3 x 106 cells/femur) compared to the traditional management (17.3 x 106 cells/femur) animals. [8]

**Impact of Chicoreus ramosus on protein levels on Cisplatin administration:**

Administration of Chicoreus ramosus considerably accrued the amount of SGOT (65.76± 1.471IU/L) and SGPT (56.925± 0.9546IU/L) in liver. the degree of SGOT and SGPT values are given in Table 3 and Table 4. Cyclophosphamide treated mice showed accrued liquid body substance SGOT and SGPT levels. This increase is often attributed to the broken structural integrity of the liver and excretory organ, as a result of these enzymes are discharged into circulation when cellular harm. [9]
Impact of *Chicoreus ramosus* on the biochemical parameters on Cisplatin administration:

The nephritic functions are often calculable by organic chemistry parameters like organic compound, breadstuff and Creatinine given in the Table 5 and Table 6. Cisplatin administration in mice was found to extend the breadstuff concentration in liquid body substance on seventh day eight.0884± 0.01980mg/dL and eleventh day 8.31723± 0.07966 mg/dL however this was considerably reduced (p < 0.05) to mg/dL on seventh day six.8785± 0.1054 and 7.1655±0.07566 mg/dL on eleventh day by the administration of *Chicoreus ramosus*. Cisplatin treated animals showed a rise within the level of organic compound seventeen.32± 0.04243 mg/dL on7th day and seventeen.81± 0.1706mg/ metric capacity unit on eleventh day in liquid body substance that was considerably reversed ( p < 0.001) to 14.73± 0.2263mg / metric capacity unit on seven th day and fifteen.345± 0.1626 mg/dL on 11t h day by the administration of *Chicoreus ramosus*. Cisplatin treated animals showed a rise within the level of creatinine one.75± 0.04243mg/dL on seventh day and one.9266± 0.06807mg/ metric capacity unit on eleventh day in liquid body substance that was reversed ( p < 0.01) to 1.6705± 0.03748mg/ dL on seventh day and one.6405± 0.02475mg/dL on 11t h day by the administration of *Chicoreus ramosus*. a serious disadvantage of current cancer therapeutic practices like therapy and radiotherapy is bone marrow suppression leading to blood disorder and ensuant suppression of body substance and cellular similarly as non-specific and specific cellular responses.

Table 1: Effect of *Chicoreus ramosus* on Relative Organ Weights in Cisplatin treated animals

Conclusion

Administration of *Chicoreus ramosus* extract in cisplatin treated mice will increase bone marrow cellularity and α- esterase high quality cells, which have been drastically reduced in immunosuppressed indicates that cisplatin brought on myelo suppression turned into reversed or inhibited via *Chicoreus ramosus* extract administration via its chemoprotective activity.

Quality of Life and Depression in Obese

K T Moly¹, Shaliya Shajan², Soniya Johny²
¹Professor cum Principal, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, ²Fourth year B.Sc Nursing Students, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi

Abstract

Background: Health-related quality of life is emerging as an important outcome in obesity studies and has demonstrated a significant impairment in Quality of life (QoL). Depression is one of the common health consequences of overweight and obesity as per WHO.

Objective: To find out correlation between depression and QoL among obese.

Methods: Descriptive co-relational study was conducted on 220 obese patients attending selected OPD’s/obesity clinic of tertiary care hospital, Kerala, India. QoL was assessed using Rand Short Form (SF-36) scale and depression using Patient Health Questionnaire (PHQ-9).

Results: The mean QoL was found to be slightly above average (50.86 +/- 12.48). Of the eight domains of QoL assessed, the mean score was poor in General health (37.76), role limitations due to emotional problems (43.97) and relatively better in pain (60.88) and social function (56.37). The QoL in mental components (49.43 +/- 13.68) was found to be poor than the physical component (54.4 +/- 20.09). Major depression was found in 51 (23.20%) of patients. A moderate negative correlation was observed between QoL and depression (r = -0.502 p value <0.001)

Conclusion: The study findings highlight poor QoL especially in the mental component of obese patients. The statistically significant negative correlation found between depression and QoL in obese is a concern and needs further exploration.

Key words: Quality of Life, Depression, Obesity.

Introduction

Obesity is one of the most common, yet among the most neglected, public health problems in both developed and developing countries (WHO) [1]. Even in countries like India, which are typically known for a high prevalence of undernutrition, a significant proportion of overweight and obese people now coexists with those who are undernourished [2]. Most available recent data from India showed 12.6 % of women were either overweight or obese, while a similar percentage of women were underweight and overweight or obese in urban India (25 % underweight and 23.5% overweight or obese) [3]. Persons with obesity have been found to have a significantly lower health-related quality of life than those who were normal weight, even for persons without chronic diseases known to be linked to obesity [4].

Obesity is often co-morbid with conditions such as osteoarthritis and lower back pain, illnesses that can result in functional locomotor limitations. Chronic generalized pain and is also a common finding in obese patients secondary to factors such as fibromyalgia, osteoarthritis, sleep disorders and reduced cardio-pulmonary fitness. Studies from developed countries have shown that obese individuals often face obstacles in society and in their day-to-day lives, far beyond health risks [4].

Quality of life (QoL) is a broad multidimensional concept that usually includes subjective evaluations of both positive and negative aspects of life. Health-related quality of life (HRQOL) is emerging as an important outcome in obesity studies. HRQOL refers to the self-reported effects of a medical condition on physical and mental functioning and well-being of patients. Obesity is associated with increased health risks and pain that can impair physical health status and impose limitations on daily activities. The fact that obesity is predominantly a life-long condition emphasizes the importance of quality of life research in this field.

A cross sectional study on QOL for obese women and men at Turkey was done by Fulden Sarac, Sebnem & Fusun. The tool used was SF 36 Questionnaire with 1752 sample. The result showed that obesity is associated with poor levels of physical & social well being. A study on QoL of pre-obese & obese patients at France was done by Laurent Letrilliant, Alain & Sarah Rosen in 2005. The researchers concluded that patient’s QoL score significantly deteriorated with increasing BMI.

Numerous studies as shown above have demonstrated that obese persons experience significant impairment in QoL as a result of their obesity, with greater degrees of obesity. QoL is defined as an individual’s satisfaction with his or her life dimensions comparing with his or her ideal life. Evaluation of the quality of life depends on individual’s value system and on the cultural environment where he lives.

Emotional suffering may be one of the most painful parts of severe obesity. Society often emphasizes the importance of physical appearance. The consequence of discrimination against individual affected by severe obesity can seriously lead to psychological depression. The negative stigma, associated with severe obesity can affect at work and can be viewed as less competent and lacking in self discipline in their life. Psychological depression is one of the common health consequence of overweight and obesity as per WHO.

One recent study found that overall, obese individuals have a 20 percent elevated risk of depression, and specifically for Caucasian college-educated people with obesity, the depression risk rises to as high as 44 percent.

In addition to societal stigma, the presence of self-directed, internalized anti-obesity attitudes are also identified in studies. Longitudinal studies have found that obesity predicts the subsequent onset of depression. Epidemiological data suggest an association between obesity and depression but findings vary across studies. Hence the investigators were interested in finding out the correlation between QoL and depression in patients who were obese.

Methodology

A descriptive, co relational study was conducted on 220 obese patients attending selected OPD’s/obesity clinic of a tertiary care hospital, India. Data was collected only from patients with a BMI ≥ 30 kg/m². The following tools were used to collect data.

**Tool I:** Interview schedule to assess the socio-demographic and clinical data.

**Tool II:** Rand Short Form (SF-36) scale to assess the QoL (Reliability > 0.80)

**Tool III:** Patient Health Questionnaire.(PHQ-9) to assess depression (Sensitivity and specificity - 88%). The PHQ-9 tool incorporates DSM-IV depression diagnostic criteria.

**Ethical Consideration:** Ethical clearance was obtained from the Institutional Ethical & Scientific Committee before data collection. Informed written consent was obtained from each subject.

The above table indicates a negative correlation between QoL and depression among the sample (r value -0.502, p value < 0.001).

Discussion

The present study was conducted on 220 obese subjects with males and females equal in number. 88.6% of subjects had one or more co-morbidities. The study sample showed a mean QoL slightly above average (50.86 +/- 12.48). But the result of a cross sectional study done by Ronette L & Ross D among 3353 sample on HRQOL varies among obese sub groups showed that obesity specific health related QoL was significantly more impaired in the group.

Among the eight dimensions of QoL assessed in this study, the mean score was relatively better in the dimensions of pain (60.88) and social functioning (56.37) probably due to lack of restrictions in their mobility status as 50 % (112 subjects) of the subjects were in class I obesity category (BMI 30 – 35 kg /m²). But it was poor in general health (37.76) and role limitation due to emotional problems (43.97). The QoL in mental components (minimum score -6, maximum score- 87 and the mean 49.43+/-.13.68) was found to be poor than the physical component (minimum score-8, maximum score-98 and the mean 54.4+/-.20.09).

Major depression was found in 51 (23.20%) patients. This study finding is in congruent with the findings of a study done in the US by Gregory E Simon et.al (2006) on association between obesity and psychiatric disorders on 9125 subjects which showed that obesity was associated with significant increase in life time diagnosis of major depression. Another study on relation between BMI & Depression by Aline Dragan and Noori Akhtar-Danesh in Canada on 36,984 individuals also showed that higher BMI is associated with more severe form of depression.

The present study findings are different from two studies conducted in Korea and Iran. A study on BMI & depressive symptoms in middle aged and older adults by Jin Won Noh et.al among Koreans in 7920 sample (2015) showed the highest level of depressive symptoms were among the underweight followed by the severely obese and then the obese. A study on the relationship between obesity and depression by Jaffar Askari et.al in Iran (2013) in 200 obese and 200 normal weight individuals showed that obesity does not lead to statistically significant increase in depression rate.

A moderate negative correlation was found between QoL & Depression in patients who are obese (-0.502 p value <0.001). This is in tune with a cross sectional study finding conducted by Jine choo, Melanie T. Turk &Sac young in 2015 on factors associated with health related QoL among125 over weight &obese Korean women. The tools used were Beck depression inventory & interpersonal social evaluation. Increased BMI, low self efficacy for weight control& higher levels of depressive symptoms were found to be significantly associated with greater impairment in total QOL.

A reciprocal link between depression and obesity was seen in another longitudinal study conducted by Florinia S and Luppina M on “overweight, obesity, and depression” at United States using Beck depression inventory in a sample size of 746.

Conclusion

The study findings highlight poor QoL especially in the mental component of obese patients. It points toward the individual and societal perceptions on obese. The statistically significant negative correlation found between depression and QoL in obese is a concern and needs further exploration.

The Effect of Enzymatic Denture Cleanser on the Physical Properties of Different Types of Denture Base Resin Materials

Khushboo Singh¹, Pradeep S², Dhanasekar Balkrishanan³, Aparna I Narayana⁴
¹Post-Graduation Student, ²Additional Professor, ³Professor & HOD, ⁴Professor, Department of Prosthodontics and Crown & Bridge, Manipal College of Dental Sciences, MAHE, Manipal, India

Abstract

Aim: To evaluate the effect of Denture Cleansers on the properties of Conventional, High impact strength and Flexible denture base materials.

Materials and Method: A total of ninety disc shaped resin specimens (20mm×3mm) of different denture base materials [Trevalon Polymethyl Methacrylate (PMMA), Valplast and Trevalon HI (High Impact)] were prepared. Commercially available denture cleansers and the control were categorized into three groups [Group I- distilled water, Group II- 0.5% Sodium Hypochlorite (NaOCl) and Group III- Daiso enzymatic cleanser] used for the immersion of these specimens. The physical properties like color stability, surface roughness and micro-hardness for each specimen was evaluated at the baseline and after six months. The data obtained was statistically analyzed using Repeated Measure Anova test and post-hoc test.

Results: There was significant change in color and micro-hardness among three denture base resins when immersed in cleansers from baseline to six months. The surface roughness of denture base resins was not within the clinically acceptable range.

Conclusion: The selection of denture cleanser should consider the duration of immersion, concentration of solution, temperature of the solution, material properties and its chemical composition.

Keywords: Denture base resins, Surface roughness, Hardness, Color stability, Denture cleansers.

Introduction

In patients with removable acrylic prosthesis, denture cleanser could be one of the important tools for maintaining excellent denture hygiene. Based on the chemical constituents, denture cleansers are categorized into alkaline peroxides, alkaline hypochlorites, disinfectants, acids and enzymes.¹

Chemically formulated cleansing agents complementary to denture hygiene can also alter the major properties of denture bases.

Corresponding author:

Additional Professor, Department of Prosthodontics and Crown & Bridge, Manipal College of Dental Sciences, MAHE, Manipal- 576104

Materials and Methodology

Three commercially available denture base resins (A-Trevalon, B-Valplast, and C-Trevalon High Impact)
Polishing discs of dimension (22×3 mm) was used to prepare the mold for making resin specimens of (20mm×3 mm) dimension. These Discs were invested using type IV die stone. The mold space thus obtained was used for the preparation of each 30 test specimens for Trevalon, Valplast and Trevalon HI.

Trevalon in the ratio of 3:1 (polymer: monomer) and Trevalon HI by weight 25gm-11ml (polymer: monomer) was mixed for 1 minute and bench pressed (pressure of 2000 psi) for 30 minutes. For Valplast specimens, Putty impression of polishing discs were made and then filled with molten Modelling wax. Valplast sprue wax was connected to make the channels for the molten Modelling wax to flow. The resins were then packed, pressed and polymerized based on the manufacturer’s instructions.

All 90 specimens with irregular nodules were finished with silicone carbide abrasive paper (200-800) and polishing was achieved with pumice-slurry for 1 minute. The specimens was then stored in distilled water for the excess monomer to leach out.

The three brands consisting of thirty specimens (A-Trevalon, B-Valplast, and C-Trevalon High Impact) specimens were immersed into three groups (Group I-Distilled water, Group II- 0.5% NaOCl and Group III-enzyme) of cleanser solutions. The duration of immersion followed was 10 minutes daily at room temperature according to manufacturer’s instructions for Daiso enzymatic cleanser (Daiso industries co., Ltd, Hiroshima, Japan), 0.5% NaOCl and Distilled water. After the stipulated duration of immersion, the specimens were washed and then stored in distilled water at room temperature. The same procedure was then followed daily for six months (180 days).

All the three different acrylic specimens were evaluated for the color change on the same side using a Spectrophotometer. The CIE L*a*b* system was followed to determine (ΔE) value before and after immersion into cleanser solution.

\[ \Delta E = \sqrt{(\Delta L)^2 + (\Delta a)^2 + (\Delta b)^2} \]

\[ \Delta L, \Delta a \text{ and } \Delta b \text{ are the differences of } L, a \text{ and } b \text{ values before and after immersion .To relate the color differences (ΔE) to a clinical point of view, National Bureau of Standards (NBS) units was considered through the formula :- NBS = ΔE ×0.92 \]

All the three different acrylic specimens roughness was valued using a Profilometer. The stylus of Profilometer was moved across the specimen surface at the scanning length of 4mm. The three readings were recorded with a distance of 1 mm between each scanning line. Analysis was based on the arithmetic mean of the three readings. The cut-off value was 0.8 mm, at 0.25 mm/s and the resolution of the record data was 0.02 µm. The roughness values before immersion (baseline) were deducted from the values after immersion for a period of six months (180 days) to obtain the average ΔRa (roughness differences).

All the three different acrylic specimens were evaluated for the micro-hardness using a Vicker’s hardness testing machine. A 100-gf load for 15 seconds was thereby applied. The diamond indenter created a pyramid indentation on the specimen surface. The diagonals of the pyramid indentation developed on the specimen surface were measured under the magnification. Three measurements of each ninety resin specimens before and after immersion into cleanser solution were noted. The mean arithmetic average (VHN) value for each sample were calculated to provide overall mean value of the resins after six months.

The data was analysed using statistical package SPSS version 20 (SPSS Inc, Chicago, IL). Descriptive analysis of the mean values and standard deviations of color stability, surface roughness and micro hardness of three different resin specimens before and after six months were obtained. Repeated measure ANOVA was undertaken to statistically determine the differences based on material treated with different cleanser solution before and after 6 months. Post hoc Tukey’s test was chosen to assess the significant difference between the different types of cleanser solution. All tests were performed at the confidence level of 95% and P value <0.05.

Results

The results and statistical analysis are summarized in the Tables 1-6.

There was a statistically significant differences in the effects of denture cleansers (Group I, II and III) on individual resin materials [Trevalon, Valplast and Trevalon HI] when immersed for 6 months (P<0.05)
0.5% NaOCl solution showed maximum color change in Valplast specimens when immersed for a period of 6 months.

Maximum surface roughness was shown by the Valplast (0.73) when immersed in 0.5% (NaOCl) from baseline to six months. There was no statistically significant differences (P=0.271) seen on the effects of denture cleansers on individual resin materials.

Maximum increase in micro-hardness was shown by the Trevalon HI when immersed in 0.5% (NaOCl) from baseline to six months.

Discussion

The null hypothesis was rejected. In the present study, NBS unit of color difference for Groups [IA, IB, IC, IIA, IIB, IIC, IIIA, IIB and IIIC] are 0.27, 0.87, 0.86, 0.41, 3.16, 1.03, 0.92, 1.78 and 1.84 respectively. Vichi et al in 2004 gave the value as when $\Delta E < 1$ (appreciable), $\Delta E < 3.3$ (clinically acceptable) and $\Delta E > 3.3$ (unacceptable). Sepulveda-Navarro et al in 2011 related NBS units clinically and classified as:- 0.0–0.5 (trace), 0.5–1.5 (slight), 1.5–3.0 (noticeable), 6.0–12.0 (much) and ±12.0 (very much). In the present study, color change of Valplast resin immersed in 0.5% NaOCl was appreciable to the naked eye.

Davi et al in 2010 stated that NaOCl (0.5%) showed statistical significant change in color on the acrylic resins over the time period of 8 hour a day for 180 days. NaOCl (5.25%) is considered to be an effective solution for antimicrobial effect. But, the high concentration might alter the property of the denture base materials. Paranhos et al., Neppelenbroek et al., and Ural et al., found (0.5%) NaOCl considered to be a suitable detergent cleansers with the antimicrobial property. The present study also showed the similar result of NaOCl (0.5 %) having a greater effect on the color stability of acrylic resin than enzymatic cleanser for a time period of 180 days. Daiso enzymatic cleanser immersion time interval, range from 10 minutes for optimal cleansing and overnight for maximum results but prolonged immersion might discolor the denture. Hence, a short immersion period of 10 minutes was routinely executed and also to standardize the same time period for comparing the results of both the cleanser solution. The present study results showed maximum color change in polyamide resin as compared to PMMA and Trevalon HI when immersed in cleanser for 10 minutes. Reason being they are hydrophilic in nature, enhance more water absorption, and leaching out of plasticizers at the faster rate.

Surface roughness could become retentive areas for microorganisms. Previous studies have stated that 0.5% (NaOCl) has significantly increased the surface roughness more for PMMA compared to polyamide. Lima et al in 2006 compared enzymatic cleanser with 0.5% (NaOCl) among different resin materials for the surface roughness. The present study, showed reduce roughness values of the resins when immersed in enzymatic cleanser compared to 0.5% (NaOCl) solution. This could be because of different fabrication techniques, duration of immersion, difference in composition of the resin materials, ease in polishing, temperature of the cleanser solution and the concentrations being used. Abuzar et al. conducted the study and mentioned the cut-off value (Roughness) Ra- 0.2 µm for the resin. Among the different brands of resin material, Trevalon HI resulted in reduce roughness values in all the three groups of cleanser solution, as it contains high cross linking structure which provides smoother surface.

The chemical nature of the cleansers affects the property of micro-hardness, an important factor which needs to be consider for the longevity of the prosthesis. Moussa et al in 2016 performed an in-vivo study that PMMA had higher hardness as compared to polyamide after 3 months of immersion in denture cleanser. C. F. Carvalho, et al. in 2012 demonstrated an in vitro study with 1% NaOCl solution on acrylic denture base resin. Result obtained was insignificant for the micro-hardness. Present study showed maximum effect on micro-hardness in Trevalon HI resin than Valplast resin, when immersed in of 0.5% NaOCl solution from the baseline to six months. This could be due to difference in the structural properties of materials and high cross linking of Trevalon HI.

Pinto Lde et al in 2010 stated that the Polyamide (Valplast) resins exhibits higher fibrous content that results in lower modulus of elasticity. Also, PMMA (Trevalon) specimens due to its continuous polymerization reaction and less release of monomer strengthen its hardness property compared to polyamide resin.

Conclusion

A very few literature have revealed clinical studies on the efficacy of enzymatic cleanser on the acrylic resins. From the results obtained it was concluded that, for color stability and micro hardness test P value of 0.05 was considered to be statistically significant. Furthermore, the study did not completely simulate the clinical scenario of wearing the dentures. Such difference may affect the result of surface treatment.

Life and Social Exclusion of the Third Genders: An Overview from Malabar Region in Kerala State

Leena Chandran¹, Suja M.K²
¹PhD Scholar, ²Chairperson, Department of Social Work, Amrita School of Engineering, Coimbatore, AmritaVishwa Vidyapeetham, India

Abstract

Transgender (TG) is the term which covers individuals who have a gender identity or gender expression than their assigned gender given at the time of birth. These individuals often cover themselves under one umbrella as the third gender. They are unable to identify themselves to a gender, either a male or as a female and they term themselves as the third gender. The society discriminates them since their behavior does not correlate with their congenital gender. The life of transgender is very difficult and stigmatized as they are considered as the most unwanted creatures of the society. Majority of them face discrimination from the society and the social stigma attached to them is so intense that they are ostracized from the main stream of the society.

Aim: To understand about the social exclusion and overall day to day life of the transgender. In this study Transwomen were the respondents Result: Majority of the transgender said that they are undergoing a miserable life and the stigma attached to them is much higher when compared to any other anti social people such as criminals, drug addicts or people with contagious diseases etc. There is significant association between the financial status and the stigma, education and the social exclusion, family support and social exclusion, family support and stigma, financial status and social exclusion. These variables are indirectly proportional to the exclusion and stigma towards the transgender. Conclusion: The study validates that when the financial status is high, or if the family support is more the social exclusion and stigma attached is less compared to those coming from low economic strata of the society. Transgender with lower economic standards normally have lower education level and they in due course of time are forced to leave their homes and end up as manual labor coolies or sex workers.

Key Words: Third gender, Transgender, Transwomen, Life, Social exclusion, Social stigma, Kerala

Introduction

Men and women are socialized into performing their respective genders which is similar to the sex assigned to them at the time of their birth and transgender does not fall in to that kind of parallel socialization¹. Deviations from these birth tagged socialization over a period are given a scowl look, confronted and stigmatized. Many manuscripts and historical evidences say that the third genders are celebrating their binaries since the time unknown. Even though they try to enjoy their privileges and cherish their importance in the myths and history the stigma attached to them makes “normal life” a dream and aspiration for them.
people born with female genitals and the assigned sex during birth is female but they find themselves as men and exhibit manly characters. Trans sexual are those who have undergone surgery to change their sex from the assigned one to the sex of their psychological choice (SRS- Sex Reassignment Surgery). They are also known as cross dressers.

Judgment of the Honorable Supreme court of India on 15th April 2014 says that, Often our society fails to realize the agony, fear and trauma which is faced by the Transgender community and also don’t value the innate feelings of them, especially whose gender is different from what is given at the time of birth. It is seen that the society often ill-treats and abuse TGs in the public places like bus stands, workplace, shopping areas, health systems, railways etc and they are marginalized and is treated as untouchables, neglecting the fact that it is the moral failure of the community to accept and to embrace different genders and their expressions and identity.

Methodology

This paper is based on the interview and discussions conducted with the transgender community in the Kozhikode District which comes under the Malabar Region of Kerala, India in the year 2018. The rationale behind selecting Kozhikode district for the study is that it is said to be the most TG friendly district in the state of Kerala. Semi structured interview schedule was used to know the basic living standards of transwomen and the research design was descriptive and diagnostic in nature. The age group selected for the study was between 25 years and 50 years. The researcher found that the transwomen community who dress themselves as women is very much visible to the community and they are more haunted by them. As the saying goes first impression comes from the dressing style of the person it is very easy for the public to locate them and to term them as Hijada, Transgender, Number 9, Aravanis, kothis (common terms used in Kerala). Keeping this “visibility factor” the researcher selected transwomen population for her study and collected data from 30 transwomen of the said age group using snowball sampling technique.

The real life of these trans-women is so miserable that they don’t earn minimum wages for their livelihood and in spite of the literacy rate of Kerala being high the stigma and ignorance towards this community is still prevailing in almost all walks of life.

Major Findings:

During the study it is seen that 60% of the respondents are non matriculate. When the society realized that these male individual are actually trans woman they slowly tried to avoid them from the inner circle and so this brought a stigma attached and hence they were forced to discontinue their studies. Vivek Diwan in his conversation with Kemal Ordek of Red Umbrella Sexual Health and Human Rights Association Turkey says that Discrimination in education makes many trans people quit before they finish their schooling, and they end up in sex work.

The transwomen of age group 20-25 says that they are accepted by the society and stigma attached is a bit less to them compared to Transgender of age 40 and above, the study also focused on their economic status and found that most of them (62%) comes from lower middle class families and their family members continue to be daily wage earners. Once their identity is revealed the stigma attached by the society towards the Lesbian, Gay, Bisexual, Transgender and Queer is more or less the same. The only difference is that it is not very easy to identify L,G,B or Q as cross dressed TGs. While checking the identity status more than half (56%) of the Transwomen expressed their strong desire to change their sex (Transsexual) by undergoing sex reassignment surgery. The consequential financial burden discourages them from realizing that dream. Some of them does Sex work along with daily wage works and only a few of them have single partner (38%). (16%) have a respectable job in the society like some government projects. 72 % of them are coolie workers and stage performance is done by many of them after their coolie works or whenever they are called for some local events.

To have a child is the ambition of many of them (84%) since they have inherent womanly characters in them. Almost all of them are ready to accept the fact that they can never bear a child (80%). They are in need of lenient laws in adoption covering their criteria of people. Most of the respondents wish to adopt a child (64%). The adoption policies in India are very strict and many of them can’t afford the additional cost involved. Some of them (21%) have become mothers of adolescent or teen age transgenders who came out of their home in search of their identity. Many of them are afraid to take
care of normal children (60%) because they fear that the stigma attached to them might pass to their “adopted children”. Considering marriage as criteria for leading a better life, TG marriages are not common in Kerala and they are not sure of the authenticity of such a marriage. Majority (42%) opines that their experience while “living together” is that, their partners might have multiple friends and many of such living together relationships end in separation. They admit and there is no bond between the partners (51%) as it is seen in a cis marriage (cis- person lives and performs physically and psychologically as what the gender is assigned at the time of birth).

Realization Phase: Majority (85%) of the transgender women (transwomen) realized that their gender identity is different and womanly characters are more in them during the age between 13 and 15.

Self Identity and Establishing Phase: 90% of the respondents said that they identified themselves as a woman during the age between 16 and 17.

Peer Group search: Most of the respondents (90%) tried to get out of the family in search of their peers during the age between 16 and 18.

Abuse:

Verbal – All the transgender women have faced verbal abuses within the family, from the society, and from their class mates.

Physical – 72% of them have undergone the tragedy of physical abuse and the rest 18% have heard sexual abusive comments. Among the 82% who have faced sexual abuse 23% is from their relatives and the rest from other neighbors, class mates and from other known people.

Domestic Violence – 73% of them said that they had to face domestic violence and verbal abuse from their family and they were forced to leave the house. Only 2 transwomen who was included in the study is staying within the family.

Partner Violence – A few 16% of the respondents said that they had to face violence from their partner and most of them left their partner due to this.

“I stay with my parents because they are aged and my elder sister is not willing to take care of them because she does not want to visit us due to my gender identity. I know she cannot cut off the blood relationship and in their words am her “brother “always. I know that she is showing this indifference because of her husband’s family and I too have adjusted to that. But she sometimes calls me. Thanks to mobile phones” – Remya (name changed) is worried about her aged parents and her sister’s family life.

The real difficulty of these people comes when they are visiting a hospital. The nursing and paramedical personnel , in spite of them holding high educational qualifications show indifference in their approach to these people hence many of them are reluctant to visit hospital unless and until it is such an emergency. Many of them prefer to consult doctors of the KSACS (Kerala State AIDS Control Society) who are known to them or to their family doctor, that too secretly. 56 % of them very seldom goes to a hospital for treatment because they are so stigmatized and many of them said that the other patients doubt they might be infected with HIV/AIDS. It is an irrational belief that Hijadas are infected with AIDS. Almost 86 % of them consult a personal/family doctor for having hormonal treatment and none of the respondents have undergone Sex Reassignment Surgery. Except 2 all other Transwomen included in the study are staying away from their family for one reason or the other they have inadequate support from their family. 35% of them visit their family once a month and a few of them once in 3 months and the rest once in 6 months. The advancement of modern communication technologies in mobile phones have reduced their sorrow due to isolation from their family they are able to communicate mobile phones.

“One of my neighbor don’t allow her kids to come to my house when am there, but thank God that her husband looks out for me whenever am there or he somehow manages to talk to me. What a contradiction (laughing). This is my situation and I can only assume what the neighbor man is thinking of me. This is the reality about us “– Says Remya (Name Changed)

The wide use of social media has made them much stronger and they are now getting their say in the society. Even though there is too much stigma attached to them by the society TGs find it convenient and safe to move around in the public. 40% of them say that the attitude of public is changing and they strongly believe that it is due to the influence of social medias. The awareness about
STDs and STIs is quite widespread amongst them and they periodically undergo medical checkup and follow a healthy physical relationship with their friends. They also conduct peer group counseling on the importance of use of condoms and periodic blood tests. The awareness programmes on STDs and STIs is having a high influence on their personnel hygiene.

**Evaluation:**

**Harassment and Stigma Attached to TGs.**

Between 2007 and 2014, around 1731 murders of transgender people was recorded globally and it is found that majority of those murders were very brutal - Human Rights Watch. Majority 95% of them had to face bitter experiences (mistreatment, denial of right to equality, lack of medical treatment) from the society and many of them lost the job or were not hired since the employer founds the gender difference in them. It is noted that these people find it very difficult to secure loans banks or other benefits from the government or banks. Severe harassment in educational institutions has made their education difficult hence many of them are dropouts. Gender based negative experiences and exploitation by the public and school/college mates have made them introvert due to which they lead an isolated life in the community alone.

“Poverty and gender violence have made our life miserable. We often dream of a life where people accept us and give us equality everywhere. In spite of the government identifying us a minority group, we are unable to enjoy the minority privileges and rights. Maybe we are born to suffer “ – says Rishi ( Name changed )

**Discussion and Conclusion**

“Recognition of transgender as a third gender is not a social or medical issue but a human rights issue,” - Justice KS Radhakrishnan. The study finds that majority of the TG population are still in the lower strata of the society. Even though there are policies for the uplifting of TGs the ultimate effect is not much, progress yet to be achieved. The TGs should be given the right to identify themselves as male or female or as a Transgender itself. Equality before law, self respect and dignity should be guaranteed in all strata of the society by the government. Strong laws should be enacted and agencies to monitor the same. Many of them are unaware of the basic rights enshrined in the constitution of India. They feel themselves as downtrodden, the ugliest and aversive class in the community. Lack of support from the family and society is the most fundamental issue which should be addressed strongly and there should be government run shelter homes for them if they are forced to leave their home for the reason they have self identified/realized what their gender originally is.

Identification and Analysis of L1 Syndrome Features in Patients with Mental Retardation

Madhan Srinivasamurthy¹, Nagaraj Kakanahalli¹

¹Research Scholar, ²Professor, Molecular Genetics Laboratory Department of Applied Zoology, Kuvempu University, Jnanasahyadri, Shankaraghatta, Shivamogga, Karnataka, India

Abstract

Background: L1 syndrome is an X-linked disorder with a spectrum of phenotypic features such as mental retardation, X-linked Hydrocephalus, Spastic paraplegia, Aphasia, and Adducted thumbs. The phenotypes are overlapping and Mental retardation is the most common symptom among individuals with the L1 syndrome. The L1 syndrome is caused by the mutations in the L1CAM gene and L1CAM gene is involved in the development of the nervous system.

Aims: The objective of the present study was to identify the L1 syndrome features in Mental retardation, and to assess the correlation between individual L1 syndrome features with mental retardation.

Method: We first identified the mentally retarded patients in various clinics, hospitals, and schools run by NGOs in Karnataka. Segregated the patient’s data based on the number of L1 syndrome features. And a detailed family history of the patients was collected and recorded.

Results: It was found that 77.39% of the MR patients have shared one or more clinical features of the L1 syndrome. Among them, 31.87% of patients have aphasia, 23.50% of patients have spastic paraplegia, 8.36% of patients have adducted thumb. The mean age at the referral of the patients was 14.53±5.53.

Interpretation & conclusions: This data revealed the co-occurrence of L1 syndrome features with Mental retardation. And the percentage of L1 syndrome features like Hydrocephalus, Aphasia, Spasticity, Adducted thumb, with mental retardation, is varied.

Keywords: Hydrocephalus, Aphasia, Spastic Paraplegia, Mental retardation.

Introduction

The hereditary neurological disorders are a diverse group of syndromes that often share common features such as Mental retardation, Brain malformations, Sensory disturbances, and muscle weakness. L1 syndrome is an X-linked inherited disorder that primarily affects the nervous system. The mutations in L1CAM gene cause L1 syndrome, and responsible for a wide spectrum of neurological abnormalities, which include mental retardation [1-2].

Studies have provided evidence for the involvement of L1 CAM mutations in various X – linked mental retardation syndromes [3]. Mental retardation is a common clinical feature of most neurological diseases. In India, there are 1.5 crore people suffering from severe mental disorders [4].

The genetics of mental retardation turns to be remarkably complex since it can result from causes...
as different as chromosomal abnormalities, genomic imprinting mutations, polymorphic repeat expansions or point mutations. Up to 28-30% of all Mental retardation cases arise due to chromosomal abnormalities. Despite that identification of a number of genes, the biological basis of the condition remains unknown, the using of molecular genetics techniques help in understanding the pathogenesis of mental retardation.

Progress in delineating the genetic basis of inherited forms of mental retardation is at present largely restricted to cases of X-linked mental retardation (XLMR), because the only X-linked recessive disease is compatible with the occurrence of affected members in multiple generations. The L1CAM gene on X-chromosome involved in causing mental retardation and also development of a group of syndromes like X-linked hydrocephalus, Spastic paraplegia, MASA Syndrome.

There have been numerous reports of families with similar forms of sex-linked mental retardation and other developmental anomalies that affect the nervous system. While the spectrum of clinical features varies, certain characteristics are common. Affected males generally have a low IQ (20-50). They might also have enlarged or asymmetric heads, Spasticity, Aphasia, and Adducted thumbs. Many families have hydrocephalus as a regular occurrence, but not necessarily in all affected individuals. The objective of the present study was to identify and co-occurrence of the L1 syndrome features in Mental retardation. And to analyze the relationship between L1 syndrome features with mental retardation.

Material and Method

Study design

The present study was approved by an Institutional Ethical Committee of the University (KU/IEC/05-09/2014-15). The study samples primarily comprised of patients with Mental retardation. In this present study, we have covered seven Hospitals in four Districts of Karnataka.

Procedure:

We surveyed more than 146 mentally retarded patients and, under L1 syndrome diagnostic criteria 113 L1 syndrome patients have been identified. Among them, some of the patients were previously diagnosed by the Doctors and some of the patients were identified with the help of doctors and clinical diagnosis. In order to collect the clinical data, the standardized questionnaire was prepared and a detailed family history of the patients was collected and recorded. All subjects have given written informed consent. The medical records were reviewed carefully for the presence of L1 syndrome symptoms. And also each patient was examined for the presence of any L1 syndrome symptoms like Hydrocephalus, Adducted thumbs, Spasticity, Aphasia, Shuffling gait, Anteverted hips, and shoulders.

Statistical Analysis

Data were analyzed using SPSS 20.0. Segregated the collected data and analyzed the phenotypes by using frequency distribution. The mean value and standard deviation (SD) were calculated for each case and each L1 syndrome feature was statistically compared using Student’s t-test.

Results

Clinically the patients were subdivided into 2 categories: 1. Isolated Mental Retardation (Mental retardation without L1 syndrome features) (22.6%). 2. Mental retardation with L1 syndrome features (77.39%) (Fig. 1).

Over 77% of the Mental retardation patients displayed a combination of various L1 syndrome features. So, the rate of the predominance of the L1 syndrome in mentally retarded patients is high, suggesting that the mental retardation is one of the primary and common clinical clues to identify the L1 syndrome patients.

Isolated Mental Retardation (Mental retardation without L1 syndrome features):

Among 146 patients 33 patients suffered from isolated Mental retardation. The family history of the 13 patients (39%) were positive. The IQ was assessed and found to be mild (57.7%), moderate (33.3%) and severe (9%).

Mental retardation with L1 syndrome features:

The patient data was analyzed based on clinical features. Among 146 patients 113 patients have shared one or more clinical features of the L1 syndrome (Fig 1). 80 MR patients have aphasia, 59 MR patients have spastic paraplegia (Fig 1).
Fig. 1: L1 syndrome features in Mental retardation

Present data shows that the IQ range of L1 syndrome patients, 50.44% were moderately affected, 30% were mild, and 19.46% were severely affected. Here, the prevalence of moderately and severely affected patients in L1 syndrome condition was more (70%) compared to isolated MR condition (42.3%).

Table 1 depicted the mean carries prevalence according to the types and severity of the L1 syndrome features. The mean of MR patients and L1 syndrome patients were 0.97±0.16 and 3.18±1.78 respectively, and the patients who have MR+L1 syndrome feature had the highest score. There was a statistically significant difference among them (p<0.05). Based on the types of L1 syndrome features, there was a statistically significant difference for the mean of all feature. Patients with MR + Aphasia had the highest mean score 0.55±0.49. However overall mean score of MR+L1 syndrome features were high 3.18±1.78 and this score was statistically significant.

Patients displayed a maximum number of L1 syndrome features:

The 23 patients displayed a maximum number of L1 syndrome features (Table 2). Main L1 syndrome features included Spastic paraplegia, Aphasia, Adducted thumb, Anteverted hips/shoulders. Patient M3 had Spastic paraplegia, walking on toes with semi-crouched legs and his family history reveals 2 babies born died before the birth of patient M3, the reason unknown for this. Patient SS6 had an Adducted thumb, progressive stiffness and contraction in lower limbs, bowed knees, irregularly shaped pupils, and inability to speak, and died at the age of 3 years. Patient SEC1 presented walking disability, shuffling gait, inability to speak. The older sister of the patient SEC46 had similar phenotypic features. The patient M5 display congenital Hydrocephalus with the Adducted thumb, Mental retardation, and Aphasia.

Age at referral for diagnosis:

The age at referral for diagnosis of L1 syndrome patients was available (n=113/146) and the range was highly variable (2.0-32.0 years, mean = 14.5 years); 32 patients (28.31%) were referred at ≤ 10 years of age, 55 patients (48.67%) between > 10 and ≤ 20 years of age, 18 patients (15.9%) between > 20 and ≤ 30 years of age, and 08 patients (7.07%) were > 30 years of age (Fig. 2). In MR with L1 syndrome condition the patients aged >30 years were found to be 7%, while in isolated MR condition patients aged >30 years were found to be 27%.

Discussion

We report a cohort of patients with Mental retardation. Some types of human Mental retardation and brain malformations are found to be due to mutations
that affect the neural cell adhesion molecule L1 \[13\]. These mutations in the L1CAM gene lead to developing an L1 syndrome. Preliminarily we identify the L1 syndrome patients based on several phenotypes like, Mental retardation, Hydrocephalus, Aphasia, Spasticity, Epilepsy, Adducted thumb, etc., and the patients or MR children who had more than three symptoms, indicates the particular patient suffering from L1 syndrome \[14-15\]. Results showed that 77.39% of the MR patients had more than one L1 syndrome characteristic and the severity of the L1 syndrome is found to be high.

Affected males generally have a low IQ \[10\]. In the present study, it was observed that 50.44% of the L1 syndrome patients have an IQ range below 70, and 19.46% of patients have an IQ range below 35 (severe). Moderate IQ patients were more in L1 syndrome condition while mild ones are more (57.7%) in isolated MR condition.

In L1 syndrome, the spectrum of clinical features varies, that certain characteristics are common \[10\], and it is in congruent with the present study. MR was the most common disability among the patients examined followed by with spasticity in lower limbs (p<0.001), Aphasia and Adducted thumb (p<0.05). Many families have hydrocephalus as a regular occurrence, but not necessarily in all affected individual \[10\] (p=0.045). Followed by Anteverted hips/shoulders (p<0.004) highly significant with other L1 syndrome symptoms.

A combination of patients with positive family history and more than three L1 syndrome characteristics was considered as a severe L1 syndrome condition \[14\]. The present study revealed similar results 83% of the MR patients associated with more than three L1 syndrome features and 53% of the patients had more than four features with nearly 48% of the patients had a positive family history. 55% of the patients were found to have consanguineous parents or marriages.

In L1 syndrome patients, only 7.07% of the patients found to be above 30 years of age. It was much variable compared to isolated MR condition (27.2%). It suggests that the survival of the MR patients with L1 syndrome condition has shown to be decreased in contrast to isolated MR patients.

Finally, it should be noted that MR is the primary symptom in L1 syndrome condition but the severity of the L1 syndrome is significantly dependent on a number of associated characteristics. And more than four L1 syndrome characteristics in an individual MR patient strongly predict the severity of the L1 syndrome.

**Conclusion**

To the best of our knowledge, only two to three studies \[3,17,18\] reported from India. The present study is first of its kind from the southern region of India to identify the L1 syndrome patients based on clinical characteristics. Our findings support that L1 syndrome is associated with widely heterogeneous phenotypes \[16\]. This data revealed that the co-occurrence of L1 syndrome features in mental retardation is varied.

Identifying L1 syndrome symptoms and L1 CAM mutations in the L1CAM gene would enable us to offer prenatal diagnosis and genetic counseling for families at high risk and also create awareness and guidance among the parents and society.

**Future prospects of the study:**

Since there is no biochemical marker, molecular analysis of the L1 CAM gene is the only way to diagnose affected individuals \[19,20\]. Hence, the present study is the first step to identify the L1 syndrome features among MR individuals and diagnose the affected families. Therefore, all male patients with two or more clinical signs typical for the L1 disease should be screened for L1 CAM gene mutations.

Adoption of Telemedicine among Dental Healthcare Professionals

Preeti Y Shadangi, Manoranjan Dash, Prof. Ayasakanta Mohanty, Jyoti Ranjan Das, Sunil Kar, Bibhuti Bhusan Mishra

Abstract

Telemedicine system within the healthcare organization are gaining momentum growth as healthcare organizations need to cut their expenditure and improve efficiency in health care services to patients remotely. The purpose of this study is to provide insights into factors affecting the adoption of telemedicine in India among Dental health care professionals working in different dental colleges and hospitals. The study proposed a model to explain the adoption of telemedicine by taking 151 dentists from India and incorporating the variables of perceived usefulness, perceived ease of use, perceived risk, perceived cost, compatibility and trust. These construct explained adoption of telemedicine in delivering the dental services remotely to patients. Trust and risk were the most significant antecedents explaining the adoption of telemedicine.

Keywords: Telemedicine adoption, Trust, Perceived usefulness, Structural Equation model.

Introduction

Telemedicine being valued as a effective digital tool to provide health care services remotely to patients where patients will not be waiting in a queue for hour . As per survey conducted by Deloitte’s of US Physicians, 23% patient had visited video visit and 14% physicians as video visit capability. This indicates the technology has not reached the point of mass adoption and use. Telemedicine is the use of ICT provide healthcare when distance separates the patients. Telemedicine is defined as the use of “the use of electronic information and telecommunications technologies to support and promote long-distance clinical health care, patient and professional health-related education, public health and health administration”. There has been a tremendous increase in demand of telemedicine for healthcare services, both nationally and globally. This sector has been growing at a tremendous pace, with the industry to touch $280 billion by the end of 2020, according to Statista.com. In India, though the healthcare sector is seeing a giant leap in providing services to the consumers, it has still not been able to expand its market in rural areas. Around 75 percent of the rural population is struggling with insufficient infrastructure and technological awareness. In such a scenario, where penetration of healthcare services hardly lives up to the mark, the concept of telemedicine makes so much sense. India has large shortage of doctors where 12,000 ophthalmologists are present in India and practicing mostly in urban areas. Teleophthamology is a new branch of telemedicine which has been successfully implemented in Tamilnadu for providing health care services to rural people. Telemedicine is broad area, but there are limited data on its clinical effectiveness and cost effectiveness of the telemedicine applications. Many benefits of telemedicine are access to information, improved access to services, improved professional education and reduced health care costs. It has many drawbacks i.e. breakdown of
relationship between health professionals and patients. Access to qualified healthcare providers, specialized consultation, timely diagnosis, accurate prognosis, effective course of treatment, and lots more can benefit rural folk and bring down the disparity in healthcare offerings between the rural and urban areas. The current technology penetration, growing population, advancing economy, and accelerating healthcare industry are all responsible for the increased demand in digital healthcare. The objective of the study is to find out the factors affecting adoption of telemedicine by the dental health care professionals working in different dental colleges and hospitals.

**Literature Review**

Ray et al (2017) studied on family perspectives on telemedicine for pediatric subspecialty care, telemedicine programs provides many facility and the options for the choice of health care delivery by patients. It is very crucial to understand perceptions and preferences which is crucial to ensure good health care delivery to patients. Pedrosa et al (2017) integrate telemedicine program with other programs thus leading to improved outcomes of pediatric patients with cancer. Yen et al (2015) The study was to explore the factors influencing physician’s intention of adopting telemedicine and they had included the TPB(Theory of Planned behavior) model. Attitude, subjective norm, perceived behavioral control were positively related to behavioral intention. Different strategies has been formulated for experienced and non experience physician’s. Judy K. Qiang, Connie Marras (2015) study of telemedicine in Parkinson’s disease found patients preferred a combination of tele-health and in-person visits. Training of nurses is an important determinant of patient satisfaction. Clinicians should consider offering telehealth to all patients for whom it is medically appropriate, especially those who experience long travel times. Mi Jung Rho1, In young Choi1, Jaebeom Lee (2013) found perceived usefulness of telemedicine directly impacted the behavioral intention to use it, and the perceived ease of use directly impacted both the perceived usefulness and the behavioral intention to use it. Dayani Jayasinghe, Richard M. Crowder, Gary Wills (2016) focusing understanding culture as important factor when implementing a telemedicine system in the rural areas of the country.

E Souza Carlos Henrique Amaral, Morbeck Renata Albaladejo (2017) found the barriers of telemedicine services are Lack of experience in the use of technology or the quality of internet signals, Multiplicity of different telemedicine platforms, Quality of image sent to the HT hospital and Political & legal issue. Rajesh et al (2015) in their study identified barriers in optimal use of telemedicine technology in health care delivery System in India are policy resources and socio-cultural levels. Successful implementation can be entailed if different stakeholders are taken into consideration i.e. doctors, paramedical and non paramedical staff, policy makers and the target community for whom it is design. Menachemi N et al (2004) identified five attributes affecting inovation adoption rates for the four adopter groups i.e physicians, patients, hospital administrators an payers. Zanaboni Pet al (2014) Telemedicine has been widely adopted due to geographical reasons but the level of use is very low and it is an alternative to face to face outpatient visits. Dash Manoranjan, Shadangi Y Preeti and Kar Sunil (2019) study on adoption of telemedicine has included the Theory of Planned Behavior (TPB) model and other predictors were included in the Extended model for predicting adoption of telemedicine among physicians.

**Material and Method**

The respondents included in the study were dental health professionals working in different dental colleges and hospitals. Stratified random sampling was used for selecting the respondents. Total 345 respondents participated from which only 151 questionnaires were accepted and analyzed. The reliability and validity of questionnaire was tested. The Cronbach alpha reliability was found to be .895 Structural equation modeling was used to validated the model to ascertain both stability and reliability of instrument. The respondents were asked on a 5 point likert scale with values ranging from (1 Strongly agree to 5 Strongly Disagree).AMOS 20 Software was used analyze the model and path analysis was done. Multiple regression analysis was done to find out the predictors on adoption of telemedicine. All the predictors were significant on the adoption of telemedicine.

<td>.20</td>
</tr>
</tbody>
</table>

The Model has χ2/df value of 2.72 with a p value less than .0001. This indicates a good fit of the model. THE CFI (Comparative fit Index) value falls within the range from 0 to 1. RMSEA has a value of 0.10. The calculated p value is 0.073, which is greater than 0.05 which indicates perfect fit. The GFI (Goodness of Fit Index) value and AGFI (Adjusted Goodness of Fit index) value is greater than .9 which represents it is a good fit. The calculated CFI (Comparative Fit Index) is 0.978. It indicates the model is a good fit.

Discussion

The different factors as identified for adoption telemedicine by health care professionals are perceived cost, perceived risk, perceived trust, perceived ease of use, perceived usefulness, and compatibility. All factors identified had significant effects on the adoption of Telemedicine of this technology. The factor compatibility with the process of delivery health care services was identified as a factor for affecting adoption of telemedicine. Since the requirement of services varies among professionals so it is advised to try to differentiate services and offer services as per the requirement of the dental professional. Trust was identified as the influential factor. Most dentists are concerned about trust on technology while adopting the new technology and trusting technology is important while doing their jobs. Technology has to be more trustworthy. Perceived usefulness has a strong influence on adoption of technology as they get more advantage from the use of the technology. Perceived ease of use is an important factor in adoption of new technology. Perceived risk was identified as the factor in adoption of telemedicine adoption. As a result, the extent to which a person believes that the use of telemedicine will carry no security or privacy threats may be more significant in determining telemedicine usage intentions. So it is recommended to prove security of services and employ guaranteeing and motivational policies to reduce professional’s perceived risk. Improving working processes, reducing potential errors, and accuracy of treatment would be beneficial for reducing the risk.
Conclusion

The study found the factors that affect the adoption of telemedicine by dental health care professionals; It is useful for understanding healthcare professionals willingness for adoption of telemedicine in order to deliver dental services through remotely to patients. The model accurately predicts the adoption of telemedicine. Trust and risk are the important factors that affect the adoption of telemedicine. Telemedicine are well accepted by dental health care professionals.

Ethical Clearance: Not Required (It does not involve any experimental data collected from human as well as Animals. The data is collected from Dental health Care Professionals working in different Hospitals which purely their personal view or opinion which does not violate the ethical standards.)

An Empirical Study on Association of Operational Efficiency and Customer Satisfaction in Tertiary Hospitals in Punjab

Pritpal Singh¹, Mohd Farhan², Mohammad Asif³

¹Assistant Professor, Mittal School of Business, LPU, ²Assistant Professor, Mittal School of Business, LPU, ³Assistant Professor, College of Administration and Finance Saudi Electronic University, Dammam, Kingdom of Saudi Arabia (KSA)

Abstract

Through this paper framework is created for association between efficiency and customer satisfaction in tertiary hospitals of Punjab. Efficiency is calculated using data envelopment analysis and satisfaction is measured using a structured questionnaire for inpatients of 8 tertiary hospitals of Punjab (3 from each region of Majha, Malwa and 2 from Doaba). Data envelopment analysis (DEA) is a non-parametric method of measuring operational efficiency of decision making units. DEA is having strong link to production theory in economics. DEA uses technique of linear programming for calculating relative efficiencies of decision making units working individually with respect to specified inputs and outputs. This paper analyzes the relation between hospital efficiency and customer satisfaction for highly efficient and less efficient hospitals in comparative perspective. The findings of paper indicate hospital efficiency observes some changes the way relationship is between patient satisfaction and institutional factor like specialized doctors and specialized equipment.

Keywords: Data envelopment analysis, Operational Efficiency, customer satisfaction

Introduction

Rising healthcare cost and quickly expanding medicinal services request have constrained human services specialist co-ops to concentrate more on both efficiency and quality to give tertiary dimension health awareness administrations. Effective use of assets has moved toward becoming issue for emergency clinics. Health care specialist organizations are typically compelled to build up their activities both in term of value and amount of their results. Availability of healthcare services is problematic in developing countries like India where bed to patient ratio is 1:1000 which comparatively very high as US and Japan. It is important to concentrate on maximum utilization of available resources while taking care of quality of service provided to customers. Recent research also indicates that focus on quality as well as quantity are essential dynamics of administrators.

The other inspiration driving this study has been to see how to address a portion of the concern of benchmarking under changing situation in the healthcare part (¹). With the opening of private medical coverage part in the post-liberalization period, the ideas of effectiveness with which the assets are utilized would expect more prominent importance in future. The requirement for creating proficiency parameters and foundation, which helps in positioning of health centers, is prone to accept basic significance (²).

Shortage of assets for human services is a very much recognized issue. In this unique circumstance, effective usage of existing money related and human resources ends up essential for reinforcing the medicinal services conveyance. The evaluation of effectiveness of wellbeing offices can direct leaders in guaranteeing the ideal usage of accessible assets (³). Information envelopment examination (DEA) has risen as a viable and mainstream strategy for assessing the effectiveness of basic leadership units (DMUs) in various areas including the wellbeing segment. There have been various examinations on evaluating the proficiency of clinics,
wellbeing focuses and the general medicinal services framework by utilizing DEA in various settings\(^{(4)}\). These investigations have been led in industrialized nations just as in center and low-salary nations, including India. A few analysts have likewise attempted broad surveys of productivity thinks about utilizing DEA in the medicinal services division\(^{(13)}\). In any case, up to this point there is no examination accessible on the effectiveness appraisal of medical clinics in Punjab, India.

Along these lines, the essential research addresses managing this study are as per the following:

**Is there any immediate or indirect effect of hospital efficiency on patient satisfaction**

**What sort of a relationship exists between specialized doctors and equipment’s availability and hospital center efficiency on patient satisfaction**

**Research Framework**

The proposed research framework of our study is presented in Fig. 1.

Three primary hypotheses are as follows

**H1.** Specialized doctor and equipment’s availability has a positive effect on patient satisfaction.

**H2.** Hospital efficiency changes the form of the relationship between. Specialized doctor and equipment’s availability and patient satisfaction as a moderator variable.

**H3.** Hospital efficiency is in correlation with specialized doctor and equipment’s availability

In some studies by researchers that some infrastructural factors like such as hospital size, teaching activity, and location might affect the patient satisfaction but patient satisfaction and efficiency are primary areas of our study but we include one institutional factor of hospital size in our study thus following model is used to find relation\(^{(5)}\).

\[
\text{Patient satisfaction} = f (\text{Specialized Equipments, specialized doctors, hospital efficiency, hospital size})
\]

**Material and Method**

Data for patient satisfaction is obtained from patients and patients companion of 8 tertiary hospitals of Doaba Majha and Malwa area of Punjab using structured questionnaire consisting of 42 questions which has been been framed evaluating each dimension, overall satisfaction and efficiency on the Likert scale ranging from 5 (mostly liked) to 1 (not liked), a sample of 780 patients are taken survey covers both private and public tertiary hospitals of Punjab, respondents are mostly in patients with minimum 1 day of stay in hospitals and from 4 different departments\(^{(6)}\).

Data envelopment analysis is used for evaluating efficiency of hospitals with set of input and output values for calculating efficiency, To Find operational efficiency Hospitals DEA frontier Software is used DEA Frontier software is developed and coded by Dr. Joe Zhu. It consists of a series of DEA models and is an Add-In for Microsoft Excel. (Dr. Joe Zhu is Professor of Operations Analytics in the Foisie Business School, Worcester Polytechnic Institute.). Inputs selected in calculating efficiency are No. of beds, Specialized doctors and No. of nurses there are various modes used to evaluate efficiency using DEA but we used Constant return to scale efficiency model in this paper.

Emergency clinics are considered to have extremely less power over their yields like inpatient days or releases. However, it is bound to expect that medical clinics have more power over the usage of assets. In this way, an info situated DEA show is broadly utilized for assessing the efficiencies of clinics. Likewise, in this paper, an info arranged DEA demonstrate has been viewed as proper. Nitty gritty discourse of DEA can be found in the investigations of Cooper et al\(^{(12)}\).
Output of DEA based model

Findings

In first stage efficiency is calculated by data envelopment analysis constant return to scale model using multiple inputs and .The return to scale refers to changes in output as all factors changes by all proportions in input there is increasing return to scale decreasing return to scale and constant return to scale. Increasing return to scale means in input is doubled production will a\'is more than doubled, decreasing return to scale means if input is doubled production will be less than doubled[7], and Constant return to scale means output changes in
same proportion as compare from efficiency scores hospitals are divided into two categories highly efficient and less efficient

In second stage to investigate effect of hospital efficiency, specialized doctors, equipment’s on patient satisfaction following regression model is used

\[ Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_1X_2 \]

One of our research questions is how to examine effect of efficiency on patient satisfaction for that we used above written model in which \( Y \) is Patient satisfaction, \( X_1 \) is efficiency, \( X_2 \) is specialized doctors and \( X_3 \) is institutional factor hospital size. Term \( b_4X_1X_2 \) represent the moderator effect of hospital efficiency on relationship between patient satisfaction and availability of specialized doctors Value of efficiency, specialized doctor availability and institutional factor hospital size is mentioned in below mentioned table.

**Table 3: Data of efficiency, satisfaction, Hospital size and specialized doctors of 8 hospitals**

</table>

In above mention table overall statistics of eight hospitals are mentioned which include value of patient satisfaction which is collected from questionnaire from patients and companion of 8 hospitals. Data of efficiency which is calculated using data envelopment analysis technique of using excel solver, size of hospital which is counted from number of beds in hospital and number of specialized doctors and in below mwnition table hospitals are divided into three categories of large sized hospital small sized hospital and mediem sized hospital based upon number of beds in hospitals.

**Table 4 Descriptive statistics of hospital efficiency, satisfaction**

<table>
<thead>
<tr>

<td>1003.00</td>
<td>70.00</td>
<td></td>
</tr>
</tbody>
</table>
From the above mentioned it can be easily analyzed that small and medium size hospitals are having high efficiency and patient satisfaction as compared to large sized hospitals and if talk about specialized doctors and availability of specialized equipment’s however average efficiency and patient satisfaction is higher for small and medium size hospitals.

To study impact of efficiency, hospital size and specialized doctors on patient satisfaction we used regression in second stage the following model is used to analyze

\[ Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 \]

<table>
<thead>
<tr>
<th>Model</th>
<th>Unstandardized Coefficients</th>

<td>-2.531</td>
</tr>
</tbody>
</table>

a. Dependent Variable: Satisfaction

This model is significant at \( p<.05 \) level here number of specialized doctors increases patient satisfaction providing support to hypothesis H1 \( b_2=.226 \). However hospital size is having negative impact on patient satisfaction \( b_3=-.033 \). But efficiency is not having significant effect on patient satisfaction there might be the case indirect relation between hospital efficiency and patient satisfaction. One of our major research question is how efficiency the form of relationship between no of specialized doctors and patient satisfaction to evaluate this second stage regression analysis is done with moderator effect. The equation is as follows for second stage regression analysis

\[ Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_1X_2 \]

Interaction term \((bX1X2)\) represent the moderator effect of hospital efficiency on the relationship between specialized doctors and patient satisfaction.
The second model is also significant and regression analysis result explains that efficiency is considered to be negative moderator between relation of number of specialized doctors and patient satisfaction. Results in table suggested that higher level of efficiency level of hospitals lessen the positive effect of specialized doctors on patient satisfaction. In this way, medical clinic productivity variable applies a negative control between accessibility of specialists and patient fulfillment\(^{(10)}\), as we theorized. Moreover, discoveries give the proof that medical clinic size has critical negative impact on patient satisfaction\(^{(11)}\). As connection among effectiveness and specialist is characterized by two techniques basically customary methodology and TQM approach. In request to think about these a connection between proficiency of medical clinics and number of specialist accessibility was dissected. As emergency clinics dependably work with various economies of scale relationship is established in term of clinic estimate relationship coefficients are analyzed and found that there was negative relationship between’s two variable for little size clinic as contended by conventional methodology no huge for medium measured and huge positive for huge size medical clinics\(^{(11)}\). There is contrast between connection of huge size and little size hospitals it implies customary methodology is upheld for little size medical clinics of value trade off while extensive emergency clinics work with TQM approach.

a. Dependent Variable: Satisfaction

As connection among effectiveness and specialist is characterized by two techniques basically customary methodology and TQM approach. In request to think about these a connection between proficiency of medical clinics and number of specialist accessibility was dissected. As emergency clinics dependably work with various economies of scale relationship is established in term of clinic estimate relationship coefficients are analyzed and found that there was negative relationship between’s two variable for little size clinic as contended by conventional methodology no huge for medium measured and huge positive for huge size medical clinics\(^{(11)}\). There is contrast between connection of huge size and little size hospitals it implies customary methodology is upheld for little size medical clinics of value trade off while extensive emergency clinics work with TQM approach.

### Conclusion

Curiously, large size hospitals are not executing just as little and medium size medical hospitals regarding scale effectiveness. In this way, these medical hospitals don’t work at ideal scale estimate. As recommended, expansive size medical hospitals may frame littler patient consideration units inside their own association. Along these lines, extensive size hospitals not just dispense with the negative impact of their non-ideal scale measure, yet in addition they shape explicit treatment units for patients\(^{(11)}\). Then again, low specialized productivity of large-estimate emergency hospitals could be halfway clarified by the imperfection of result estimation. In second stage investigation we analyzed that particular specialists has positive effect on patient fulfillment, anyway effectiveness contrarily directs the relationship this implies understanding fulfillment changes because of accessibility of specialists may be affected by dimension of medical clinic productivity. So hospital clinics can chip away at lessening their procedure cost and on the off chance that quiet thinks proficiency starts things out for clinic, at that point it will make negative effect as a primary concern of patient. Just concentrating on the powerful usage of assets without fundamentally thinking about quality. Presently emergency clinic directors have a decision. They can overlook efficiencies and simply center around accomplishing high-est nature of consideration, or the other way around. Now an ideal arrangement may be “ideal consideration.” as Rewar, D. Indi-cated, “ideal consideration” could be accomplished by considering a “balance” among proficiency and quality. Further utilization of Linear Programming, Simulation displaying and other numerical devices can be valuable for operational booking, asset allotment investigation for medicinal services managers

Abstract

Aim: The purpose of this study is to assess the consumption patterns of school canteen food among children aged 10-12 years in Mumbai city.

Methodology: A cross-sectional study was conducted among 300 children in the age group of 10-12 years to assess their food preferences in school canteen and tiffin through a self-administered questionnaire. Anthropometric measurements were taken. 20 schools across Mumbai were randomly selected to assess the school food environment. The canteen food menu was recorded through observation and classified into HFSS and Healthy foods. Perceptions of canteen operators regarding healthy foods were assessed through interviews. Adherence to Government’s guidelines for addressing the consumption of HFSS foods in schools was examined.

Results: Higher percentage of students from private schools are overweight or obese, as compared to government school students (p<0.005). 65% children carried HFSS foods in tiffin. A significant association was found between the frequency of eating at canteen and the type of school that the children belong to (p<0.005). 41.2% children who ate from the canteen more than 3 times a week were overweight. HFSS foods brought more sales to 78% of all participating schools. It was found that none of the 20 schools completely followed all the 7 guidelines addressing the consumption of HFSS foods in school canteens.

Conclusion: Easy availability and affordability of HFSS foods, combined with less availability of healthier food choices are contributing factors to increasing obesity among children. There is an urgent need for the enforcement of proper school canteen policies and modifications in the canteen services.

Keywords: Unhealthy foods, HFSS, school canteen, adolescents, food choice, obesity, government.

Introduction

Adolescence is a phase of multi-level growth and development. Risk-taking behaviour begins to develop in this age and there is a strong desire for social-evaluation and social-acceptance.¹ As they begin to lead a more personalized lifestyle, food preferences begin to change and there can be various determinants for this.

The globalization of fast foods has opened the gates for many alternatives to choose from, for every consumer.² Unhealthy food choices are one of the most important precursors of overweight, obesity and development of Non-Communicable Diseases.³ The rise in intake of HFSS foods i.e. High fat, high salt and high sugar foods and fast foods have led to an evolution in dietary patterns.

Adolescents spend 6-7 hours in a learning environment, 5 days a week.⁴ School policies and practices targeting nutrition and physical activity, are capable of meaningfully impacting students’ health.⁵ Thus, the school environment can have a significant role to play in developing the right eating habits and spreading awareness about the ill effects of unhealthy foods and for the promotion of healthy eating behaviours.

Materials and Method

20 schools in Mumbai that provided the consent for participation were included in this study. 300 children from 2 government and 2 private schools aged 10-12 years, were selected via randomized cluster sampling, and administered a Multiple Choice Questionnaire. This comprised of questions regarding the frequency of carrying a tiffin to school, the types of food carried in tiffin, frequency of eating from school canteen or food sellers in the campus, most preferred food items, most popular foods available, and factors affecting their food choice. Anthropometric parameters of the children including height, weight, waist and hip circumference were measured.

The food menu of the 20 schools was recorded in an Observational Inventory, made by categorizing foods under ‘High fat’, ‘High salt’, ‘High sugar’ and ‘Healthy’.

Food Standards and Safety Authority of India (FSSAI) 2015 specifications for identifying HFSS foods were considered for the cut off values of nutrients. The food menu of the 20 schools was recorded in an Observational Inventory, made by categorizing foods under ‘High fat’, ‘High salt’, ‘High sugar’ and ‘Healthy’.

Canteen operators were interviewed using a Structured Interview Schedule to get an insight about their perceptions of healthy foods, demographics and sales of canteen, presence of canteen policies and other aspects related to canteen management.

The 7 guidelines laid down by the FSSAI in collaboration with the Ministry of Women and Child development for the quality, quantity and type of foods available in school canteens have been made mandatory to be followed by all schools. The Adherence to these guidelines was examined through interview and observation.

Findings

Anthropometric results

This study concluded that children studying in private schools had a higher weight, BMI, waist circumference, and hip circumference children from government schools (p=0.001), which is shown in Table 1. This highlights the possibility that those belonging to high socio-economic status, preferably studying in private schools, had a higher prevalence of overweight and obesity. The availability of unhealthy food options in tiffin, and more importantly in school canteens have been known to affect the weight status of children. It was found that 41.1% children who had the frequency of eating from the canteen more than 3 times a week were overweight and 31% were obese.

Affordability of HFSS foods

Higher socio-economic status (SES) would provide better affordability, which is one of the determinants of making food choices. Most of the HFSS foods are priced between 5 to 20 rupees, which makes it quite affordable to students, thereby facilitating more consumption.

The present study indicates that a higher percentage of government school children ate from the canteen 3 times a week or every day of school compared to children from private schools. (p<0.005). Figure 1 illustrates the frequency of eating from the canteen with a comparison between children from both the type of schools.

Figure 1: Accessibility of HFSS foods

Easy accessibility of unhealthy food options interferes with the possibility of making a healthier food choice. Location of the canteen contributes to the accessibility. Findings show that the 80% of schools that had a canteen within the school campus had 46% of HFSS foods in the menu. The remaining 20% schools with food stalls or vendors outside the campus or at the school gate, had 73% HFSS foods available. This compels the children to buy more HFSS foods than healthy foods because of the easy access.

Availability of HFSS foods

Across all school canteens surveyed in the present study, the canteen menu consisted of 60% foods that were...
HFSS foods. As shown in Figure 2, a higher percentage of government schools had high salt foods (71.40%) and all of them (100%) had high sugar foods available in their canteens, as compared to private schools who had a higher percentage of high fat foods available (100%). It has been found in multiple Indian and western studies that canteen food services offer unhealthy foods.9-12

Figure 2:

Another physical aspect of the school food environment that impacts the dietary habits of adolescent school children, is the tiffin box. 80% of the participating children carried tiffins to school, out of which 65% carried HFSS foods in their tiffin. Even when children are carrying tiffins, 86.8% of them still prefer to eat from the canteen. Thus, regardless of carrying a tiffin, children liked to indulge in canteen foods.

Lack of healthy food options

High fat and high salt foods from the canteen appeared to be favourites among children. (Table 1) Students’ preference for unhealthy foods has been found to influence what is sold in the canteens.13

This supports another finding of this study that a higher percentage of both government and private schools (74.15%) stated student demands and cost effectiveness as the key factors for determining the menu of the canteen.

As Table 1 shows, HFSS foods contributed to majority of the total canteen sales wherein more high salt and high sugar foods were sold in private schools than government schools. 18.7% of the schools also depended on easy methods of preparation and faster services as another important aspect of deciding the menu. This is where the proclivity for fast foods comes into the picture. Children stated their preference for canteen foods mainly for their taste, followed by lower costs, availability and convenience. These findings form a potential link between the demand and supply of unhealthy food options in schools.

*IAP z scores*: High waist circumference = >0.525, above 70th percentile

**Overweight** = 0.55-1.34 (males), 0.67-1.64 (females); **Obese** = >1.34 (males), >1.64 (females)

*High fat foods* = Vada pav, samosa, Frankie, bread pakoda, bhajiya, French fries

*High salt foods* = Fried rice, schezwan rice, noodles, Chinese bhel, manchurian, chips, wafers

*High sugar foods* = Chocolate, pastry, icecream, lollipop, ice candy, toffies, doughnut

*Healthy foods* = Idli, dosa, Veg paratha, Dal rice, Veg pulav, Roti sabji, upma, poha, khichdi, Veg sandwich, milkshake, fruits, egg.

Perceptions of canteen operators and barriers to change

Most of them believed that it was not feasible to offer healthy foods in a canteen. The cost effectiveness for each food item on the menu is a top priority. Apart from this, several barriers are faced by the canteen operators, the major one being the singular role of school principal in the final decisions of canteen services which deprived them of flexibility of frequent experimentations. Lack of response on the side of children to buy new, healthier substitutes on the menu was another issue. The logistics involved for introducing new, healthy options put a speed breaker in making even the slightest change.

Adherence to government guidelines

The present study is one of the first Indian studies to evaluate the adherence to these 7 specific guidelines by the schools. It was found that none of the 20 schools completely followed all the 7 guidelines. Figure 3 clearly indicates that Guideline 1, which bans the sale of HFSS foods in school canteens was clearly not followed by 90% of schools. Evidently, there is a lack of enforcement of these guidelines and recommendations.

Figure 3:

Role of school authorities

In the present study, in spite of the presence of a school canteen policy and a school canteen committee in 60% of schools, out of which 92% are private schools, more than half of the menu (52%) contains of foods high in fat. The proportion of healthy food choices available in school canteens is scanty.

Also, there is no involvement of parents, student representatives and nutritionists in the school canteen committee of any school.

Conclusion

A significant population of this age group is already on the borderline for obesity and continued exposure to unhealthy food and faulty dietary behaviours will accelerate the issue. Along with the affordability of HFSS foods, the easy availability is a major setback. Schools being an impactful centre for learning, do not have efficient strategies to ensure development of healthy food habits in children.

Interactive promotional activities for encouraging healthy food habits among children can model healthy food environments in schools as well as homes. Nutrition
education and awareness can prove to be influential.

Presence of HFSS foods in tiffin highlights the fact that parental education and willingness of implementing nutrition based practices at the home front is equally important to target.

These findings point to the need to create effective school food policies in Indian schools to provide a healthy school food environment. Future research is required to test the feasibility of the implementation of school food policies and to address the issues in implementation of the same.

Assessing the Future Assessors: A Health Literacy Assessment Using the Newest Vital Sign

Rathnakar P Urval¹, Priyanka Kamath², Medha Urval³, Kashvi Gupta⁴, Ashwin Kamath⁵

¹Professor & Head, Department of Pharmacology, Kanachur Institute of Medical Sciences, Deralakatte, Mangalore, Karnataka, India, ²Assistant Professor, Department of Pharmacology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India, ³Junior Resident, Department of General Surgery, SDM College of Medical Sciences, Dharwad, Karnataka, India, ⁴MPH Student, School of Public Health, University of Michigan, Ann Arbor, MI 48109, USA, ⁵Associate Professor, Department of Pharmacology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Background & Aim: Health literacy (HL) has been defined as the ability to obtain, process, and understand basic information and services needed to make appropriate health decisions. This study aimed to determine the HL of undergraduate medical students using the Newest Vital Sign (NVS), a nutrition label-based HL tool.

Method: This was a cross-sectional study conducted among newly admitted first year medical students using the Newest Vital Sign. Following informed consent, under supervision, the participants were handed over the nutrition label with six questions. Questions were asked in sequence, and continued even if the participant did not get the first or the second question right. If a participant got the first four questions right, it was considered a sign of adequate literacy.

Results: The study involved 110 participants out of which 72 were females. Overall, 87% of the participants had adequate health literacy, 11% had a possibility of limited health literacy, and less than 2% had a likelihood of limited health literacy. The mean of the total time taken to answer the questionnaire was 9.89 ± 2.25 minutes. More than 50% of the participants answered the questionnaire in the time range of nine to eleven minutes. Only <25% participants took longer than ten minutes to solve the questionnaire.

Conclusion: It was observed that more than 85% of the participants had an adequate level of health literacy. NVS, which is based on a nutrition label, is a very simple tool, and the test can be easily administered in ten minutes.

Keywords: Newest Vital Sign, Health Literacy, Students, Education, Time

Introduction

Health literacy [HL] is defined as the ability to obtain, process, and understand basic information and services needed to make appropriate health decisions.¹ Many aspects of health like health knowledge, health status, use of health facilities and cost have been found to be closely related to HL levels by many studies.² Health literacy is itself dependent upon more general levels of literacy. Even people with adequate literacy skills may not understand medical vocabulary and the basic concepts in health and medicine.³

Adequate health literacy is important as one has to frequently fill various registration forms in the hospital, sign consent forms, read food and medicine labels and inserts, understand physician’s instructions and various
healthcare messages which often are text based. People with limited health literacy are more likely to make medication errors, and they have less health knowledge, worse health status, more hospitalizations, and higher healthcare costs than people with adequate literacy.4

Many tools are available to test health literacy, but many a times the application of these tools may not be practical in a busy outpatient department (OPD) setting due to time constraints.5 In 2005, Weiss (Pfizer Inc.) developed a new screening instrument based on a nutrition label usually present on an ice cream container, the Newest Vital Sign (NVS), to assess level of health literacy.4 The Newest Vital Sign is a simple and fast way to identify those with limitations in health literacy skills. The tool, which tests literacy skills for both numbers and words, has been validated against a previously validated measure of health literacy, Test of Functional Health Literacy in Adults (TOFHLA), and has been shown to take approximately three minutes to administer.6

The objective of our study was to determine the health literacy of newly enrolled undergraduate medical students using NVS. This student population represents well-educated individuals with limited exposure to the complex medical terminologies; it is expected that they would be able to easily understand the information presented in the nutrition label. Since an earlier study had shown the health literacy may not be adequate even in highly educated individuals and no study has been done in the Indian population using NVS, the data from the current study would provide a rough, although limited, measure of health literacy in well-educated individuals as assessed using NVS.

Materials & Method

This was a cross-sectional study conducted among newly admitted first year (first semester) medical students, using the Newest Vital Sign (Copyright Pfizer Inc.; used with permission). It consists of an ice cream nutrition label which is provided to the participant, and six questions are asked to determine their understanding of the nutrition label. After seeking approval from the Institutional Ethics Committee, volunteers who consented to participate were recruited into the study. The test was administered by the study investigators. After obtaining the informed consent, the demographic data of the participant was recorded and NVS was administered.

The participant was handed over the ice cream nutrition label, which was retained with the participant for the entire duration of the test. The test contained six questions; the participant was allowed to refer the label as often as desired, during the course of the test. No upper time limit was set in which the test had to be completed. However, if the participant was still trying to solve the first or second question at the fifth minute, the likelihood of the participant having limited literacy was considered high. Questions were asked in sequence, and continued even if the participant did not get the first or the second question right. If the participant got the first four questions right, it was considered a sign of adequate literacy.

No prompts were given if a participant found it difficult to answer a question. The participants were not told if they’ve answered a question correctly or not at the end of each question. The score was not revealed to the participants until the entire test was completed. The maximum possible score was six (one mark per question). A score of 0–1 suggests high likelihood of limited health literacy; 2–3, possibility of limited health literacy; and score of 4–6, sign of adequate health literacy. The data was analysed using SPSS version 11.5 (Chicago, IL, USA). Descriptive statistics were used to present the results. The comparison of the scores between the gender groups was done using Student’s t-test. A p-value <0.05 was considered statistically significant.

Results

The study involved 110 participants out of which 72 (65.45%) were female. Eleven out of the 110 participants were Malaysians. Barring two participants, the medium of instruction of all the other participants was English.

Table 1 shows the number of participants who correctly answered each of the questions. Overall, 87% of the participants had adequate health literacy, 11% had a possibility of limited health literacy, and less than 2% had a likelihood of limited health literacy. The mean score was 5.00 ± 1.38 in males and 5.07 ± 1.23 in females (p = 0.787).

The mean time taken to answer the questionnaire was 9.89 ± 2.25 minutes. There was no significant difference in time required for completion of the questionnaire between males and females (p = 0.715). More than 50% of the participants answered the questionnaire in the time range of 9–11 minutes. Only about 25% of the
participants took longer than 10 minutes to answer the questionnaire.

**Discussion**

Health literacy has emerged as a concept that could play a vital role in improving health care system delivery and health status of the public in general. Lower levels of health literacy has been seen to be associated with worse outcomes, increase in emergencies, along with lesser use of preventive services. Instruments such as the Rapid Estimate of Adult Literacy in Medicine (REALM), Short-TOHFLA (S-TOHFLA) have been developed to test health literacy. However, there is no gold standard tool to determine the same.

NVS has not yet been widely tested in our country. In a study conducted in a tertiary care hospital, using the REALM questionnaire it was observed that more than 50% patients had a below average health literacy, though it was better in the younger age group (<25 years), compared to older adults. A striking fact was similar observation to earlier studies, where in general education of the patient did not exactly reflect the health literacy levels; even an individual with a post graduate qualification had a low health literacy.

NVS is a relatively simple tool to study health literacy which has the advantage of not being time consuming to administer and tests prose literacy, numeracy, and document literacy skills. In our study, first year medical students who had recently joined the course were chosen to participate as this group of young adults would not have received more than three months of medical education at the time of the conduct of the study. Hence, they could be considered to represent any well-educated young adult. This study showed no difference between male and female participants in health literacy similar to an earlier study which had reported no difference in HL among male and female participants. Overall, 87% of the participants had adequate health literacy, 11% had
a possibility of limited health literacy, and less than 2% had a likelihood of limited health literacy. In an earlier study the average time taken to complete NVS was observed to be 2.63 minutes. However, in our study the average time taken was 9.89 minutes.

The use of an ice cream label is especially relevant as prior research has shown that a lower level of comprehension of food labels correlated highly with low-level literacy and numeracy skills. It was observed that 89% of the study population used food labels, which makes the NVS a tool that patients can easily relate to. The study also found that even persons with good reading skills could have difficulties interpreting food labels.

Our study has certain limitations. The results of our study do not represent the health literacy status in the general population or the patient population. Moreover, the young medical students may have been able to relate better to the food label used to assess the health literacy but the same many not be suitable in the general population where reading food label is not a routine practice. The results are also not generalizable to students from other disciplines. However, considering that there are hardly any health literacy studies conducted in India using NVS, our study provides a rough estimate of the health literacy status in a well-educated medical student population. Our study also showed that NVS is a simple and rapid test to administer.

An earlier study conducted to study the difference in the Short Test of Functional Health Literacy in Adults (S-TOFHLA) and NVS, among and between a sample of English and Spanish-speaking patients showed that the results pertaining to levels of health literacy were likely to vary depending on the instrument used. A similar observation was made in another study which compared S-TOFHLA and NVS among children caregivers. The NVS was found to be more sensitive in picking up limited health literacy levels in younger population. This is another factor that needs to be kept in mind when a tool to assess health literacy is administered. A study conducted in Japan with a Japanese version of NVS demonstrated good validity and reliability. This test has also been found to be a valid measure of health literacy in the UK, along with being easy to administer and rapid. However, this is yet to be validated in India, for which further studies with larger sample size that is representative of different population and groups, are needed.

**Conclusion**

This study was carried out to study the health literacy level among first year medical students using the nutrition label-based NVS tool. It was observed that more than 85% of the participants had an adequate level of health literacy. NVS is a very simple tool, and the test can be easily administered in ten minutes. However, this needs to be studied further among patient population, which will enable us to determine whether this tool can be widely used to study health literacy.

The Cost of Falls among the Elderly in Kattankulathur Block, Tamil Nadu

Roshni Mary Peter, Alex Joseph, K R. John

1Assistant Professor, Department of Community Medicine, 2Assistant Professor, Division of Epidemiology, School of Public Health, 3Former Professor and Head, Department of Community Medicine, SRM MCH &RC, SRM IST, Kattankulathur

Abstract

Background: Fall injuries are a major public health concern in elderly. About 28-35% of the elderly people aged 65 years are experiencing fall each year and the prevalence of fall increases to 32-42% in elderly aged 70 years. Falls are one of the major problems in the elderly and are considered as one of the geriatric giants. As the frequency of fall increases with increasing age and frailty level the costs to treat fall injuries are also likely to rise.

Materials and Method: A community based cross-sectional study was conducted to estimate the costs of fall-related injury in the elderly in the rural Kattankulathur Block. The survey carried out among elderly contacted from 11 villages selected randomly. Semi structured questionnaire was used to collect data regarding cost of fall.

Results: 140 elderly were reported to have fallen at least once in the past one year among 747 elders contacted. The mean costs per fall victim, was found to be 4563 Rs, the mean costs among males were 5636 Rs and among Females were 3656 Rs. In the Linear Regression analysis, Age, Kind of Facility, Time taken to take decision for seeking treatment was found to be significant with the cost associated with fall.

Conclusion: Fall prevention must be emphasized in public health polices and health programs for elderly people. Falls are an emerging public health problem and a barrier to an active ageing in India. The increasing number of falls in elderly aged 70 and above has a considerable effect on the cost of treatment. There is a need for collective efforts of health professionals, researcher, policy makers and health care delivery system to promote active ageing and prevent fall injuries.

Key words: Fall, Elderly, Cost estimation, Linear Regression and Community.

Introduction

The global share of older people (aged 60 years and above) increased from 9.2 percent in 1990 to 11.7 percent in 2013 and will continue to grow reaching 21.1 percent by 2050.1 Injuries resulting from falls in elderly people are a major public health concern, representing one of the main causes of longstanding pain, functional impairment, disability and death in this population. The problem is going to worsen since the rates of such injuries seem to be raising in many areas, as is the number of elderly people in both the developed and developing world. Although not all falls lead to injury, about 20% need medical attention, 5% results in fracture and other serious injuries such as severe head injuries, joint distortions, soft-tissue bruises, contusions and lacerations results in 5–10% of falls. 2,3 The problem

of falls in the elderly population is clearly more than simply a high incidence, but also it impose a significant financial burden on the healthcare system.

**Magnitude of the Problem:**

About 28-35% of the elderly people aged 65 years are experiencing fall each year \(^4,^5,^6\) and the prevalence of fall is increasing to 32-42% of the elderly aged 70 years.\(^7,^8\) The incidence of falls appears to vary among countries as well. For instance, a study in the South-East Asia Region found that the prevalence of fall ranges from 6-31%\(^9,^{10}\) while another study conducted in Japan found that 20% of older adults fell each year.\(^11\) A study in the Latin/Caribbean region found that the proportion of older adults who fell each year ranging from 21.6% in Barbados to 34% in Chile.\(^12\) A significant number of Falls which results in injuries can result in the long term use of healthcare services leading to high healthcare costs.\(^13\) Falls among elderly have a huge impact on government funded programs, eight percent of Medicaid expenses in US for older adults were spent on falls.\(^14\) In USA and Australia with respect to lifetime costs, falls rank the second largest contribution of the economic burden of injuries.\(^15\)

A Community based Multi-centric Study conducted for the purpose of evaluating Health Problems among the Elderly during the year of 2003, in 10 states across India, shows the incidence of fall (History of a single fall in the last 6 months) was 14% and it is estimated that in India nearly 1.5 to 2 million persons are injured every year.\(^1\) The current demographic transition in India shows that southern India has an increased number of older adults over 60 years of age and it is expected to maintain the trend in the future as well.\(^16\) In India there are not much studies published available which had tried to estimate the cost of fall injuries among the elderly adults.

There are multiple perspectives by which economic consequences can be measured which includes societal, payer and provider based depending on the decision making process. The societal perspective takes the view of all costs of an injury relevant to society, this includes both the direct (medical and non-medical) and indirect costs which includes loss of productivity.

**Materials and Method**

The study was conducted in the Kattankulathur block, a revenue block in the Kanchipuram district situated on the northern East Coast of Tamil Nadu, India. As per 2011 census, the population of the Kattankulathur block comprises of 39 villages with a total population of 2, 18,000.

The present study is a community based cross-sectional design to estimate the costs of fall-related injury in the elderly in the rural Kattankulathur Block. The sample was selected from the 11 villages randomly selected by probability proportional to size sampling technique followed systematic random selection of 747 elderly people above 60 years of age. History of fall during the past one year was used to identify fall events by door to door survey.

Considering the prevalence of 14% as reference value, absolute precision as 5%, and 99.99% confidence interval the sample size was calculated as 724. However 747 elderly were enrolled for our study.

Inclusion criteria include Individuals who are aged 60 years and above experienced fall, who are permanent residents in the study area. Exclusion criteria include Individuals who are below 60 years, participants those who did not give informed consent and those with the permanent disability or those who were bed-ridden for a very long time. Individuals with a known history of serious illness and people with mental illness were excluded.

**Findings**

In the survey carried out, 747 elderly were contacted from 11 villages selected randomly. 140 elderly were reported to have fallen at least once in the past one year. About 54% were females and 46% were males.

Among the total 138 participants injured, 112 (82%) had totally recovered after the fall and 26 (18%) had not fully recovered from the consequences of fall at the time of interview. Among the 140 participants, 57 participants (41%) daily activities were not affected, they were able to move around freely, 57 participants (41%) had restricted activity and 25 participants (18%) were bedridden after the fall.
Among the 140 participants, 92% of the elderly were having the economic dependence on others while 54% were fully dependent, 38% were partially dependent and only 8% of the elderly were independent. Among all the 140 participants, 126 participants (90%) availed medical attention. 125 participants (90%) seek medical attention on the same day itself, 15 participants (10%) sought after 2-3 days. Visiting to an allopathic doctor was the most common practice 65 (51 %), followed by 35 participants (27%) that required hospitalization, and 26 participants (20%) visited traditional healers.

</tbody>
</table>
Among the 69 participants who were treated as outpatients, 36 participants (49.2%) had to spend about less than 1000 Rs, 29 (44.6%) about 1001-5000 Rs and 4 (6.2%) in a range of 5001-10000. In those 35 participants who were Hospitalized and treated as inpatients, 4 (11.4%) had an expense of 1001-5000 Rs, 25 (71.4%) had an expense of 5001-10000 Rs and 6 (17.1%) more than 10000 Rs. Among the 26 participants who got medical care from traditional healers, 20 (76.9) % had to spend less than 1000 Rs, 5 (19.2%) had an expense of 1001-5000 Rs and 1 (3.8%) had an expense of More than 10000 Rs. There was a significant difference between the cost and type of treatment.

Direct medical cost includes clinician visit, hospitalization, diagnostic testing, drug treatments and therapeutic procedure. Rs. 2894 was the mean cost with 95% CI (2251 -4818) for direct medical expenses, with a minimum of Rs 0 to a maximum of Rs 35000 spent towards meeting the direct medical expenses. Direct nonmedical expenses associated with receiving medical treatment, such as the cost of transportation to and from medical services Rs 685 with 95% CI (503 -844) was the mean cost for direct non-medical expenses, with a minimum of Rs 0 and maximum of Rs 6,000 spent towards meeting the direct non-medical expenses. Indirect cost involves loss of wages for the patient as well as the bystander; Rs 352 with 95% CI (260 – 491) was the mean cost for indirect expenses, with a minimum of Rs 0 and maximum of Rs 3,000 spent towards meeting the indirect expenses.

</table>
Linear Regression of the cost associated with fall and risk factors was performed after doing log transformation of the total cost to transform a normal distribution. In the analysis, Age, Kind of Facility, Time taken to take decision for seeking treatment was only found to be significant with the cost associated with fall.

**Discussion**

The current study is a community-based cross-sectional study that aims to estimate the costs of falls among the rural community elderly in southern Indian population. Among the 140 participants, there were 130 participants who had expenses for seeking the medical care, a critical assessment done by PHFI (public health foundation of India) states that, In India, only 25% of people have health insurance coverage, and medical expenses are predominantly borne out-of-pocket.\(^\text{17}\) The average costs of fall among elderly in our study was found to be 4563 Rs, males were reported to have higher average cost compared to females. The 2017 National Health Policy report quotes according to Central Bureau of Health Intelligence statistics that 35 crore individuals, 27\% of the total population of India were covered under any insurance in 2015-16. The medical expenses are mostly borne out of pocket and elderly is more vulnerable to such financial burden.

Community-based falls-prevention programs is an attractive proposition for cost-effectiveness. A study conducted by **Vidmantas Alekna** et al shows that the mean estimated healthcare cost was 254 EUR (Rs.21,262 Indian Rupee) per patient receiving fall-related medical care.\(^\text{18}\) Mostly economic analyses are dependent upon the assumptions they make, this can lead to inaccurate cost estimations. The current study showed that falls have relevant economic burden.

**Conclusion**

Falls are one of the major problems in the elderly and are considered as one of the geriatric giants. The frequency of fall increases with age and frailty level. Falls often signal the “beginning of the end” of an older person’s life. Fearful of such an outcome, older adults often restrict their activity to avoid the risk of falling. Unfortunately, this very behavior actually increases the risk of falling by causing loss of muscle and strength. In India one third of older adults aged 60 years and older live below poverty line up to 65\% of older adult are economically dependent, especially windowed women. Non affordability is a case of not seeking treatment among older adults. Fall prevention must be emphasized in public health polices and health programs for elderly people. Falls are an emerging public health problem and a barrier to an active ageing in India. There is an urgent need for coordinator and collaborative. Efforts of health professionals, researcher, policy makers and health care delivery system to prevent for promote active ageing. In India only 25\% of people have health insurance coverage and medical expenses are predominantly born out of package. Fall related injuries may affect a person’s savings, increase the economic burden of care giver and contribute to neglect of older adult.

**Limitation**

The cost associated with fall was based on self reported data, the recall was poor and the subjects were not fully aware of the actual cost, often relatives paid towards the expenses. The reported cost is only an estimate of actual cost which has incurred within a year from the date of survey.

**Ethical Considerations:** This study was approved by the Institutional ethical committee of SRM Medical College Hospital and Research Centre, Kattankulathur, Tamilnadu.

Variation in Lip Thickness in Individuals with Angle’s Class I, Class II and Class III Malocclusion - A Cephalometric Study

S.Subashree Rathi¹, Arvind Sivakumar²

¹Post graduate student, Department of Orthodontics and Dentofacial Orthopaedics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical And Technical Sciences(SIMATS), Saveetha University; ²Craniofacial orthodontic consultant, Cleft and craniofacial institute, Senior Lecturer, Department of Orthodontics and Dentofacial Orthopaedics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical And Technical Sciences(SIMATS) Saveetha University

Abstract

Introduction: Facial harmony is achieved by both hard tissue and soft tissue of an individual. The aim of this study is to determine the lip thickness individuals with Angle’s class I, Class II and Class III Malocclusion. To evaluate the variation in lip thickness among these three groups. MATERIALS AND METHOD: The material includes the lateral cephalometric radiographs of thirty individuals with ten in each group. Each group is further divided into five male and five female subjects with vertical growth pattern. The basic upper lip thickness was then measured according to the definition of Holdaway. The measured values were then subjected to statistical evaluation. RESULTS: The mean of groups 1, 2 and 3 were 14.2, 12.6 and 14.4 respectively. One way ANOVA shows a statistically significant correlation between the three groups with a significance value of 0.013 (P<0.05). According to post hoc Tukey’s HSD test, lip thickness in class 2 individuals is significantly lower than the lip thickness in class 1 and class 3 individuals. CONCLUSION: Within the limitations of the study, it could be concluded that the basic upper lip thickness of class II individuals is lower compared to class I and class III individuals.

Keywords: lip thickness, malocclusion, skeletal class I, Holdaway

Introduction

The orthodontic diagnosis, early in the 1900’s, even before Angle classified malocclusion, was the clinical evidence of the anteroposterior relationship of mandible to the maxilla. With the development of cephalometric x-ray by Broadbent in 1931¹, there were more reliable methods of orthodontic diagnosis. Since the time, hard tissue values were only considered for the diagnosis and treatment planning. Holdaway⁵ Bradely⁶ Park and Burstone⁷ are one among the few who emphasized the use of soft tissue measurements along with hard tissue measurements.

Holdaway⁵ stated that “Usually as we correct malocclusions, we bring about changes in appearance that are pleasing to all concerned. However, most orthodontists who have practiced for even a few years have had the unpleasant experience of finding that some patients’ faces looked better before the orthodontic corrections were made.” Holdaway⁵ also stated that “Better treatment goals can be set if we quantitate the soft-tissue features which contribute to or detract from that ‘physical attractiveness stereotype’ which has been ingrained into our culture.”
The soft tissue changes that occur during orthodontic treatment plays an important role in the diagnosis and treatment planning. According to the studies conducted by Oliver and Wisth, there seems to be an influence of lip structure on the lip response. In a study conducted by Oliver, it was found that there was a correlation between thin lips/high lip strain and incisor retraction, there was no significant correlation found in case of thick lips or low lip strain. Also, Wisth found that lip response, as a proportion of incisor retraction, decreased as the amount of incisor retraction increased. This seems to indicate that the lips have some inherent support.

Facial harmony is achieved by both hard tissue and soft tissue of an individual. Knowledge of facial tissue depth is very important pertaining to dentistry and forensics. In order to perform reconstructive surgeries like placement of graft, the depth of soft tissues should be known prior to the surgery, which are different for each individual, to achieve a good result. The first person to publish about the soft tissue depth for any application was Welcker in 1833. Later, various authors have studied the facial soft tissue thickness of Africans, American, European, Japanese, Caucasian adults etc.

Goëyenc et al examined the differentiations of soft tissues in skeletal Class I, dental Class I, Class II, and Class III patients in Anatolian Turkish population. With all these points in mind, we intend to analyse the variations in the average lip thickness of individuals with skeletal class I, class II and class III.

Materials and Method

This retrospective study was designed to analyse the variations in lip thickness which comprised of a total sample size of 90 subjects which was divided into three groups with thirty subjects in each group. The pre-treatment cephalograms were obtained to do the analysis. The criteria for patient selection was as follows:

Class I, class II, class III skeletal pattern in the respective groups 1, 2 and 3. Class I skeletal pattern represents a balanced profile, class II pattern represents a retrognathic profile and class III pattern represents a prognathic profile.

Normal growth and development

No history of previous orthodontic treatment.

All subjects were positioned in the cephalostat with the sagittal plane at a right angle to the path of the x-rays, the Frankfort plane parallel to the horizontal, the teeth in centric occlusion, and the lips slightly closed. The landmarks were marked based on the definitions provided by Holdaway. The radiographs were traced and corresponding points marked using Facad software for cephalometric tracing. All the measurements were done by the same investigator to prevent bias.

According to the literature, the basic upper lip thickness is measured from approximately 3 mm below point A and the drape of the upper lip. The pictorial representation of the landmarks used to measure lip thickness is given in figure 1 and figure 2.

Figure 1: Pictorial representation of the landmarks used for measurement of upper lip thickness
A - Deepest point on maxilla
a - 3mm below point A along anterior curvature of maxilla
a’ - Point on external border of upper lip parallel to FH plane.
All statistical analyses were performed with the SPSS software package. For each variable, the arithmetic mean and SD were calculated. One-way ANOVA and post hoc Tukey’s HSD analysis was performed to check for statistical significance.

**Results**

Table 1 shows the descriptive statistics of basic upper lip thickness for each type if malocclusion. The mean of groups 1, 2 and 3 were 14.2, 12.6 and 14.4 respectively. The distribution of the basic upper lip thickness values under each type of malocclusion is

<table>
<thead>
<tr>
<th>Group</th>
<th>Mean</th>
<th>Standard Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skeletal Class I</td>
<td>14.215</td>
<td>1.891052</td>
</tr>
<tr>
<td>Skeletal Class II</td>
<td>12.69</td>
<td>2.48255</td>
</tr>
<tr>
<td>Skeletal Class III</td>
<td>14.47368</td>
<td>1.342403</td>
</tr>
</tbody>
</table>

Oneway ANOVA shows a statistically significant correlation between the three groups with a signifiance value of 0.013 (P<0.05). According to post hoc Tukey’s HSD test, lip thickness in class2 individuals is significantly lower than the lip thickness in class 1 and class 3 individuals. (Table 2)

**Discussion**

Facial attractiveness or harmony does not solely depend on the hard tissues. The soft tissue dimensions also vary depending on the length of the tissue, thickness of the tissue and its postural tone.\textsuperscript{19,20} Facial soft tissue measurements are of importance to maintain an optimum facial attractiveness. Many human body parts including the face undergo development with bilateral symmetry.\textsuperscript{24} The soft tissue should be assessed in its own merit by the orthodontist in order to obtain a positive treatment goal.\textsuperscript{21}

In the current study, the distribution of the upper lip thickness over a plot area shows even distribution with mild variations. Lip thickness in class II falls well below the line from class I and class II. It is depicted in the pictures below. (figure 3 – 6)
The reason for reduced lip thickness in skeletal class II individual could be owing to one of the following many reasons. Short hypotonic upper lip and inability to close the mouth, that is incompetent lips, could be one of the reasons for this. In case of prognathic maxilla in skeletal class II individuals, the soft tissues compensates and tries to camouflage the prognathism and hence the lip thickness is reduced.

Evaluating the upper lip thickness as an integral part of treatment plan is important because, changes in position of upper incisors will alter the position of upper lip. The soft tissue contour plays a major role in the final outcome of the treatment. Soft tissue analysis enhances the maintenance of normal facial forms and any abnormalities detected are corrected orthodontically or surgically. Soft tissue analysis, should not therefore replace the comprehensive clinical examination, it is used as an adjunct which results in optimal facial esthetics.

Earlier studies by Grosaores et al showed that males have thicker upper lips than the females and in addition they said that there is difference in lower lip thickness between males and females.22

Ayla et al studied the variations in soft tissue thickness in individuals with different occlusion patterns. It was found out that the upper lip thickness was significantly lower in the Class I group when compared with the other two classes and it was more prominent in males compared to females.23

**Conclusion**

Within the limitations of the study, it could be concluded that the basic upper lip thickness of class II individuals is lower compared to class I and class III individuals.

A Cross Sectional Study on Factors Influencing the Delay in Clinical Diagnosis in a Super Specialty Eye Hospital

Sachin Suresh Shinde¹, Kishore Babu Marivina², Madhavi Latha³, Sukesh Krishna Chaitanya Loka⁴

¹Research Scholar, KL University, Vijayawada, ²Professor& Principal-College of Management, KLEF, Vijayawada (AP), ³Retina Consultant-Super specialty hospital Eye Care, ⁴Clinical Pharmacologist, Krishna Institute of Medical Sciences Hyderabad

Abstract

The present dissertation addresses the service gaps and the causes behind it, specifically in super-speciality eye hospital with a wide range of multi-specialists. It includes the hierarchical process flow at a typical modern-day care Eye hospital.

A Survey has been conducted in which the patients are posed a questionnaire during their first visit to the OPD, to provide constructive feedback and grievances. A qualitative feedback of this is done by using MS Excel and other service tools. The results have pointed out the locations and causes of delay

By performing a Fish-bone analysis (cause-effect), the causes for delays in clinical diagnosis (done in various phases) are identified and plausible solutions are furnished to upgrade which would be a part of the continuous quality program.

This research helps the reader understand the process of service, its results and implications that are proposed as a solution to overcome the above issue.

Key words: Diagnosis, Delay, Factors, Ophthalmology, Super specialty hospital

Introduction

There is an increased demand in Consultations for Eye hospitals. This demand comes mostly from patients with chronic eye diseases, such as macular degeneration, glaucoma, and diabetic eye disease. These patients are at a greater risk of developing irreversible loss of vision. These conditions require long-term follow-up with up to date treatment procedures. But these follow-ups are more likely to be postponed or discontinued due to various reasons like negligence and socio economic hurdles. Sustained maintenance of patients’ revisits is as important as getting new patients. Nothing works best than person to person publicity.

In present scenario, an Ophthalmology hospital¹ is exclusive setups and is a group practice. The services are subdivided based on specialties like Cornea, Glaucoma, Retina, Refractive surgery, Cataract surgery, Orbit- Oculoplasty and Uvea clinics. Hence most of the patients require inter departmental referrals. Ophthalmology hospitals most of the times fail to routinely meet the expectations and consequently may not respond adequately to the patients’ queries.

In recent years, a growing emphasis on patient-centered care² consumerism in medicine has further exemplified the importance of effective doctor-patient communication

Types of delays encountered³ in day to day practice:

Detection delay
Service delay
Diagnostic delay

**Statement of the Problem:**

In a typical hospital setup a diagnosis is meant to provide a reliable description of the clinical condition. Provisional diagnosis (PD) is the first considered diagnosis which initiates the first phase of management, whereas confirmatory or Final diagnosis (FD) is only obtained when we go through the chronological organization and critical evaluation of information obtained from the history, physical examination, and investigations. Until we get the final diagnosis we cannot start the treatment. During the process of attaining final diagnosis a patient should go through multiple steps which involve medical and non-medical personnel which is a long process which ends in parents dissatisfaction.

This thesis data may be an eye opener to both medical and non-medical personnel for understanding and revising the process of service planning and service delivery. Necessary intervention measures may be undertaken toward improvisation of diagnostic skill of the supporting staff and doctors for quality hospital services.

**Literature Review**

Feigenbaum[^4] said that quality is a patient determination, not an engineer’s determination. It is based on the patient’s actual experience with the service measured against his or her requirement stated or unstated, conscious or merely sensed, technically operational or entirely subjective & always representing a moving target in a competitive market.

Garud[^5] pointed out that quality is different things to different people According to Crosby, quality is ‘conformance to requirements.’ (zero defects). With reference to healthcare, quality is defined as a ‘level of excellence’ in achieving the desired result. There are several components of quality in the field of health care: access to services, relevance to the need, effectiveness and safety, equity, social acceptability & efficiency and economy.

According to Sakharkar[^6] Quality is defined as adherence to standards & criteria that are based on current knowledge & sound experience. Quality is achievable through ongoing evaluation of patient care, which would assure the hospital that all was done to justify the diagnosis, treatment & outcome & to pinpoint inadequacies in medical care for rectification for the future cases.

Gronroos[^7] postulated the two components, technical quality, which involves what; the patient is actually receiving from the service, and functional quality, which involves the manner in which the service is delivered.

Nadkarni[^8] has reported that the rapidly expanding scope of the healthcare has lead to increasing complexity in its delivery. Patient satisfaction is increasingly taken as an important measure of quality.

According to Woodrufe[^9] service quality is of crucial importance to both patients and service providers. Organizations are becoming increasingly aware of the importance of quality in maintaining competitive advantage. Quality should be functional, not restrictive and should reflect the overall business or business like activities of the organization.

Donabedian[^10] developed seven attributes of healthcare quality

- Efficacy
- Effectiveness
- Efficiency
- Optimality
- Acceptability
- Legitimacy
- Equity

Lytle and Mokwa[^11] reported that maintaining that service quality depends on 2 variables, expected service and perceived service. They further said that a healthcare service product is a bundle of tangible and intangible benefits that satisfy patient’s needs and wants. Two research group’s linked perceived quality on the part of the consumers to the level of employee satisfaction with work roles. Both groups maintained that such factors as job design, role clarity and autonomy affect employee attitudes, which in turn affect patient experience in institution.

Mittal and Baldasare[^12] measured the effect of certain quality factors in the physicians’ practice and found that physician competence, communication, respect, caring, taking time to learn history and follow up treatment were weighted more heavily if the patients were not satisfied.
Patient Satisfaction

Pollock & Evans \(^{13}\) wrote about audit of patient satisfaction. They said “managers want cost effectiveness, doctors want to cure patients and keep their morbidity and mortality down, but what do patients want?” This question often gets pushed to the bottom of the list, if it gets asked at all and it is really the most important. In general, patients want competence, courtesy, kindness, consideration and information, they want continuity of care, they want the opportunity to decide for themselves having discussed matters with their doctors and be a partner in the decision about how to treat their disease.

According to Delbanco\(^{14}\) techniques to measure the quality of the healthcare proliferate and improve, health professionals are beginning to accept that patient and their families hold unique vantage points as experts witnesses of care and that they should plan their services to reflect the needs of patients. Patients satisfaction is now a critical variable in any calculation of quality or value and therefore in the assessment of corporate accountability. It is a legitimate and important measure of quality of care.

The increasing cost of health services and the need for better use of available resources is a concern for healthcare providers. Consequently, it is evident that there is a need to measure the efficiency of health care to determine if proper use of available resources is made. According to Fitzpatrick \(^{15}\), patient satisfaction is an important and widely accepted measure of care efficiency.

Objectives of the study

1. To assess the service gap in Eye-hospitals from entry to exit.
2. To identify patient expectations in Eye-hospitals.
3. To evaluate cause of delay.
4. Analyzing the gaps in service.
5. Preparing steps in service delivery improvement.

Methodology

Introduction:

The study was conducted from January 15 to March 15 at Super specialty hospital Eye Hospital which is a super specialty eye care centre with multiple departments i.e. cornea clinic, Glaucoma clinic, Cataract clinic, Refractive surgery clinic and retina clinic.

Research Design

The present study is cross-sectional study conducted for a period of 60 days to the OPD initial visit patients at Super specialty hospital eye hospital.

Ethical Consideration

Formal consent letter and permission is approved from the medical director at head office. Patients are informed about the purpose of the study and the research design and said them their data will be confidential. They should not bias and patient participation is purely volunteer job.

Instrument and Component

Questionnaire was designed for assessing the cause for service gap and health object of hospital

Sample Size

A total of 200 OPD patients were interviewed and requested to fill the questionnaires who are voluntarily involved in a period of one month.

Inclusion Criteria

New OPD patients who are interested to fill the questionnaire before exit of hospital.

Exclusion Criteria

Old OPD patients or follow up cases
Not interested to fill the questionnaire

Sampling Procedure

Sampling technique is simple random technique with sampling size of 200 to the new OPD patient.

Data Analysis

The collected data is analyzed by using descriptive statistical tool M.S excel and service quality tool and analyze by “Cause-Effect Analysis”(fish bone technique)
Data Analysis And Interpretation

All the survey data was collected and analyzed by using MS Excel and service quality tool. Survey questionnaire has been incorporated into excel sheet for data analysis.

Data sample analysis

For Registration

Table 1. Time taken for registration

<table>
<thead>
<tr>
<th>S.No</th>
<th>Particulars</th>
<th>Total</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>02-04 min</td>
<td>77</td>
<td>38.5%</td>
</tr>
<tr>
<td>2</td>
<td>04-05 Min</td>
<td>82</td>
<td>41.0%</td>
</tr>
<tr>
<td>3</td>
<td>&gt; 05 Min</td>
<td>41</td>
<td>20.5%</td>
</tr>
<tr>
<td>4</td>
<td>Grand Total</td>
<td>200</td>
<td>100%</td>
</tr>
</tbody>
</table>

Interpretation:

Around 39% of patients were 02-04 min of waiting time at reception.

Patients who are illiterate has taken more waiting time for registration and those 41 patients has taken staff or attendant support to fill the registration form.

Few patients i.e. Uneducated / patients are having some queries about doctor availability or would like to have specialized consultation requirements. Has taken some to get register themselves.

Average Time Taken at Refraction

Table 2. Average time taken at refraction

Time taken refraction

<table>
<thead>
<tr>
<th>S.No</th>
<th>Particulars</th>
<th>Total</th>
<th>Percentage</th>

<td>109</td>
<td>54.5%</td>
</tr>
<tr>
<td>4</td>
<td>Grand Total</td>
<td>200</td>
<td>100%</td>
</tr>
</tbody>
</table>

Interpretation:

Around 16.5% of patients take 01-05 min for completing the Refraction process. These patients are cooperative who come for normal sight check up and Emergency patients only patient’s history and problem will be mentioned in Case sheet takes less time.

Nearly 29% of patients take 05 – 10min of time for refraction process. They are Cooperative patients, and they come with complaint of Blurry vision, sight check up etc.

Around 54.5% of patients are taking more than 10min for refraction process; this could be due to non-cooperative patients, illiterates ,more no. of patients at peak hours, non-availability of Optometrists.

TIME TAKEN AT PRIMARY CONSULTATION

Table 3. Time taken at primary consultation

Primary Consultation

<table>
<thead>
<tr>

<td>8</td>
<td>4%</td>
</tr>
<tr>
<td>5</td>
<td>Grand Total</td>
<td>200</td>
<td>100%</td>
</tr>
</tbody>
</table>

Interpretation:
Nearly 62% of the patients will be spending 30-60 min in hospital. These patients could have come for General Eye check up, and some patients may come again after few days for further procedures like dilatation.

Nearly 24% of the patient will be in hospital for 1 – 2 hours; this is due to dilatation process.

Around 10% of patients will be in hospital for 2-3 hours, here they will be advised to undergo for scans, investigations etc.

Few patients constituting of 4% will come to the hospital in the same day with various reasons (less money, urgent work etc).

Table 5. Average Time Taken For Investigations

<table>
<thead>
<tr>
<th>Investigations</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>21</td>
</tr>
<tr>
<td>No</td>
<td>179</td>
</tr>
<tr>
<td>Grand Total</td>
<td>200</td>
</tr>
</tbody>
</table>

Interpretation:
Only 21 of the patients are advised for investigations. It can be advised at Primary or Cross consultation level.

Most delays are seen in cases advised after cross consultation or lack of availability of optometrist.

Table 6. Overall delay at location wise

<table>
<thead>
<tr>
<th>S.No</th>
<th>Particulars</th>
<th>Total</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Registration</td>
<td>6</td>
<td>3%</td>
</tr>
<tr>
<td>2</td>
<td>Doctor Consultation</td>
<td>17</td>
<td>8.5%</td>
</tr>
<tr>
<td>3</td>
<td>Refraction</td>
<td>38</td>
<td>19%</td>
</tr>
<tr>
<td>4</td>
<td>Investigations</td>
<td>14</td>
<td>7%</td>
</tr>

<td>Advised for next visit</td>
<td>125</td>
<td>62.5%</td>
</tr>
<tr>
<td>6</td>
<td>Grand Total</td>
<td>200</td>
<td>100%</td>
</tr>
</tbody>
</table>

Interpretation:
On overall analysis the delay at Registration process is at 3%. At doctor consultation level it is up to 8%. And more delay is at Refraction process, which is at 19%. And at Investigations it is 7%. The patients advised for next visit are of 63%.

Findings & Suggestions

LOCALITY:
Findings: Rural patients who visit hospital through reference come at peak hours and hence a delay expected in every stage.

Suggestions: Phone call appointments can be taken where by basic details like Name, Age, and Phone number. Referral type can be mentioned in Registration forms. By the time the patient enters the hospital, a personalized case sheet can be created before hand to save time.

Online appointments/ Aadhar card number linkage to hospital server.

PURPOSE OF VISIT

Findings: Delay in consultation due to allotment process of the right patient to the appropriate concerned specialty doctor who can justify the problem.

Suggestions: Patients who have been referred from other hospitals or diabetic patients can be sent to concerned (Retina) specialty department directly.
instead of waiting at primary doctor and then referring to specialist.

**Average time taken for registration**

**Findings:** Patients from Rural areas finds difficulty in giving their details and understanding the process etc.

**Suggestions:** Basic details can be taken in peak hours, a diagrammatic chart can be prepared, which shows the patient movement in stages. A Staff member should accompany the patient.

**Average time taken at refraction**

**Findings:** Refraction process usually gets delayed at Peak hours 11am-1pm.

**Suggestions:** Availability of Optometrists at peak hours should be maintained. They should be trained in such a way that the job is done promptly and in perfection. All optometrists should be trained for all investigation procedure and roster of the optometrist should be scheduled.

**Time taken at primary consultation**

**Interpretation:**

**Findings:** Delay at primary consultation

**Suggestions:** This occurs in peak hours and lunch time so known and appointment patients can be suggested to come at lean hours.

**Time Taken at Cross Consultation**

**Findings:** Delay at Cross consultation

**Suggestions:** Timings of Specialized doctors should be mentioned in Panel board and working days/timings should be maintained and updated daily.

Receptionist should be intimated about doctor’s schedule priorly.

**Total Time Spent By Patient**

**Findings:** Patient waiting time is more than expected.

**Suggestions:** Maximum time for a normal patient to be spent at hospital should be under 35mins.

Patient who has to undergo surgery, initially have to complete their battery of investigations for whom the time should be from 60-90mins. Fast track services can be planned

**Conclusion**

Service gaps exists in our hospital setup. As a part of continuous qualitative improvement program, service gaps should be analyzed and rectified to sustain in the market and implementation of other service sector models is suggested. Fast track services can be planned

**Conflict of Interest:** NIL

**Source of Funding:** Self

**Ethical Clearance:** Ethical clearance had been obtained from eye care hospital, Vijayawada

Impact of Power and Politics on Employee’s Health and Performance in Private Nursing Homes of West Bengal, India: An Empirical Study Using Structural Equation Modelling (SEM)

Satakshi Chatterjee¹, Arunangshu Giri², Pradip Paul³

¹Assistant Professor, Department of Pharmaceutical Management, ²Associate Professor, School of Management & Social Science, Haldia Institute of Technology, Haldia, West Bengal, India, ³Senior Manager (Retail Sales), Haldia Divisional Office, Indian Oil Corporation Ltd., Haldia, West Bengal, India

Abstract

Organisational power and politics are embedded in each and every organisation and healthcare industry is not the exception. Healthcare is considered to be very important for any nation as this industry deals with providing quality services for one of the basic amenities which is required to survive and that is health. The employees of these institutions are the cardinal links who are responsible for dealing with the lives of the patients who seek their services at the times of their need. As such, the employees would give the best output when they are provided with an environment which would help in their individual growth without any kind of hindrances of any manner. In this study, secondary data was used to develop a hypothesized model and primary data was used to support the research model. This study focuses power and politics having impact on Employee Health and Performance. Structural Equation Modelling (SEM) using SPSS and AMOS Software was used as analytical tool. Thus, this study reveals that organisational power and politics has a deep impact on the health of the employees which in turn affects the performance of the employees and their productivity levels as well.

Keywords: Power; Politics; Employee Health; Employee Performance; Healthcare industry; Structural Equation Modelling (SEM).

Introduction

The healthcare system of India is in a state of disrepair. Because of this, the quality of services offered by the medical professionals is declining rapidly. Health has become a necessary amenity of the common people. This demand drives the growth of the healthcare industry very promptly. Power and Politics are present across all the organisations. Power is the empowerment of the working professionals which aids them in decision making. It often leads to organisational politics. Politics may be defined as the irrational behaviour of the employees to gain a certain number of advantages which, under normal circumstances, would be beyond their reach. Power and politics, if not properly handled, can lead to a creation of a negative ambience which will be hampering the health of the organisation in the long run. Some of the other negative effects of power and politics are: decreasing concentration of the employees, worsening of the attitude of the employees over time, de-motivating the employees, creating job stress and it also helps in the propagation of wrong information through the informal communication system of the organisation. All of these factors collectively lead to the plunging work performance of the individuals. This is because their attention is diverted to the wrong areas which restricts them to focus on their work and deliver their hundred per cent. Satisfaction of the employees

in the healthcare industry is of paramount importance. It is seen that power and politics has a negative impact on them by causing havoc in their personal as well as domestic life by causing unnecessary stress. Hence, the factors influencing the organisational power and politics must be delved deeper.

**Literature Review**

There are two kinds of power: positive and negative (Somoye, 2016)⁠¹. Power is often depicted negatively in the organisational context. Negative use of power can lead to the obstruction of various efforts of empowerment of the employees. This can lead to the complications in the relationship between the employees in the various job roles (Tjosvold, et al., 2006)². Negative use of power is responsible for the creation of job stress in the employees which has a negative impact on their health as such (Lo, et al., 2014)³. Power is also responsible for influencing politics of an organisation. A research study suggests that the employees of the various organisations have a set perception of organisational politics in their minds. Negative perception of the organisational politics need to be controlled (Jain, et al., 2018)⁴. It can also be held responsible for messing up the commitment level of the employees (Rahman, et al., 2013)⁵. As a result, the employees lose their drive to succeed and they become de-motivated which automatically lowers their degree of work engagement (Ahmad, et al., 2016)⁶. Power and Politics are very much real in the nursing homes as well, which are the crucial points of contact of the healthcare industry. They have an adverse impact on the mental health as well as physical health of the employees by increasing their job stress (Cropanzano, et al., 1997)⁷. The mental health is affected by the power and politics of the organisations which results in growing work frustration, increased level of anxiety amongst the workers, decreased level of work enthusiasm for their respective work, increased aggressiveness and many more. The physical health of the employees are also affected which results in fatigue (Fan & Smith, 2017)⁸. In nursing work which is relevant in the nursing homes, fatigued employees have lower work performance (Barker & Nussbaum, 2011)⁹. Also, often times, the workers in the healthcare industry has to work crazy hours as a result of which they are at risk of developing chronic diseases like spondalitis, misbalanced posture, problems related to movement and many more. Work life balance is also hampered in this scenario. The employee’s tendency to commit errors increases significantly and their work performance goes down drastically. Thus, increasing the performance of the employees is a critical issue which is being focused upon across various organisations. It has been seen that both power and politics are influential to the employee’s health and work performance (Muda, et al., 2014)¹⁰. Thus, the productivity of the employees plummets as well (Pradhan, et al., 2016)¹¹.

**Hypotheses Development**

H1: ‘Politics’ negatively influences ‘Employee Health’ in Private Nursing Homes.

H4: ‘Power’ negatively influences ‘Employee Performance’ in Private Nursing Homes.

H5: ‘Employee Health’ positively influences ‘Employee Performance’ in Private Nursing Homes.

**Research Methodology**

In this study, primary as well as secondary data has been used for establishing research model (Figure 1). For survey purpose, a structured questionnaire was prepared with related variables collected from literature review. All factors and the variables have been directly taken from previous studies. 5 point Likert type scale (from strongly agree: 5; agree, 4; neutral, 3; disagree, 2; strongly disagree, 1) was used for evaluating the responses of the employees of Private Nursing Homes of West Bengal. Sample element was collected in different stages. In the first stage, a district was selected randomly in West Bengal. After that Private Nursing Homes were chosen from selected district through convenience sampling in the second stage. In the 3rd stage, employees were chosen for giving feedback from selected Private Nursing Homes through random sampling. 197 responses out of distributed questionnaires to 200 employees were finally collected for this study. The survey period was
from 10th January, 2019 to 5th March, 2019.

**Analysis and Findings**

For developing the research model and establishing the hypothesis, Structure equation modeling (SEM) by AMOS has been used in this study. Through structural model, model fitness indexes have been checked. The overall Cronbach alpha which is 0.821 (more than 0.70) shows the acceptable range of reliability of data set. The fitness indices were checked and all hypotheses were tested here (Table 1 and 2). Path analysis was executed for checking the impact of Power and Politics on Employee Health and Performance in Private Nursing Homes of West Bengal.

Path Analysis for Hypothesis Testing

H1: ‘Politics’ negatively influences ‘Employee Health’ in Private Nursing Homes of West Bengal.

Structural model supports this hypothesis. Organisational politics creates distractions for the employees as a result of which they are unable to focus on their work. Their efficiency decreases drastically and it ultimately results in job stress. Thus, the employees’ health starts to deteriorate which in itself becomes a barrier to the employee’s increase in productivity (Schneider, 2016)\textsuperscript{12}.

H2: ‘Power’ negatively influences ‘Employee Health’ in Private Nursing Homes of West Bengal.

Structural model supports this hypothesis. Power resides in a limited number of employees within the nursing homes. It is imperative that these individuals would be inclined to misuse their power under dire circumstances. This de-motivates the other employees present in the organization as they feel their contributions are not being recognized by the organization as the top leaders do not hold their work accountable for the success of the nursing homes. This de-motivated state of mind of the employees lead to the deterioration of their physical as well as their mental health.

H3: ‘Politics’ negatively influences ‘Employee Performance’ in Private Nursing Homes of West Bengal.

Structural model supports this hypothesis. This study reveals that organizational politics is responsible for negatively influencing the work performance of the employees because of lower commitment levels on their part (Abbas & Awan, 2017)\textsuperscript{13}. This can be prevented by understanding the perception of the employees regarding the organizational politics transpiring in a workplace. A thorough understanding of the employee’s perception regarding organizational politics will help in adoption of various strategies which will help in the minimization of the affect of the organizational politics on the employees and help them to increase their work performance.

H4: ‘Power’ negatively influences ‘Employee Performance’ in Private Nursing Homes of West Bengal.

Structural model supports this hypothesis. Negative use of power amongst the decision makers of the organization de-motivates the subordinates as they feel that they have zero contribution towards the functioning of the organization, thus, rendering them feeling useless. It is given that each and every decision of the organization involves a certain use of power. This leads to the generation of a lot of stress in the employees which also affects their level of job satisfaction as well. As a result, the work performance of the employees goes down altogether.

H5: ‘Employee Health’ positively influences ‘Employee Performance’ in Private Nursing Homes of West Bengal.

Structural model supports this hypothesis. Job stress is responsible for hampering the physical as well as the mental health of the employees of the nursing homes. The health of the employees should be maintained in the optimal condition as the performance of the healthy employees yield more quality services as compared to the unhealthy ones (Ratnawat & Jha, 2014)\textsuperscript{14}.

Implications of the Study

Organizational power and politics are deemed to be the evils of the organizational society and they are responsible for creating a lot of negativities in the minds of the employees. As healthcare is a service industry, the employees are the anchors of the entire organization which holds everything in place. So, the organizations must work at eradicating these useless restrictions and simultaneously put exertion on inculcating an organizational culture within the organization which facilitates the growth of the individual employees who

Note: * & ** indicate 1% & 5% level of significance
are embedded within the organizations. Growth in the work performance of the individual employees would automatically increase the satisfaction index of the patients, who are the main customers of the nursing homes. Patient loyalty would be very easier to achieve in these cases. However, this could only be achieved through the increased quality of services being delivered by the employees of the nursing homes. Thus, the rights of the employees must be protected and an environment must be built inside the nursing home which would facilitate the growth of the employees as well. Employees will deliver their best if they are mentally fit without any stress and tension and this would only be possible by removing such factors from the organizations which proves to be a negative influence on them. Power and politics is one such negative influence and so it must be removed.

Conclusion

In this paper, it can be observed that power and politics are not seen in a positive light by the many employees in the private nursing homes of the healthcare industry. These factors are responsible for causing multiple hitches in the proper functioning of the organizations as they are having a deep impact on the health of the employees. The employees often feel powerless because of the organizational power and politics. Because of that, they become laidback in their attitude regarding their work. This restricts them from traversing the extra mile which would enrich their work performance with quality. This hindrance has a colossal impact on the growth of the organizations as well. Thus, it is in the best interest of the organizations to address the power and politics and also to devise ways by which the effect of these two factors can be negated as much as possible. The quality of work performance being delivered by the employees can lead to the satisfaction of the patients which measures the growth of the healthcare industry.

Ethical clearance: Ethical approval for this study has been taken from Authority of different Private Nursing Homes of West Bengal for executing the data collection process in their organization smoothly. Also Employees have been assured for keeping complete confidentiality of their feedback regarding our research topic.

Abstract

The aim of the study was to evaluate the potentiality of aluminium gallium arsenide laser in caries diagnosis and caries inhibition. Dental caries is the one of the most common oral affliction affecting humankind. The management strategies are dependent on the stage at which caries is detected. The incipient carious lesions are characterized by subsurface dissolution due to more fluoride ions in the 50-100 microns of the tooth’s outer surface. Sub surface, non cavitated lesions are amenable to remineralization, thus early detection and diagnosis is of prime importance. Aluminium gallium arsenide lasers have wide range of clinical applications like diagnosis in field of operative dentistry and endodontics, soft tissue conditions. Its applicability in hard tissues of teeth is still being explored. 10 Patients of either sex, between age of 18 years to 25 years having initial pit and fissure caries on first or second mandibular molar were included in the pilot study and its respective contralateral tooth served as control. The laser fluorescence method values were noted for both test/treatment and control. The concerned teeth - was irradiated with 810 nm Aluminium gallium arsenide (AlGaAs) diode laser (Whitestar™, Creation, Verona, Italy) for 30 seconds followed by application of remineralizing paste containing casein phospho peptide amorphous calcium phosphate with fluoride (CPP-ACP-F). The contralateral tooth type serve as control-(Group A), in which after noting laser fluorescence readings only remineralization paste was applied. The laser fluorescence method values are noted. Thereafter follow up at 3, 6 monthly intervals included serial scanning with Laser fluorescence pen and comparison with baseline reading. The readings determined if caries has been inhibited, arrested or progressed. Statistical analysis was done using paired ‘t’ test to compare control and test groups and calculation of the mean. Laser fluorescence values in test group have remarkably decreased soon after irradiation and this was followed by further decrease in values even during follow up. Laser fluorescence can be used as tool for diagnosis of dental caries and laser irradiation leads to caries inhibition.

Keywords: Aluminium Gallium Arsenide Laser, Laser fluorescence, Caries Inhibition, casein phospho peptide-amorphous calcium phosphate with fluoride (CPP-ACP-F)

Introduction

Dental caries is a dynamic multifactorial progressive disease of the hard tissues of the teeth with varying phases of demineralization and remineralization. When the oral condition is conducive for demineralization of the tooth, it is seen that the 50-100 microns of surface...
layer doesn’t show any dissolution, this is due to increased ion concentration of fluoride ions in surface layer. The subsurface layer has less amount of fluoride and more of carbonate ions hence this leads to sub surface carious lesions. It is such incipient subsurface lesions, non cavitated lesions which have the potentiality to be remineralized. Thus it is imperative that an accurate and reliable diagnosis of non-cavitated occlusal caries is made because these lesions can be arrested and reversed at an early stage by preventive measure like remineralization.\textsuperscript{1-3}

Traditionally diagnosis of dental caries was based on visual detection. In addition the diagnosis of early noncavitated carious lesion also requires detection and diagnostic aids which are more valid and reliable. There is a plethora of such devices flooding the market. One such valid and reliable method is laser based fluorescence caries detection method.\textsuperscript{4}

The remineralizing strategies included remineralizing paste alone or in conjunction with high powered lasers with varying results.\textsuperscript{5} High powered lasers are losing out to low powered lasers owing to their cost, bulky machines and non-availability of optimal laser beam diameter to irradiate occlusal tooth surface.\textsuperscript{5-7} Low powered laser have a large number of clinical applications mainly directed toward soft tissues. But today they are being explored as an alternative to high powered lasers in hard tissue applications.\textsuperscript{8-10} Currently the research is ongoing to develop a versatile laser which is portable, highly efficient, cost effective and has a wide range of clinical applications. One such development is aluminium gallium arsenide lasers (Al Ga As). The greater selectivity of these wavelengths in targeting and removal of the carbonate group from the enamel mineral molecule results in greatly increased acid resistant enamel. Additionally the altered mineral has greater uptake of topically applied fluoride and thus greater acid resistance and leads to remineralisation of noncavitated lesions.\textsuperscript{9,10}

Thus this study was undertaken to assess the potentiality of aluminium gallium arsenide laser irradiation in caries inhibition.

**Material and Method**

**Material**

Laser fluorescence for caries detection

Aluminium Gallium Arsenide Laser

Casein phospho peptide- amorphous calcium phosphate with fluoride paste (CPP – ACP F)

**Method**

Ethical Clearance for the study was undertaken in A. B. Shetty Memorial Institute of Dental Sciences Nitte (Deemed to be University), Mangaluru. Patients of either sex, between age of 18 years to 25 years reporting to OPD of Conservative Dentistry & Endodontics of AB Shetty Memorial Institute Of Dental Sciences, Mangalore, having initial pit and fissure caries on first or second mandibular molar were included in the pilot study and its respective contralateral tooth served as control. The carious lesion selected was designated as 1.0, where the site of lesion is 1(pit and fissure) and size 0 (The initial lesion can be identified but there is no surface cavitation and has potential of remineralization).

The proposed sample size is 10 in both groups. Informed Consent was taken. Oral prophylaxis is done. Suspected incipient lesions were short listed using Ekstrand criteria & ICDAS index during visual examination. Preoperative I.O.P.A radiograph/ OPG Digital radiograph were be taken to rule out any periapical pathology. But the diagnosis was conclusive by a more specific and highly sensitive method of caries diagnosis that is Laser fluorescence method. The Laser fluorescence pen (Laser fluorescence pen 2190, KaVo, Birbech Germany) scanned the area of interest on the tooth surface to record the peak value which could range from 0 (sound) to 99 (caries) (Lussi criteria). A reading of 15-20 indicates enamel caries (diagnostic read out is Baseline Reading). The laser fluorescence method values are noted for both test and control. The concerned teeth - (Group B) was irradiated with 810 nm AlGaAs diode laser ( Whitestar\textsuperscript{TM}, Creation, Verona, Italy) for 30 seconds followed by application of remineralizing paste CPP-ACP F.(GC –Tooth Mousse). The contralateral tooth serve as control-(Group A), in which after noting Laser fluorescence device readings only remineralization paste was applied. The laser fluorescence method values are noted for both test and control. The concerned teeth - (Group B) was irradiated with 810 nm AlGaAs diode laser ( Whitestar\textsuperscript{TM}, Creation, Verona, Italy) for 30 seconds followed by application of remineralizing paste CPP-ACP F.(GC –Tooth Mousse). The contralateral tooth type serve as control-(Group A), in which after noting Laser fluorescence device readings only remineralization paste was applied. The laser fluorescence method values are noted. Thereafter follow up at 3, 6 monthly intervals included serial scanning with Laser fluorescence pen and comparison with baseline reading. The readings determined if caries has been inhibited, arrested or progressed. A radiograph is taken to assess if caries has progressed. The results were
tabulated and computed. Statistical analysis was done using paired t test to compare control and test groups and calculation of the mean.

TABLE 2: Gives comparison of control with test group at different time intervals. Comparing test value with control at each level and p-value given at the end of the table shows that there is significant difference between the values of test and control. The control group and test group are compared at each time interval i.e preoperative, postoperative, and at 3 months and six months follow up. It has been observed that soon after laser irradiation the caries inhibitory role of the laser has led to a statistically significant difference between both the groups at postoperative period, 3 months follow up and 6 months. The laser irradiation leads to decrease in caries value as assessed by diagnodent.

**TABLE 4:** Gives the comparison between test group preoperatively with test group at time intervals of postoperative, 3 months and 6 months.

**Graph 1 - Mean Diagnodent Values**

The mean values of diagnost show that there is decrease in values of test group at all-time interval postoperatively even though to begin with the test group had higher values than control group.

**GRAPH 1:** Gives mean values of laser fluorescence reading. The mean values of laser fluorescence show that there is decrease in values of test group at all-time interval postoperatively even though to begin with the test group had higher values than control group.

**Discussion**

Dental caries is one of the most prevalent oral diseases of the world. It is the result of localized chemical dissolution of a tooth surface resulting from metabolic events in a biofilm. There is no global consensus or construct on the criteria for detection of carious lesions. But as the current management of dental caries rests on strong foundation of minimal invasive dentistry it follows as corollary our method of caries detection, case selection and management strategies would also do so. Thus in this study we have selected site 1 size 0 lesions given by Mount and Hume.11

The initiation of carious lesion begins with subsurface dissolution, this is due to the fact that 50-100microns of surface layer is resistant to decay as a result of the increased concentration of fluoride ions. Subsurface dissolution can be remineralized 2 To harness the phase of remineralization, it is important that caries be detected before cavitation. There are various diagnostic aids available for the clinician with varying degree of sensitivity and specificity. Lussi et al in an invitro study evaluated the new laser fluorescence device – Diagnodent pen with older version of diagnodent. The clinical finding were correlated with the histogical reading. The authors found that diagnodent was more sensitive a tool than specific.12 Based on past invivo and invitro studies 12-14 laser fluorescence method of caries detection was considered in the study. It was found that laser fluorescence method can be used to monitor dynamic progression of demineralization and remineralization.

Fluoride is a gold standard in caries prevention. Newer remineralization past like CPP ACP have been used alone or in combination with fluoride with varying degree of success.15-17 Jayarajan J et al conducted an invitro comparative study of the remineralizing potentiality of CPP ACP and CPP ACP F. The changes were evaluated by diagnost and scanning electron microscopy. Both the groups showed statistically significant remineralization results. Due to inclusion of NaF in CPP ACP F, it showed better remineralizing potential than CPP ACP alone.16 Thus in our study we
used CPPACP F as a remineralizing paste both in test and control.

Hicks conducted a scanning electron microscopy to assess the surface changes when surface treatment is done with argon alone or with fluoride. Both combinations had a caries inhibitory role. Niazy MA in an in vitro study evaluated whether the enamel cream and the laser had a synergistic effect on enamel and root caries. It was observed that there was a synergistic effect of CO2 laser and CPP ACP, this was more so evident on the root dentin Lasers like CO2, Nd:YAG, Erbium :YAG have all said to have a caries inhibitory role. The mechanism of action of each is varied and still under investigation. These high power lasers didn’t sustain the interest of the researchers as clinically the machines were bulky, costly and the inability to have a beam diameter of size of the tooth’s occlusal surface led to search for an cost effective but versatile alternative. Aluminium gallium arsenide (AlGaAs) lasers were one such alternative.

Sant’anna De G R carried out a FT –Raman study to analyse the compositional changes in enamel induced by a combination of low level lasers and photo absorbing cream. It was found that low level lasers like diode lasers modified the organic matrix content which led to caries inhibition. In the study we have used 3.5 watts of aluminium gallium arsenide laser for its caries inhibitory role. It was found in this study that Laser fluorescence values in test group have remarkably decreased soon after irradiation and this was followed by further decrease in values even during follow up. With 30 sec of Aluminium Gallium Arsenide laser application the test tooth had shown remarkable reduction in laser fluorescence reading thereby indicating that tooth has been structurally altered and improved and thereby inferring that the remineralization potential of a tooth with laser treatment has been enhanced. Clinically and radiographically there was no progression of the lesion. (TABLE 1, 2 & GRAPH 1)

This was in agreement with study by Sant’anna De G R and the hypothesis that there is change in crystalline structure of hydroxypapatite crystals due to the removal of carbonate ion and increased uptake of fluoride , a change bought about by these AlGaAs lasers. The comparison between test group preoperatively with test group and similarly control groups at time intervals of postoperative, 3 months and 6 months shows that there is significant difference between the values. (TABLE 3 & 4) This was in agreement with study by Sant’anna De G R

**Conclusion**

The results of the study seem promising however long term clinical trials should be undertake to assess the viability of using aluminium gallium arsenide laser (AlGaAs) in caries inhibition.

Tooth Brushing in Pre-school Children: An Indian Perspective of Parental Challenges

Sonia Sivadas¹, Ashwin Rao², Arathi Rao³, Karuna YM⁴, Anupama Nayak⁴

¹Former post graduate Student, ²Associate Professor, ³Professor, ⁴Assistant Professor, Department of Pedodontics and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education

Abstract

Background: A number of barriers to oral hygiene maintenance of children by parents have been reported in the literature. It is important to identify barriers faced by the parents in each individual child and give them customized solutions relevant to the Indian Scenario.

Aims: To unveil the challenges faced by the parents regarding tooth brushing of their preschool child in Mangalore city and to evaluate the awareness of parents to prevailing tooth brushing recommendations.

Settings and Design: Cross sectional Questionnaire study.

Method and Materials: The parents of the preschool children were asked to complete a pre-tested and validated questionnaire evaluating the problems faced by the parent during routine tooth brushing and assessing the knowledge of the parent regarding newer tooth brushing recommendations.

Statistical analysis used: The obtained descriptive data was statistically Analyzed using SPSS version 16 software.

Results: 43.7% of the parents responded that their children do not cooperate while tooth brushing with different quoted reasons. 37% of the parents experienced difficulties to brush their child’s teeth mainly due to lack of access to all areas of the mouth. 50% of the parents were not brushing all surfaces of the teeth. Only 8% of the parents started brushing when the first tooth erupted and 38% of the parents made their children brush twice a day. 68% of the parents spent 1-3 minutes for brushing, 62% of the parents rinse their child’s mouth minimally after brushing, 63% parents used a pea size of toothpaste, 64% of the parents used children’s toothpaste, 51% of the parents thought that fluoride is more important in preventing cavities and 48% of the parents were aware that their child’s toothpaste contained fluoride.

Conclusions: Most common reasons for uncoperativeness while tooth brushing was because of the willingness of the children to brush themselves. Main difficulty in tooth brushing was to access all areas of the mouth. Knowledge of the parents regarding frequency of tooth brushing and age at which brushing has to be started was deficient.

Keywords: Tooth brushing, Children, Challenges, oral hygiene

Introduction

Good oral hygiene maintenance habits, if acquired during the early years of life, will be deeply ingrained in the child’s mind and this lays the foundation for a healthy, disease free oral cavity.¹ Also poor dental health in early childhood is a strong predictor of future dental problems.² Thus maintaining good oral health is
important among preschool children.¹

Tooth brushing remains the most efficient means of oral hygiene maintenance in children.³ While various innovative designs of toothbrushes are commercially available, effective tooth brushing however depends on use of technically correct tooth brush, brushing pattern and on patient compliance.³,⁴ The brushing ability of the children greatly varies not only according to their age but also to their individual dexterity and motivation.⁵,⁶

There exists various recommendations and guidelines on tooth brushing, as well as on selection and usage of toothpastes in children. Dental professionals should help and motivate parents to supervise and assist their children’s tooth brushing as per these guidelines.⁶

Late initiation of brushing, frequency of tooth brushing and lack of parental involvement in brushing are the significant factors responsible for caries experience at 6 years.⁷,⁸ To effectively handle these factors, it is important to identify barriers and facilitators, referred to as determinants, that parents report while maintaining the oral hygiene of their preschool children. A number of barriers to oral hygiene maintenance of children by parents have been reported in the literature viz lack of knowledge, the cost and availability of toothbrushes/toothpaste, difficulty establishing a routine, the influence of family, and managing child behavior.⁹-¹³

However, these studies are not Indian studies. Considering the Indian scenario, the challenges encountered by the parents while caring for their child’s tooth might be totally different. Thus the present study was conducted to unveil the challenges faced by the parents regarding tooth brushing of their preschool child. Another aim of the study was to evaluate the awareness of parents of preschool children to prevailing tooth brushing recommendations.

Materials and Method

Institutional ethical committee clearance was obtained before the commensal of the study. It was a cross sectional study.

Sample size and study subject selection:

Assuming prevalence of parents who faced challenges during tooth brushing and who had awareness to new tooth brushing recommendations as 60%, keeping the error as 10 % of the prevalence, the sample size obtained for the present study was 266. To obtain this sample size parents of pre-school children in the age group between 2-5 years of various English medium kindergarten schools in Mangalore were selected. Parents who either partially filled or not returned questionnaire were excluded from the study.

Procedure:

The parents of the preschool children who were included in the study were asked to complete a pre-tested and validated questionnaire. The questionnaire consisted of twelve questions. Part A of the questionnaire (3 questions) evaluated the problems faced by the parent during routine tooth brushing. Part B of the questionnaire (8 questions) assessed the knowledge of the parent regarding newer tooth brushing recommendations in preschool children. The obtained descriptive data was statistically Analyzed using SPSS version 16 software. The level significance was kept at p< 0.05.

Findings

A total of 269 completed questionnaires were collected and analyzed. The mean age of the preschoolers whose parents were included in the study was 3.84 (SD 0.78). 43.7% of the parents responded that their children do not cooperate while tooth brushing. The reasons given by the parents for uncooperativeness were various patterns of behavior viz sleepiness and crankiness just after waking up or before going to sleep (33%), willingness of the children to brush themselves (40%), dislikeness of the taste of toothpaste (6%), inattentiveness and playfulness (28%). 37% of the parents experienced difficulties to brush their child’s teeth for reasons viz lack of access to all areas of the mouth (40%), difficulty to restrain the child (17%), unawareness regarding proper child positioning while brushing (8%) and fear about toothpaste ingestion by the child (10%). When completeness of the tooth brushing was evaluated, 50% of the parents were not brushing all surfaces of the teeth. Reasons given for the same included difficulty in retracting the lips (28.7%), tightness of the cheeks posed by the child (28%) and interference of the tongue during brushing (25.6%). On analyzing the second part of the questionnaire, it was found that only 8% of the parents started brushing when the first tooth erupted, 38% of the parents made their children brush twice a day, 68% of the parents spent 1- 3minutes for brushing, 62% of the parents rinse their child’s mouth minimally after
brushing, 63% parents used a pea size of toothpaste, 64% of the parents used children’s toothpaste, 51% of the parents thought that fluoride is more important in preventing cavities and 48% of the parents were aware that their child’s toothpaste contained fluoride.

Discussion

The knowledge and beliefs of parents have direct influence on health behaviors and outcomes of their preschool children. Mothers play a pivotal role in determining children’s oral hygiene practices and behavior. To formulate the strategies to efficiently prevent caries basic knowledge about the methods of caring for the teeth is essential. Thus it is indeed meaningful to know the challenges faced by the parents while maintaining the oral hygiene of their preschool child, along with evaluating their awareness towards prevailing tooth brushing recommendations.

In the present study, out of all the oral hygiene maintenance strategies, tooth-brushing was chosen because there exists a plausible evidence which states that early brushing using fluoridated toothpaste is: associated with lower levels of mutans streptococci; highly caries protective and the predictor of future tooth brushing habits. Campanaro et al identified child’s cooperation to be the most commonly discussed facilitator to tooth brushing. In the present study, 44% of the parents responded that the children were non cooperative during tooth brushing. However, the encouraging factor was that in spite of the uncooperativeness majority of the parents (87%) did not compromise on the tooth brushing. One of the reasons that the parents gave for uncooperativeness was that children were sleepy and cranky just after waking up or before going to sleep. This may be overcome during morning by making the tooth brushing to be a part of bath. Once the child feels fresh after a couple of mugs of water during bathing, it’s good time to start brushing. Another reason given by the parents was playfulness and inattentiveness of children. Though mischievous is inbuilt by default in children, discipline in performing daily routine like tooth brushing should be cultivated by making the child importance of oral health. Shirzad et al concluded that oral health education program among pre-school children via health-promoting school approach was useful in improving the oral hygiene behaviors among the preschool children. Thus oral health education can be given to preschool children in the form of stories for instance “Spiderman would brush his teeth so he doesn’t get cavities”. Huebner et al stated various methods in their study which parents used while brushing their children’s teeth like telling stories (distraction), showing elder sibling brushing (modelling) and explaining the consequences of not brushing (emotional reactions) parents. These methods can also be tried to gain the cooperation of the child.

Another finding of our study is that 39.5% of the parents responded that children want to brush themselves, which lead to the uncooperative behavior while brushing. Thus majority of the parents (34.9%) allowed the child to brush but under their supervision. Only 1.5% of the parents brushed their children’s teeth themselves inspite of children’s demand to brush themselves. According to AAPD 2014 guidelines tooth brushing should be performed for children by a parent twice daily and according to AAP parent should brush their child’s teeth atleast once a day until the child is of 8years of age. Thus parental education in this regard is essential. However, child’s initiative to brush can be encouraged by allowing to engage in playful tooth brushing after which the parent can take over.

A small percentage of children in the present study (6%) were reluctant to brush as they did not like the taste of the tooth paste. This can be overcome by trying different mildly flavored children’s tooth paste medicated with optimum fluoride and xylitol (both are anti carious agents) according to the suitability to children’s taste. Huebner et al in their study mentioned that parents used various child-oriented supplies such as cartoon-character toothbrushes and flavored toothpastes as effective enticements.

36% of the parents in the study found brushing in children to be a difficult task for various reasons. A majority (40%) found it difficult to access all areas of the mouth as children do not retract their lips and tightens their cheeks while brushing. Retracting the child’s lips and cheeks while brushing becomes important due to the high tendency for food accumulation in this area. Ramos-Gomez et al explained the method of retracting the child’s lips and cheeks while brushing along the gingival margins. They also suggested the use of spongy handle of an age-appropriate sized toothbrush to prop open the child’s mouth. Tell-show-do and modeling may
make the brushing job easier for the parents.

Part B of our study revealed that majority of the children were brushed once a day (61.3%) and the most common age at which tooth brushing started was at 2 years while the AAPD guidelines recommend the implementation of the oral hygiene measures no later than the time of eruption of the first primary tooth. The guidelines further state that tooth brushing should be performed for children by a parent twice daily, using a soft toothbrush of age-appropriate size and the correct amount of fluoridated toothpaste. In the present study, only 41.9% of the preschool children were brushed at least twice daily. Thus the awareness of parents regarding the brushing frequency was found to be limited in comparison with that of other parts of the world. Interestingly in our study majority of the parents (51%) felt that fluoride is more important in preventing caries than calcium. Though 63.6% of the parents opted for using children’s toothpaste, majority of them did not know if their toothpaste contains fluoride or not.

The present consensus states that rinsing with water after brushing with fluoride toothpaste can reduce the benefit of fluoride toothpaste. Results of our study showed that 63% of the parents followed the current norm of minimal/no rinsing, with 68% of the parents spending average 1-3 minutes for brushing their child’s teeth. 58.6% of the parents used a pea size amount of toothpaste. However, the amount of toothpaste on the brush should be age related. No more than a smear or rice-sized amount of fluoridate toothpaste should be used for children under age three; no more than a pea-sized amount should be used for children ages three to six.

Through this study, an insight into the challenges that the parents face while performing tooth brushing for their children could be obtained along with evaluating their knowledge and awareness regarding the prevailing tooth brushing recommendations. With this background an appropriate oral health education program can be planned for the parents of preschool children of Mangalore. But, since the study sample was from English medium schools of Mangalore, results can’t be generalized to rural aspects of Mangalore, which needs further exploration.

Conclusion

Within the limitations of the study, following conclusions can be drawn:

Most common reasons for uncoperativeness expressed by children while tooth brushing was because of the willingness of the children to brush themselves and sleepiness/crankiness just after waking up or before going to sleep.

Main difficulty in tooth brushing was to access all areas of the mouth as children do not retract their lips and tightens their cheeks.

Knowledge of the parents regarding frequency of tooth brushing and age at which brushing has to be started is seen to be deficient.

Clinicomicrobiological Insight into Bacteremia due to Gram Positive Cocci

Soumya Shrigiri¹, Sevitha Bhat², Archana Bhat K³

¹MBBS Student, ²Associate Professor, ³Assistant Professor, Department of Microbiology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Bacteremia due to Gram positive cocci poses a challenge to clinicians due to the delay in diagnosis and multidrug resistance among these bugs.

Aim: To study the associated infections, risk factors & antibiotic resistance in Gram positive cocci, to note antibiotic treatment and outcome in bacteremia.

Materials and Method: Observational study was carried out in Microbiology laboratory of a tertiary care centre. Blood samples were cultured using BacT/ALERT system. Antibiotic susceptibility pattern was done by Vitek 2 compact system.

Results: Enterococcus faecalis and Staphylococcus aureus were the most common isolates of clinically significant Gram positive bacteremia. Skin and soft tissue infections, infective endocarditis, urosepsis and biliary tract infections were the common sources. Health care related infections (55%) were predominant in contrast to hospital acquired bacteremia (15%) indicating that prior invasive procedures increases the risk of blood stream infection. Mortality of 34% was observed.

Conclusion: Timely diagnosis of sepsis, identification of risk factors and co morbidities, choosing the appropriate antibiotic therapy is crucial in the management of Gram positive bacteremia.

Key words: Bacteremia, Gram positive cocci, Staphylococcus aureus, Risk factors

Introduction

Incidence of Gram-positive bacteremia & bloodstream infections (BSI) has increased in the hospital. Staphylococcus aureus is a major cause of endocarditis with increasing reports of MRSA. The risk factors associated with invasive S. aureus infection include dialysis, IV drug abusers, HIV infection, IV catheters, heart disease, cancer, diabetes mellitus. Vancomycin is used in the treatment of MRSA, however Vancomycin MIC >1 μg/mL may be associated with higher treatment failure and mortality.

Enterococcus spp. is a cause of Gram-positive bacteremia. Risk factors for Enterococcal infection include gastrointestinal colonization, renal insufficiency, neutropenia, transplantation, urinary or vascular catheters, prolonged hospital/ICU stay, prior surgery.

Groups A, C, G streptococci are rare causes of bacteremia & endocarditis. The associated debilitating conditions are risk factors in these patients. Group B streptococcal bloodstream infections occur in the presence of predisposing factors: age >65 years, diabetes mellitus, cirrhosis, cancer. Group D streptococcal bacteremia is associated with infective endocarditis in elderly patients with no H/O valve disease.

Streptococcus pneumoniae is another important cause of bacteremia. Invasive pneumococcal disease is
common in children <2 years old, older adults (>65 years old), immunocompromised patients and individuals with co-morbidities.6

Bacteremia due to Viridans group Streptococci is common in neutropenic patients, but can occur in non-neutropenic patients as well.5

The prompt identification and appropriate antimicrobial therapy of Gram positive bacteremia can reduce morbidity and mortality. Risk factors for acquisition, co-morbid conditions, empirical treatment, change in antibiotic after the sensitivity and MIC report and its impact on clinical outcome of bacteremia are of a concern. There has been no similar study from this region. Hence this study was undertaken.

**Aims and Objectives**

To identify the Gram positive cocci in blood and study their antibiogram.

To study the major risk factors, associated infections/co-morbidities in patients with bacteremia caused by Gram positive cocci.

To note the antibiotic treatment and outcome in patients with Gram positive bacteremia.

**Materials and Method**

**Study setting:** The study was conducted in the Microbiology laboratory, Kasturba Medical College, Mangalore, a tertiary care hospital.

**Study design:** Time bound descriptive study

**Study sample: Inclusion criteria:** Patients admitted with suspected sepsis in whom paired blood culture samples yielded Gram positive cocci. Quick SOFA score(adults) and SIRS criteria (paediatric age group) were considered for inclusion.6

**Exclusion criteria:** Patients with negative blood culture or with positive blood culture yielding coagulase negative Staphylococcus(CONS), Gram negative bacilli, and yeasts.

Hospital acquired Blood stream infection (HA-BSI): Patients with positive blood culture > 2 days of admission or ≤1 day after discharge.7 Health care related Blood stream infection (HCR-BSI): Patients with positive blood culture > 2 days of admission along with one of the following: Prior hospitalization (in the last 90 days); long term haemodialysis; prior invasive procedures; long term intravascular devices for parenteral nutrition or chemotherapy or immunosuppressive therapy.7 Community acquired Blood stream infection (CA-BSI): Patients who donot fulfill the criteria for HA- BSI or HCR-BSI and who have a first positive blood culture ≤ 2 days after admission.7

The study proceeded after clearance from the Institutional Ethics Committee. Blood culture was done using Bac-T ALERT microbial detection system(Biomeriux, Inc. Durham, North California, USA). Identification &antibiotic susceptibility was done by Vitek Compact 2 system and interpretation was as per CLSI guidelines. Medical records were examined for clinical details,treatment and outcome . Bacteriological culture from other sites was noted to trace the probable source of sepsis.

**Statistical analysis:** For categorical variables, statistical test chi square was done.p value <0.05 was taken as statistically significant.

**Results:** Of the 4812 blood culture samples received from January-August 2018, 482 (10.01%) showed positive growth. Of these 482 isolates, Gram positive cocci other than CONS constituted 47 (10.01%). The other 435 isolates were Coagulase negative Staphylococcus, Gram negative bacteria and yeast.

The Gram positive cocci isolated are as shown in table 1. The mean time to positivity (in hours) ranged from 9-18 hrs.

Of the 25 sources traced, the predominant ones included intravenous catheters (n=10, 21.3%) infective endocarditis (n=4; 8.5%) and skin and soft tissue infection (n=4; 8.5%) and urinary tract infection (n=3; 6.3%). Of the total 4 skin and soft tissue infections (n=4), 3 were due to *S. aureus* and the other was due to *Enterococcus faecalis*. All the endocarditis cases were secondary to *S. aureus*. Dialysis catheter related bacteremia was due to *E. faecalis*. Bacteremia secondary to biliary tract infection was traced in 2 cases with *Enterococcus faecalis*. The case of Pneumococcal bacteremia was secondary to Pneumonia.

Majority of Gram positive coccal bacteremia were healthcare related (n=22, 55%), followed by community acquired infections (n=13, 32.5%) and hospital acquired infections (n=5, 12.5%).

The antibiogram of *Staphylococcus aureus* and *Enterococcus faecalis* are shown in tables 4 and 5 respectively. Among the 4 MRSA strains, 1 was resistant to Linezolid.

Only one *Enterococcus faecium* was isolated from blood and it was sensitive to Erythromycin, Vancomycin, Teicoplanin, Linezolid, Tetracycline, Ciprofloxacin but resistant to High level gentamicin, ampicillin and penicillin. The patient had an intra-abdominal source and was put on teicoplanin and meropenem.

*Streptococcus pneumoniae* was sensitive to Erythromycin, Clindamycin, levofloxacin and Vancomycin but resistant to Penicillin, ceftriaxone and cefotaxime. The patient was an elderly, immunocompromised patient with chronic lung disease and pneumonia was treated with levofloxacin and vancomycin and the condition improved.

Viridans *streptococcus* (n=2) isolated were sensitive to Ampicilin, Penicillin, cefotaxime, Erythromycin, Clindamycin, Vancomycin, Methicillin, Linezolid, Tetracycline, Ciprofloxacin but both the isolates were resistant to Clindamycin. We observed 2 cases of VGS bacteremia. 1. Elderly patient with respiratory tract infection, history of prior surgery and antacid administration, renal insufficiency and hypoalbuminemia. 2. Paediatric patient with haematological malignancy and neutropenia with sepsis. Both the patients expired.

The empirical antibiotics used were ceftriaxone, cefaperazone, piperacillin tazobactam, clindamycin, amikacin, meropenem and Vancomycin. Clindamycin, linezolid, vancomycin or rifampicin were used for the treatment of MRSA.

Out of the total 47 patients with Gram positive cocci bacteremia, mortality was observed in 16 patients (34%). However, majority (n=25, 53.2%) showed improvement with adequate antibiotic treatment.

**Discussion**

Gram positive cocci have emerged as pathogens in bacteremia leading to sepsis and septic shock. In our study of clinically significant Gram positive bacteremia, *S. aureus* and *Enterococci* were the common agents. In a study from Spain, 37% (n=459) of the total 1229 bacteremia cases were by Gram-positive cocci. In a study by Cordonnier et al prevalence of Gram-positive cocci bacteremia was 21%. In our study, 78.7% (n=37) of the cases with Gram positive bacteremia were adults of which 54% (n=24) were >65 years. Age affects the clinical presentation and outcome of bacteremia and is an independent risk factor for death due to sepsis.11

Colonization with VRE is a risk factor for bloodstream infection. Risk factors include exposure to antibiotics, immunosupression, hematological malignancies, increased ICU stay. VRE colonization occurs in GI tract, skin, genitourinary tract and oral cavity. In our study, vancomycin (8.33%, n=2) and teicoplanin resistance (8.33%, n=2) was detected using automated methods. Both the strains that were vancomycin resistant were *E. faecalis*. One of them, was resistant to teicoplanin as well, and was isolated from an immunocompromised patient with renal failure and hypoalbuminemia and the patient died. The other strain that was resistant to vancomycin was isolated was from an immunocompromised patient was sensitive to teicoplanin. The patient condition improved with combination therapy with piperacillin tazobactam and teicoplanin. *E. faecalis* strain that was teicoplanin resistant was sensitive to Vancomycin, the patient had an intra-abdominal source and was treated with vancomycin and rifampin and the condition of the patient improved. *Enterococcus faecium* isolated from a patient with gastrointestinal insufficiency was resistant to High level gentamicin, ampicillin and penicillin. The condition of the patient improved with combination therapy with teicoplanin and meropenem. In cases of Enterococcal bacteremia empiric antibiotics used were piperacillin tazobactam, ceftriaxone, meropenem, teicoplanin and...
vancomycin. Based on the antibiotic sensitivity report a combination therapy of ampicillin and high level gentamicin or streptomycin, vancomycin or teicoplanin or rifampicin were used.

Patient with a penicillin resistant *Streptococcus pneumoniae* bacteremia was treated with levofloxacin and high dose ceftriaxone.

One of the VGS bacteremia patients died due to rapid progress to acute respiratory distress syndrome (ARDS) and shock. In one of the two total cases of VGB, Imipenem and rifampicin was used.

Our study of clinically significant Gram positive bacteremia showed a mortality of 34% and a majority (53.2%) improved with adequate treatment. This supports the view that appropriate antibiotic therapy still remains the mainstay of treatment in patients with suspected sepsis.

**Conclusion**

The current study reveals that Gram positive cocci is an emerging cause of bacteremia. *Enterococcus faecalis* and *Staphylococcus aureus* were the most common isolates of clinically significant Gram positive bacteremia. Skin and soft tissue infections, infective endocarditis, urosepsis and biliary tract infections were the common sources traced. Health care related infections (55%) were predominant indicating that prior invasive procedures increases the risk of blood stream infection. Mortality of 34% was observed and a majority (53.2%) improved with adequate treatment. Hence timely diagnosis of sepsis, identification of risk factors and co morbidities, choosing the best empiric antibiotic and de-escalation or change in antibiotic therapy is crucial in the management of Gram positive bacteremia.

A Study on Cost Minimization in Operating Room; Through Team Learning at Tertiary Care Hospital of South India

T. Bharathi
Lecturer, Faculty of Management, Sri Ramachandra Institute of Higher Education & Research (Deemed to be University), Porur, Chennai, India

Abstract

Increase in number of surgeries and minimizing cost of surgeries will circuitously maximize OR profitability. Reducing the cost of surgery is possible only by team effort of health professional. This study analyses the cost involved in the operating room of tertiary care hospital of south India. The informative data collected from the staff members of operating room at tertiary care hospital of South India were analysed by comparing the cost incurred before the learning module presentation and after the presentation. The use of gloves varied between surgeries and the maximum of 10 pair of gloves were used in only one surgery (2%) and on an average, B. Sc Nurses used more IV fluids when compared to DGNM nurses, found to be statistically significant. After the study presentation, considerable decline in the usage of materials, machines and other things in numbers was significant. After Team learning, there is a considerable decline in the usage of materials and infrastructure. Continuous medical education should be mandatory for promotion and other human resource welfare activities, which will give complete effort for learning.

Key Word: Operating room, Surgeries, Cost management.

Introduction

Healthcare is one of the fast growing industries in both, developing and developed countries. Historically, surgical interventions has taken place in the traditional environment of the hospital operating room (OR) suite. The operating room has been one of the highest revenue generators for healthcare organizations. The OR in a hospital, is a convergence of man, materials, money, methods and so on. Infrastructure with highly advanced equipments, expenses under human resources like salary and procurement of consumables come under overhead costs. Increase in number of surgeries and minimizing cost of surgeries will circuitously maximize OR profitability and in turn hospital profitability which always stands as management staffs’ major attraction. Surgery, anaesthesia, and nursing are three vital departments involved in OR management. Cost can be minimized by mobilizing essential resources when these three fields work in an amicable manner. Learning best Operation theatre practices and reinforcement will be helpful for desired changes in the healthcare personnel, which will be helpful to reduce the cost incurred in Operating Room. Cost of surgery to be fixed based on the expenses for that particular surgery. Low operating cost is possible only when the cost of surgery is minimized. Reducing the cost of surgery is possible only by team effort as it involves anaesthetists, doctors, nurses, technicians and supporting staff.

This study analyses the cost involved in the operating room of tertiary care hospital of south India. This would helps to understand how cost of operative room could be minimized through teaching of quality practices to the operating team. Study also assesses the effectiveness of the team learning and increase in efficiency through the learning.
Method and Materials

The study area is confined to operating room of Chennai Medical College Hospital and Research Centre. This study was approved and designed by the Institutional Ethical Committee of Chennai Medical College Hospital and Research Centre, Trichy, India. The research was Descriptive Research Design depends mainly on primary data collected through well framed structured questionnaire to obtain the well considered opinions of the respondents. The sampling technique used in this research study is convenient sampling with number of participants of 100.7 Findings were about the distribution and average usage of materials for two set of samples and comparison of cost before and after the presentation. The collected data from the staff members were analyzed by comparing the cost incurred before the learning module presentation and after the presentation. Number of gloves, caps, IV fluids used, minutes of air conditioner and electrical items utilized were analysed. Learning module had a brief introduction about Building support among physicians to reduce supply costs; blocking time; adjusting or block time and releases; proactively avoiding gaps due to equipment problems; case start times and controlling turnover times.

Results

Data shows that 4 pair of gloves were used in 7 surgeries (14%), 24 surgeries (48%) used 5 pair of gloves, 16 surgeries (32%) used 6 pair of gloves, 2 respondents (4%) used 7 pair of gloves and the maximum of 10 pair of gloves were used in only one surgery (2%) (Table 1). Additional data in table 3.; showed that 3 pair of gloves were used in 5 surgeries (10%), 27 surgeries (54%) used 4 pair of gloves, 14 surgeries (28%) used 5 pair of gloves and the maximum of 6 pair of gloves were used in only 4 surgeries (8%) (Table 1).

Before presentation, among 18 B. Sc Nursing samples, none of them used 3 and 6 IV fluids for any of the surgery. 6 respondents (12%) used 5 IV fluids and 12 respondents (24%) used 4 IV fluids for each surgery. Among 32 DGNM samples, only 1 surgery (2%) used 6 IV fluids, 8 surgeries (16%) used 3 IV fluids, maximum of 19 surgeries (38%) used 4 IV fluids and 4 surgeries (8%) used 5 IV fluids. On an average, B. Sc Nurses used more IV fluids when compared to DGNM nurses (Table 2). The usage of IV fluid by the B. Sc nurses during surgery was found to be more than the usage of IV fluid by DGNM nurses which is found to be statistically significant (p<0.05) (Table 3).

After presentation, among 21 B. Sc Nursing samples, 3 respondents (6%) used 2 IV fluids, 14 respondents (28%) used 3 IV fluids for each surgery and 4 respondents (8%) used 4 IV fluids. Among 29 DGNM samples, 14 surgeries (28%) used 2 IV fluids, maximum of 14 surgeries (28%) used 3 IV fluids and 4 surgeries (8%) used 4 IV fluids. On an average, B. Sc Nurses used more IV fluids when compared to DGNM nurses (Table 3). The usage of IV fluid by the B. Sc nurses during surgery was found to be more than the usage of IV fluid by DGNM nurses which is found to be statistically significant (p=0.042) in Pearson Chi-Square.

By comparing the samples collected before and after the presentation, different statistical interpretation of different variables selected shows considerable decline in the usage of materials, machines and other things in numbers (Table 4). Students sample (t) test was administered for the two set of samples collected before and after presentation, which shows significant changes in all statistical interference (Table 5).

**Discussion**

Two sets of data were collected with the same questionnaire, whereas 50 samples were collected before the presentation and 50 samples were collected after the presentation. Findings were about the distribution and average usage of materials for two sets of samples and comparison of cost before and after the presentation. After Team learning, there is a considerable decline in the usage of materials and infrastructure. Continuous medical education should be mandatory for promotion and other human resource welfare activities, which will give complete effort for learning. Periodical individual material audit for a staff should be in practice to give them ideas about their scientific procedures. Check list should be checked and counter signed in various levels of personnel for the materials used in operating room. This will ensure the optimum utilization of materials which impact the cost of the surgery. Exchange of staff members on routine at possible places will help the project manager/ Head of the department to identify the root cause of excessive cost if any.

Team work is essential for the success of anything. To bring out remarkable output, change should be adapted by each and every one participating in an event. Team in Operating room includes the personnel involved in holding area, surgical ward, surgical suite and they have to analyze in planning, implementation and evaluation. Starting from assessment of patient for anaesthesia fitness, room preparation, transferring the patient, scrubbing, gloving, gowning, basic aseptic techniques, assisting the anaesthetist, positioning the patient, preparing the surgical suite, safety of the patient and post-operative care in the recovery room involves cost to the patient as well as cost to the management if the surgery cost are fixed before the surgery.

Cost minimization in operation room is not possible without team effort. For most of the cases, lack of awareness about the value of cost and its influence made the team to ignore significant things which impact in revenue and other promotional activities. Team should focus on the same goal to achieve it with ease. As like that, with team learning cost levied by the patient can be reduced and revenue can be increased on other hand. It is important to learn things in work place, also to bring in behavioral changes to practice the learnt model. Advancements in science and technology always results in downsizing the utility in all aspects. It will be excellent if a cordial team with learning interest is involved in any process to bring fruitful results.

Abstract

The global prevalence of oral diseases across all ages demands the immediate need for oral health promotion measures. The impact and retention of oral health message vary depending upon the mode of delivery. Thus present study compared the effectiveness of different modes of oral health education delivered to preschoolers. A randomized controlled study with three groups (n=40) compared the effect of oral health education delivered through drama mode enacted by peers, dentists and a control group with no oral health education intervention. Debris Index Simplified (DI –S) component of Oral Hygiene Index Simplified (OHI –S) modified for primary dentition was used to measure the oral hygiene status. Statistical analysis was performed using SPSS version 21 for descriptive and inferential statistics like paired t test, ANOVA and post hoc tests. p< 0.05 was considered statistically significant. Oral health education delivered by drama mode had a significant impact on the preschoolers. The study concluded that the same oral health information when delivered by different modes had different impact on the preschoolers.

Key words – Preschoolers, Drama, Oral health education.

Introduction

The prevalence of dental caries varies from 27 to 54% in Indian preschoolers¹. The prevalence of gingivitis is 53%². The cost of dental treatment is increasing at a catastrophic rate and a large proportion finds dental treatment unaffordable. Hence these dental diseases can cause a huge impact on the quality of life of this age group later in life. An array of determinants contribute to this high rate including dietary pattern, oral hygiene practices, socioeconomic status of parents and lifestyle³. China.¹

METHODS: In total, 2880 cases involving preschool children were selected by stratified cluster sampling. The dental examination methods and criteria followed the WHO guidelines. SPSS 19.0 was used for the statistical analysis. Chi square tests were used to compare the caries prevalence among children with different social characteristics. Non-parametric tests were used to compare the decayed, missing and filled teeth (dmft. Primary prevention focusing on health promotion measures at a professional level can be carried out by dentists by diet and oral hygiene practice counseling.

Health education is the pillar in prevention of disease. School years are the most influential period in any individual’s life and oral health information can be disseminated and periodically reinforced in these years. This is the period when a person develops attitudes, beliefs and skills which he sustains lifelong⁴. Various behavioral factors like frequent intake of sugary food, improper oral hygiene measures and failure to visit a dentist influence oral health of preschoolers⁵.
Conventional health education which gives normative advice does not result in sustained dental behaviors. Research has shown that peer led health education is as effective as health education given by experts. Innovative approaches engaging the peers, experts and teachers may have a better effect in retaining the oral health messages. The present study thus aims at comparing the effectiveness of conventional health education given by dentists, health education by peers through drama mode and a control group.

**Materials and Method**

The study was conducted in an aided higher secondary school in Bengaluru from March 2015 to June 2015. Ethical clearance was obtained from the Institutional Review Board of Vokkaligara Sangha Dental College. Permission for conducting the study was obtained from the school authorities. Informed consent was obtained from the parents. Sample size was estimated from results of a previous study. A total sample size of 120 was estimated for a power of 80% at 5% level of significance using nMasters 2.0 Sample size software.

A pilot study was conducted on 20 participants. 2 examiners recorded oral health status. They were trained and calibrated before the study. Inter examiner reliability was obtained as 0.78. Children who were found uncooperative, whose parents failed to give informed consent and who had the index teeth missing were excluded from the study. Children who had a full set of primary dentition were included. Oral Hygiene Index Simplified modified for primary dentition was used to record the oral hygiene status. The study group was divided into 3 groups. Children were randomly allotted to the three groups by systematic sampling and the examiners were blinded of the allotment. From the school register, the class teacher allotted the first child to dentist group, second child to drama group and every third child to control group.

Oral hygiene status of the preschoolers was measured before the intervention. Examination was done using mouth mirror and explorer under natural light. For children in the drama group, a 15 minute drama which gives information on oral hygiene practices, correct brushing technique, diet and dental caries and importance of dental visit was shown. The drama was enacted by senior students of the school who were given a four hour training by the dentist. The drama was video graphed. Group B received oral health education from the dentist. This oral health educational lecture by the dentist lasted for 10 minutes by the use of layman language, and active participation and appreciation of a positive behavior was ensured. Model and oral hygiene aids like tooth brush and toothpaste were used. The third group, Group C acted as the control group in whom oral examination was done at baseline and no oral health education was given.

The programme was evaluated three months later and the DI-S scores were recorded for all the three groups of pre-schoolers. Oral health education was given to all groups by dentists as well as drama mode and participants of all the three groups were distributed toothbrushes at the end of the study.

Statistical analysis was done using SPSS version 21 and level of significance was set at 5%. Paired t test was used for comparing the oral hygiene scores of each group before and after intervention. ANOVA and Tukey’s post hoc tests were used for comparing the oral hygiene scores of the three groups.

**Results**

A total of 120 preschoolers took part in the study of whom 42.5% were females and 57.5% were males. The difference in age and gender between the three groups was not statistically significant (Table 1).

At baseline, the mean DI-S values for drama, dentist and control groups were 1.8043 +/- 0.85516, 1.8118 +/- .73908 and 1.7823 +/- .68190 respectively. ANOVA showed no significant difference in mean DI-S values between the three groups at baseline (p = 0.984) (Tables 2,3).

Post intervention, the mean DI-S values for drama, dentist and control groups were 0.9727 +/- 0.65981, 1.6418 +/- .67624 and 1.7885 +/- .67624 and the difference in means was significant (p=0.000). ANOVA showed a significant difference in the mean DI-S scores between the three groups. Post hoc tests revealed that the mean difference in DI-S scores between drama and dentist group and drama and control group was statistically significant (Tables 4, 5).

When the baseline and post intervention values were compared for each of the three groups, the mean difference in DI-S was significant for both drama
and dentist group. The control group had a slightly higher DI-S compared to baseline which was not statistically significant (Table 6, Figure 1).

Figure 1: Comparison of pre and post intervention OHI-S scores
Discussion

The present study compared the effectiveness of oral health education by three different modes among preschoolers. Retention of messages is the indicator of success of any health education program. The mode of delivery of any oral health education should be determined by the age of the recipients. This study compared health education delivered by drama enacted by senior students of the school, dentists and a control group.

Drastic improvement in oral hygiene was noted among the drama group. Children in this group had oral health education delivered with fun and in an interactive manner which made learning an enjoyable activity and kept them motivated. Children found the drama very interesting and their known seniors enacting their favorite cartoon characters created an element of attention in them. The same information when conveyed by dentists also significantly improved the oral hygiene of the preschoolers but lesser than that by the drama group and the difference was statistically significant. The formal delivery of oral health education by the dentists might not have created the level of motivation as the one delivered by the drama. The control group had an increase in the oral hygiene score which was not significant.

Friel S. et al found that mass media has a positive impact on the oral health knowledge and behavior of Irish children compared to a control group\textsuperscript{10}. Srivastava R. et al compared the effectiveness of oral health education delivered by teacher and a dental professional in school children. The oral health education delivered by the dental professional was more effective compared to the former group\textsuperscript{11}. Soleymani MR et al compared story telling and creative drama modes in improving children’s personal hygiene. Both these methods improved personal hygiene but there was no statistically significant difference between the two modes.(6)Haleem A et al compared the effect of repeated and reinforced oral health education by dentists, teachers and peers. One time oral health education could not bring any marked change in oral health status in any of the three groups while 6 months after repeated and reinforced education oral health status improved significantly in all the groups\textsuperscript{12}. The results of our study are similar to that by John et al where oral health education was delivered by three groups, dentist, school teachers and dental residents mimicking cartoon characters. There was a significant improvement in oral health in all three groups except the control group and the highest improvement was for the drama group\textsuperscript{13}.

Teachers are often the role models for students. The information conveyed to the students must be imparted to the parents also for effective maintenance of oral hygiene. Different vehicles of health education can be used in combination and the idea of health promotion schools should be emphasized. Parents can be given oral health education by teachers who are already trained by dentists. Frequent reinforcement of these messages is mandatory. Behavior changing theories like Social Learning Theory and Health Belief Model emphasize that knowledge, attitude and behavior can be changed by a joint effort of mass media, community and individual interactions\textsuperscript{10}. The WHO Health Promoting School approach mandates a combination of school teachers, health professionals, students, school personnel, parents and policy makers for promoting health in school children. Our study showed a significant improvement in oral hygiene in the groups educated by dentists as well as in the drama group. So a combination of these modes is likely to produce more promising results. A study by Shirzad et al in Iran showed that the health promoting school approach is more effective in improving the oral health behavior than a control group in preschoolers\textsuperscript{14}.

Long term effects of any health education intervention need to be evaluated. The persistent effects are usually seen with reinforcement of health education messages. It is seen that the positive effects of oral health education interventions are generally short lived with the effects fading away in the course of time\textsuperscript{15}. The effects of repetition and reinforcements on oral hygiene status have to be evaluated with long term longitudinal studies. The number of contacts with the target group is one factor determining the success of a health education program. Evidence suggests that at least four contacts with a target is necessary for the intervention to be successful\textsuperscript{16}.

This study had certain limitations. It was conducted in only a single school which limits the generalizability of the study. It considered only oral hygiene status before and after intervention. The various other factors that can affect the oral hygiene practices like parents knowledge and socioeconomic factors were not evaluated. The most prevalent diseases of preschoolers being caries and gingivitis would also have been considered. The time
period of 3 months is not sufficient to measure these diseases.

A Population Based Study on ‘At-Risk’ Under 5 Children in Rural South-India

V. Samya1, A Meriton Stanly2, Ramesh Harihara Iyer2

1Assistant Professor, 2Professor, Sri Ramachandra Institute of Higher Education and Research, Porur, Chennai

Abstract

Introduction: Most of the childhood morbidities that occur under 5 years of age are preventable by taking very simple methods. Application of risk strategy in under-5 children help in improving the health-status and decreasing the childhood mortality.

Aim: To estimate the prevalence of ‘at-risk’ under 5 children in a rural area and to find out its associated factors.

Materials and Method: A population based cross-sectional study was undertaken in the rural area of Tamil Nadu. 370 children were selected by simple random sampling method.

Results: 55.9% of the children were at-risk (95 % CI 53.32-58.48). Majority (66%) of the at-risk children were 37-48 months. Type of family (adjusted OR 2.1, 95% CI 1.3-3.5, p=0.003), type of housing (kutcha house: adjusted OR 6.3, 95%CI 2.7-14.8, p=0.000; semi pucca house: adjusted OR 1.9, 95% CI 1.1-3.6, p=0.026), and personal hygiene of the primary care giver of the child (adjusted OR 3, 95% CI 1.9-4.8, p=0.000) were significantly associated with ‘at-risk’ under 5 children.

Conclusion: there is a high prevalence of ‘at-risk’ children, which indicates the need for risk approach in preventing the morbidity and mortality in under 5 children.

Keywords: under 5 children, at-risk, prevalence.

Introduction

The problem of overpopulation poses as a great burden and an obstacle to achieve adequate health care for the vulnerable population in India which mainly constitutes women and children. Children especially those who are less than 5 years are affected by various health issues and morbidities which may ultimately lead to childhood mortality. Indicators of child health in middle income countries show that there is still a long way to go to improve child health. The census 2011 shows, the percentage distribution of deaths to total deaths are maximum in the under 5 age group and more among the female children. Infant deaths in India and death of 0-4 year children account for 13.6% and 16.7% respectively of the total deaths in the country.

The mortalities in children under 5 years of age are mostly due to infective origin or due to lack of proper sanitary measures which can be prevented easily by taking appropriate measures. The ‘risk approach’ can prove as a good strategy to provide better health care services. It aims at correcting the inverse proportion of availability and accessibility of health care vis-a-vis its need by reallocation of existing resources. An individual may be at risk because of biomedical, social or environmental reasons. When a group is identified as ‘at risk’ it indicates that the frequency of risk factors is higher compared to others.

Though there are many studies about ‘at risk’ under 5 children done in various parts of India, there weren’t any done in south India. The prevalence rate of at risk under 5 children is quite high in the other studies. Hence is important in taking up this study which will bring out magnitude of the ‘at risk’ under 5 children in the rural community which when adequately addressed can help in achieving better health and good quality life in rural India.

The objectives were to estimate the prevalence of ‘at risk’ under 5 children and its associated demographic and environmental factors

**Methodology**

A population based cross sectional study was done at the field area of Nemam village in Poonamallee block of Thivallur District in Tamilnadu. Among the 2373 children under 5 years in the village, 841 were from Nemam sub-centre, 541 children belonged to Kuthambakam sub-centre and 991 children were from Pappanchanthram sub-centre.

The lowest prevalence used to estimate sample size was 54.5%. With limit of accuracy 10% of prevalence and Z (1-α/2) value 1.96, the estimated sample size was 319. Assuming a non-response of 15%, the final sample size was 370. Using under 5 children register maintained at the PHC, 131 children from Nemam, 84 children from Kuthambakkam, and 155 children from Pappanchathram were selected by simple random sampling method.

**Operational Definitions:**

‘At risk’ under 5 child

Based on WHO criteria, the child was identified as ‘at risk’ if they had any one of the following

- Birth weight <2.5kg
- Twin births
- Birth order 5 or above
- Birth spacing < 2yrs
- Present weight below 70% of expected weight for age
- Early lactation failure and artificial feeds below 6 months
- Major congenital anomaly
- History of deaths of >2 siblings below 12 months of age
- Death of either or both parents
- Chronic or recurrent gastroenteritis and/or recurrent respiratory infection (recurrent infections that is >5-6 episodes of infection per year)
- Mother working outside >8hrs a day
- Delay in giving supplementary feeds i.e. more than 6 months
- Mid arm circumference <12.5cm (1-5yrs)

**Data Analysis**

Data entry and analysis was done using Statistical Package for Social Sciences (SPSS) version 16 software. Descriptive statistics was used to analyse the background variables and using chi square, the associations of risk factors were analysed. Backward Wald logistic regression model was used to analyse the significantly associated factors and adjusted OR and 95% CI was obtained.

**Results**

There were 51.1% male children and were males and 48.9% female children with a mean age of 32.4 months (SD 15.58) ranging from 1 to 60 months. (Table-1) 72.7% of the children lived in nuclear or extended nuclear families and 27.3% of them belonged to joint family. Majority of the children (72.4%) belonged to medium SLI followed by high SLI (21.6 %) and low (5.9%). Majority of the mother’s occupation (94.9%) belonged to the semiskilled category followed by unskilled work (5.1%). Among the mothers, 5.4% of the mothers were working for more than 8 hours. Most of the fathers (52.4%) were unskilled workers followed by semiskilled work (45.9%) and skilled worker was 0.3%.

**PREVALENCE OF ‘AT RISK’ UNDER 5 CHILDREN**

A child was considered to be ‘at-risk’ even if one of the 13 criteria given by WHO was present. 207 (55.9%) children were found to be at-risk with a 95% CI of 53.32 to 58.48. The prevalence was 55.6% among the male children and 56.4% among the females. Among those
children at-risk, majority of them belonged to the age group of 37-48 months (66%). Children less than 1 year of age had the lowest prevalence 46.2%. (Table-2)

It was found that the majority of the children at-risk (47.6%) had only one of the 13 risk factors, followed by 30.6% of the children had 2 risk factors, 17% children had 3 risk factors, 4.4% of the children had 4 risk factors and only 0.5% of the children had 5 risk factors.

The most common at-risk factor was birth spacing <2 years which was 42 %, followed by delay in supplementary feeds (27.9%). The prevalence of chronic or recurrent diarrhoea and/or ARI was 2.2% and 15.8% respectively. Low birth weight and weight <70% of the expected weight for age was 14.3%. (Table-3)

Children living in nuclear family (OR 2.2, p = 0.001), children born to illiterate mothers (OR 1.8, p<0.05) and the children who lived in houses with low or medium SLI (standard of living index) were significantly at a higher risk to become an at risk child. As the standard of living increased, the risk of being at risk decreased which was statistically significant (table 4).

Children living in kutchha houses were at a higher risk of being at risk when compared to children living in pucca houses (OR 7.16, p<0.0001), similarly children in semi pucca houses were at a significantly higher risk of being at risk compared to those children in pucca houses (OR 2.42, p<0.05). As the housing standard decreases, the risk of being at risk increases. Children living in overcrowded houses (OR 2.3, p<0.0001), living in houses without a sanitary latrine (OR 2, p<0.003) were significantly at a higher risk of being ‘at risk’. There was a significantly increased chance of the child to be at risk where the personal hygiene of the caregiver was unsatisfactory (OR 3.04, p<0.0001).

The significant risk factors associated with ‘at risk’ under 5 children were included in the logistic regression model. Using Backward Wald, the logistic regression model revealed that unsatisfactory personal hygiene of the care giver (Adjusted OR 3.007, 95%CI 1.9-4.8, p<0.001) was a significant risk factor. Children living in a katcha house had a higher risk (adjusted OR 6.3, 95%CI 2.7-14.8, p=0.000), followed by children living in semi pucca house (adjusted OR 1.9, 95% CI 1.1-3.6, p=0.026) than those living in pucca houses. Children belonging to a nuclear family (Adjusted OR 2.2, 95% CI 1.3-3.5, p<0.001) were significantly associated to children at risk. Details in table 4.

Discussion

The prevalence of at-risk under 5 children (55.9%) in this study was similar to the study done in Loni, Ahmednagar, Maharashtra [4] which reported a prevalence of 54.7 % S.Sharma and B.P. Gupta in Pachhad block Sirmour district, Himachal Pradesh also showed a high prevalence (65.7%). Another study by S.K. Bhasin et al. showed the prevalence of at-risk under 5 children to be 65.3%. Aswar et al. reported a
prevalence 64.97% in the rural district of Nagpur, and Singh et al reported 47.9% Kapil et al reported a figure of 63%, while Chaudhary et al and Lai et al reported 51% of children were classified ‘at-risk’. P.K. Dutta et al reported 51.7% of the children to be at risk. This reinforces the fact that ‘risk approach’ is an appropriate and effective strategy.

Those children belonging to a nuclear family were having a significantly higher chance to be-at-risk (OR 2.2, p = 0.001, $\chi^2$ 11.6). The absence of grandparents and other near relatives places a greater burden on the nuclear families in terms of responsibilities of child rearing where as in a joint family there is sharing of responsibilities which gives the family greater economic and social security and support in child rearing. Similar results were found in the study done in Loni and Mohd Juniad, where a significant association was found between type of family and at-risk children; children reared in nuclear families were more at risk.

There was a significant association of at-risk children with the type of house in which they lived. Similar findings were observed in the study by Shubhada Sunil Avachat et al, where 31.3% of the children in kaccha houses, 32.2% of the children in semi pucca and 36.4% of the children in pucca houses were found to be at risk. ($\chi^2$ for linear trend 21.6, p<0.05). The study by Sharma et al also had similar findings; 96.8% of those children in kaccha houses, 74.3% of the children in semi pucca houses and 30.7% of the children in pucca houses were at risk ($\chi^2$ for linear trend 122.6, p<0.001). Similar findings were observed in a study by Mohd Juniad where type of housing was significantly associated. This reinforces the fact that good housing standards is known to be associated with increased morbidity and mortality.

The current study showed there was a significantly increased chance of the child to be at-risk when the personal hygiene of the caregiver was unsatisfactory (OR 3.04, p<0.001). When the personal hygiene is good, it is definitely effective against diarrhea. Khadse et al had similar findings where proper handwashing after defecation and before food handling protected against recurrent diarrhoeal episodes which is one of the risk factors for a child to be coined as ‘at-risk’. Another study by Kariuki et al showed significant reduction in diarrhoeal episodes where the child handlers practiced handwashing, had a soap for handwashing at household. The study by Vani K. Boorah concluded that washing hands by the caregiver before feeding the children can reduce diarrhoeal incidence.

**Conclusion**

Prevalence of ‘at-risk’ under 5 children in the rural population of Tamil Nadu is high. This points out the need to identify the ‘at-risk’ children in the Indian villages. This study has also confirmed that fact that improving the educational status of the mother, standard of living, personal hygiene and sanitation are important strategies in lowering the prevalence of ‘at-risk’ under 5 children. While the healthcare workers provide a routine health care to all under 5 children, simultaneous identification of ‘at-risk’ children can be done. By doing so depending on the risk factors, the children can be given appropriate care depending upon the availability of resources and proper referrals can be done. Thus there is a need and scope for identification of ‘at-risk’ children by the health workers and enhancement of their competence for appropriate management.

Friction Fit Implant Supported Removable Prosthesis

Vignesh Kamath¹, Shruthi Rao², Arjun Hegde³

¹Assistant Professor, Department of Prosthodontics, Faculty of Dentistry Melaka Manipal Medical College, Manipal Academy of Higher Education, Manipal, Karnataka, India, ²Private Practitioner, ³Assistant Professor, Department of Conservative Dentistry, Faculty of Dentistry Melaka Manipal Medical College, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

The field of implant dentistry has gained vast acceptance and popularity over the years. The ideology and concepts in this field have evolved and changed dramatically in recent years. Although implants offer a good outcome in partially edentulous patient, the outcomes have been better in completely edentulous patients in whom the retention and stability of the denture were extremely poor. A newly evolving idea in the field of implant dentistry is the use of SynCone for the rehabilitation of edentulous ridges. SynCone helps in immediate loading of the prosthesis under local anesthesia whereas in case of delayed restoration it serves as a prefabricated retentive component for both maxillary and mandibular edentulous ridge. This is a case report of rehabilitation of partially edentulous maxillary arch.

Keywords: SynCone Concept, Delayed Loading and Friction Fit.

Introduction

The field of implant dentistry has gained vast acceptance and popularity over the years. The ideology and concepts in this field have evolved and changed dramatically in recent years. Although implants offer a good outcome in a partially edentulous patient, the outcomes have been better in completely edentulous patients in whom the retention and stability of the denture were extremely poor. Before the introduction of these Osseointegrated prostheses complete dentures were the only treatment option available for patients with the edentulous ridge. The treatment of patients with edentulous ridges with the help of Osseointegrated implant-supported prostheses have shown effective results in numerous studies. A newly evolving idea in the field of implant dentistry is the use of SynCone for the rehabilitation of edentulous ridges. The main quality of this concept is its adaptability, cost-effectiveness, and minimal invasion. SynCone helps in immediate loading of the prosthesis under local anaesthesia whereas in case of delayed restoration it serves as a prefabricated retentive component for both maxillary and mandibular edentulous ridge.

This is a case report of rehabilitation of maxillary arch with metal reinforced denture. (SynCone Concept)

Material and Method

A 47-year-old male patient reported to the Department of Prosthodontics with a chief complaint of missing teeth [Figure 1a-c]. The patient who was already a denture wearer was not satisfied with his present denture due to lack of retention. Patients overall systemic condition was unremarkable. Based on the overall intra oral health and condition of the patient, overdenture using Syncone concept (delayed loading) was considered as a suitable treatment option as the
patient can remove the denture for better maintenance.

**Treatment Planning:**

After the clinical examination of the maxillary ridge, a radiographic stent was fabricated after which Orthopantomograph (OPG) was carried out. Adequate bone was noticed in the maxillary arch. Hence it was decided to place 4 Ankylos CX (Dentsply Implants, Germany). Two 8 mm implants were placed in the posterior region and two 11mm implants in the anterior region.

The radiographic stent was converted to a surgical stent which was used during the implant placement for knowing the exact position for the implants.

**Surgical Procedure:**

The entire procedure was done by infiltrating local anaesthesia (LA), 2% lignocaine with adrenaline. After injecting the LA a full thickness mucoperiosteal flap was then raised by placing a buccal releasing incision at the midline. Following this sequential osteotomy was done. A Lindemann side cutting bur was used to perforate through the cortical plate, followed by 2mm pilot drill, 3.2 mm final osteotomy drill and 3.5 x 11 mm bone reamer were used. Between each drill paralleling pins were placed to check for the parallelism between the implants. Two 3.5 x 11 mm and two 3.5 x 8mm Ankylos CX (Dentsply Implants, Germany) implants were placed [Figure 2]. Sulcus formers were placed for all the implants to avoid second stage surgery [Figure 3]. The flaps were approximated and sutured using 4-0 vicryl sutures.

**Prosthetic Part:**

The patient was recalled after four months of the initial procedure for the prosthetic phase. The abutment parallelism was checked in the cast using paralleling gauge [Figure 4a and 4b]. Taper cap degulor for syncone (5˚) were placed on to the abutments [Figure 4c]. A pattern resin framework was made on the cast and was casted using chrome cobalt so that strength of the denture is improved and to obtain a passive fit [Figure 5a and 5b]. Retentive beads were incorporated on the pattern resin framework for the retention of acrylic. Vent holes were made on the metal frame so that excess resin cement flows out and which will also act as retentive tags. A special tray was fabricated on the working cast [Figure 6a]. The abutments were transferred in the patient’s mouth using transfer jig. Following which the degulor cap was then transferred into the patient’s mouth. Next, the degulor caps were sandblasted on the outer surface to increase micro and macro mechanical retention. The degulor caps were picked into the metal framework using resin cement. The metal framework with the degulor cap was placed back into the abutment in the patient’s mouth. The special tray was used to make pick up impression using polyether impression material [Figure 6b]. The metal framework with the cap was then picked up in the impression which was followed by pouring the cast. The secondary cast was obtained [Figure 6c] then a denture base and occlusal rim were fabricated which was followed by recording jaw relation. Trial of waxed up denture was done [Figure 7a and 7b], and later it was processed [Figure 8]. Denture fit in was done, and an orthopantomograph (OPG) was made to check for the fit [Figure 9a-b].

Discussion

The major factor responsible for the success of any implant-supported prosthesis is the primary stability. According to Engqvist et al. the two essential aspects for the survival of an implant is the bone quality and bone resorption.

The use of conservative complete denture is very popular in edentulous patients, but they are associated with many shortcomings including lack of required retention, stability support which leads to other drawbacks like difficulty in speech mastication and aesthetics. Adelle et al. in their study highlighted the effective result of treatment of patients with edentulous ridges with the help of Osseointegrated implant-supported prostheses in their 15 years follow up study.

An implant-supported prosthesis helps in overcoming these disadvantages especially in patients with limited capability, severely resorbed alveolar ridges and loss of facial tissue support. The taper principle over the years has clinically proven its benefit in the implant-supported prosthesis. SynCone concept aims at providing the benefits for anchoring implant-abutment connections providing an extremely stable fit without any micro-movement thus facilitating a tension free fit.

This concept provides a great reduction in the prosthetic body. This system constitutes of pre-machined titanium abutment with predetermined sulcus heights and a particular angulation of 4°, 5°, or a 6° taper. For the maxillary arches with the correction factor included these abutments are also fabricated in 15°, 22.5° and 30° angulation.

Studies have concluded that in spite of periodic removal and cleaning of the denture a constant retentive force expected was about five years.

Zhang et al. conducted a study assessing the long term retentive characteristics of the Ankylos SynCone. The study concluded that the SynCone conical crown system potentially provides better adequate and constant retentive force in implant supported overdentures.

Marco et al. in their study found out that implant supported overdenture using SynCone concept had a success rate of 98.9%.

Studies have shown that the survival rate of implants is better and more in the lower jaw than in the upper jaw.

A study conducted by Jemt revealed that the five-year survival rate of the fixed implant-supported prostheses in the edentulous maxilla was 92%.

A randomized controlled trial carried out by Fischer et al. showed no significant difference in early and delayed loading of implants in the edentulous upper arch after five years of function. Overdentures that are supported by Osseointegrated implants help in overcoming the drawbacks of overdenture supported by natural teeth like dental caries and periodontal disease they also concluded in their study that when lip or facial support is required for a prosthesis the implant supported overdenture is the treatment of choice.

The SynCone concept is gaining wide popularity because of the telescopic design of the coping and its high-end retention. These two characteristics of this system help the prosthodontist in fabricating a prosthesis that has high stability and excellent performance as a fixed restoration which at the same time can be removed by the patient for daily maintenance. By using the SynCone system in the field of implant dentistry, a new dimension in the rehabilitation of missing natural teeth can be foreseen.

Conclusion

An implant supported maxillary overdenture along with sufficient retention and stability also restores
proper phonetics, aesthetics and good hygiene. The excellent retention, stability and functional and aesthetic properties offered by the SynCone concept make it a favorable choice in implant supported overdentures and the field of implant dentistry.

Analyses of Subject Wellbeing on Exercising Men, Women Students and Sedentary Men, Women Students

W. Vinu1, A. Arun Mozhi2

1Assistant Professor, Department of Physical Education and Sports Sciences, Annamalai University, Chidambaram, India, 2Assistant Professor, co-ordinator Psychology Wing, D.D.E, Annamalai University, Chidambaram

Abstract

The purpose of the study was to analyse the men and women students with habit of exercise and sedentary men, women students on psychological variable subject wellbeing. For the purpose of the study 60 students were selected from Annamalai university, in which 30 from department of physical education which consist of 15 women regular exercise practicing students the group was named as EWG and 15 men regular exercise practicing group which was named as EMG. and 30 students were selected from other departments who did not participate in any physical exercise and were sedentary which consist of 15 female students and the group was named as SWG and another 15 consists of men students and the group was named as SMG. The EWG and EMG groups participated in regular physical activities and SWG and SMG group underwent their routine life and did not under go any physical exercises. The Students were tested on their well beingness with Subject wellbeing inventory by Suhanya, B.T and Sananda Raj. H (2002). The data collected from the Four groups were statistically analysed by ANOVA. Both exercise groups (EWG and EMG) had influence of exercise over Subject wellbeing. But It was found Exercise influence on subject wellbeing was higher in EMG when compared with other three groups.

Key Word: Subject Wellbeing, Exercising Men, Women, Sedentary Men, Women Students.

Introduction

Earlier analysing the benefits of Physical exercise, it is necessary to define Physical Exercise precisely. Exercise is any activity that enhances or maintains physical fitness and overall health and wellness. Kylasov1. It is performed for various reasons, to aid growth and improve strength, preventing aging, developing muscles and the cardiovascular system, honing athletic skills, weight loss or maintenance, improving health and also for enjoyment. Many individuals choose to exercise outdoors where they can congregate in groups, socialize, and enhance wellbeing. In the adult population regular exercise has consistently been associated with higher levels of wellbeing such as fewer depressive and anxious symptoms and higher levels of subjective wellbeing. Longitudinal studies showed that exercise participation at baseline predicted fewer internalizing problems at follow up 2(Camacho et al.,1991; Wise et al.,2006; de Moor et al.,2008). In general, studies show increased levels of psychological wellbeing found in exercisers are the reflection of causal effects of exercise

Diener, Ed (1984)3. developed a tripartite model of subjective well-being in 1984, which describes how people experience the quality of their lives and includes both emotional reactions and cognitive judgments.

Quality of life is an overarching term for the quality of the various domains in life. It is a standard level that consists of the expectations of an individual or society for a good life. These expectations are guided by the values, goals and socio-cultural context in which an individual life. It is a subjective, multidimensional concept that defines a standard level for emotional, physical, material and social wellbeing. It serves as a reference against which an individual or society can measure the different domains of one’s own life. The extent to which one’s own life coincides with this desired standard level, put differently, the degree to which these domains give satisfaction and as such contribute to one’s subjective
well-being, is life satisfaction.

Emotions can be defined as a positive or negative experience that is associated with a particular pattern of physiological activity.” Emotions produce different physiological, behavioural and cognitive changes. The original role of emotions was to motivate adaptive behaviours that in the past would have contributed to the passing on of genes through survival, reproduction, and kin selection.4, 5

Cognition is “the mental action or process of acquiring knowledge and understanding through thought, experience, and the senses”.6 It encompasses many aspects of Intellectual functions and processes such as attention, the formation of Knowledge, memory, judgement and evaluation, reasoning, problem solving and decision making, comprehension and production of language. According to LauraMandoloni physical exercise is a strong gene modulator that induces structural and functional changes in the brain, determining enormous benefit on both cognitive functioning and wellbeing. Physical Exercise is also a protective factor for neurodegeneration. The term subjective well-being is defined as an individual’s experience of affective reactions and cognitive judgments. Happiness is sometimes used interchangeably with subject wellbeing, but the terms mean different things. Although wellbeing and happiness are correlated, subject wellbeing has a more wide-ranging definition. Subject wellbeing looks at satisfaction generally, as well as a sense of satisfaction according to a person’s standard. Assessing life satisfaction involves experience and future expectations. Having a high Subject wellbeing involves having “pleasant emotions, low level of negative mood, and high life satisfaction” (Diener, Lucas, & Oishi, 2002)7. (Puetz et.al., 2006)8. Exercise psychologists have recently examined the relationship between the different types of commitment to exercise operationalized through the notion of motivation toward physical exercise and Subject wellbeing. (Carver and Scheier, 1998; Tangney et al., 2004)9 and was found to play a key role in the development of Subject wellbeing (Hofman et al., 2011)10.

Subjective well-being measures how people think and feel about their life. It has three components. Cognitive evaluations of a person’s life, Positive affects (a person’s emotions, moods and feelings) Negative affects

12American psychologist Ed. Diener is credited with developing subjective well-being. He noted in The Oxford Handbook of Positive Psychology that an essential ingredient to the good life is that people like their lives. An ideal subjective well-being “includes experiencing pleasant emotions, low levels of negative moods, and high life satisfaction.”

Methodology

Normative survey method has been used in the present study to collect data from men and women students with habit of exercise and sedentary men, women students on psychological variable Subject wellbeing from Annamalai university, Department of Physical Education and from other departments, Chidambaram, TamilNadu. This study is an attempt to analyse the men and women students with habit of exercise and sedentary men, women students on psychological variable Subject wellbeing. This study was made use of comparison of different groups used have been categorised as follows 15 women regular exercise practicing students EWG and 15 men regular exercise practicing group which was named as EMG. and 30 students were selected from other departments were sedentary group which consist of 15 female students and the group was named as SWG and another 15 consists of men students and the group was named as SMG. The EWG, EMG groups participated in regular physical activities and SWG, SMG group underwent their routine life and did not under go any physical exercises.

Tool Used: Subject wellbeing inventory by Suhanya, B.T and Sananda Raj. H (2002.)13. The personal data Schedule is used to collect relavent information from the four groups of viz ‘Women, Men exercise practicing (EWG, EMG) and Sedentary Women and Men Group (SWG, SMG). The instructions for administration have explained to the subjects and Confidence of the responses assured by the investigator. (ANOVA) was computed for the data collected from ‘Women, Men exercise practicing (EWG, EMG) and Sedentary Women and Men Group (SWG, SMG). Further, since four groups were involved, whenever the F ratio was significant, Scheffé’s post hoc test used to determine which of the paired mean differed significantly.
Result of Study

The data collected from the Four groups were statistically analysed by ANOVA and the results are presented in table-1

(The required table value for significance at 0.05 level of confidence with degrees of freedom 3 and 56 is 2.77 and degree of freedom 3 and 54 is 2.78)

*Significant at .05 level of confidence.

Table-1 shows that the mean value of EWG, SWG, EMG and SMG groups are 53.20, 51.26, 53.66 and 51.53 respectively. The obtained ‘F’ ratio value of 27 for mean values of EWG, SWG, EMG and SMG were higher than the required table value of 2.77 for the degrees of freedom 3 and 56 at 0.05 level of confidence. So, there was a significant difference found between the groups due to exercise training.

The adjusted test means of EWG, SWG, EMG and SMG groups are 52.64, 51.26, 53.82 and 51.53 respectively. The obtained ‘F’ ratio value of 9.76 for adjusted test means of EWG, SWG, EMG and SMG groups were higher than the required table value of 2.78 for the degrees of freedom 3 and 54 at 0.05 level of confidence. It is observed from this finding that significant differences exist among the adjusted test means of between four groups Since, the adjusted test for ‘F’ ratio value is found to be significant the Scheffe’s test is presented in table: 2.

</table>
The result of Table - 2 shows the adjusted mean differences between the EWG and SWG is 1.38 showing there was a significant difference occurred among EWG and SWG. Meanwhile the obtained mean value EWG of 52.64 is higher than the mean value of SWG 51.26 so effect of exercise has influence over the psychological dimension of subject wellbeing. The comparison between SWG and SMG mean difference of 0.27 shows there is insignificant difference occurred between both men and women sedentary group so there was no positive sign in subject wellbeing and it was also found men sedentary group was better than the women sedentary group with the confirmation to post mean value of SMG was higher than the SWG. The comparison between EMG and SMG mean difference of 2.56 shows there is significant difference occurred between both EMG and SMG and it was also found EMG group was better than the SMG with the confirmation to adjusted mean value of EMG was higher than the SMG it is confirmed exercise has influence on the psychological dimension subject wellbeing. The comparison between EMG and SWG mean difference of 2.33 shows there is significant difference occurred between both EMG and SWG and it was also found EMG group was better than SWG with the confirmation to adjusted mean value of EMG was higher than the SWG it is confirmed exercise has influence on the psychological dimension subject wellbeing. The comparison between EMG and EWG with a mean difference of 1.18 shows there is significant difference occurred between both EMG and EWG and it was also found EMG group was better than the SMG with the confirmation to adjusted mean value of EMG was higher than the EWG it is confirmed exercise has more influence on the psychological dimension subject wellbeing on EMG group. Both exercise groups (EWG and EMG) had influence of exercise over Subject wellbeing. But it was found Exercise influence on subject wellbeing was higher in EMG when compared with other three groups.

**Discussion on Findings**

The results of the present study reveal that both exercise groups (EWG and EMG) had influence of exercise over Subject wellbeing.

These results are in conformity with the findings of the studies undertaken by the following Psychologist and Sports Scientist. According to (Argyle, 2001) Leisure and recreation have beneficial effects on Subject wellbeing. Exercise, for example, improves mood states in the short term and, in the long term, leads to increased subject wellbeing. Exercise provides better psychological and physical health outcomes; the pursuits of leisure and recreation and exercise often involve interaction with other people. Like places of work and places of worship, places of recreation and exercise classes all involve connection with other people which research shows promotes Subject wellbeing. (Gregory A Panza) “These findings were generally consistent with subjective measurements of physical activity. Higher levels of sedentary behaviour are associated with lower subjective well-being”.

The following studies are lined up with cognitive associated with physical exercise which is one of the important dimension of subject wellbeing. Physical Exercise affects brain plasticity, influencing cognition and wellbeing (Weinberg and Gould, 2015). (Fernandes et al., 2017). Experimental and clinical studies have reported that Physical Exercise induces structural and functional changes in the brain, determining enormous biological, and psychological benefits. Physical Exercise stimulates blood circulation in the neural circuits involved in cognitive functioning (Erickson, 2012).

The effects of physical Exercise on cognitive functioning have been shown across the lifespan from childhood to the old age (Hotting and Roder, 2013). It has been evidenced that cognitive functions that are influenced the most by brain maturation, such as attention or cognitive flexibility, and the cognitive functions that depend the most upon experiences, such as memory, are the most sensitive ones to Physical Exercise.

Due to Physical Exercise Cerebral structural changes, levels of neurotransmitters increased (e.g., serotonin, beta-endorphins) Physical exercise decreases anxiety, depression, dysfunctional and psychotic behaviours, hostility, tension, phobias, headaches. Physical Exercise increases assertiveness, confidence, emotional stability, cognitive functioning, internal locus of control, positive body image, self-control, sexual satisfaction.

There are consistent evidences that Physical Exercise has many benefits for people of any age, improving psychological wellbeing (Zubala et al., 2017) and quality of life.
Psychological research evidenced that Physical Exercise can even modulate the personality and the development of Self (Rodgers W. M)\(^2\). Moreover, Physical Exercise has been correlated with hardiness, a personality style that enables a person to withstand or cope with stressful situations (Weinberg and Gould, 2015)\(^3\).

These results should lead to reflect on beneficial effects of physical exercise and to promote its use as a modifiable factor for prevention, to improve cognitive abilities, Quality of life and Emotions which are the dimensions of subject wellbeing.

![Figure:1 Showing the mean value of four groups](image)

**Conclusion**

Both physical exercise practicing groups (EWG and EMG) had influence of exercise over Subject wellbeing. But it was found Exercise influence on subject wellbeing was higher in EMG when compared with other three groups. Further study is required to find out why women exercise group is lesser in subject wellness compared with men exercise group.

Knowledge, Attitude and Practices Towards Household Solid Waste Management among Semi-Urban Residents- A Community based Cross Sectional Study from Southern Part of Coastal Karnataka, India

Eshwari K1, Ranjitha S Shetty2, Akhila D3, Beulah Sarah James4, Akhilesh Kumar Pandey5

1Assistant Professor; 2Associate Professor; 3Postgraduate, Department of Community Medicine, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India, 4Palliative Care Officer, E.D Hospital, District Health and Family Welfare, Mysore, India, 5Lecturer/Statistician, Department of Community Medicine, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India

Abstract

Objectives: To determine the knowledge, attitude and practices towards household solid waste management and the perceived barriers for its proper disposal among residents of a semi-urban area.

Method: A community based cross sectional study was conducted among semi-urban residents of field practice area of a Medical College in Karnataka, India. A total of 441 households were included in to the study. A face-to-face interview was conducted using a pretested semi-structured questionnaire to assess the knowledge, attitude and practices among the residents towards management of household solid waste. Data was entered using Epi info mobile app and was analyzed using Easy R(EZR) software.

Results: The overall knowledge (60.3%), attitude (61.5%) and practices (72.8%) towards solid waste among the participants was near satisfactory. More than 90% were aware about the effects of inappropriate management of waste on health and environment. It was identified that having a better education and holding a skilled and professional jobs were the independent predictors of knowledge and attitude.

Conclusion: The gaining momentum among public towards management of solid waste can be further strengthened by taking in to account the identified predictors like education and occupation of the residents.

Keywords: Solid waste, Household, Knowledge, Attitude, Practices, Waste management, Environment

Introduction

Improper solid waste disposal and management is the source of air, water and soil pollutions and a cause of serious health hazard.1,2 Globally, million tons of municipal solid waste are generated every day and India with the fastest growing economy and as the second most populated country in the world, facing a major challenge in handling solid waste.3,4 India with rising population and living standards is struggling to handle the simultaneous acceleration in waste generation. The appropriate management of household solid waste requires a combination of methods like recycling, municipal landfill and source reduction.5,6 In metropolitan cities nearly one fourth of the municipal waste is not even collected due to the existing inadequacies in transportation and disposal mechanism.7
Understanding the public concerns, knowledge and behaviours is critical to achieve an efficient solid waste management system. A study among coastal residents of southern India documented unsatisfactory waste management practices in nearly three fourth households and it also concluded, the lack of knowledge on segregation and recycling as major determinants. The existing literatures also highlights the lack of knowledge and poor attitude among the residents for inappropriate waste management. Therefore, the present study was undertaken to assess the knowledge, attitude and practices regarding household solid waste management among residents in one of the semi-urban area of a coastal district, Karnataka, India.

Method

A community based cross sectional study was carried out among semi-urban residents of a coastal district of Karnataka. Anticipating an average knowledge of 50% towards household solid waste management among the residents, sample size was estimated to be 441. Study protocol was approved by the Institutional Ethics Committee (IEC No.-175/2018) prior to initiation of the study.

Data collection methodology

A responsible adult from each household was chosen and a face-to-face interview was conducted using a pre-tested semi-structured questionnaire after obtaining written informed consent. The socioeconomic status was assessed using modified BG Prasad classification. The responses were entered through Epi-info application on android mobile devices.

Information regarding socio-demographic characteristics of the study participants, their perception about different methods of waste disposal and its harmful effects on health and environment etc. were documented. Likewise, participant’s opinion regarding segregation of waste at the source and responsibility of keeping the community clean were recorded to assess their attitudes. The household’s method of waste collection and storage practices were observed with help of a checklist.

In all the respective domains the responses were scored, the correct responses were given the score of one whereas zero for wrong answers. All the scores in the respective domains were summed to obtain the final scores for every respondent. The final scores in the respective domains were divided using percentiles into three parts, first 30% of the score was categorized as poor, between 30% to 60% as average and above 60% as satisfactory. During analysis average and satisfactory categories were merged and named satisfactory and compared against poor or unsatisfactory category.

Statistical method

Data was analyzed using SPSS version 15.0 and was summarized as frequencies and percentages. Further to identify the predictors of knowledge, attitude and practice scores univariate and multivariate analysis were carried out.

Results

A total of 441 households were visited interviewing one adult member from each household. Of the study participants, 91.61% were in the age range of 26 to 50 years. The female predominance (60.14%) in the present study could have been due to the study team visit to households during working hours. Majority (80.7%) of the participants were Hindus followed by Muslims (11.6%) and Christians (7.7%) while 60.79% of them belonged to nuclear families. About two third (68.03%) of the participants had completed secondary education and nearly one fourth (24.72%) graduation. About 38.5% participants were engaged in unskilled work, 35.60% professional, 16.33% skilled and whereas 9.52% were unemployed. Nearly half (53.1%) belonged to middle socio-economic status followed by 26.3%, 20.6% to upper and lower class respectively.

![Figure 1: Prevalence of Knowledge, attitude and practice about solid waste management among the study participants (n = 441)](image-url)
As shown in Fig [1], the knowledge, attitude and practices regarding household solid waste management were above average in three fourth of the study participants based on the scores. Majority (90.25%) considered waste collection by the municipality on a regular basis to be the safest method followed by composting (20.86%). Burning (67.57%) and dumping indiscriminately (64.17%) and throwing away to water body (53.06%) were considered the most unsafe methods of waste disposal. More than 90% of the residents were aware about the adverse health effects and environmental damages of inappropriate waste management. Similarly, diarrhoeal diseases and respiratory illnesses were quoted by 65% and 43% of the participants respectively as adverse health effects.

About 72.79% of the residents were of the opinion that wastes should be segregated as bio-degradable / non-biodegradable at household level. Although 44.22% of the respondents believed that it is impractical to live without using plastic material, 50% opined re-using the plastics would reduce its load on the environment. Encouragingly, 85.94% felt that it is necessary to attend activities related to waste management at community level. Similarly, 91.16% said proper disposal of waste is a shared responsibility of government and the residents.

During the visits, 71.20% of the residents had maintained separate bins for dry and wet waste and on a regular basis it was collected by the municipality. Also 20.18% of the participants reported using burning as a modality for dry, non-plastic wastes.

Spearman rank correlation test demonstrated a positive linear relationship between knowledge, attitude and practice scores although the strength of correlation was weak.

</tbody>
</table>

As illustrated in Table [1] although knowledge was determined by level of education, occupation and socioeconomic status, on multivariable analysis only education status emerged as an independent predictor (p<0.05). With respect to attitude occupation of the participants was found to be associated, however on multivariable analysis it was insignificant.

As depicted in Table [2], high literacy levels and having skilled or professional jobs were found to be significantly associated with practices and these factors emerged as significant predictors on multivariate analysis as well.

**Discussion**

In present study knowledge regarding waste management was above average in nearly three fourth (60.3%) of the participants. Studies have documented prevalence ranging from 70 to 90% during 2015 through 2019.\(^9,13,14\) Whereas a study by Kumar et al reported, 85.2% of residents being unaware about waste generation and its disposal and the busy work schedule of the residents was reported as the barrier for the appropriate management.\(^15\) The attitude (61.5%) and practices (72.8%) towards waste management were in line with knowledge in present study and were in concordance with the study results of Almasi et al and Shahzadi et al.\(^13,14\) However, the proportion of participants with satisfactory practices were fewer in comparison to present study and the lack of resources and help from the municipal authority were the identified causes.

According to a study by Ogah et al from Nigeria, handing over the waste to collecting agency or municipality was considered safest (71%) and it is in agreement with the present study (79.13%).\(^16\) Probably better education could have lead to greater awareness among the residents. However, in a study among rural residents 60% considered burning as the primary method followed by mixed opinion of burning and burial (40%).\(^9\) Similarly, Shahzadi et al mentioned that 40% of the respondents quoting burial as method for disposal of household waste.\(^14\) With respect to effects of mismanagement of waste, according to Kiran et al 82.5% participants knew spread of diseases as impact on health and rodent nuisance, unpleasant site and unpleasant odor as effects on environment and this was in concordance with the present study (90%).\(^9\)

Based on community studies the proportion of residents practicing waste segregation at generation extends between 10-40%, whereas in the present study almost three fourth were practicing segregation.\(^9,17,18\) This was possible because separation of waste in to wet and dry was made mandatory by the municipality. In a study by Kiran et al, nearly one third residents were reusing the carry bags to reduce its purchase and in present study 50% preferred reusing plastic bags.\(^9,15\) According to Kiran et al, 90.8% of the residents felt as a generator of waste, they play a major role in its disposal and this was in agreement with present study and similar opinion by Ambat et al.\(^9,19\) In disagreement to above the residents in China felt that government should play a major role in recycling the waste than residents as mentioned by Huang P et al.\(^20\)
The statistically significant linear relationship between knowledge, attitude and practices (p< 0.001) scores in present study signify any action towards improving awareness regarding waste management is expected to bring a definitive positive change in attitude and practice. Similar observation has been documented by Laor et al.8

In agreement with the saying that older persons have greater desire to conserve resources for future generations by optimum utilization of valued resources many studies have reported higher abstract knowledge and practices towards solid waste management among elderly and this was in concordance with present study.21,22 Educational status, professional job and high socioeconomic status were identified as significant correlates for knowledge, attitude and practices towards solid waste management and this was in conformity with studies by Almasi et al and Banga et al.13,23

**Conclusion**

In present study majority of the people were aware that improper disposal of waste damages the environment and can spread various infections affecting health. Also the efforts towards reusing the plastic waste by the residents is commendable. However, a significant proportion were burning the waste which needs to be addressed through awareness programs explaining the effects of burning and on health and environment. Having better education and occupation were identified as determinants of perception and practice regarding waste management and this will definitely help in sustaining further efforts.

**Acknowledgement:** Authors would like to thank all the research participants for their active participation in the study. We also acknowledge the invaluable help of the Medico-Social Workers and Auxiliary Nurse Midwives of the Department of Community Medicine, KMC, MAHE, Manipal in data collection process.

Awareness Regarding Preconception Care among Women in Reproductive Age Group

Sunila L1, Lekha Viswanath2, Anju Philip T3

1Postgraduate Student, 2Associate Professor, 3Assistant Professor, Dept of Obstetrics and Gynecologic Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Health Sciences Campus, Kochi, Kerala, India

Abstract

Preconception care is an important factor which determines the outcome of pregnancy. Many of the women among reproductive age group are unaware about the importance of preconception care and they do not follow preconception care. The purpose of the study is to assess the awareness regarding preconception care among women in reproductive age group. A quantitative research approach with descriptive survey design was used in the study. The study was conducted at Nayarambalam panchayath in Ernakulam District and ward 9th and 11th was selected using one stage cluster sampling. The study was conducted among 200 women with in the age group of 18-44 years. The awareness regarding preconception care was assessed using a semi structured questionnaire. Data analysis was done by using descriptive and inferential statistics like frequency, percentage and chi square. The study shows that 15% of the participants have good level of awareness, 74% have average level of awareness and 11% have poor level of awareness regarding preconception care. More than 60% of the participants responded correctly to items like the importance of preconception care (77%), early sign of pregnancy (69%), number of TT immunization during pregnancy (63%). The areas were least number of women responded correctly are importance of smoking cessation (33%), immunization against Rubella (37.5%) and Birth spacing (39.5%). Only 48% of the women were aware of folic acid supplementation during preconceptional period. This study highlights the role of nurse to make the women aware about the preconception care and importance of practicing preconception care.

Key words: awareness ,preconception care ,women,reproductive age group

Introduction

Preconception care is an important part of health care for women of reproductive age. Majority of women did not realize that they are pregnant until the first trimester. By that time organogenesis is well advanced and it may have been affected the women. Knowledge on preconception care has the potential of changing behavior, modifying risk factors and improving the health status of women in reproductive age2. So advice regarding preconception care should be given to all individuals of reproductive age.

The major aspects of preconception care include practicing regular and moderate exercises, taking a well balanced diet involving fruits and vegetables, avoid exposure to pollutants, hazards and infections, correction of medical disorders, weight management, financial preparation and immunization.
A cross sectional survey was conducted by Coonrod D V et al to determine knowledge and attitudes regarding preconception care in a low income Mexican American population. The sample consisted of 305 reproductive age women at an urban public hospital. The average knowledge of preconception care score was less. Areas of higher knowledge included the effects of pregnancy of folic acid, alcohol use, substance use, verbal, physical and sexual abuse, and lower knowledge was found for the effects of cat litter and fish products. The study concluded that most participants are interested in preconception education and preconception health has a positive effect on pregnancy.

Public health service recommended that all women of child bearing who are capable of becoming pregnant should consume 400 microgram of folic acid daily. A study conducted by Hilton J on folic acid intake of women in USA. The result showed that all the participants were found to have an inadequate intake of folic acid. They lack knowledge about folic acid and the role of folic acid to prevent birth defects.

Every women of child bearing age should be viewed as a potential mother. There fore awareness regarding preconception care, identifying and treating risk factors prior to conception and adopting healthy life styles may improve the health of the women and coming generation. Thus a study on preconception care has a great concern in this present scenario.

The purpose of the present study is to identify the awareness regarding preconception care among women of reproductive age group in order to identify the need for preconception care.

Method

A quantitative research approach with descriptive survey design was used for the study. The study was conducted in a semi urban area (Nayarambalam panchayath) of Ernakulam District, Kerala. Two wards of the area are selected using one stage cluster sampling. All the women of reproductive age group(18-44 years) who were willing to participate were till the required sample size of 200 was met. The unmarried women were excluded from the study.

A semi structured questionnaire was used to assess the awareness regarding preconception care. It consists of 26 items distributed into the areas of importance of preconception care, components of preconception care, folic acid supplementation, diet, avoidance of smoking, time for stopping oral contraceptives, genetic counseling, prevention of infections, teratogenicity, early pregnancy signs of ovulation and normal duration of pregnancy.

Ethical clearance was obtained from Thesis review committee of Amrita Institute of Medical Sciences and Research Center. Permission for conducting the study obtained from the concerned authorities of selected area (Nayarambalam panchayath). Informed consent was obtained from each participant before collecting the data.

Results

The collected data was analysed using both descriptive and inferential statistics.

Socio demographic data

Most of the samples 90(45%)are in the age group of 30-40 years with a mean age of 34 years. Regarding duration of married life majority 74(36%) of them between 5-10 years. 63(31.5%) samples had completed higher secondary education and 60(30%) of them are graduate. Majority of them 131(65%) are multi gravid mothers and most of them 181(91%) had no history of abortion.167(83.5%) of samples had no history of medical illness like hypertension ,anemia, diabetes mellitus ,thyroid disorders ,and epilepsy. Most of them 199(99.5%) had no history of genetic disease.

Awareness regarding preconception care

The awareness regarding preconception care was good in 15%,average in 74 % and poor in 11%.( figure 1). The mean score was 13.48+/-. 3.9 (Max.26) and the scores ranged from 02-24 (Table .1).

More than 70% of the women were aware of importance and components of preconception care. The areas were the awareness scored least was importance of cessation of smoking (33.5%), immunization (37.5%) and birth spacing (39.5%). (Table 2)

Association between awareness and selected demographic variables

There was no significant association between the level of awareness and selected demographic variables like educational qualification, monthly income, duration of married life, number of pregnancies and abortions.

Discussion

The findings of the present study showed that 15% of participants had good, 74% had average and 11% had poor level of awareness regarding preconception care. The mean score of participants regarding preconception care was 13.48 +/- 3.9. The areas were the awareness scored least was importance of cessation of smoking (33.5%), immunization (37.5%) and birth spacing (39.5%). The majority of the women responded correctly for importance of preconception care (77%), early sign of pregnancy (69%) and time for preparation for pregnancy (66.5%). Only 48% of women were aware about preconceptional folic acid supplementation and only 45.5% were aware about the diet rich in folic acid, 55% were aware about diet rich in iron, 61% were aware about duration of pregnancy and 56% were aware about sign of ovulation. There was no statistically significant association found between awareness regarding preconception care and variables like duration of married life, monthly income, educational qualification, number of pregnancies, number of abortions.

Similar study conducted in USA by Moura.ER et.al (2010) among 106 women with DM to identify their knowledge regarding maternal and fetal risk related to diabetes and preconception care. It is found that 41% have adequate knowledge regarding preconception care and 54% had limited knowledge regarding maternal and fetal risk. The study findings are consistent with the findings of the present study as majority had average awareness regarding preconception care and complication of diabetes (50.5%) . A cross sectional study conducted by Nasar .H., Jalloun .m, Sabbah .M to assess the awareness and intake of folic acid among 600 married Lebanese woman showed that 60% of the women were heard about folic acid. Only 6.2% had taken folic acid during pregnancy. These study results supporting the present study.

A cross sectional study conducted by Bener.A, A.L Maadid regarding knowledge, attitude and practice on folic acid among 1480 Arabian Quatar women. The results showed that 53.7% were heard about folic acid awareness of folic acid were significantly associated with educational status of women. The findings of study shows less consistent with present study may be because of less sample size.
Since the sample of the study is selected from a semi urban area, the findings cannot be generalized, but the study findings have implications in various areas like community settings. Midwives can conduct home visit and screen for high risk couples who have family history of genetic illness, poor glycemic control, complaint of infertility, anemia, hypertension and make appropriate referrals. Although medical education curriculum includes the content of preconception care, the different aspects of it especially diet, exercise, teratogenicity and genetic counselling can be included in detail. The administrators can make policy to impart various health education programmes to eligible couples. And based on the present study the field of research on preconception care can be expanded.

Majority of the women lacked knowledge on the important aspects of preconception care like immunization ,cessation of smoking, birth spacing, time of sexual intercourse to get pregnant. The findings of the study conclude that measures should be taken for improving the awareness regarding preconception care so that better maternal and fetal outcome can be achieved.

**Conclusion**

The study results shows that majority of the women were unaware about preconception care and did not practicing preconception care. Many of the women were unaware about the importance of Pre conceptional folic acid supplementation. This study highlights the role of nurse to make the women aware about preconception care and the importance of practising preconception care.

A Comparative Study on Health Profile and Health Seeking Behaviour of the Elderly in Urban and Rural Areas of Bangalore, Karnataka

Akila GV1, Arvind BA2, Arjunan isaac3

1Assistant Professor, Sri Ramachandra Institute of Higher Education and Research-Chennai, 2Associate Professor, Department of Epidemiology, NIMHANS-Bangalore, 3Associate Professor, MSRamaiyah Medical College-Bangalore

Background: Significant variation is observed in medical disorders and age-related physiological decline among the elderly.1 Insights can be gathered from the variation of health profile depending on the geographic location.

Method: This comparative cross sectional study was conducted among the 510 elderly, aged 60 years and above, in the Urban and Rural field practice area of a medical college. Information were obtained using predesigned pretested semi structured questionnaire

Results – Three fourth of the study population complained of suffering from at least one morbidity. Diabetes (28%) and hypertension (27%) were the common morbidities identified in urban area whereas it was joint pain (39%) and visual impairment (23%) in the rural area. In urban area, 86.3% used private health facilities whereas in rural area, 89% used public health facilities.

Conclusion- Study showed a significant difference in the health profile and health seeking behaviour of the elderly in urban and rural areas. Hence health intervention and health programmes have to be planned taking into account these differences.

Key Words: health profile; health seeking behaviour; elderly; urban; rural.

Introduction

Longevity is the victory of development; better nutrition, health care, sanitation, education and socio-economic well-being has led to longer lives of humans.2 Across the world, countries are experiencing population ageing.3 According to Census 2011, elderly population constituted 8.3% of the total population.4

Age, socio-economic status, living condition, health issues and other background characteristics determine the needs and problems of the elderly.5 Living conditions, availability of resources and facilities are notably different in urban as compared to rural areas, resulting in differential influence on elderly morbidity.6 According to 2011 Census, 71% of elderly population reside in rural areas; 29 % live in urban areas.7 However, only limited information is available based on comparison of health problems and health care utilization of the elderly residing in rural and urban areas in our country.

India being a developing country with majority of its population below 30 years, serious consideration has not been given to problems of the elderly.8 Furthermore, studies on various aspects of elderly health are conducted either in the context of urban societies or rural societies, comparative studies are scarce. In this context, the present study was undertaken with the objective of comparing health problems and health seeking behaviour of the elderly in urban and rural field practice area of a medical college in Karnataka, India.
Methodology

A comparative community based cross sectional study was undertaken for a period of one year (2014) in the urban and rural field practice area of Medical College, Bangalore. Urban Health centre provides health services to people in two wards covering a population of 87,259. Primary Health centre in rural area caters to the health needs of 23 villages covering a population of 20,835. The study subjects were persons aged 60 years and above and permanent residents (residing for > 6 months) of the study area. Assuming prevalence of geriatric morbidity as 43%, at 80% confidence level and design effect of 1.5, the minimum required sample size for urban and rural area worked out to be 242 and 240 respectively. Sample size was calculated using the software open epi version 3.01.

For the present study, we adopted stratified multistage cluster random sampling technique. In the urban area, the sample size of 242 was proportionately divided between two wards (Ward 17 and 36). The wards are further divided into Census Enumeration Block (CEB) which is taken as a cluster for the study (107 CEBs and 70 CEBs in ward 17 and 36 respectively). Assuming an average of 500 individuals in each CEB and if 7% of them are elderly, 4 CEB from ward 17 and 3 CEB from ward 36 were selected using simple random sampling technique in order to get the required sample size. In the selected CEBs, the households were numbered serially and complete enumeration of the elderly was carried out.

In rural area, the villages were taken as a cluster and were stratified according to sub-centres and the sample size of 240 was proportionately divided among the three sub-centres. Under each sub-centre, one village was selected using simple random sampling technique. In the selected villages, houses were numbered serially and survey was undertaken.

Before conducting the study, ethical clearance was obtained from Institutional Ethics Committee. House to house survey was conducted to identify all the elderly in the study area. An informed written consent with either signature or thumb print was obtained from each individual, prior to interview. A pre-tested semi-structured questionnaire was used to collect information on socio demographic characteristics and health profile of geriatric population. Information pertaining to socio demographic factors/characteristics such as, age, gender, education, religion, employment status, marital status, type of family, family size, socio economic status, were collected. Socio economic status was assessed using updated B.G Prasad classification. Based on the perception about current health status, the elderly were asked to self-rate their health as very good, good, moderate, bad, very bad. It indicated a subjective assessment about their own health status. Information on all morbidities, both acute and chronic, which the elderly person was suffering from at the time of questionnaire administration was obtained and corroborated with medical records, wherever available. Information pertaining to medication that the elderly person took for the health problem was obtained. Place where the elderly subject sought treatment was also collected.

Statistical Analysis

Qualitative variables such as, socio demographic characteristics, morbidity profile were expressed as frequency and percentages. Quantitative variables such as age was summarized using mean and standard deviation. Difference in proportions of health problems and health seeking behaviour in urban and rural areas was tested using chi- square test / Fishers exact test of significance. P<0.05 was considered as statistically significant.

Results

Mean age of the study population was 69.6±8.8 years. Mean age of the elderly in urban area was 67.8±7.2 years and in rural area, 71.4± 9.8 years (P < 0.001). Females (59.4%) were predominant in the study settings. In rural area, 83.9% of the elderly were not literate yet 20% of the elderly were employed whereas in urban area, 31% were not literate and only 9.4% were employed. For an elderly family plays a major support system. In rural area, joint family system was predominant whereas in urban area, it was nuclear family ( P < 0.001). Most of the elderly in urban area belonged to upper socioeconomic class whereas those in rural area belonged to lower socioeconomic class( P < 0.001).

Table 1 indicates morbidity status of the study population. It is observed that in urban area, 66.3% of
the elderly rated their health to be good whereas in rural area, only 42.4% rated their health as good \([P<0.001]\). Majority (75.7%) of the study population complained of some disease or disorder but only 31.8% of the study population were taking medication for their morbidity. The elderly taking medication were less in rural (16.9%) area when compared to urban area (46.7%) even though the proportion of elderly suffering from morbidity was not significantly different. Among the elderly, 36.1% complained of two morbidities and 17.3% of them complained of three morbidities. The proportion of number of morbidities per person was similar in both urban and rural areas.

In the present study, it was observed that 29.1% of the elderly in the study area suffered from joint pains followed by hypertension (19.0%) and diabetes (18.0%). In urban area, the elderly suffered mainly from lifestyle disease such as, diabetes (27.97%), hypertension (27.40%), followed by joint pains (22.59%) and visual impairment (9.6%). In rural area, 38.93% of the elderly suffered from musculoskeletal problems like joint pains, followed by visual impairment (22.7%), hypertension (10.32%) and diabetes (7.66%) (Figure 1).

Among the study population, 51.4% and 47.8% accessed public health system and private health system respectively. In urban area, 86.3% of elderly accessed private health system and in rural area 89% of elderly accessed public health system for treatment of common ailments \([P<0.001]\) (Figure 2).

**Discussion**

Health care should be based on the felt needs of the elderly. Problems and needs of the elderly in urban areas are different from that in rural areas. Deeper comparative studies will help in better understanding of the health problems, enabling the government to provide better health services. Majority of studies in India are done in either urban or rural area.\(^{10-16}\) Comparative community based studies are very few. Highlight of the present study is that it focuses on difference in morbidity pattern and health seeking behaviour of the elderly between urban and rural areas.

Only half (54.3%) of the elderly in the study population perceived their health to be good. Similar results were observed in a study based on the data collected by National Sample Survey Organization (NSSO).\(^{17}\) Different pattern of morbidity in urban and rural area, better socio economic status and literacy in urban area could be some of the factors influencing this observation. Three fourth of the study population complained of some morbidity. A study done by Srinivas PJ et al. (64%) in both urban and rural areas and studies done Kumar et al. (65.3%) and Bhat et al. (65.3%) in rural area showed slightly lesser prevalence of morbidity than our study area whereas studies done in urban area by Barua et al. (78.4%), Nikumb et al. (93.12%), Gurmeet Kaur et al. (87.6%) showed higher prevalent morbidity than our study area.\(^{11-15,18}\) Differing study settings, nature of morbidity assessed and the way it was assessed could contribute to these observed differences. But generally, these studies, including the present study, indicate that prevalence of morbidity is considerably high among the elderly.

In the present study, in rural area, majority (38.93%) of the elderly reported having musculoskeletal problems like joint pains, whereas in urban area, the elderly mainly reported diabetes (27.97%), hypertension (27.40%). This increase in the level of musculoskeletal problems in the elderly in rural area may be due to occupation since majority of elderly in rural area were working as farmers or agricultural labourers, which involves strenuous physical activity. Similar observation was seen in studies done by Sharma et al., Alam M et al. in urban and rural areas.\(^{19,20}\) Large population based studies in diabetes and hypertension observed their prevalence to be more in urban area when compared to rural area, similar to our study findings.\(^{21,22}\) Studies done by Jadav et al. (65.5%) and Anand et al. (36.6%) showed high prevalence of joint pains among the elderly in rural area, similar to our study findings.\(^{23,24}\) This highlights the need to plan and deliver area specific health services based on the epidemiology of health conditions among the elderly. Since nearly 2/5 of the elderly are having musculoskeletal problems, rural health teams must be adequately trained to identify and provide appropriate care for such conditions.

Proportion of elderly taking medication was less in rural area (16.9%) when compared to urban area (46.7%). Difference in morbidity pattern could possibly explain this variation. Urban elderly mainly suffered from lifestyle disorders such as, diabetes and hypertension, which require lifelong medication, whereas rural elderly suffered mainly from joint pain for which they were taking intermittent treatment. A study done by Swami MH et al. reported similar findings.\(^{25}\)
In urban area, 86.3% of elderly accessed private health system and in rural area 89% of elderly accessed public health system for treatment of common ailments. Similar pattern was observed in studies by Alam M et al. in selected states in India, and Hakmoosa A et al. in rural area. Issues regarding availability, accessibility, affordability, and also quality of health services, are more likely to determine the choice of health care services.

Though the study was undertaken systematically with all methodological rigour, it does have certain limitations. Firstly, we collected information on self-reported morbidity and this can result in underestimation of actual morbidity among elderly, both in urban and rural areas. Secondly, elderly population selected in the urban area were from generally upper socio economic status and hence they do not represent urban elderly population, thereby limiting the generalisability of the findings.

**Conclusion**

The present study uncovers the difference in morbidity and treatment seeking pattern among elderly in the study area based on the background of differing socio-demographic profiles. This has as an implication for planning and implementing appropriate health services in the study area. Larger representative studies using standard diagnostics methods to detect morbidity would facilitate policy makers, program managers and health service providers to completely understand the urban-rural difference in morbidity among the elderly. Such observations may provide evidence to reorient the service being provided through existing health care facilities and also support National Programme for the Health Care for the Elderly and policies related to elderly, to comprehensively address the needs of elderly in urban and rural areas.

Effectiveness of a Parent Education Programme on Quality of Life of Children with Epilepsy

Anila K P1, Rajee Reghunath2

1Professor, Amrita College of Nursing, AMRITA Vishwa Vidyapeetham, Kochi, Kerala, India,
2Principal, Amala College of Nursing, Amalanagar PO., Thrissur, Kerala, India

Abstract

Purpose: To assess the effectiveness of a parent education programme on quality of life of children with epilepsy and find correlation between the quality of life and the selected demographic and clinical variables of children.

Method: The research approach was quantitative and the design was one group pre-test post-test. The sampling technique was convenience sampling. The sample size was 30 children affected with epilepsy. Data was collected by using the standardized tool of Quality of Life in Epilepsy for Adolescents Questionnaire: QOLIE AD 48 Version1 and a questionnaire on demographic data. The analysis was done by using descriptive statistics, paired t-test and Pearson correlation.

Results: The findings showed that the mean score in pre-test in epilepsy impact in children is 14.14±2.89 and the average value of post-test is 15.80±2.80 and the p-value shows <0.001, so there is a statistical significant change in quality of life in pre and post-test intervention. In memory/concentration, the pre-test mean score is 8.34±1.22 and the post-test mean score is 9.35±1.06. In attitude towards epilepsy, pre-test mean score is 3.48±0.45 and the post-test is 3.98±0.45. In physical functioning the pre-test mean score is 3.73±0.86 and the post-test is 4.77±1.02. In social support, pre-test mean score is 1.42±0.36 and the post-test is 1.42±0.36. Since the p-value is <0.001 for all these areas, the relation with the quality of life of children is statistically significant. The variables of social stigma, school behavior and health perception are also shows significant relation (p-value is <0.05) with the quality of life. The demographic variable of standard of studying and quality of life of children shows positive correlation and it is statistically significant (p value-0.000). The clinical variables of age at diagnosis (0.375, p value-0.04) and duration of seizure time (0.583, p value-0.001) are having statistically significant relation with the quality of life of children with epilepsy.

Conclusion: The study depicts the importance of implementing an education programme for parents and children with epilepsy it would help to improve knowledge and follow healthy practices and through which the children can lead a good quality of life.

Key words: Epilepsy, Children, Parent Education Programme, Quality of Life.

Introduction

Epilepsy is a chronic disorder of the brain that affects people in every country of the world. It is characterized by recurrent seizures. Seizures are brief episodes of involuntary shaking which may involve a part of the body (partial) or the entire body (generalized) and sometimes
accompanied by loss of consciousness and control of bowel or bladder function. The episodes are a result of excessive electrical discharges in a group of brain cells. Different parts of the brain can be the site of such discharges. Seizures can vary from the briefest lapses of attention or muscle jerks, to severe and prolonged convulsions. Seizures can also vary in frequency, from less than one per year to several per day.¹

Epilepsy is the tendency to have seizures for two or more episodes. As many as 1 in 20 people will have a single isolated seizure at some point in their lives whereas 1 in 200 will subsequently be diagnosed with epilepsy. In children the rates are 1 in 100 having epilepsy. Of those diagnosed with epilepsy throughout the lifespan an estimated 30% have first seizures in the preschool years with 17% of those being in the first two years of life alone. So seizures are common place events in the early childhood years.¹

In recent years there has been a broadening of focus on the measurement of health, beyond traditional indicators like mortality and morbidity to include measures like impact of illness on daily living. ‘Quality of life’ has been described as the missing measurement of Health which has been given due attention in the last few years.²

Quality of Life is an important consideration of ill health, as it has a great impact on health and illness, and has emerged as an important indicator of the success or failure of the treatment of disease. Health related QOL has become an important outcome measure in chronic disease. The children with epilepsy are at increased risk for poor health related QOL/ (HRQOL) even in the absence of active seizures. Clinicians who aim to achieve optimal seizure control also need to focus on improving HRQOL. This can only be accomplished by recognizing how different features of the epilepsy itself ie. Co-morbid conditions, as well as psychosocial factors can all make a difference to health related QOL.³

A research study conducted on quality of life among 102 children with epilepsy between 5-15 years of either sex. QOL was measured by QOLCE questionnaire, a 76 item, parent reported questionnaire. Cronbach alpha was used to determine the internal consistency of the subscales and Pearson correlations to determine construct validity. The t-test and analysis of variance were used to compare mean QOLCE scores. The factors affecting QOL included age, place of residence, socioeconomic condition, maternal education, seizure type and frequency and number of anti epileptic drugs.⁴

The children with epilepsy and their families face a variety of mental, social, emotional and physical issues that requires a comprehensive, holistic health care. It was also noticed that there are misconceptions about epilepsy among parents. The misunderstanding and negative attitude towards children with epilepsy is likely to contribute to perceived feeling of stigma and discrimination among the affected children and it can affect their quality of life. The emphasis on holistic care would equip the nurse begin an integral part of the health care team to be more competent and sensitive while caring for the child which would in turn improve the quality of Life.⁵

Although anxiety disorders are highly common and have a negative impact on quality of life in patients with epilepsy of all ages, the number of studies in children and adolescents is relatively small. In a sample of 44 children and adolescents with epilepsy, it was found that 16% prevalence rate of anxiety using the revised Children’s Manifest Anxiety Scale (RCMAS).⁶

Children with epilepsy are also reported to experience academic underachievement in relation to their IQ. The child often experiences significant restrictions of activities, leading to lower QoL. Children with chronic illness have been shown consistently to be at a greater risk of behavioural disturbances than healthy children. This applies particularly to children with neurological disorder such as epilepsy. Although the effort to control seizures is of primary importance, there remain many problems concerning the psychological management of the child and his or her parents and their relationship to the social milieu in which they live.⁷

Nursing is concerned not only with outcomes like survival and decrease morbidity but that with the patient as a whole and also the quality of life. Since nurses are concerned with how perceptions shape the response and reactions of human beings, information about quality of life will provide an insight to a child’s expectations, vulnerable domains and perceived needs. And the insight will help nurse to engage themselves in nursing interventions that are appropriately to the needs of such children. Quality of life refers to that which makes life worth living and connotes the caring aspects of nursing
because nursing is concerned not only with survival and decreased morbidity but with the whole wellbeing of children.  

A controlled multicenter evaluation study on efficacy of an educational program for parents of children with epilepsy (FAMOSES), reveals that parents of the group significantly improved in epilepsy specific knowledge (group x time interaction<0.001), coping (p<0.01), fears (p<0.05) and in speaking about epilepsy (p<0.05) compared with the control group. No effects were found on disease related variables. Nearly all of the participants rated the programme as very good (71%) or good (27%). The participants improved in knowledge, coping and epilepsy related fears. The education program is a valuable component of comprehensive epilepsy care.

A systematic review of qualitative studies on experiences of children with epilepsy conducted among 43 articles involving 953 participants aged 3 to 21 years across 21 countries. Children with epilepsy often require antiepileptic medications. An estimated 80% of participants have an associated behavioural disorder or cognitive impairment. Studies have shown that children with epilepsy report impaired quality of life, low educational attainment, social stigma, and low self esteem. Peer and parental support is most important in health related quality of life of children. Most of the participants with epilepsy believed that strong social support enabled them to accept the disease.

The objectives of the study were to assess the effectiveness of a parent education programme on quality of life of children with epilepsy as well as to find the correlation between the quality of life of children and the selected demographic and clinical variables.

Materials and Method

The study was conducted among 30 children with epilepsy admitted in Paediatric Neurology ward at AIMS, Kochi. The data collection was started after obtaining Ethical Clearance certificate from the Ethics Committee and Scientific committee of Amrita Institute of Medical Sciences and Research Centre(AIMS), Kochi. The sample was selected by convenience sampling technique based on inclusion criteria. After building rapport with the parents and children, written informed consent was obtained from each parent and written assent from each child. Administered the questionnaire of QOLIE AD-48. The tool consists of two sections; section A includes 20 items related to socio demographic and clinical variables, section B includes 48 items. It took approximate one hour to complete the data collection from each child.

Statistical Analysis

Statistical Analysis has done using IBM SPSS statistics 20 windows (SPSS Inc., Chicago, USA). For all the continuous variables the results are either given in mean ± standard deviation and for categorical variables as percentage. To compare the mean difference of Pre and Post Intervention Paired sample t- test applied for parameter test. To obtain the relationship between two variables correlation is applied. Probability value (p value) less than 0.05 is considered for statistical significance.

Results

Section I - Description of Sample Characteristics based on Socio-demographic variables.

The socio demographic profile of the children with epilepsy revealed that most of them 18(60%) were male children. Also 13(43.3%) of them had only one sibling and 19(63.3%) of them were second born child. Regarding the recreation in leisure time, 18(60%) of them were interested in watching TV . In response to the food habits, 30(100%) of them were prefer to have non-vegetarian food.

Section II - Description of Sample Characteristics based on Clinical Variables.

The sample characteristics based on the clinical variables show that the frequency of seizures among children, 8(26.7%) of them get seizures once in five months. Also among 6(20%) of subjects each get monthly and once in six months respectively. Out of total subjects 16(53.3%) of them get seizures during sleep. With regard to the medications 16(53.3%) of them have three medications regularly. Also 8(26.7%) of them are taking medications for more than four years. The immunization status shows that 100% of the subjects are immunized. Among all the subjects 29(96.7%) of them do not have any co-morbidities. The data show that 14(46.7%) of them have stress as the predisposing factor for epilepsy and 11(36.7%) of them have loud noise as the predisposing factor for epilepsy.
Section-III - Effectiveness of the Parent Education programme on Quality of Life of Children with Epilepsy.

</tbody>
</table>

Data on Table-1 shows that the average score in pre-test in the subscale variable of epilepsy impact in children is $14.14 \pm 2.89$ and the post-test value is $15.80 \pm 2.80$ and the p value shows $<0.001$, so there is a statistical significant change in quality of life in pre and post-test intervention. In memory/concentration, the pre-test mean score is $8.34 \pm 1.22$ and the post-test mean score is $9.35 \pm 1.06$. In attitude towards epilepsy, pre-test mean score is $3.48 \pm 0.45$ and the post-test mean score is $3.98 \pm 0.45$. The values in physical functioning show that the pre-test mean score is $3.73 \pm 0.86$ and the post-test mean score is $4.77 \pm 1.02$. In social support, pre-test mean score is $1.42 \pm 0.36$ and the post-test mean score is $1.42 \pm 0.36$. Since the p-value is $<0.001$ for all these areas, the relation with the quality of life of children is statistically significant. The subscale variables of social stigma, school behavior and health perception are also shows significant relation (p-value is $<0.05$) with the quality of life of children with epilepsy.

Section-IV – Correlation of Quality of Life of Children and the selected Demographic variables.

Table-2 Correlation of Quality of Life of Children and the selected Demographic variables.

<table>

<td>&lt;0.001</td>
</tr>
<tr>
<td>Order of Birth</td>
<td>30</td>
<td>-0.486</td>
<td>0.006</td>
</tr>
</tbody>
</table>
The data on Table 2 explains the comparison of scores of quality of life of children with selected demographic variables. The variable of standard of studying and quality of life shows positive correlation and it is statistically significant (p value-0.000). The variables such as age of the children and order of birth are having negative correlation but it is statistically significant. There is no significant association between quality of life of children and the demographic variables such as gender of the child, number of siblings, recreation etc.

**Section-V – Correlation of Quality of Life of Children and the selected Clinical Variables.**

Analyses on correlation of quality of life and the selected clinical variables done. The result shows that the clinical variables of age at diagnosis (0.375, p value-0.04) and duration of seizure time (0.583, p value-0.001) are having statistically significant relation with the quality of life of children with epilepsy.

**Discussion**

Objective-1: Assess the effectiveness of a parent education programme on quality of life of children with epilepsy.

The pre-test mean score subscale variable of epilepsy impact in children is 14.14 and the post-test value is 15.80±2.80. In memory the pre-test mean score is 8.34 and the post-test mean score is 9.35. In attitude towards epilepsy, pre-test mean score is 3.48 and the post-test score is 3.98. The values in physical functioning show that the pre-test mean score is 3.73 and the post-test score is 4.77. In social support, pre-test mean score is 1.42 and the post-test score is 1.42. Since the p-value is <0.001 for all these areas, the relation with the quality of life of children is statistically significant. The variables of stigma, school behavior and health perception do not have any significant relation with the quality of life.

The present study is supported with a study on education of children with epilepsy and their parents by the modular education programme for families. It was a prospective, controlled and multicenter study with a pre-post design. The sample were 31 children with epilepsy participated in the education programme. The study revealed that children who attended the program, showed improvements in the domains perceived restrictions (significant, medium effect size) absence from school and seizure frequency.11

Objective-2: Find correlation between quality of life of children and the selected demographic and clinical variables.

The variable of standard of studying and quality of life shows positive correlation and the age of the children and order of birth are having negative correlation. There is no significant correlation between quality of life and the variables such as gender of the child, number of siblings, recreation etc. The clinical variables of age at diagnosis and duration of seizure time are having statistically significant correlation with the quality of life.

**Conclusion**

Children with epilepsy experience vulnerability, disempowerment, and discrimination. Addressing stigma, future independence, and fear of death may improve the overall quality of life of children with epilepsy. Hence, measures to improve the QoL of children with epilepsy should be stressed upon in addition to the regular treatment.

Modelling the Factors Responsible for Better Health Service Quality: Perception of Service Providers

Meenakshi Sood¹, Bunty Sharma², Sahil Gupta³, Shuchi Dawra⁴, Chanchal Kaushik²
¹Associate Professor, ²Assistant Professor, Chitkara School of Health Sciences, Chitkara University, Punjab, India, ³Assistant Professor, ⁴Associate Professor, Chitkara Business School, Chitkara University, Punjab, India

Abstract

The aim of present study is to explore various dimensions of service quality of Indian Healthcare sector from care provider’s perspective. Total of 362 healthcare providers including clinicians, staff nurses, lab & Imaging technologists, pharmacists and hospital management staff from both private and government hospitals participated in the study. The questionnaire had 5 dimensions taken from SERVQUAL along with three newly identified dimensions. Descriptive analysis of data was done besides mean for each dimension. Finally, exploratory and confirmatory analysis on SPSS 23 and AMOS version 21 was done to arrive at final set of dimensions and items under each. The findings suggested that all 8 dimensions are important for service quality of healthcare sector in India. The study adds to existing knowledge on service quality of healthcare by taking a different and unique care providers’ perspective.

Keywords: Accessibility, Accreditation, Affordability, Healthcare service quality, Service providers, SERVQUAL

Introduction

The healthcare industry has emerged vastly in India and is expected to advance at a compound annual growth rate (CAGR) of 16-17 per cent during the year 2017-2022 and plays an undisputed role in improving the facilities and access to medical facilities and quality care for the people worldwide. In addition to quality healthcare services, healthcare industries are providing enormous job opportunities and playing a critical role in the country economy¹. Quality is an important aspect of the healthcare industry and is responsible for important and productive strategy for stability and profits of the industry, which ultimately affect the economy.² There are challenges in measuring healthcare service quality. Firstly, patients do not have necessary information and capability to assess technical quality. Secondly, the relationship between quality and patients’ satisfaction is still not very well understood.³

Healthcare service quality is closely associated with patient satisfaction, loyalty, and healthcare organizations⁴ productivity and profitability.⁴ There are wide spread factors that are responsible for heterogeneity and dynamism of healthcare service quality, making it very important to understand and identify them.⁵

There is a need to develop a scale that measures the quality of hospital services. Academicians, practitioners, policy and decision makers are still in the process of identifying valid tools to assess service quality.⁶ The first tool was developed by Donabedian in 1980 and it had 4 factors namely, timeliness, efficiency, effectiveness and improvement of care services.⁶ Later in 1988 Parasuraman et al. developed the famous tool SERVQUAL for service industries banking, telecom etc. This tool had 5 factors tangibility, empathy, responsiveness, reliability and Assurance.⁷ The factors are always susceptible to changes according to the economy of a country, type of service sector and development & growth of countries. Babakus 1992 and Bowers 1994 emphasised the need to tailor it according to healthcare industry.⁸

Most of the studies have been done around the globe using SERVQUAL questionnaire to assess the quality of healthcare industry. However, studies
identified new factors in addition to SERVQUAL, which show remarkable impact on the quality of healthcare industry. Among the newly identified factors, three factors accreditation, affordability and accessibility have been proven to contribute major role in improving the quality of industry. Accreditation has emerged as a new perspective to assess the quality of healthcare industries as it contributes to loyalty and commitment of the consumers to industry and provides scope for the industry to improve by reducing the gap between patient expectations and perceptions.

Cost is another important factor for the patients mainly in developing countries like India. Therefore, the affordability of patients concerning healthcare services is an important variable to consider. However, affordability could be an important factor in developing countries like India.

While quantifying the service quality of healthcare industries, ease of service access for the patients is an important area to be considered. Waiting list, distance of healthcare facility and stay length of the patient in the hospital are the major variables under accessibility. Although the contribution of accessibility was not that significant in comparison with other SERVQUAL factors in developed countries but it could be an important asset for quantifying the quality of service provided in Indian hospitals.

Although loyalty of consumer has always been the top priority in every business sector, healthcare concerns suffice with excellent medical services alone. Singularly, healthcare stands out giving much lower credence to have loyal patients. After all medical care is a type of service where people seek when they need but of course do not want it. Therefore, healthcare quality evaluations are problematic due to difference in service size, complexity, specialization within healthcare organizations.

Objective of the study: The main objective of the study was to get healthcare provider’s perspective on service quality dimensions of healthcare. The study added 3 dimensions namely affordability, accessibility and accreditation to existing 5 dimensions of SERVQUAL. The study identified and analysed the impact of each dimension on service quality of Indian Healthcare.

Theoretical Framework

According to present research framework, the relationship between provider’s perception and quality has been observed. Servqual factors like tangibility, reliability, responsiveness, empathy, assurance and 3 newly identified factors, viz, accessibility, affordability, accreditation can work as precursors for healthcare service quality.

Research Methodology

Object/Respondent of study: The service providers including clinicians, nursing staff, pharmacists, laboratory technicians, imaging technologists, hospital administrative, healthcare researchers and academicians belonging to seven public and private hospitals of Chandigarh (U.T), Panchkula (Haryana) and Mohali (Punjab) were involved in this study. Data was taken on and off the campus of hospitals. The respondents, which were involved in present study had at least two years of experience in healthcare industry and sufficient knowledge of health system of India.

Questionnaire design

The questionnaire for the study was designed and edited in the month of September to October 2017 using SERVQUAL scale as baseline and broadening it based on literature review (research papers, articles, magazines and manuscripts on healthcare service quality, patient’s expectations and satisfaction, and databases like Web of Science, Science Direct, EBSCO, ProQuest) to understand healthcare service quality, views of hospital administrative staff and healthcare professionals. Three new dimensions were added namely, accreditation, accessibility and affordability after extensive literature review and in depth interviews of researchers, academicians and clinicians to check their implications and importance in India.

Pre-questionnaire/Pilot study

The pre-testing of questionnaire was done in November 2017-January, 2018 on healthcare service providers of public and private hospitals on 45 respondents. The reliability and validity/internal consistency of questionnaire was also analyzed. The Cronbach’s alpha was found to be more than 0.8, which was found to be in acceptable limits.

Formal questionnaire

In questionnaire, total 33 questions were present representing the 5 dimensions of ServQual and 3 new
dimensions identified. Questions from TAN (1-5) for Tangibility, REL (6-10) for Reliability, RES (11-14) for Responsiveness, AS (15-18) for Assurance, EMP (19-22) for Empathy, ACE (23-26) for Accessibility, AFF (27-28) for Affordability, and ACC (29-33) for Accreditation. Likert-type scale was used for scoring of responses: 1- very dissatisfied, 2- satisfied, 3- neutral, 4- satisfied and 5- very satisfied.

The final and formal questionnaire was distributed to respondents using snowball sampling in the seven hospitals. A total of 392 respondents/service providers questionnaire were recovered. Incomplete, invalid and outliers were excluded and finally 369 valid questionnaires were retained.

**Data entry, proofreading and analysis**

For data entry and proofreading software SPSS version 23 was used. To address the described objectives, tools and technique used were Exploratory Factor Analysis, Confirmatory Factor Analysis to confirm and validate the factors, and then Structural Equation Modelling (SEM) was to measure the influence.

**Data Analysis and Results:**

Data was analyzed using the Statistical Package of Social Sciences (SPSS) version 23 and AMOS version 21 for calculating means, correlation and conducting exploratory and confirmatory factor analysis.

The Bartlett’s test of Sphericity confirmed (Chi square=4316.988, df= 233, p= 0.001) the factorability of data. The KMO measure here is 0.823, which is greater than 0.5, hence there is a more than sufficient sample size to run the PC Analysis as KMO measure above 0.7 means data is suitable for EFA.

**Results**

The mean and standard deviation of the constructs were Tangibility (4.54, 1.02), Reliability (4.49, 1.12), Responsiveness (4.29,1.12), Assurance (4.25,1.19), Empathy (4.4,1.13), Accessibility (4.45,1.07), Accreditation (4.55,1.08) and Affordability (3.87,1.07). The primary steps in analysis was measuring the proposed model using EFA that confirms the correct loading of variables and corresponding factors with the help of Eigen value. Total 33 variables were studied, which were already existing and newly identified as well. Only 8 factors had been extracted with Eigen value of 1 and theses contribute to 74.8% of total variance.

The problem of common method bias was identified using Harman’s one factor test. However, the common method bias was not considered in present study as the variance by first factor was less than 50%.

The use of CFA (Confirmatory factor analysis) was done to test the validity of factors and measurement model as well. The results of CFA confirmed a good fit ($\chi^2 = 1261.6$, DF$= 1115$, GFI=0.88, AGFI= 0.81, NFI= 0.90, RMSA= 0.022 and CI= 0.025-0.048) (Table2). The unidimensional motion of constructs was also confirmed with CFA, which provides a strong confirmation of validity of factors. The value of cronbach’s alpha for all the measures was observed higher than 0.70, which confirmed the reliability of studied factors/constructs. Similarly, the factor loading of all the measures was found significant (p<0.0001) and within adequate limits. The range for construct reliabilities was observed from 0.812(Affordability) to 0.765(Accessibility). Two-step confirmation of convergent validity of measurement model was recorded. The first step of confirmation was significant and high value of factor loadings and construct reliability. The high value of average variance extracted (AVE) than 0.5 but lower than values of composite reliability confirmed the convergent validity of model.

The average variance extracted, MSV and ASV values of the construct are found to be Tangibility (0.733,0.72,0.519), Reliability (0.741,0.67,0.587), Responsiveness (0.730,0.718,0.499), Assurance (0.761,0.690,0.674), Empathy(0.749,0.732,0.523), Accessibility (0.718,0.701,0.393), Accreditation (0.716,0.654,0.513) and Affordability(0.725,0.721,0.631) respectively which was also confirmed as AVE of each construct was higher than squared correlation coefficient of other coefficient. The maximum shared variance (MSV) and average shared variance (ASV) were also measured and confirmed the divergent validity of present model as their values were less than respective AVE of given construct.

**Structural Equation Model (SEM)**

The hypothesis was tested using structural equation model to establish the relationship between health service quality and patient satisfaction along with studied variables, considering the cause and effect. Several indicators were used to evaluate overall model
fitness such as $\chi^2(<3)$, GFI ($>0.90$), AGFI ($>0.80$) and RMSR ($<0.080$), which proved validity of direct effect model.

Moreover, the relationship was statistically significant (at 0.001 probability level) and in the hypothesized direction.

This showed that Healthcare Service Quality contributes positively towards Patient Satisfaction.

Discussion

In present study, comprehensive exploration of service quality from service provider’s perspectives with qualitative and quantitative methods had been done. Total eight domain had been finalized for determining service quality in healthcare industry namely tangibility, empathy, reliability, responsiveness, assurance, accessibility, accreditation and, affordability, while five other domains had been deleted during EFA for having less than 0.5 value and considered as irrelevant in context to healthcare service quality. The present study generated a total of 33 items and reduced to 24 items after EFA and discussion with experts. High correlation was observed between the items having factor loading above 0.5 and hence the factors were identified. The final 24 items were loaded logically and rechecked by experts in order to confirm that all the domains were sufficiently observed and calculated.

The concept of health service quality from service provider’s perception was not standardized; hence, internal validity was determined in order to validate present questionnaire. The items construction was explored broadly and CFA was tested out on six models. Out of six models, only one model was accepted as best appropriate model in present context. The model retained all the original items of finalized eight domains. With the help of CFA, percentage variance due to individual domain/construct and their respective relationship with service quality is also determined. A significant and moderate positive relationship was observed (Table 3). Maximum variance was contributed by tangibility (86.1%) followed by responsiveness (77.3%) and reliability (76.2%), while minimum variance given by affordability (62%) followed by accessibility (69.6%) and accreditation (72%). The present results testify the already confirmed and significant variable of healthcare service quality. 11,12

The present study emphasized on addition of new dimensions like accreditation, affordability and accessibility to the concept of SERVQUAL while measuring service quality of health sector, which could contributes significantly in changing the perception of healthcare service quality among service providers and service users.

However, the present study was done in a small geographical area; hence its transferability to whole of India needs to be confirmed by further studies.

Theoretical Implications

The study helps us to understand various factors contributing to service quality of healthcare sector in India. It emphasizes that there are factors beyond five given in SERVQUAL, which could be industry specific and should be considered while studying service quality.

Practical implications

The current study has added to the existing knowledge pool in terms of service quality of Indian health system as understanding healthcare service quality. It will help the health authorities to formulate new health policies ensuring better patient satisfaction.

In conclusion, the research will be useful for all stakeholders all patients, providers of health care and policy makers:

- Patients/Consumers: They will receive better quality of service or treatment, once the areas with scope for improvement are identified
- Health care Professionals/Providers: will understand dimensions of service quality and their priority for good and satisfactory services to patients
- Policy Makers: to formulate new Health Policy, Accreditation norms keeping dimensions of service quality in consideration

However, we strongly recommend that further research to evaluate overall service quality score for healthcare sector in India in addition to comparison of service quality of healthcare providers in the public Vs the private sector should be carried out.

Effectiveness of Prenatal Classes During Third Trimester to Reduce Anxiety Level and to Improve Birth-Preparedness among Primigravid Women

Divya Bhadran¹, Anusuya. V. Prabhu², Lakhra Alma Juliet³

¹2nd year MSc Nursing, Obstetrics and Gynecological specialty, ²Assistant Professor, Sr. Scale, Dept. of Obstetric and Gynecological Nursing, Manipal College of Nursing Manipal, ³Assistant Professor Dept. of Fundamental Nursing, Manipal College of Nursing Manipal, Manipal University, Manipal, Karnataka

Abstract

Background: The pain during labor is because of uterine contractions and cervical dilation and psychological factors like stress, anxiety and fear. The labor pains can affect a woman’s emotional control and it can be correlated with the anxiety and fear¹.

Objective: To determine the effectiveness of prenatal classes on reduction in anxiety level and birth-preparedness among primigravid women.

Method and Material: A quasi-experimental one group pretest-posttest study design was used comprising of 76 primigravid women. Purposive sampling technique was used to select the samples and simple random sampling technique (chit method without replacement) was used to select the samples for experimental and control groups. 38 samples each in experimental and control group. Data were collected using Demographic Proforma, anxiety assessment scale and knowledge regarding birth preparedness. Experimental group received prenatal classes during 35 and 36 weeks of gestation. Control group received routine care.

Results: Study results showed prenatal classes found to be effective in reducing anxiety level regarding labour and improved birth preparedness among primi gravid mothers. Majority of the primigravid women did not had prior information regarding birth preparedness 36 (97%) in control group and 31 (89%) from experimental group. Comparison of pretest post-test anxiety scores of experimental group was df 26, t (18.9) (p < 0.001). And comparison of post-test anxiety score of experimental and control group was df 70, t (16.61), (p < 0.001). Effectiveness of pre-test and post-test birth-preparedness scores of experimental group df 36 , t (23.38), (p < 0.001).

Conclusion: The findings of the study illustrated that anxiety is common during pregnancy. Birth preparedness classes will help primi mothers to reduce anxiety regarding delivery and well prepare physiologically and psychologically to phase delivery and to have better pregnancy outcome.

Key words: prenatal classes, labor, third trimester, anxiety, birth preparedness Primigravidas

Introduction

In olden days mothers used to pass their knowledge to their daughters in order to guide them throughout their pregnancy. In current scenario, women’s wisdom about birth is lost as birth has become a medical event. So, in order to support the woman throughout her pregnancy structured educational programs for preparation in childbirth called prenatal classes has come up².
A quasi-experimental study was conducted among the pregnant women to find out the impact of childbirth preparation on antenatal depression. One group pre-test, posttest research design was used. In the pretest 70% of antenatal mothers had moderate level of depression. After the childbirth preparation classes the percentage of depression has come down to 43% of borderline clinical depression. On analysis by paired ‘t’ test a statistically significant impact of childbirth preparation classes was found on the antenatal depression. Thus the study concluded that the childbirth preparation during the antenatal period has a positive impact on decreasing the depression among pregnant women.

A quasi-experimental study was conducted to assess the effects of antenatal education on maternal prenatal and postpartum adaptation among 120 antenatal mothers. The experimental group received antenatal education, the control group received only standard care. The data was collected using demographical data form, prenatal self-evaluation questionnaire (PSEQ) and postpartum self-evaluation questionnaire (PPSEQ). There was a statistically significant difference between the intervention and control groups. Hence they concluded that antenatal education had a positive effect on prenatal adaptation, but no effect on postpartum adaptation.

A randomized controlled trial was conducted to evaluate the Birth Preparation Programme (BPP) on lumbo-pelvic pain, urinary incontinence, anxiety and exercise among 197 low risk primigravid aged between 16 to 40 years with gestational age more than 18 weeks. The data collection was done on three occasions, initially at 18 – 24 weeks, next at 28 – 30 weeks and final at 36 – 38 weeks of pregnancy. The tools used in this study were STAI (State Trait Anxiety Inventory) and PPAQ (Pregnancy Physical Activity Questionnaire). The risk of urinary incontinence in BPP participants was found significantly lower at 30 weeks of pregnancy (42.7%), whereas in control group it was 62.2% and at 36 weeks of pregnancy in experimental group 41.2% and in control group 68.4%. Participation in the BPP encouraged women to exercise during pregnancy (p=0.009). No significant difference was found between the groups regarding the anxiety level, lumbopelvic pain, type or duration of delivery and weight or vitality of the newborn infant.

**Material and Method**

A quantitative study using Quasi-experimental pretest-posttest study design was adopted to investigate the effectiveness of prenatal classes regarding labor during third trimester to reduce anxiety level and to improve birth-preparedness among primigravid women of Udupi District Karnataka.

Purposive sampling technique was carried out to select the samples and simple random sampling technique (chit method without replacement) was used to select the samples for experimental and control groups. The inclusion criteria for sample selection were, Primigravidas with 35 weeks of gestation, who were aged between 18 to 30 years, who were able to speak, read, write and understand Kannada or English language, with no complications related to pregnancy and without any history of psychiatric illness attending the OBG Out Patient Department’s of tertiary level Hospital Udupi and Manipal. Purposive sampling technique was used to select the samples and simple random sampling technique (chit method without replacement) was used to select the samples for experimental and control groups. 38 samples each in experimental and control group. Data were collected using Demographic Proforma, anxiety assessment scale and knowledge regarding birth preparedness after explaining the purpose of the study and getting the written consent. Experimental group received prenatal classes during 35 and 36 weeks of gestation. Control group received routine care. One antenatal mother from experimental group and 3 antenatal mothers from control group were excluded from the middle of the study because they have delivered before 37 completed weeks of gestation.

Anxiety Assessment Scale was developed by the researcher which consisted of 36 items and evaluated by using four point Likert type scale, the options being strongly agree, agree, disagree and strongly disagree with a score of 1, 2, 3 and 4 respectively for positive items and reverse scoring of 4, 3, 2, and 1 for negative items. The maximum score of the tool was 144 and the minimum score 36. The scoring system of level of anxiety was 36:

- 72 low level anxiety, 73 – 109 moderate level anxiety and 110 – 144 high level anxiety. Birth-Preparedness
Knowledge Questionnaire consisted of 28 items. The score ranges are 0 – 9 poor preparedness, 10 – 19 average preparedness and 20 – 28 good preparedness. Institutional Ethics Committee clearance and Hospital Ethical Committee clearance (IEC 734/2014) was taken from the Institution and hospital and confidentiality was maintained where ever required. Content validity was obtained by administering the tool to seven experts. Data was collected from 21st January, 2015 till 28th February 2015. Identified the samples who are at 35 weeks of gestation with help of their antenatal card. Antenatal women between 18–30 years of age with 35 weeks of gestation meeting the sampling criteria were selected for the study. Pre-test of anxiety and birth-preparedness were assessed in both the groups. Following the pretest, on the same day, first session of prenatal classes were taken for experimental group which included the signs of labor, physiological changes during labor, and deep breathing exercise demonstration along with re-demonstration. On the next visit at 36 weeks experimental group received the second session of prenatal classes which included the deep breathing exercise, care of newborn and breast feeding. Post-test was assessed at 37 weeks of gestation. The relevant data were collected, compiled and analyzed using SPSS 17.0 version for calculation of percentages.

Results

Data presented in Table 1, shows that majority of primigravid women belonged to the age group of 20–24 years in experimental (62.2%) and control group (71.4%). Most of them were PUC qualified in both experimental group (45.9%) and control group (57.1%). Majority of primigravid women in experimental group (100 %) and control group (74.9 %) were married for 12 – 24 months. Majority of the primigravid women from experimental group (97.3 %) and control group (87.9 %), did not have any prior information regarding childbirth.

Table 2 depicts that there is a significant difference in the mean pre-test and post-test anxiety scores of primigravidas within the experimental group since the p value 0.001 is < 0.05. Therefore, it is inferred that prenatal classes has a significant effect on reducing the anxiety of primigravidas in the experimental group than the control group. Table 3 depicts that the mean post-test scores in the experimental group is greater than the mean post-test scores of the control group with a mean difference of 19.74. The independent sample ‘t’ test was computed which shows that the p value 0.001 is < 0.05, which is statistically significant. Therefore, it is inferred that the prenatal classes on labor helped in reducing the anxiety of primigravid woman on childbirth. Table 4 depicts that there is a significant difference in the mean pre-test and post-test birth-preparedness scores of primigravidas within the experimental group since the p value 0.001 is < 0.05. Therefore, it is inferred that prenatal classes has a significant effect on enhancing the birth-preparedness among primigravidas in the experimental group. Table 5 depicts that the mean post-test birth preparedness score in the experimental group is greater than that of the control group with a mean difference of 9.57. The independent sample ‘t’ test computed shows that the p value = 0.001 which is < 0.05. Hence, it was inferred that there is significant improvement in the birth preparedness. Therefore, it is inferred that the prenatal classes on labor helped in enhancing the birth preparedness of primigravid woman on childbirth.

Discussion

Findings of the present study showed prenatal classes were found to be effective in reducing the anxiety of primigravidas. On comparison of the post-test scores of the experimental and control group a mean difference of 19.73 was obtained. Independent ‘t’ test shows t = 16.61 and p = 0.001, which shows a statistically significant difference. The findings of the present study were supported by a study conducted among 195 Iranian mothers to assess the effects of prenatal education on stress and labor pain who attended the health center after their 16 weeks of gestation. The experimental group received six to eight sessions of prenatal education about childbirth whereas control group received only routine care. The tools used to collect data were Visual Analogue Scale (VAS) and McGill questionnaire, and Hospital Anxiety and Depression Scale (HADS). The ‘t’ test result showed a significant difference in levels of stress experienced by experimental group (Mean:14.±4.69 ) and control group (Mean :16.79± 4.86 ) with p value of 0.002. The VAS suggested that the level of pain perceived by the experimental group (Mean: 85.68± 18.5) was lower compared to the control group (Mean: 90.99 ± 14.72) by a p value of 0.03. According to this study, prenatal education and the presence of a doula during birthing will significantly reduce childbirth stress and labor duration.
Effectiveness of prenatal classes on birth preparedness of primigravidas.

The findings of the present study showed prenatal classes were found to be effective in enhancing the birth preparedness of primigravidas. On comparison of the post-test scores of the experimental and control group a mean difference of 9.50 was obtained. Independent ‘t’ test shows $t = 22.40$ and $p = 0.001$, which shows a statistically significant difference. The findings of the present study was supported by a study conducted by Stoll & Hall among a total of 624 antenatal Canadian women on childbirth education and obstetric interventions. The aim of this study was to determine the association between attendance at childbirth classes and maternal psychological states, rates of obstetric interventions and breastfeeding initiation. From that 350(56 %) attended the childbirth education classes. Attending prenatal classes was associated with higher rates of vaginal delivery among women in the study samples.

Knowledge, Attitude, Practice and Barriers for Self-care among Type 2 Diabetes Mellitus Patients in Rural Tamil Nadu

Aliya Jasmine¹, Ramesh Harihara Iyer²

¹Assistant Professor, ²Professor, Dept. of Community Medicine, Sri Ramachandra Medical College & Research Institute, Porur, Chennai

ABSTRACT

Objective: To assess the knowledge, attitude, practice and barriers for self-care among type 2 diabetes mellitus patients attending a rural health centre in Tamil Nadu.

Methodology: This was a part of a quasi-experimental study. Diabetes patients attending the rural health centre were included. A structured questionnaire was used to assess the knowledge, attitude, practice and barriers against self-care.

Results: Most of the study participants had good (76.6%) or moderate knowledge (6.5%). Attitude (96.1%) and practice (85.7%) towards the disease was poor. The most commonly reported barrier for self-care was either lack of awareness or lack of time.

Conclusion: Improved self-care practices will minimize morbidity and mortality associated with Diabetes. This study has highlighted lack of awareness as a major barrier for self-care. This has to be addressed by improving health literacy in the community. Developing Behavioural Change Communication programmes need to be developed to address poor awareness in both clinical and community settings.

Keywords: attitude, barriers, Diabetes, knowledge, practice, self-care.

Introduction

Diabetes Mellitus is a group of chronic metabolic disorder causing hyperglycemia or raised blood sugar, which eventually leads to serious damage involving various parts of the body. It is a major public health problem of the 21st century. Currently, there are 425 million people with diabetes and by 2045 this number is predicted to increase to 629 million. The largest increase in prevalence will take place in developing economies. India has around 73 million people living with diabetes. Indians present with diabetes one or two decades earlier when compared with their western counterparts. The age of onset in India has been shifting towards ever-younger people within the past decade.

Diabetes is responsible for various multi-systemic complications causing diabetic nephropathy, diabetic neuropathy, diabetic retinopathy, foot ulcers and gangrene leading to amputations, increased risk for cardiovascular disease and stroke. The current healthcare system in India faces a major challenge owing to the increasing trend of Diabetes in both urban and rural areas. The rising burden of diabetes-related health costs in a country where most of the health expenditure is out of pocket expenses is also a concern.

Modifiable risk factors associated with the complications are unhealthy diet, physical inactivity, obesity, hypertension, poor medication compliance. Complications can be prevented or delayed by improving health literacy regarding these modifiable risk factors.

Awareness in rural population is poor with many misconceptions about the disease. Most of these patients are unaware about the various complications that occur in diabetes. Knowledge of Diabetes can play a crucial role in improving self-care practices and reducing the disease related complications by better care and early identification.
The necessity for greater awareness regarding prevention, diagnosis, risk factor control and disease management has been supported from previous KAP studies. KAP levels among people living with diabetes need to be investigated to aid in future development of programs and techniques for effective health education.

Methodology

This study is a part of a quasi-experimental study. It was done in the Primary Health Centre, Nemam belonging to Poonamallee block in the Thiruvallur district, Tamil Nadu. Type 2 Diabetes Mellitus patients who have been diagnosed to have the disease for at least 6 months and have been enrolled in the Non-Communicable Disease register at PHC, Nemam were included in the study. As 77 subjects fulfilled the inclusion criteria and were ready to participate, they were included in the study.

Written informed consent was obtained from all the participants. A structured questionnaire was developed to assess knowledge, attitude, practice and barriers for compliance to self-care among the type 2 DM patients.

KAP scoring: There were a total of 14 items to assess knowledge, 7 items to assess attitude and 13 items to assess practice. DM knowledge was scored by assigning one point for each correct response (total score=14). We considered a score of 10-14 as ‘Good Knowledge’, a score of 6-9 as ‘Moderate Knowledge’ and 0–5 as ‘Poor Knowledge’. Attitude responses were summarized and a score of 0–3 was considered ‘Negative Attitude’ and a score of 4-7 as ‘Positive Attitude’. Practice was assessed similarly, each question was given 1 point for correct practice and 0 point in case of incorrect practice. A score of 0-6 was considered as ‘Poor Practice’ and a score of 7–12 was considered as ‘Good Practice’.

Permission was sought from the concerned authorities to conduct the study at the Primary Health Centre.

Results

A total of 77 participants were included in the study. Among them, 42.3% were male. More than half of the patients (55.1%) were more than 55 years. Illiteracy was high (47.4%) in the study population. Occupation wise most of the study subjects were unemployed (32.6%). Only 21.8% of the participants had family history and 16 (20.5%) participants had Diabetes for more than 5 years.

According to the KAP scoring, only 5 (6.5%) had good knowledge and most (76.6%) of the participants had moderate knowledge. Majority (96.1%) of the participants had a negative attitude towards the disease and self-care practices. Similarly most of them (85.7%) reported poor self-care practices.

Knowledge Assessment: The mean knowledge score of the study population was 7.4 ± 2.14. The range obtained in this study was 2 to 11, with 14 being the maximum score. Among the 77 participants, 5 (6.5%) had good knowledge, 59 (76.6%) had moderate knowledge and 13(16.9%) had poor knowledge.

Majority of them were aware of the symptoms of DM, need for diet modification and symptoms of Hypoglycemia. Only 32.5% of the study subjects were aware of the complications of DM. Only a small proportion of participants aware of the need for regular foot care (16.9%), oral care (11.7%) and eye care (11.7%). Although awareness of foot care was low, 51.9% were aware of diabetic foot. Details are given in Table 1.

Attitude Assessment: The mean attitude score was 1.7 ± 1.02. Out of 77 participants, 74 (96.1%) had negative attitude and only 3 (3.9%) had positive attitude towards self-care. More than half of the study participants had a
negative attitude towards diet modification (76.6%), regular check-up (89.6%), medication compliance (79.2%) and exercise (84.4%). Most of the participants had positive attitude towards monitoring weight (44.2%) and avoiding tobacco use and smoking (49.4%). Details are given in Table 2.

Practice Assessment: Similar to the attitude, 11 participants reported good self-care practices (14.3%) and 66 (85.7%) reported poor practices. The mean score was 4.2 ± 1.98. Although attitude towards regular blood sugar check-up was poor, 88.3% reported monitoring their blood sugars regularly at the primary health centre. Very few exercised (15.6%) and monitored their weight (24.4%) regularly. Of the 77 individuals, 50 (64.9%) study subjects reported to have not forgotten to take medication in the last 2 weeks 53 (68.8%) participants reported to carrying medications while travelling. Details are given in Table 3.

Barriers for self-care practices: Lack of awareness was reported as the most common barrier for foot care (83.1%), exercise (45.5%), oral care (89.6%) and eye care (35.1%). Lack of time was most common barrier for dietary modification (35.1%), blood sugar check-up (48.1%) and second common barrier for exercise (32.5%). Lack of healthcare facility was reported as a barrier for regular eye and blood sugar check-up.
The details are given in Figure 1 and Figure 2.

**Discussion**

Type 2 diabetes mellitus is a challenging non-communicable disease requiring judicious care and self-management. For this purpose there is a need to create awareness among the diabetic patients regarding various aspects of clinical care including the consumption of drugs, oral hygiene, foot care, periodical follow up etc. This study was carried out among 77 diabetic patients in the primary health center. Majority of the patients belonged to the age group of 56 – 75 years (47.4%) and were females (56.4%). The educational status of our study participants was 51.3% while majority of them (73.1%) were employed. The duration of type 2 diabetes mellitus in our study population was less than 5 years in 78.2% of the participants. In a study done by Fatema K et al, majority of the participants were females (58%) similar to our study. In addition about 37.2% participants were over 50 years of age, which is also similar to our study. 6 Similar findings were observed in a study done by Shah VN et al and similarly, in a study done by Alsous M et al, majority of the participants were beyond 40 years of age (25.8%) and females predominantly participated in this study (69.3%). 7, 8

In our study, we elaborately assessed the level of knowledge, attitude and practices towards diabetes and self-care. We observed that majority of the participants were aware of symptoms of diabetes and the need for diet modifications. However, only 32.5% of the participants were aware of complications of diabetes mellitus and
very negligible percentage of participants were aware of foot care (16.9%), oral care (11.7%) and eye care (11.7%). Similar findings were observed in the study by Shah VN et al.²

The assessment of attitude level among the study participants showed that majority of the participants had negative attitude towards diet modifications, regular checkups and compliance with medication and exercise. However, they had a positive attitude towards monitoring weight and avoiding tobacco and smoking. This reflects that the participant’s attitude towards care and self-management and diabetes was considerably poor. In a study done by Shah VN et al., 65% of the participants felt that they were responsible while approximately 39.07% of the participants felt that doctors were responsible for diabetic care and management. ⁷ In another study done by Alsous M et al 46.3% of the participants had positive attitude towards the diabetes care.⁸

With regards to the prevalence of self care practices among diabetes patients, majority of the participants had regular blood checkups and appropriate use of footwear. Similarly about 44.9% of the participants followed diabetic diet and 68.8% were compliant to treatment and carried medications even while travelling. In our study, we also assessed the barrier for self care practices among these patients on various parameters. It was observed that majority of the participants felt that lack of awareness was a key barrier for inadequate foot care (83.1%), exercises (45.5%) and diet (14.3%). Moreover, when we assessed the barriers for monitoring other complications, lack of awareness was reported as the important factor for poor oral care (89.6%) while lack of health facility was cited as an important reason for inadequate eye care (45.5%). With regards to periodical monitoring of blood sugar, lack of time was the most common reason cited for lack of compliance (48.1%). In a study done by Shah VN et al about 70.2% of the participants examined sugar level was periodically and 56% of the participants underwent foot care examination periodically, similar to our study. ⁷ However in a study done by Alsous M et al 37.7% of the participants did not practice periodical exercises, similar to our study.⁹

Self care of diabetes in essential component management of Type 2 Diabetes mellitus. Self care activities consist of a set of behavior which improves the diabetic status and prevents complications. These activities include following a regular and strict diet plan, regular exercises, self glucose monitoring, foot care and compliance to medications and checkups.⁹ ¹⁰

In order to achieve effective self care and management, it is important to educate the patients and their family members regarding the disease and the importance of non medical therapeutic activities like exercises and diet plans. Therefore in this context a detail assessment of the knowledge attitude and practices is necessary.

Our study demonstrated that although patients had adequate knowledge, when it comes to attitudes and practices, they were seen to be lacking in these parameters. Moreover the barriers to effective implementation of self care practices seemed to be increase in the lack of awareness. ¹¹

Considering the fact that self care practices play a significant impact in effective diabetes management, it is the important for the care providers to consider imparting adequate education to these patients on the self care aspects. It is important that they take time in evaluating the patient’s level of awareness and their false notions and perception, to make specific and realistic targets for effective diabetic control. The health care provider should make inclusive decision making with a good team of doctors, nutritionist, psychotherapist, podiatrist, and last but not least the patients and their immediate care provider. Each patient may be provided with a tailor made, customized regimen for diet and exercises which may result in effective implementation and practically achievable diabetic care goals. ¹² ¹³

Health Status of Assam: A District Level Analysis

Bhargab Das

MPhil Research Scholar, Dibrugarh University, Assam

ABSTRACT

Health is a state of complete physical, mental and social well being, not simply the absence of diseases or infirmity (WHO, 1948). On the other hand, health status is a concept with the help of which health can be measured. Health status in physical sense influencing factors like height, weight, nutrition, agility and flexibility or ability to move, sanitation and compliance with prescribed medications, treatment, activity etc. The present paper attempts to analyze the health status of the Rabhas, one of the most backward tribal communities of Assam. The necessary data to fulfill the objective of the present study have been collected through a structured household questionnaires prepared for the study. To assess the health status among Rabhas various standard health indicators like infant mortality rate, Maternal Mortality Rate, Crude Death Rate, Crude Birth Rate, Morbidity Prevalence Rate etc. are used. The results of the study reveal that status of health of the Rabhas is not satisfactory. The Infant Mortality Rate of the community is found as 47.17 per thousand live births which is higher than the state average and national average. The Maternal Mortality Rate of the community is also found much higher than the national average and state average. Therefore in order to improve the health status of the Rabhas the health infrastructure, delivery system, manpower, resources all has to be strengthen enough so that it can be utilized the community people in a proper way.

Keywords: Health Status, Rabhas, Goalpara.

Introduction

Health is a state of complete physical, mental and social well being, not simply the absence of diseases or infirmity (WHO, 1948). Health system includes all activities whose primary purpose is to promote, restore or maintain individuals physical, mental and social well being (WHO, 2000). On the other hand, health status is a concept with the help of which health can be measured. Health status in physical sense influencing factors like height, weight, nutrition, agility and flexibility or ability to move, sanitation and compliance with prescribed medications, treatment, activity etc. Some parameters of health status are sex ratio, density of population, life expectancy, mortality, morbidity, birth rate, nutrition and access to health care system1.

The health status of Assam is not satisfactory. The conventional health indicators put Assam in the band of poor-performing states along with the other such states of north and central India2. Assam has not been able to achieve the desired health outcomes with very high infant mortality rate and maternal mortality rate. Poor literacy rate, low per capita income and improper water and sanitation facilities etc. all have contributed to some extent in some form to the underdevelopment of the health sector3.

Profile of the Tribe: One of the scheduled tribes in the plain districts of Assam, the Rabhas belong to the Indo-Mongoloid group of people and have similarities with other members of Boro group such as Garo, Mech, Kachari and Hajong. The Rabhas are widely concentrated in the districts of Goalpara, Baksa, Kamrup, Udalguri and Kokrajhar of Assam. Besides Assam, they are also found in Meghalaya, Manipur, West Bengal, Bangladesh and Nepal. According to 2011 census the total Rabha population of Assam is 296,189 which constitute 0.95 percent of the total population and 7.63 percent of total ST population of the state. Among the districts, Goalpara...
has the highest number of Rabha population with 35.03 percent (103,757) of total Rabha population of Assam live there followed by Kamrup (R) and Udalguri districts with 30.73 percent (91,034) and 10.42 percent (30,873) of total Rabha population live there respectively (Census of India, 2011). According to the Report of Assam Mahila Samata Samiti (AMSS) the superstitious evil practice of witch hunting is very common among the Rabhas. Witch hunting is a form of gender violence, much ugly; less discussed and largely overlooked. Lack of education and lack of availability of access to a standard of health care facilities perpetuated the presence of witch hunting practices. Again a study of Assam Institute of Research for Tribal and SC reveals that the morbidity rate among the Rabhas is very high. Thus it is very essential and important to study the health status of the community in details.

Profile of the Study Area: The present study is conducted in the Goalpara district of Assam. Goalpara is one of the oldest districts of Assam which was originally created by the British in 1876. The total geographical area of the district is 1824 square kilometers. Presently the district shares the common boundaries with Dhubri district on the west; Kamrup district on the east; Brahmaputra River on the North and East Garo Hill district, Meghalaya on the south. The district has five revenue circles with eight development blocks. The revenue circles are Balijana, Dudhnoi, Lakhipur, Matia and Rangjuli. Goalpara district occupies 11 towns and 829 villages (District Census Handbook, Goalpara).

According to 2011 census the total population of the district was 1,008,183 of which 5, 13,292 (50.91 percent) were male and 4, 94,891 (49.09 percent) were female. Out of the total population 86 percent population live in rural areas and only 14 percent live in urban areas. The district has 45,094 SC population and 231,570 ST population. The population density of the district is 553 (census of India, 2011). The main communities living in the district are Boro, Rabha, Hajong, Garo and Miri. Among these communities Rabha is the most dominant one.

In 2016, the government of India named Goalpara district of Assam as one of the country’s 250 backward districts. It is one of the 11 districts of Assam currently receiving fund from the Backward Regions Grant Fund Programme.

Objective

1. To analyze the health status of the Rabhas of Goalpara district of Assam.

Methodology

The methodology to be followed in the study is outlined below.

Sampling Design: The samples for the study have been drawn by following multi-stage sampling technique using both random and purposive methods of sampling.

Selection of District: In the first stage we selected the appropriate district for the collection of the samples. For the present study Goalpara district of Assam has been selected purposively as the sample district as it contains the highest numbers of Rabha population of Assam. According to 2011 census, 35.03 percent of the total Rabha population of Assam live in Goalpara district.

Selection of Revenue Circle: The selected district has been further classified into 5 Revenue Circles. They are Matia, Rangjuli, Balijana, Lakhipur and Dudhnoi. From these 5 Revenue Circles Balijana, Matia and Dudhnoi have been selected purposively as sample Revenue Circles as these three Revenue Circles contain the highest number of Rabha villages.

Selection of Development Blocks: Balijana Revenue Circle has two development blocks namely Kharmuja and Balijana of which Balijana has been selected as it has more Rabha villages than Kharmuja. Again Matia Revenue Circle has two development blocks i.e. Matia and Krishnai of which Krishnai development block has been selected purposively as it contains more Rabha villages than Matia development block. Again from Dudhnoi Revenue Circle Kuchdhowa development block has been selected as it is the only development block of the revenue circle.

Selection of Villages: Next step involves the selection of the sample villages from each selected development block. Here we selected two Rabha villages from each development block randomly. Therefore a total of six Rabha villages are selected for our present study. Here a village containing more than 50 percent Rabha population is defined as Rabha village.

Selection of Households: Finally from each of the sample villages 20 percent of total Rabha households in each of the villages were selected randomly as the sample households for investigation. A total of 276 households were covered by the study.

**Survey Tools:** The necessary data to fulfill the objective of the present study have been collected through a structured household questionnaires prepared for the study. For the objective primary data relating to the health status of the sample households have been collected and analyzed by using simple statistical technique of percentage and presented in tables and diagrams. To assess the health status among Rabhas various standard health indicators like infant mortality rate, Maternal Mortality Rate, Crude Death Rate, Crude Birth Rate, Morbidity Prevalence Rate etc. are used.

**Results and Discussions**

The WHO defined health as “a state of complete physical, mental and social well being and merely the absence of disease or infirmity.” Poor health leads to capability deprivation and poverty. Again poverty leads to low standard of living, malnutrition and lack of basic amenities. So good health is very important for all round development of the people. Health indicators are quantifiable characteristics which describe the health status of a particular population. These indicators are basically used by governments to guide health policy. In this section an attempt has been made to analysis the achievements in health among the Rabhas with the help of different standard health indicators.

**Infant Mortality Rate:** The Infant Mortality Rate is a very important indicator that represents Human Development. It is also the most important component of mortality that can represent well being of human beings. It is used as a proxy to the life expectancy variable when data on life expectancy at birth is not available. According to SRS, the Infant Mortality Rate is the number of children dying before their first birthday. Mathematically, the Infant Mortality Rate can be defined as:

\[
\text{IMR} = \frac{D_0}{B} \times 1000
\]

Where, \( D_0 \) = Number of deaths within one year of any reference period

\( B \) = Total number of live births during the same reference period.

In the present study Infant Mortality Rate of the community is found as 47.17 per thousand live births which is higher than the state average of 44 and national average of 34 in 2016 as per the NITI Ayog data. Thus we can say that IMR of the Rabha tribe is much higher than the state and national average.

**Maternal Mortality Rate:** Maternal Mortality or death due to cause related to pregnancy and child birth, is another key health outcome indicator which has a wider capability implication. Maternal death is defined by WHO as “the death of women while pregnant or within 42 days of termination of pregnancy from any cause related to or aggravated by the pregnancy or its management but not from accidental or incidental cause.” Mathematically, MMR is defined as

\[
\text{MMR} = \frac{M_0}{B_0} \times 100000
\]

Where, \( M_0 \) = All maternal deaths occurring within a reference period.

\( B_0 \) = Total number of live births during the same reference period.

In the present study, 1 maternal death has been found during the period of 5 reference years and hence 0.2 maternal deaths per year. Thus the Maternal Mortality Rate of the community is found 943 per 100000 live births which is much higher than the national average of 130 and state average of 237 in 2014-16 as per NITI Ayog.
Crude Death Rate: Crude Death Rate is another important indicator of mortality. It can indicate the present health achievement of a population. It measures the number of deaths per 1000 population in a particular period of time. Mathematically, it is defined as

\[ CDR = \frac{D}{P} \times 1000 \]

Where, CDR = Crude Death Rate  
D = Total registered death during a calendar year. 
P = Total number of population in a specified year.

In the present study it is observed that a total 31 deaths took place during the reference period of 5 years and hence the average death is 6.2 per year. And the estimated Crude Death Rate of the sample population is 5.01 per thousand population which is lower than the state average of 7.01 and Indian average of 6.50 in 2015 (Source: Office of the Registrar General and Census Commissioner, India).

Crude Birth Rate (CBR): The Crude Birth Rate is the widely used measure of fertility. As the name implies it is the crude measure of public health. The Crude Birth Rate is the number of live births per year per 1000 midyear population. The mathematical formula for calculating CBR is

\[ CBR = \frac{B}{P} \times 1000 \]

Where, CBR = Crude Birth Rate 
P = Total midyear population in a particular area 
B = Total number of births in a particular area

In the present study data for live births is calculated for a period of last 5 years. So after calculating total number of live births for the last 5 years, the annual birth has been calculated. In the present study 106 live births are found and hence the average number of births per year is 21.2. Thus the estimated Crude Birth Rate for the sample population is 17.15 per thousand population which is lower than the state average of 20.8 and national average of 19.27 in 2015 (Source: Office of the Registrar General and Census Commissioner, India).

Growth of Rabha Population: In order to measure the population growth among the Rabhas we calculated the Natural Growth of Population. The Natural Growth of population takes into account only the birth rates and death rates. It does not take into account the population changes due to migration of people from one place to another place. Natural increase in population is defined as the difference between Crude Birth Rate and Crude Death Rate.

\[ \text{Natural Increase in Population} = CBR - CDR \]
\[ CBR = \text{Crude Birth Rate} \]
\[ CDR = \text{Crude Death Rate} \]

In the present study the Growth rate of the population is found to be 12.2 which is slightly lower than the national average of 12.77 and the state average of 13.7 in 2015.

Morbidity Prevalence Rate (MPR): Morbidity Prevalence Rate is an important health indicator. Morbidity affects the normal functioning of the human beings. Morbidity is a state of affair in which an individual is physically and mentally suffering. The MPR is the frequency with which a disease appears in a particular population.

\[ \text{Morbidity Rate} = \frac{\text{Number of ailing persons}}{\text{Total Population}} \times 1000 \]

The MPR can be studied in terms of acute disease and chronic disease. Ailments of less than 30 days duration are treated as acute and more than 30 days are treated as Chronic (NSSO 1998). Among the sample population, the Morbidity rate is found 97.89.

Mode of Treatment of Disease: It is important to study the mode of treatment in order to have idea of the health status of a particular community. A primitive backward society uses more traditionally known medicines and traditional way of treatment than modern drugs and modern technologies. The diseases are treated by Kabiraj or Bej in such societies. However, with development and advancement in science and technology and spread of education, people started visiting hospitals and doctors for treatment of diseases. It is found from field survey data that 94 respondents i.e. 34.18 percent of the sample respondents still depend on the Bej or Kabiraj for treatment of diseases. On the other hand, the remaining respondents i.e. 181 respondents (65.81 percent) use to visit doctors for the treatment of diseases. Thus we can say that a huge proportion of the respondents is still depended on traditional or primitive methods of treatment which is not a good sign.
Figure 1: Distribution of Respondents by Mode of Treatment

Conclusion

From the above discussion it is found that the status of health of the Rabhas is not satisfactory. The Infant Mortality Rate of the community is found as 47.17 per thousand live births which is higher than the state average and national average. The Maternal Mortality Rate of the community is also found much higher than the national average and state average. However, the estimated Crude Death Rate of the sample population is 5.01 per thousand population which is lower than the state average of 7.01 and Indian average of 6.50. In the present study the Growth rate of the population is found 12.2 which is slightly lower than the national average of 12.77 and the state average of 13.7 in 2015. It is found from field survey data that 34.18 percent of the sample respondents still depend on the Bej or Kabiraj for treatment of diseases. On the other hand, the remaining respondents i.e. 65.81 percent use to visit doctors for the treatment of diseases. Thus in order to improve the health status of the Rabhas the health infrastructure, delivery system, manpower, resources all has to be strengthen enough so that it can be utilized the community people in a proper way.

Acoustic Analysis of Infant Cry Using Multidimensional Voice Program—A Preliminary Study

Deepa N Devadiga¹, Remyasree T², Aiswarya Liz Varghese³, Ananthakrishna T⁴
¹Associate Professor, Department of Speech and Hearing, School of Allied Health Sciences, ²Post Graduate,
³Assistant Professor-Selection Grade, Department of Department of Audiology and Speech Language
Pathology, Kasturba Medical College, Mangalore, ⁴Assistant Professor-Selection Grade, Department of
Electronics and Communication Engineering, Manipal Institute of Technology, Manipal Academy of Higher
Education, Manipal, Karnataka, India

ABSTRACT

Crying is the only communication means that the baby has in the first month of life. It is expected that some aspects of the infant cry sound can be directly related to neurological deficits or damage, as well as to genetic anomalies and respiratory problems. Assessment of infant cry is a powerful screening tool to evaluate the neurological status of the newborn within its early biosocial context. However, till date it is not clear how acoustic analysis of cry using the Multi-Dimensional Voice Program (MDVP) will serve as a marker in differentiating the normal cry from the abnormal cry especially when birth cry is analysed for the purpose.

Keywords: Birth cry, Acoustic Analysis, MDVP, Normal and Abnormal Cry

Introduction

Crying is referred to as natural, alarm to alert the needs of the infant and motivating the listener to respond [¹]. The first cry of the new born is defined as the baby’s very first exhalations of the first breath within 20 seconds after birth [²]. During the first cry, metabolic acidosis occurs due to hypoxia during birth. The baby experiences a feeling of cold due to differences in temperature. This sudden extensive temperature difference terrifies the newborns, and thus takes a deep breath and during the following exhalation starts crying with all its strength [³].

It is postulated that crying originates in the nervous system, thereby reflecting the neural veracity, which may be useful in early identification of infants at risk for adverse developmental consequences. Hence, presence of an abnormal cry could be suggestive of any dysfunction or deficit of central or peripheral nervous system [⁴]. The preterm infant with excessive crying may reflect the occurrence of behavioural problem and the parenting stress even after few years which is in accordance with the previous studies [⁵, ⁶, ⁷].

Earlier studies were mainly based on the auditory analysis alone. The fundamental frequency has been found to be a discriminative feature in severe medical problems such as Sudden Infant Death Syndrome [⁸], hypoglycaemia/hyperglycaemia [⁹], brain damage [¹⁰], cleft palate [¹¹] and others.

Need of the Study: Assessment of infant cry is a powerful screening tool to evaluate the neurological status of the newborn within its early biosocial context. Although, there were methods to explore the infant cry using several other methods, till date it is not clear how acoustic analysis of cry using the Multidimensional voice program (MDVP), a commonly used software, will serve in differentiating the normal cry from the abnormal cry especially for the birth cry. Hence the present study is an attempt in this direction.

Aim of the Study

- To analyze the birth cry in normal and high risk infants using acoustic measures of voice

DOI Number: 10.5958/0976-5506.2019.02465.3
**Objective of the Study**
- To profile and compare birth cry in normal and high risk infants using acoustic measures

**Method**

A cross sectional research design with convenient sampling procedure was adopted. The research protocol was approved by Institutional Ethical Committee. Informed consent was obtained.

A total of N=40 participants were grouped based on gestational age into two groups, normal infants as Group I and high risk infants as Group II.

**Group I:** Group I consisted of normal infants, with gestational age from 37-42 weeks with (n=25) [Males =10, Females=15].

**Group II:** Group II consisted of high risk infants, with (n=15) [Males = 7, Females=8].

**Inclusion Criteria**

**Group I**
- The infants born from 37-42 weeks of gestation period with no complications.

**Group II**
- The infants born before 37 weeks or after 42 weeks of gestation period
- Infants susceptible to events associated with birth and the adjustment to extra uterine survival based on the high risk register maintained at hospital.

**Exclusion Criteria**
- Infants born to mothers aged over 40 years and less than 16 years during delivery were excluded in Group I.

**Procedure**

**Questionnaire:** A questionnaire was developed in order to collect information pertaining to demographic details, prenatal, perinatal, and post natal histories.

**Data Recording:** The birth cry was recorded using the dynamic unidirectional microphone (UTP-30), at a frequency response of 100-15,000 Hz in the labour room (Normal Delivery) or Labour theatre (C section) < 30 seconds after birth. The microphone was connected to the lap top with PRAAT -5114 Software. The microphone was maintained at a distance of 10 cm during the recording. Each cry was recorded for 30 seconds. The recorded data were saved in wave format for further analysis.

**Data Analysis:** In the recorded data, the noise was controlled using Audacity software.

The following steps were carried out in order to reduce the background noise to a minimum level.
- Spike noise reduction
- If the sample considered was weak, it was amplified (here the new peak amplitude was maintained at ‘0’ level)
- Finally, the overall noise level was removed from the entire signal and all the signals units were combined

**Acoustic Analysis:** All the samples were transferred to MDVP software. The cry was analysed for selected acoustic parameters.

**Statistical Analysis:** The statistical analysis was performed using the SPSS version 15. Descriptive statistics was performed. Independent t test was done to compare the means between the two groups. A p value less than 0.05 was considered statistically significant.

**Result**

**Fundamental Frequency Related Measures:** The mean value obtained was found to be higher for Average Fundamental Frequency and Highest Fundamental Frequency among the normal infants as compared to high risk infants, except for the Lowest Fundamental Frequency which was higher in high risk infants. However there was no significant difference for Average Fundamental Frequency, t (38) = 0.267, p = 0.20, Highest Fundamental Frequency, t (38) = 0.801, p = 0.095 and for Lower Fundamental Frequency, t(38) = -0.175, p = 0.437 between normal and high risk infants.

**Frequency and Amplitude Perturbation Measures:** The mean value for Shimmer in dB was higher in high risk infants. There was significant difference observed for shimmer in dB, t (38) = -0.221, (p<0.05) between the normal and the high risk infants. The mean obtained for
Absolute Jitter was higher in normal infants as compared to the high risk infants. However there was no significant difference observed, t(38) = 0.699, p = 0.263 between normal and high risk infants.

The mean value of Shimmer percentage was higher in high risk infants compared to normal infants and the mean value obtained for Jitt was higher in normal as compared to the high risk infants. However, they were not statistically significant with jitter percent, t(38) = 0.535, p = 0.117 and Shimmer Percent, t(38) = -0.258, p = 0.482.

**Noise Related Measures:** The mean value of Noise to Harmonic Ratio was higher in high risk infants. However, No significance was observed for Noise to Harmonic Ratio, t(38) = -0.247, p = 0.944 between normal and high risk infants.

**Voice Break related and Sub- Harmonic Measures:**
The mean of the Degree of Voice Break and Degree of Voiceless was higher in normal infants compared to high risk infants. The mean value of Degree of Sub- Harmonic was higher in high risk infants. No significance was observed for Degree of Voice Break, t(38) = 1.609, p = 0.895, Degree of Voiceless, t(38) = 0.442, p = 0.420 and Degree of Sub- Harmonic, t(38) = -0.080, p = 0.611 between normal and high risk infants.

**Discussion**
The acoustic analysis was carried out using the most commonly used software, the Multidimensional Voice Profile (MDVP). MDVP is advanced software with which it is possible to analyse 33 quantitative voice parameters, which are subdivided under 8 groups. However, in the present study, selected parameters were analysed for the birth cry signal.

**Fundamental Frequency related parameters:** In the present study, the results revealed an overall increase in Average Fundamental Frequency, Highest Fundamental Frequency in the normal infants as compared to high risk infants. However, it was observed that mean values obtained for F0 particularly in preterm, respiratory distress and hyperbilirubinemia high risk infants was higher as compared to the F0 in normal infants which is in consensus with the previous investigations [12]. The F0 is as important parameter in the objective assessment of the cry signal, and it is defined by number of cycle per second vibration of the vocal fold. The fundamental frequency is influenced by the vibration mode of the vocal fold, the amount of sub glottal pressure and the co-ordination of the various intrinsic laryngeal muscles. Because of the anatomical difference of the vocal tract, newborn infants have higher fundamental frequency and resonances than adults. Previous reports indicate that the high risk infants tend to be physically smaller in size at birth when compared to normal infants and resulting in high pitch. A higher F0 is reported in infants diagnosed to have hyperbilirubenemia as compared to normal infants [13]. In the present study respiratory distress infant showed higher F0 as compared to normal infants. The results are consistent with the other studies which demonstrate that the birth cry of an Respiratory Distress Syndrome infant have the F0 of higher pitch than the normal full term infants [14]. The meconium aspirated infants have a reduced pitch in cry when compared to normal infants. In the present study, it was seen that F0 was lower in meconium aspirated syndrome as compared to normal infants. Meconium aspirated syndrome infants breathe the meconium content in the amniotic fluid which enters in to the lungs during the delivery and may prevent from the normal respiration. Those infants have weak cry because the reduced vital capacity leads to the lower pitch and loudness. Intra Uterine Growth Retardation is another condition associated with the risk for developing respiratory inhibition after birth [15]. The immature respiratory system leads to increased risk for hypoxia. Those infants have the restriction in the body growth from the uterus and have an overall reduction in the body size. The smaller vocal fold structures in those infants may produce low pitch when compared to full term infants, which is in agreement with the present study.

**Frequency and Amplitude Perturbation Measures:**
In the present study, Jitta was found to be lower in preterm when compared to normal infants. It was also observed to be lower in meconium aspirated syndrome, hyperbilirubenemia, and respiratory distress syndrome compared to the normal full term infants. This Jitta value depends on the stability of the fundamental frequency, as the F0 increases the Jitta values will reduce. So the reduced jitta value of the preterm infants indicating the higher F0, which is similar to the findings of the present study.

There was significant difference observed for Shimmer in dB (p<0.05) between two groups. Shimmer in dB expresses the average period to period variability of
the peak to peak amplitude. Usually these irregularities in the shimmer measures are associated with breathy or weak voice. Human larynx is not fully developed during birth, the cartilaginous and membranous portion of the vocal fold matures post natal [16]. New born have 60 to 75% of total length in the posterior chink of the glottis. This will result in an increase in the hoarseness of the voice when compared to adults. Hence, this ShdB was found to be higher in new born infants. Most of these high risk infants were born by caesarean and have the risk of the health complications. Several factors that lead to the caesarean delivery include pre-term, meconium aspiration, mother’s bleeding condition etc. If an infant is delivered as preterm, the respiratory system is not fully developed. Hence this immature airway makes it difficult for the infant to breath and that can leads to weak production of the cry [17]. So this could be one of the factors that contribute to the irregularity of the short term amplitude among high risk infants.

**Noise Related Measures:** The current study results revealed that high risk infants had slight increase in the Noise to Harmonic Ratio as compared to the normal infants although not statistically significant. The NHR values are an index of degree of hoarse voice. Hence, it is a good indicator of the breathiness of the cry units. The current result is at par with the literature that, preterm infants have a reduction of energy in the signal with larger spectral tilt over time, indicating the breathy voice in preterm infants compared to normal infants [18]. Hence, preterm infants are expected to have a higher NHR values as compared to normal infants.

**Voice Break related and Sub-Harmonic Parameters:** In the present study, all parameters were increased in normal infants as compared to high risk except for Degree of Sub-Harmonic which was found to be higher in high risk as compared to normal infants. Voice breaks measures indicate the ability to sustain the voice without any interruption, the Sub-Harmonic component estimates the irregularity of the vocal fold vibration. The high risk infants have more latency of the cry units compared to normal infants, hence the voice break measure was higher in normal than high risk infants. Pre term infants have an immature laryngeal system that leads to the irregularity in the vocal fold vibration resulting in increased sub harmonic. Hyperbilirubinemia infants were also found to have increased Degree of Sub Harmonics values as compared to normal infants, indicating that there is variability in the pitch of the cry signal. The Degree of Sub Harmonics value was increased in the preterm infants as compared to normal, indicating loose adduction and the escape of the air through the vocal folds, thereby leading to irregular vibration of the larynx.

**Conclusion**

It suggests that acoustic analysis which is non-invasive in nature can be used to characterize birth cry between normal and abnormal birth cry. However a large sample size is required to come to conclusive findings. Thus birth cry analysis could be used as a diagnostic marker in differentiating between normal and high risk babies and thereby can contribute to early disorder identification and prompt intervention.

An Analysis of Access to Primary Health Care Services: A Study in Jorhat District of Assam

Sampurna Khound
PhD. Research Scholar, Omeo Kumar Das Institute of Social Change and Development, VIP Rd. Upper Hengrabari, Guwahati, Assam

ABSTRACT

The present study tries to find out the access to primary health care services. Primary health care services are very important for the health outcomes of the mother and that of the child and in ensuring that both maternal and child deaths are prevented. These types of services also positively contribute to improve the health status and also economic development. Study of these services is necessary in developing areas where infrastructure to deliver these services is minimal or lacking. This study has been done in two development block of Jorhat district. A cross sectional household survey was conducted for the sample of 242. Accessibility has been studies in three aspects like availability, affordability and acceptability. Study also tries to cover the disparities in accessibility in different socio-economic groups.

Keywords: Accessibility, Availability, Acceptability, Primary Health Care.

Introduction

Health is one of the vital indicators of quality of human life. So it is very essential that health services reached each and every corner of the country. Bhore committee in 1946 suggested a comprehensive health care service an integration of preventative, promotive and curative so that every individual able to received it. According to the recommendation of this committee, Government of India set up three-tier health care delivery system i.e. primary, Secondary and Tertiary. In the three-tier health care system primary care provided services at the village level, secondary care at a subdivision and district level and tertiary care at the regional level. Health has been declared a fundamental right in many countries. National governments all over the world are striving to expand and improve their health care services. The concept of primary health care came into light in 1978 following an international conference in Alma-Ata USSR which declared that primary health care was a key to attain health for all. India is a signatory to the Alma-Ata declaration of 1978 and was committed to attain the goal of “health for all by the year 2000 A.D., through the Universal provision of primary health use service (Government of India, 1983).

With physical existence of expanding, access to health care especially in rural areas is a crucial priority for government. In India a large proportion of people live below the poverty line in rural areas. In those areas since primary health care plays an important role, critical priority has been given to primary health care by government of India. But physical accessibility of public or private health care facility is a challenge in rural areas. The access to health care is therefore, rightly defined as the potential and actual entry of a group of population into the health and health care delivery system.18

The Institutes of Medicine defines access to health care as “…the timely use of personal health services to achieve the best possible outcomes” 7. Access to health care depends on availability, awareness, affordability and accessibility to health care services13. Along with availability of physical infrastructure, facilities and health workers, accessibility is important for good health.
outcome. The physical existence is a necessary but not a sufficient condition for accessibility. There are various factors which influence the people attitude towards access to health services such as knowledge about disease, awareness about medical facility and cost of the service\(^1\). In short, access to health care is a combination of affordability, availability and acceptability of the prevalent health care system\(^8\). In this study, access to primary health care facility has been looked into in the light of availability, affordability and acceptability of health care facility.

**Objectives and Methodology**

The sole objective of this paper is to examine the accessibility of primary health care facility.

**Data Source:** Both secondary and primary sources of information have been used while conducting the study. The primary data is collected through multi-stage sampling method with the help of a structured questionnaire which has been prepared keeping in mind the objectives of the study. The secondary data has been collected from different sources like the Directorate of Economics and Statistics, Directorate of Public Health, Planning Board, District Medical Offices, Journals, Books etc.

**Sampling Design:** A multi-stage sampling design has been drawn for selection of the sample. From the two sub-divisions in Jorhat district, in the first stage of sampling, two development blocks viz. Jorhat block and Titabor block have been purposively selected on the basis of having the highest concentration of rural population. i.e., In the second stage, two gaon panchayats have been purposively selected on the basis of concentration of highest rural population. In the third stage, from the two gaon panchayats, 25% of villages have been selected which add up to four villages. In the fourth stage, from these four villages, 10% of the households have been randomly selected which is shown in Table below.

**Analytical Tool:** Tabulation has been done to present the collected information in a systematic way. The study has been presented using simple statistical tools like percentages, averages.

**Result and Discussion**

Access to health services is how people make use of or take advantage of the services being provided. However, access cannot be ensured only through expansion of the service, it should be affordable as well as acceptable also\(^1\). The physical access implies the distance to the service provider, affordability means that the service is economically accessible and acceptability implies that people have knowledge about the service and they ready to receive it.

Expanding access to primary health care is a critical priority of the government of India. Efforts towards it address numerous issues and much progress has been reported. The health care system in India, at present has a three tier structure to provide health care services to its people. The first tier know as primary tier, has been developed to provide health care services to the vast majority of rural people. The primary tier comprises three types of health care institutions -sub centre (SC), primary health centre (PHC) and community health centre (CHC). In Assam, at present 975 PHCs, 10 CHCs and 4604 SCs are working. In Jorhat district, seven Block PHCs, six CHCs, 27 mini PHCs and 144 SCs are working (Joint Director of Health Service, Jorhat). Various types of family welfare programmes, immunization programmes and family planning measures are being executed by these primary health care service providers. The Assam government has played a pro-active role in creating provisions of health care facilities for the past several decades to all those who are in need of these facilities and services.

**Availability of Primary Health Services:** Adequate and equitable distribution of health care facilities in rural areas is critical to human capital development. Adequate number of health institutions should be set up in the rural areas of a particular district so that the villagers need not travel long distances to seek medical facilities.

**Distance to the nearest SC/PHC/CHC:** Distance to the health care is an important determinant of health care availability.

Source: Field survey

From the above Table (2), it is observed that 47.52 percent of the households have a SC at a distance of less than one km. While only 35.12 percent of the households are located within 3-5 km from the nearest PHC and CHC respectively. For majority of the households (68.88 per cent), the PHC and CHC are located at a distance of more than eight km. It is also reported that around 95 percent of people are situated at a walk able distance from the SC, a large proportion of people depend on rented vehicles and other public services to reach these facilities.

Affordability of Health Care Services: Affordability depends on various socio-economic variables, such as income of the household, occupation, family size and caste etc. Here an attempt has been made to analyse the relation between health expenditure and the above mentioned socio-economic variables. The following table has been constructed to depict the relation.

Table-3: Health Care Expenditure among Socio-economic Groups (in percentage)

Source: Field Survey

From Table 3, it is observed that among the social groups, the expenditure on health by the backward caste like the Scheduled Caste and Scheduled Tribe is comparatively low than the other caste. The monthly per capita consumption expenditure of the households show that the percentage share of health expenditure increases
as the monthly per capita consumption expenditure of the sample households increases. 26.27 percent of the households whose MPCE is above 3500, spent more than 30 percent of their non-food expenditure on health services. There is a positive relationship between the size of family and health expenditure. As the family size increases, expenditure on health also tends to increase. Occupation wise data shows that the agriculturists and daily wage earners are ready to spend only 10 to 20 percent of their income on health services.

**Health Care Acceptability:** Acceptability can be defined as willingness of a person to receive or buy a health service (Simon, 2007). The acceptability of any health care system/medical practice among a given population is determined by different elements. It is very crucial to understand the factors that influence the different choice that people make between different available health care systems as also their very acceptance/willingness to avail any medical practice. Here, acceptability is being looked into the process of making a choice for medical care by the different socio-economic groups.

**Choice of Provider:** A table has been constructed to show the choice of providers among different socio-economic groups.

</tr>
</tbody>
</table>

**Source:** Field Survey

The above Table 4 shows that with an increase in monthly per capita consumption expenditure, the preference for private health care providers increase. Among the social groups, a significantly higher proportion of the scheduled caste (78.18) is found to have opted government sources followed by the scheduled tribe at 75 percent. Occupation wise, it is found that people engaged in government services prefer to take advantage of the private service providers. On the other hand, people who are agriculturists and daily wage earners opt for government service providers as they cannot afford the costly services of the private health care service providers.

**Type of Institution:** Selection of institution depends on type of disease and distance to the facility centre. The sample households reported that the complex cases which cannot be cured in the rural health institutions are referred to a higher facility as most of the PHC and CHC are not in a position to deliver specialised health care services.

Source: Field Survey

It appears from the Table 5 that 47.89 percentages of households seek treatment from the district hospital. Likewise, 13.38 percent of the households seek treatment in the PHC and CHC, particularly those belonging to the Bekajan block as it is located at distance from the Jorhat town. However, treatment sought from the private hospitals is relatively lowers (14.79). 23.94 percent of the households visit private clinics for treatment.

Most of the maternal deaths are attributed to the lack of proper care at delivery. To improve the quality of human resources a major trust of all welfare programmes has been directed towards maternal health. In Jorhat district it seems to have been working good and almost all the mothers during 5 years in the survey area reported that their delivery took place in various health institutions. The ASHA workers are doing their job in a good manner which helps to improve the institutional delivery.

Opinion on Government Service: The respondents were enquired as to how much they are satisfied from the services provided by the PHC and CHCs. The respondents gave a mixed response. Most of the respondents reported that waiting room facility, availability of medicines, provision of operation theatres, ambulance facility and testing laboratory in primary health centres are rather poor. During the ensuing discussions, some major issues came to light. There is lack of basic facilities in the PHCs and sub-centres like the building, water and electricity, proper in-patient facility etc. Moreover, at many places, there is no laboratory facility and basic medicines are also not available. So, very often most of the tests are done in outside laboratories. Often they work in haste and fail to give a patient hearing to the problems of the patient. Lack of cleanliness and heavy rush are also reported as the two major reasons for low preference for government health services.

Conclusion

The primary focus of the present study has been to look into the accessibility of primary health care facilities. They are designed to function as important components of the overall economic and social development programmes. Investments have been made under the different government programmes to meet the demand of the rural people. Although majority of the patients belonging to the economically poor households prefer rural health institutions, those institutions have failed to become a choice for the economically well to do households as those who can incur higher health care expenditure often choose urban centric secondary health care services. Though the households at large are aware of the availability of service in the primary health centres but the motivation for utilisation of the services of the PHCs is very poor. It needs an effective and continuous strategy to develop the demand and motivation to avail the primary health services. The process of current evaluation should be strengthened to monitor the performance of the primary health centres. Further strengthening and capacity building of public health facility should be done regularly. Young doctors should be motivated to work in the rural area for some time to serve the people. Government should take steps for improvement so that people can choose a particular health facility rather than forced to go because of lack of money.

ABSTRACT

In this paper, a new variant of elimination of adaptive artifact from Electrocardiography (ECG) signals is presented. ECG is a noninvasive method for indirect assessment of monitoring the stroke volume, cardiac output and other hemodynamic parameters. But this method is affected by various non-stationary artifacts such as sinusoidal artifacts (SA), respiration artifacts (RA), muscle artifacts (MA) and electrode artifacts (EA) while acquiring the ECG signal which leads to ambiguity in diagnosis. Hence these artifacts should be eliminated for accurate diagnosis. For filtering these artifacts, we proposed several hybride adaptive filtering techniques based on conventional Least Mean Square (LMS) algorithm. These are Normalized Median LMS (NMLMS), Sign Regressor NMLMS (SRNMLMS), Sign NMLMS (SNMLMS), Sign Sign NMLMS (SSNMLMS) are the hybride variants of LMS algorithm. Based on these adaptive algorithms, we developed several adaptive signal enhancement units (ASEUs) and performance is evaluated on the real ECG signal components obtained from MIT-BIT database. Among these techniques, SRNMLMS based ASEU performs better in the filtering process. The signal to noise ratio improvement (SNRI) for this algorithm is calculated as 21.6985 dBs, 7.9864 dBs, 7.8346 dBs and 10.6857 dBs respectively for SA, RA, MA and EA. Hence, the SRMLMS based ASEUs are more suitable in ECG signal filtering in real time health care sensing systems.

Keywords: Adaptive Filter, Hemodynamic parameters, Electrocardiography, signal enhancement, stroke volume.

Introduction

Electrocardiography (ECG) is a simple, inexpensive and noninvasive method to monitor the changes of electrical impedance in thorax which is due to the periodic changes of blood volume in aorta. An appropriate thorax model can be used to estimate Stroke Volume (SV), Cardiac Output (CO) and other hemodynamic parameters¹². In the ECG field Impedance Plethysmography³ methods are used to study the fluids flow in the cardiac area. Several comparative studies are carried out in the field among noninvasive ECG and invasive methods like thermodilution that shown promising results in favor of ECG⁴⁵. With the technology improvement wearable devices with ECG sensors are designed to facilitate recordings in long term and offer comfort to the patients⁶. Since the initiation of ECG there has been an increased in the improvement of technique reliability and cardiac parameters⁷⁸.

During the extraction the ECG signals are influenced by physiological and non-physiological artifacts. The tiny features of the desired signal components are masked by the artifacts and causes ambiguities during diagnosis. The major artifacts contaminated with the desired ECG components are Sinusoidal Artifacts (SA), Respiratory Artifacts (RA), Muscle Artifacts (MA) and Electrode Artifacts (EA). These artifacts should be removed to obtain high resolution ECG signal for estimating stroke volume and intensity. As the artifacts are not stationery in nature and hence, we can’t predict the characteristics of artifacts, so conventional filters with fixed coefficient are not preferable for filtering. So that adaptive filtering

techniques are preferable to update the filter weights in according to the statistical nature of the signal and noise component. In [11-12] conventional Least Mean Square (LMS) and Recursive Least Square (RLS) adaptive algorithms are used to enhance the ECG signal resolution. But the drawbacks of these algorithms are high steady state error, and impulsive noise. To resolve these drawbacks and to enhance the performance of artifact cancelation we developed several Adaptive signal enhancement units (ASEUs) based on some hybrid variants of LMS. With these hybrid algorithms we can also achieve less computation complexity. In [13-15] Rahman et al. proposed some adaptive noise cancellers to enhance the cardiac signal and brain activity using several variants of LMS. In this paper, we considered the same framework for the development of ECG signal filtering techniques.

The performance of ASEUs for ECG analysis in a typical health care sensing system can be improved by various hybrid techniques. Signal enhancement capability, convergence rate, and computational complexity are the interesting characteristics in any typical health care sensing system. The basic adaptive algorithm is Least Mean Square (LMS) algorithm. High steady state error and impulsive noise are the main drawbacks of LMS algorithm. To overcome these drawbacks, we proposed Median LMS (MLMS) algorithm. In this paper further to improve convergence rate, filtering capability and to reduce computational complexity we also implemented various sign versions of MLMS algorithms. The various variants of MLMS algorithms are Sign Regressor MLMS (SRMLMS) algorithm, Sign MLMS (SMLMS) algorithm and Sign Sign MLMS (SSMLMS) algorithm. The algorithms implementation is discussed in the next section. Based on the simulation results the SRMLMS based ASEUs perform well than remaining variants.

Enhancement of Electrocardiography signals using Hybrid Techniques: During the extraction, the ECG signal is influenced by several artifacts that cause ambiguity in the diagnosis. Hence the artifacts should be eliminated in order to estimate accurate hemodynamic parameters of ECG. Adaptive filtering techniques are used to remove the non-stationary artifacts. Figure 1 shows the typical block diagram ASEU. It consists of FIR filter and weight update mechanism. In this paper several signal processing techniques are proposed for developing various ASEUs.

![Figure 1: A typical adaptive signal enhancement unit](image)

Here we developed several strategies for weight update mechanism. First consider a conventional LMS based adaptive filter with tap length N. The input to the ASEU is raw ECG signal u(n), it contains desired signal Z(n) as well as noise components R(n). r(n) is reference signal correlated with R(n) generated by the reference generator is applied as input to the FIR filter. Let w(n) is the impulse response of the FIR filter, y(n) be the FIR filter output, d(n) be the error signal generated in the ASEU. The weight updating mechanism for an LMS based ASEU can be mathematically written as,

\[ w(n+1) = w(n) + \alpha u(n)d(n) \]  

Where, \( w(n) = [w_0(n) w_1(n) \ldots w_{N-1}(n)] \) is the nth tap weight vector, \( u(n) = [u(n) u(n-1) \ldots u(n-N+1)] \) is input sequence, \( d(n) = u(n)-w^T(n)r(n) \) and ‘\( \alpha \)’ represents a step-size.

**Median LMS Algorithm (MLMS):** The performance of the LMS algorithm and its derivatives is significantly degraded when it is subjected to input signals that are influenced by impulsive noise, sometimes this leads to instability. This problem can be overcome by using a nonlinear filter to smoothing the noisy gradient components. This modification leads to median LMS [16].

The weight updating mechanism for an MLMS based ASEU can be mathematically written as,

\[ w(n+1) = w(n) + \alpha.med_L [u(n)d(n), u(n-1)d(n-1) \ldots u(n-L)d(n-L)] \]  

This algorithm is normalized with reference to data vector results Normalized Median LMS algorithm (NMLMS) algorithm. In this algorithm the fixed step
size varies with respect to the input data samples, i.e., $a$ is replaced with $a(n)$. The weight update equation for NMLMS is given by,

$$w(n + 1) = w(n) + a(n).\text{med}_{l}[u(n)d(n), u(n-1)d(n-1) \ldots u(n-L)d(n-L)]$$

...(3)

Where, the step size parameter is written as,

$$a(n) = \frac{\alpha}{c + \|u(n)\|^2}$$

Sign variants of NMLMS: Here, we developed new algorithms that use signum [17] of either the error signal components, the input signal components, or both, have been derived from the various NMLMS based adaptive algorithms for simple implementation. Hence, computation time will be reduced particularly the time required for “multiply and accumulate” (MAC) operations [86]. The sign-based techniques result in the reduction of the computational complexity of the filter and, therefore, is suitable for biotelemetry applications. In this paper we developed three sign variants of NMLMS namely Sign Regressor NMLMS (SRNMLMS), Sign NMLMS (SNMLMS) and Sign Sign NMLMS (SSNMLMS). The weight updating mechanism for these three variants is as follows respectively.

$$w(n + 1) = w(n) + a(n).\text{med}_{l}[\text{Sign}\{d(n)\}u(n), \text{Sign}\{d(n-1)\}u(n-1) \ldots \text{Sign}\{d(n-L)\}u(n-L)]$$

...(4)

$$w(n + 1) = w(n) + a(n).\text{med}_{l}[\text{Sign}\{d(n)\}u(n), \text{Sign}\{d(n-1)\}u(n-1) \ldots \text{Sign}\{d(n-L)\}u(n-L)]$$

...(5)

$$w(n + 1) = w(n) + a(n).\text{med}_{l}[\text{Sign}\{d(n)\}u(n), \text{Sign}\{d(n-1)\}u(n-1) \ldots \text{Sign}\{d(n-L)\}u(n-L)]$$

...(6)

Where

$$\text{Sign}\{u(n)\} = \begin{cases} 1 : u(n) > 0 \\ 0 : u(n) = 0 \\ -1 : u(n) < 0 \end{cases}$$

...(7)

Simulation Results

To demonstrate that the proposed algorithms are truly effective in clinical situations, the method has been validated using various ECG recordings taken from the MIT-BIH data base. In our simulation experiment we have taken four ECG recordings (1,2,3,4, 5) from five different persons. These records are contaminated with SA, RA, MA and EA. Various SEUs for ECG enhancement is developed using the LMS, NMLMS, SRNMLMS, SNMLMS, SSNMLMS algorithms. In the evaluation procedure of the proposed techniques, we considered Signal to Noise Ratio Improvement (SNRI) for our experiments, averaged and compared with conventional LMS based Adaptive Signal Enhancement Unit (ASEU). Tables 1 give the characteristics of proposed implementations. Due to space limitation we have shown the experimental results only for two artifacts. The experimental results of artifact cancellation are shown in Figure 2, Figure 3, Figure 4, Figure 5 respectively for SA, RA, MA and EA.

Filtering of Sinusoidal Artifacts (SA) Using Adaptive Algorithms: In this experiment SA components are removed from input raw ECG. This is given as input to ASEU shown in Figure 1. The reference signal is generated from the reference generator which is correlated to SA. Based on error value the adaptive algorithm associated with the ASEU automatically updates the of FIR filter coefficients. The performances of these implementations are compared with reference to SNRI. These are averaged for four experiments for each artifact and are tabulated in Table 1. Based on these performance measures it may be concluded that SRNMLMS based ASEU performs better in SA filtering of ECG signals. Hence, this technique is recommendable for the implementation in real time health care monitoring devices.
Filtering of Respiration Artifact (RA) using Adaptive Algorithms: In this experiment RA components are removed from input raw ECG. This is given as input to ASEU shown in Figure 1. The reference signal is generated from the reference generator which is correlated to RA. Based on error value the adaptive algorithm associated with the ASEU automatically updates the of FIR filter coefficients. Figure 2 shows the simulation results for removal of RA. The performances of these implementations are compared with reference to SNRI and is shown in Tables 1. By comparing the performance measures among all the algorithms, it seems as SRNMLMS based ASEU is better with reference to the filtering ability. Hence, these realizations are well suited for real time implementations.

Filtering of Muscle Artifact (MA) using Adaptive Algorithms: In this experiment MA components are removed from input raw ECG. This is given as input to ASEU shown in Figure 1. The reference signal is generated from the reference generator which is correlated to MA. Based on error value the adaptive algorithm associated with the ASEU automatically updates the of FIR filter coefficients. Figure 3 shows the simulation results for removal of MA. The performances of these implementations are compared with reference to SNRI and tabulated in Table 1. By comparing the performance measures among all the algorithms, it seems as SRNMLMS based ASEU is found to be better. Hence, these realizations are well suited for real time implementations.

Filtering of Electrode Artifact (EA) using Adaptive Algorithms: In this experiment EA components are removed from input raw ECG. This is given as input to ASEU shown in Figure 1. The reference signal is generated from the reference generator which is correlated to EA. Based on error value the adaptive algorithm associated with the ASEU automatically updates the of FIR filter coefficients. The performances of these implementations are compared with reference to SNRI. These are averaged for four experiments for each artifact and are tabulated in Table 1. By comparing the performance measures among all the algorithms, it seems as SRNMLMS based ASEU is better with reference to SNRI. Hence, these realizations are well suited for real time implementations.

Figure 3: Typical ECG enhancement results of RA cancelation (a) ECG signal contaminated with RA, (b) ECG filtered with LMS algorithm, (c) ECG filtered with NMLMS algorithm, (d) ECG filtered with SRNMLMS algorithm, (e) ECG filtered with SNMLMS algorithm, (f) ECG filtered with SSNMLMS algorithm

Figure 4: Typical ECG enhancement results of MA cancelation (a) ECG signal contaminated with MA, (b) ECG filtered with LMS algorithm, (c) ECG filtered with NMLMS algorithm, (d) ECG filtered with SRNMLMS algorithm, (e) ECG filtered with SNMLMS algorithm, (f) ECG filtered with SSNMLMS algorithm

Figure 5: Typical ECG enhancement results of EA cancelation (a) ECG signal contaminated with EA, (b) ECG filtered with LMS algorithm, (c) ECG filtered with NMLMS algorithm, (d) ECG filtered with SRNMLMS algorithm, (e) ECG filtered with SNMLMS algorithm, (f) ECG filtered with SSNMLMS algorithm

Conclusion

In this paper several efficient adaptive signal enhancement techniques are developed for ECG signal enhancement. In order to achieve convergence speed and enhancement capability we are used various ASEUs based on LMS, NMLMS, SRNMLMS, SNLMS and SSNMLMS algorithms. These techniques are tested in real time to eliminate artifacts like SA, RA, MA and EA from desired ECG signals. The experimental results are shown in figures 2-5. From the experimental results we can conclude that SRMLMS based ASEU is better with reference to filtering ability and SNRI. Hence, these realizations are well suited for real time applications.

A Health Status of Assam: A District Level Analysis

Bhargab Das
MPhil Research Scholar, Dibrugarh University, Assam

ABSTRACT

Health is a productive asset that influences economic development significantly and also a part of the basis of human capabilities and integral part of welfare. Health enhances the economic development by improving the human capital and reducing economic cost of illness. Good health augments labor productivity and helps in boosting economic growth. In this regard the present study attempts to analyze the scenario of health status across the districts of Assam. The scenario of health condition is shown in terms of ranking and group of districts with the help of composite health status index constructed by using Principal Component Analysis. The results of the study reveal that there is high degree of disparity among the different districts of Assam in terms of health status. In terms of health status Dibrugarh district tops the list followed by Sivsagar, Jorhat and Tinisukia districts. On the other hand, Dhubri and Kokrajhar districts got the bottom position in the list followed by Darrang, Goalpara, Barpeta and Karimganj districts.

Keywords: Health Status, PCA, Assam.

Introduction

Health has an important role in the development of an economy, good health deals with good income. As defined by WHO, it is “a state of complete physical mental, and social wellbeing, and not merely the absence of disease or infirmity.” Health may be defined as the ability to adopt and manage physical, mental and social challenges throughout life. In 1984, WHO revised the definition of health and define it as the extent to which an individual or group is able to realize aspirations and satisfy needs and to change or cope with the environment. Health is a resource for everyday life, not the objective of living; it is a positive concept emphasizing social and personal resources, as well as physical capacities1.

In this 21st century, the concept of health is an ability that opened the door for self assessments to become the main indicators to judge the performance of efforts aimed at improving human health. There are certain key factors that have been found to be influencing the health status of the people2. According to the WHO, the main determinants of health include the socio and economic environment, the physical environment and the person’s individual characteristics and behaviors.

According to WHO, health care facilities are hospitals, primary health care centers, isolation camps, burn patients units, feeding centers and others. In emergency situations health care facilities are often faced with an exceptionally high numbers of patients some of whom may require specific medical care. Therefore it includes health care centers, medical, nursing home, pharmacies and drug stores, medical laboratory research, hospitals and specialized care centers.

Good health augments labor productivity and helps in boosting economic growth. As per the World Development Report 1993, it identifies four channels through which health helps in boosting economic growth

- It reduces production losses caused by worker illness.
- It permits the use of natural resources that had been totally or nearly inaccessible because of disease.
- It increases the enrollment of children in school and makes them better able to learn.
- It frees for alternative uses resources that would otherwise have to be spent on treating illness (World Bank, 1993).

DOI Number: 10.5958/0976-5506.2019.02468.9
Status of Health in India: The concept of health services was emerged and was evolved during the colonial rule. With expansion of colonial rule, the health services too expanded, getting organized into the Indian Medical Services by 1764. During the time of Government of India Act 1919, health became a provincial subject and health services have different character. In the year 1910 state finance most of the medical institutions which were around 75% and it moved to 92% in the year 1940 and it keeps on increasing. However, during the time of independence some of the health indicators were quite poor in India. Sir Joseph Bhore submitted the report on health survey and development in 1946, which was a landmark in the evolution of health services in India. The committee focuses on the medium and long term perspective for the development of the medical services. According to the committee, health services should be placed as close as possible to the people in order to ensure maximum benefit; and consciousness on health should be stimulated around the people with help of education.

In the post independence era, from the mid-1950s to early 1970s, effort to improve the human health, were treated at best. Many committees had been formed with the intention of providing health services to the people. The improving access to the essential health care services for the poor is a major issue to be looked on. The health status of the country has been increasing by time. Health status is a multidimensional concept, requiring multiple indicators and multiple methodologies for adequate measurements. For the country as a whole, latest available data indicates the following progress under NRHM in terms of key measurable health outcomes:

The Total Fertility Rate (TFR) has been reduced from 2.9 in 2005 to 2.5 in 2011, IMR from 58 in 2005 to 44 in 2011, Crude Birth Rate(1.9) (CBR) and the MMR was estimated at 178 during 2010-12 from 254 in 2005.

So, it is observed that there have been steady improvements in the core maternal and child health indicators at all India level. However, India being a diverse country, the pattern of progress of various State/Uts are different, which is something really interesting to explore.

Even though India has been achieved accelerated economic growth over the last two decades, it has rated poorly in human development indicators and health indicators. India compares scantily with developing countries like China, Sri Lanka and Bangladesh in many health indicators such as life expectancy at birth, infant and under-five mortality levels, etc. (GOI, 2005, 2008, 2010). In 2010, life expectancy at birth in India (65.13 years) is lower than that of China (73.27 years), Sri Lanka (74.72 years), Thailand (73.93 years), Nepal (68.39 years) and Bhutan (68.39 years). India’s position is even poor compared to these countries in terms of infant mortality rate, which is 48.6 in India as against 13.7 in China, 10.8 in Sri Lanka, 11.0 in Thailand, 38.6 in Bangladesh, 40.6 in Nepal and 43.6 in Bhutan for the year 2010 (World Bank Online Database). A similar picture is discernable if we compare India’s position with these developing countries in terms of other health indicators like maternal mortality rate, total fertility rate, birth rate, death rate, immunization, etc. The poor health condition is one of the major reasons for India’s poor rank in the UNDP Human Development Index. Out of the 187 countries, India ranked 134th in the latest UNDP Human Development Index for the year 2011, which is below the rank of the countries like Sri Lanka (97th), China (101st) and Thailand (103rd).

Status of Health in Assam: With the increasing health indicators there is an improving in the economic growth as a whole. For looking on the status of health in Assam there is a wide range of indicators. We will mainly look at the few health indicators namely crude birth rate, crude death rate, infant mortality rate, ante natal care, and Immunization. For Assam CBR and CDR condition is better in urban areas but it is below the national average in rural areas. Whereas the condition in IMR is below the nation average in both the rural and urban areas.

Source: Bulletin on Rural Health Statistics in India, 2011.

The fact evident from the table that the country as a whole and the state, the health condition of the rural areas is in miserable condition compare to the urban areas. With this view rural health care should be an area of special priority of any government in a country or state.

Objective

To analyze the scenario of health status across the districts of Assam.

Methodology

Data Source: The present study is entirely based on secondary sources data which are collected from the following sources—

1. Statistical Handbook of Assam.
2. Annual Health Survey (AHS),
4. Sample registration system,

Method: The study has taken only undivided 23 districts of Assam instead of 33 districts due to the unavailability of data on health status for the newly formed districts of Assam. In this study the development of the health sector is measured through health status. Here development of health sector is measured in terms of improvement in various health status indicators such as Infant Mortality Rate, Institutional Delivery, Morbidity Rate, Immunization Rate and Ante Natal Care.

To construct the health status index, the variables that are used as a percentage are

1. Infant Mortality Rate (the Infant Mortality Rate is the number of children dying before their first birthday per 1000 live births) \( (Y_1) \),
2. Morbidity Rate (Percentage of persons suffering from any type of acute illness) \( (Y_2) \),
3. Ante Natal Care (Percentage of mothers who had get ante natal check up in the first trimester) \( (Y_3) \),
4. Institutional Delivery (Percentage of delivery at institutions) \( (Y_4) \),
5. Immunization (Percentage of children aged 12-23 months fully immunized with BCG, Measles, three doses of polio and DPT) \( (Y_5) \),

Here the reciprocal of Infant Mortality Rate and Morbidity Rate are considered for calculation to make the variable unidirectional.

The scenario of health condition is shown in terms of ranking and group of districts with the help of composite health status index constructed by using Principal Component Analysis.

PCA is a useful technique for transforming a large number of variables in a data set into a smaller and more coherent set of uncorrelated factors, the Principal Components. PCA is a multivariate statistical technique used to reduce the number of variables in a data set into a smaller number of ‘dimensions’. The PCA is a more sophisticated tool than the HDI which can tackle the linear aggregation problem faced in the UNDP’s HDI. In mathematical terms, from an initial set of \( n \) correlated variables, PCA creates uncorrelated indices or components, where each component is a linear weighted combination of the initial variables. For example, from a set of variables \( X_1 \) through to \( X_n \).

\[
P_{C1} = a_{11}X_1 + a_{12}X_2 + \ldots + a_{1n}X_n
\]

\[
P_{Cm} = a_{m1}X_1 + a_{m2}X_2 + \ldots + a_{mn}X_n
\]

Where \( a_{mn} \) represents the weight for the \( m \)th principal component and the \( n \)th variable.

The variance \( (\lambda) \) for each principal component is given by the Eigen value of the corresponding eigenvector (Huang, 1974). The components are ordered.
so that the first component (PC1) explains the largest possible amount of variation in the original data, subject to the constraint that the sum of the squared weights ($a_{11}^2 + a_{12}^2 + \ldots + a_{1n}^2$) is equal to one. The second component (PC2) is completely uncorrelated with the first component, and explains additional but less variation than the first component, subject to the same constraint. Subsequently, components are uncorrelated with previous components; therefore, each component captures an additional dimension in the data, while explaining smaller and smaller proportions of the variation of the original variables. The higher the degree of correlation among the original variables in the data, the fewer components required to capture common information.

After the construction of the health status indices, the districts were categorized on the basis of the average value criteria. On the basis of average value criteria districts were divided into two categories—

1. Sound Group: This group includes the district having index values higher than the state average.
2. Lagging Group: This group includes the districts having index value lower than the state average.

Results and Discussion

Health Status Index and Status of the Districts: The composite index of the health status is prepared through the econometric tool Principal Component Analysis (PCA) by using the variables like Infant Mortality Rate, Morbidity Rate, Immunization, Institutional Delivery and Ante natal care for the year 2011-12. The first component is serving as the principal component because its Eigen value is more than 1 and it explains 47.40 5% of the total variances. The equation of the health status index is constructed by statistical method of linear aggregation of the original indicators such that

$$Z = W_1X_1 + W_2X_2 + W_3X_3 + \ldots \ldots + W_nX_n$$

The status of the district is shown through their comparative position in health status by ranking with the help of the values of the composite indices.

<table>
<thead>
<tr>

Source: Calculating through using PCA from the data of Annual Health Survey 2011-12

From the above table we can see that there are disparities or inequalities among the different districts of Assam in terms of health status. Dibrugarh district tops the list followed by Sivsagar, Jorhat and Tinsukia districts. On the other hand, Dhubri and Kokrajhar districts got the bottom position in the list followed by Darrang, Goalpara, Barpeta and Karimganj districts. The above table reveals that out of 23 districts 11 districts have index values more than the state average. On the other hand, the remaining 12 districts index values lower than the state average.

Grouping of Districts in Terms of Health Status: There are so many researchers have used PCA and constructed health status index and grouped the states into sound group and lagging group by using ‘Average Value Criteria’ while they found disparities in health status among the different states of India.
Table 4: Grouping of Districts Based on Index Values

<table>
<thead>
<tr>
<th>Health Status Index</th>
<th>Sound Group</th>
<th>Lagging Group</th>
</tr>
</thead>
</table>

From the above table we can see that there are huge disparities among the different districts of Assam in terms of health status. Out of 23 districts only 11 districts including Dibrugarh, Sibsagar, Jorhat, Tinsukia, Golaghat, Kamrup, Dhemaji, Nalbari, Cachar, Lakhimpur and Sonitpur have health status index values higher than the state average and fall in the category of sound group. On the other hand, 12 districts including Kokrajhar, Darrang, Dhubri, Karimganj, Morigaon, Nagaon, Karbi Anglong, Goalpara, North Cachar Hill, Hailakandi, Bongaigaon and Barpeta have health status index values lower than the state average and fall in the category of lagging group.

**Conclusion**

Health is a productive asset that influences economic development significantly and also a part of the basis of human capabilities and integral part of welfare. Health enhances the economic development by improving the human capital and reducing economic cost of illness. The above study reveals that there is high degree of disparity among the different districts of Assam in terms of health status. In terms of health status Dibrugarh district tops the list followed by Sibsagar, Jorhat and Tinsukia districts. On the other hand, Dhubri and Kokrajhar districts got the bottom position in the list followed by Darrang, Goalpara, Barpeta and Karimganj districts. Out of 23 districts only 11 districts have health status index values higher than the state average and fall in the category of sound group. On the other hand, 12 districts have health status index values lower than the state average and fall in the category of lagging group.

A Review of the Perception of Healthcare Quality among Patients and Employees

Bijo Mathew¹, Raja Narayanan¹, Amit Mittal¹
¹Chitkara Business School, Chitkara University, Punjab, India

ABSTRACT
As the healthcare is a service industry, patients come to hospital to avail various healthcare services while searching for quality within the services they avail. The term service is any activity or benefit that one party can offer to another that is essentially intangible and does not result in ownership of anything. Due to its intangibility and heterogeneity, healthcare quality requires a multidimensional definition which encompasses various stakeholder needs and expectation. This study reviews existing models in healthcare services and attempts add new relevant dimensions which may be proven empirically.

Keywords: Healthcare; service quality; perception of patients, satisfaction

Introduction
Quality has become an essential part of our daily living. Customers are constantly seeking goods and services of high quality. This demand for quality has led organisations to regard quality as a strategic objective to sustain in the aggressive market. Mosadeghrad¹ (2013) discussed the definitions of quality from different perspectives. Quality has varying definitions because of its subjective nature and intangibility. Parasuraman et al.², (1985) defined Quality as “meeting and/or exceeding customers’ expectations”. Another definition of Quality by Flood (1993, p.226) is “meeting customers’ (agreed) requirements, formal and informal, at the low cost, first time and every time”. The Indian healthcare sector is at a critical juncture and needs special attention, which also includes other allied areas such as hospital management, OTC drug consumption (Sehgal and Mittal³, 2019), healthcare tourism and so on. Due to its intangibility and heterogeneity, healthcare quality requires a multidimensional definition which encompasses various stakeholder needs and expectation (Mosadeghrad⁴, 2013). Healthcare quality is defined by Donabedian⁵ (1980, p.5) as “the application of medical science and technology in a manner that maximises its benefits to health without correspondingly increasing the risk”. Another definition of healthcare quality by Leebov⁶ et al. (2003, p.4) says “doing the right things right and making continuous improvements, obtaining the best possible clinical outcome, satisfying all customers, retaining talented staff and maintaining sound financial performance”.

Patients and Employee Perception—Discussion
Crossing the quality Chasm report describes in order to achieve the healthcare quality, hospital to meet six attributes of healthcare system such as safe, effective, timely, efficient, equitable and patient-centered. Willems & Ingerfurth⁷ (2016) explored the difference in perception of hospital quality between the patient and the employee based on different variables in Germany. The various dimensions indicated in the paper were hygiene quality, process quality and information quality. Due to a significant difference in background, there was a contrasting perception gap about the hospital quality among different stakeholders. The study shows that for the hospital quality, employee score is consistently lower than the patient and heterogeneous in their evaluations. Abuosi⁸ (2015) conducted study on the perception between the outpatients and healthcare providers regarding the quality of care in Ghana. This research was performed on the basis of the gap model of service quality by Parasuraman et.al⁹ (1985), using different dimensions of care quality, namely financial access, adequacy of resources and services, fairness of care, effectiveness of care, interpersonal aspects of care, technical aspects of care and overall care. This research demonstrated that there is an overall significant difference in perception between patients and healthcare...

providers regarding the quality of care. However, this research was restricted only to outpatients, and perceptions of quality of care for inpatients may vary significantly owing to distinct expectations of care. The relationship between service quality and patient satisfaction has been illustrated by Shabbir et al16 (2016), lead showing positive correlation between the healthcare service quality and the patient satisfaction. Patient satisfaction was also evaluated by examining the difference between the quality of service perceived and expected. Positive inclination of the patient will frame abilities were measured as significant for improving knowledge about the cancer therapy with good technical relieving and life-prolonging therapy. Among the most important finding from this study was the nurses’ knowledge about the cancer therapy with good technical abilities were measured as significant for improving patient satisfaction and create a feeling of safety and security. Tornwall & Wilhelmsson12 (2010) investigated that satisfaction of patients were high with the standards and quality of nursing care. These results are also comparable to those studied by Riccio13 (2001) that patients are usually satisfied with nursing care quality and standards. Fascinatingly, patients are progressively satisfied with the communication skills and interdisciplinary collaboration among the nurses and workers. Henoch et al14. (2012) examined in their research regarding the association of the opinions of the lung cancer patients and their family members regarding various dimensions of the quality of care provided. The significant finding from this research is that both patients and family members reported that they received low quality care. The study found that there was a difference in the importance of different aspects of care between the ratings of patients and their family members, where family members rated the importance of nursing care items instead of patients. Fung, & Mercer15 (2009) explored patient perception on the process of consultation and the treatment outcomes for measuring the quality of physician care. Interestingly, for a comfortable environment that facilitated the patient’s ability to speak freely with their doctors, human skills such as laughing, being courteous and subjective welcome was considered significant. Zhao et al16. (2009) conducted a research among 221 nurses and 383 patients in 18 non ICU nursing units in Chinese hospitals. The study was limited only to nursing category and limited number of variables used to study the perception gap. Likewise, Lee & Yom17 (2007) discovered patients to be more satisfied with nursing care than their nurses. Such a distinction has emerged in the literature on the opinions of the nurses and patients. While nurses value the personal aspects of care, their patients value greater nursing skills and abilities. Padma et al18. (2009) explored different service quality dimensions from patient and attendants (patient’s family and friends) perspectives in Indian Hospitals. Service quality is defined as the evaluation of service encounters by the customers resulting from a comparison of customer expectations with perception of actual service performance (Lewis19, 1989). The authors discussed about the different models of service quality like SERVQUAL model by Parasuraman et al20. (1985, 1988) and Gronroos’ (1984, 1990) model. There are three components of service quality in Gronroos’ model21 (1984, 1990) such as functional quality, technical quality and image of the service provider. Technical quality relates to therapy given, infrastructure etc., and functional quality relates to how the service is delivered such as service friendliness, staff, timely delivery, etc. The patients who are satisfied remain faithful and are willing to pay more for the improved services. (Padma et. al22., 2009). From a customer point of view, an experience is a holistic phenomenon that encompasses all the interactions that occur from needs recognition to need fulfillments (Verhoef et al23., 2009). The authors identified 22 main categories and 51 subcategories of quality dimensions that are sorted under direct interactions (Staff attitudes and behaviours, personalisation, communications, competence, availability of persons, staff efficiency, staff reliability relationship with staff and relationship with other patients); indirect interactions (procedures and processes, facilities and premises, accessibility, timeliness, speed, external communication, medical outcome. Polsa et al24., (2010) conducted a study on how the cultural features may influence the service quality perception in one of the hospital in China. The research demonstrates that the cultural values of Chinese patients and their evaluation of the health service are linked and further analyzes point to the impact of cultural values on perceptions of service quality. Badri et. al25., (2007) discussed about the different models of service quality (with one, two, three and four constructs) and the healthcare satisfaction for discharge patients and tested these service quality models in those discharge patients in government hospitals in UAE. The final suggested model of the writers’ is based on the three constructs – process and administration, quality of care, and information. The model involves eight main dimensions that include empathy and personal attention, facilities and tangibility,
competency, professionalism, availability, administration rules and regulations, transition to home, and involvement and information. This study explains that all these dimensions in healthcare quality are important towards patient satisfaction. Naidu (2007) discussed about the various factors affecting the quality of healthcare and satisfaction of patients. The author identified various dimensions that can affect the patient satisfaction such as access, caring, healthcare output, communication and tangibles. These factors are strongly linked to aspects of general service quality such as responsiveness, reliability, assurance, empathy and tangibles. This paper discovered patient satisfaction and quality of healthcare to be fundamental in improving efficiency and image of healthcare services. This article also discussed about the understanding the staff perception of patient priorities and perceptions. Silvestro (2005) addressed that understanding perceptions of employees concerning patient expectations and perceptions helps to define gaps and to take action through training to close gaps. Mwachofi et al. (2009) explored about the socioeconomic and organizational factor influencing perception of quality and patient safety among nurses in hospitals in Saudi Arabia. The factors which enhance the patient safety and the probability that nurse use their own facility include; ability to communicate suggestions, fewer noticeable mistakes, information technology training and support, and a confidential error reporting system. The factors influencing patient satisfaction were discussed by Alhashem et al. (2009). For measuring quality of health services, the authors used patient satisfaction as an important indicator. The writers used Ware et al. (1978) model-based questionnaire, are split into six care aspects such as accessibility, technical, interpersonal, availability, comfort, convenience and overall. Evidence from multiple research has shown that healthcare providers suggestions help planners and policy makers identify health system bottlenecks; enhance the utilisation and sustainability of health care services in the general population (Songstad, et al., 2012). In fact getting the opinions of healthcare providers on health services is a realistic instrument for assessing and improving the health system.

**Proposed Model**

The model proposed for this study is shown in the Figure 1 and is mainly derived from the gaps model of the service quality of Parasuraman et al. (1985) as well as based on the theory of principal-agent paradigm (Eisenhardt, 1989; Jensen & Meckling, 1976). One criticism of the SERVQUAL model was that it concentrated only on the service’s functional aspects and not on the technical aspects (Padma, et al., 2009). Hence the proposed model is modified by incorporating more variables of healthcare service quality dimensions which are identified from the existing literatures.

Experience of Sore Nipple and the Remedies Used among Postnatal Mothers

Janet Prameela D’Souza¹, Shobha Kamath², Elsa Sanatombi Devi³
¹MSc Nursing, Assistant Professor, ²MSc Nursing, Lecturer, ³PhD Nursing, Professor, Manipal College of Nursing Manipal, MAHE, Manipal

ABSTRACT

Objective: To assess the experience of postnatal mothers regarding sore nipples, to explore the remedies adopted for sore nipple symptom relief and to compare the experience of primipara and multipara mothers regarding sore nipples.

Method: An explorative survey design was adopted and 200 postnatal mothers were selected by purposive sampling technique. The data were collected by administering demographic proforma, semi structured questionnaire on experience of sore nipple and remedies adopted for the management of sore nipple.

Results and Conclusion: The study findings revealed that, 120 (60%) mothers developed sore nipple problem within one week. Pain persisted for more than one week for 120 (60%) mothers. Majority of the mothers, 180 (90%) used remedial measures for the relief of pain. Most of the primi para mothers, 160 (80%) expressed it as “very severe” “horrible” and “intolerable” pain compared to multipara mothers. The study concluded that despite of having sore nipple, all the mothers continued breast feeding, so that baby will not be deprived of its nutrition.

Keywords: Experience, sore nipple, remedies, postnatal mothers, breast feeding

Introduction

Mother’s milk is an ideal and exclusive food for the infant for initial six months. Breast feeding meets the total nutritional needs of the infant.¹ Feeding the baby is a wonderful experience for the mother, but in some cases, mothers’ may face difficulties in feeding their newborns due to several reasons. Sore nipple is a very common problem encountered by the mothers during the initial weeks following delivery. This problem produces lot of discomfort to the mother, which makes her unable to feed her baby and finally the baby will suffer by not getting adequate nutrition. There is a high incidence of trauma to the nipple during the first four weeks of postnatal period. A descriptive survey study was conducted among postnatal mothers attending OBG private practice physician’s office in South Texas. Survey questionnaires were administered to them and it was found that about 42.7% mothers had sore nipple problems within four weeks. Many a times sore nipple lead to interruption and complete cessation of exclusive breastfeeding due to severe pain involved with it.²

Sore nipple which commonly causes pain, frequently arise from the baby due to improper latching. There will be too much pressure put on the nipple when adequate areola is not latched onto as well as improper release of suction when feeding ends. When breast pumps are not used correctly or some form of topical measures can also aggravate this condition.³ Infection can also lead to sore nipple and there will be severe pain when baby bites on the nipples. A study result conducted in Matuail reported problem of sore nipple among 1.75% postnatal mothers.⁴

Across sectional study was conducted among a cohort of mothers in northeast Brazil to find the prevalence and factors responsible for sore nipple. About 1,243 mother-child dyads were assessed at maternity ward and 30 days after delivery. The prevalence of cracked nipples
was 32% in the first 30 days postpartum. The factors responsible were poor breastfeeding technique, breast engorgement, caesarean section and use of a feeding bottle. Researchers concluded that the prevalence of sore nipple was very high among the postnatal mothers and postnatal characteristics were responsible for this condition. A study explored the incidence of nipple pain, associated factors and its impact on exclusive breastfeeding. About 1,649 postnatal mothers during their one week follow-up visit were included in the study. Nipple pain incidence was 9.6% on day seven. Primiparity, inappropriate positioning and latching, tongue tie etc., were the predisposing factors.

With this background information and the research gap identified, the researchers thought of conducting a survey to explore the experience of sore nipple and the remedies adopted for pain relief among post-natal mothers. The purpose of the study is to identify the various remedies used to relieve symptoms of sore nipple so that these can be utilized by the postnatal mothers if there is development of sore nipple. The knowledge obtained can be utilized by frontline health care professionals for teaching the postnatal mothers regarding the same.

Material and Method

Research approach and study design: Quantitative approach and an explorative survey design was adopted for the study.

Target population: The population consisted of all primipara and multipara mothers attending immunization clinics of a tertiary care hospital of Udupi district.

Sampling: All primipara and multipara mothers experienced sore nipple problem were selected by purposive sampling technique. The sample size obtained was 200.

Selection Criteria: The inclusion criteria for the selection of sample were all mothers visiting immunization clinic till 6 months after the delivery, experienced sore nipple problem and willing to participate in the study. Mothers who did not experience sore nipple problem, had complications during postnatal period like breast abscess were excluded from the study.

Tools used:
- Demographic proforma
- Semi structured questionnaire on experience of nipple sore
- Semi structured questionnaire on remedies adopted for the management of nipple sore

All the tools had 100% agreement by the validators in terms of accuracy, relevance and appropriateness. The reliability of the tool was established by administering the tool to 20 postnatal mothers attending the immunization clinic. Inter-rater reliability method was adopted to find out the internal consistency and the score was $r = 0.85$.

Procedure: Permission was obtained from Institutional Research Committee. This study fit into the guidelines and the procedures followed were in accordance with the Helsinki Declaration of 1975. Ethical clearance was obtained from IEC, Kasturba Hospital, Manipal (IEC 741/2016). Participant information sheet was explained to individual participant and consent was obtained from the eligible participants. Anonymity and confidentiality was assured. Tool on demographic proforma and semi structured questionnaires were administered to find the experience of nipple sore and remedies adopted for the management of sore nipple.

Findings: The data was compiled and analyzed using SPSS 20 version. Descriptive statistics was used for sample characteristics.

</table>

As per the results shown in table 1, the mean age of the mothers was $27.7 \pm 3.62$ years and most of them 115 (57.5%) were primipara. The study results revealed that
about 120 (60%) mothers developed sore nipple problem within one week. Pain was persistent for more than one week among 125 (62.5%) mothers. Majority 170 (85%) of the mothers used remedial measures for pain relief.

Fig. 1: Pie diagram showing percentage distribution of remedies used for sore nipple pain relief

The data presented in the Figure 1 shows that, majority of the mothers used Lanolin cream 70 (41.17%) and about 40 (=23.52%) of them used breast milk as remedial measure to get relief from sore nipple. About 20 (11.76%) of them used ghee, 15 (8.82%) coconut oil, 10 (5.88%) of them used nipple shield. About 10 (5.88%) of the mothers used more than one remedy for the treatment of sore nipple. Only 5 (2.94%) mothers used other measures like ayurvedic paste and analgesic tablet for pain relief.

Most of the mothers described pain as “very severe”, “very difficult to tolerate”, horrible pain. Most of the primi para mothers expressed it as “horrible pain” compared to multipara mothers. Despite of having sore nipple, all the mothers continued breast feeding. The study concluded that despite having sore nipple, mothers have continued feeding the babies, bearing all the pain, and trying various measures to relieve pain, so that baby will not be deprived of its basic nutrition.

Discussion

This study has revealed that about 60% postnatal mothers developed sore nipple problem within one week and these findings are similar with the findings of the study conducted by Mallikarjuna HB et al where they found that maximal onset of breastfeeding problem was significant in the first two weeks of neonatal period and breast feeding problems are common even among predominantly breastfeeding rural community. Suresh H et al reported that before discharge nearly 89% of mother newborn dyads had one or more breastfeeding problems including sore nipple (30.3%). Reordan et al concluded that 96% mothers had experienced sore nipple problem during first week of lactation. Buck et al argued that 79% of the women experienced nipple pain within one week, more than half of the women experienced discomfort beyond 3 weeks and 20% of women continued to have pain beyond 8 weeks.

The results of this study about the remedies adopted reveals that about 70 (41.17%) mothers used Lanolin cream and about 40 (23.52%) of them applied breast milk as remedial measure to get relief from sore nipple. These findings are congruent with the study findings conducted by Buck ML where 91% of women used topical treatment on their nipples during the first week and 94% continued breast feeding. Mohammadzadeh et al compared the effect of breast milk and lanolin cream among sore nipple mothers and application of breast milk was found to be more effective than lanolin cream, whereas Neto et al contradicted these findings where they found that lanolin cream application was better than breast milk application.

In this study, most of the mothers described pain as “very severe”, “very difficult to tolerate”, and “horrible pain”. Most of the primi para mothers expressed it as “horrible pain” compared to multipara mothers. Zeimer et al in his report concluded that majority of the mothers rated the pain as moderate to intense. Some articles reports that mothers will experience sore nipple in a variety of forms such as nipple pain ranged from minor, temporary soreness to absolute agony sometimes resulted reluctantly in premature weaning. Several women said that they dreaded the baby waking up and needing another feed. Some said that they didn’t want to resent the baby for hurting them and “considered giving up”.

Despite of having sore nipple, all the mothers continued breast feeding, bearing all the pain, and trying various measures to relieve pain, so that baby will not be deprived of its basic nutrition. This study explored experiences of the postnatal mothers during breastfeeding with regards to very common problem i.e., sore nipple and the different remedies used for the pain relief. Most of the time postnatal mothers may not express these problems with anyone. They will accept it as part of their postnatal period. When it is unbearable, they may
express it to close relatives or may seek medical help. By obtaining the information from mothers, researchers can impart this information to other postnatal mothers who may experience the same problem. The nurse can help the mothers by preparing them during the prenatal period only, so that the mental trauma experienced by them will be less.

The study was conducted for small representative group of whole population in selected setting, hence the results could not be generalized.

Conclusion

Sore nipple is a very common condition where postnatal mothers will have different experiences and opinions. Some women may experience it and some may not experience it at all. Some may have a brief feelings of discomfort. For some mothers it may be a common reason for the avoidance of termination of breastfeeding. Nurses need to have a working knowledge about the causes and treatments for nipple sore so that they can address this issue at right time and need to take corrective measures, so that mothers discomfort will be reduced, they will be at ease and the infant’s get right nutrition at right time leading to proper growth and development of healthy infant.

Conflict of Interest: The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Prevalence of Insomnia, and Sleep Hygiene Techniques Practiced among Elderly Residing in Selected Old Age Homes of Udupi and Dakshina Kannada District, Karnataka

Laxminarayan Iyer¹, Renjulal Yesodharan², Asha K Nayak²
¹Former Postgraduate Student, ²Assistant Professor, Department of Psychiatric Nursing, Manipal College of Nursing Manipal, Manipal Academy of Higher Education, Manipal

ABSTRACT

Insomnia is viewed as both a symptom and a disorder which affects a large set of population. Poor sleep may increase many medical problems like pain, diabetes mellitus, and psychiatric conditions like depression, dementia, and anxiety disorder.

Objectives: To determine the prevalence of insomnia and sleep hygiene activities practiced by elderly in selected old age homes.

Materials and Method: A total number of 181 elderly were participated in the study. A non-probability convenient sampling technique was incorporated for the selection of participants. Informed written consent was obtained after explaining about the study. Demographic proforma and insomnia severity index scale were used to collect the data.

Result: Among males, the mean Insomnia severity score was 12.59 ± 5.045 (95% CI 11.46-13.72%) whereas in females 10.26 ± 6.20 (95% CI 09.05-11.48%). Out of 181 participants 122 (67.4 %) had scores at or above the cut off score which indicated insomnia. With regard to sleep hygiene practiced by the elderly, 71.3% of the elderly used to get exposed to sunlight in the late afternoon and 75.1% used to take hot water bath two hours before bed time.

Conclusion: Insomnia was common among elderly residing at old age homes. Elderly should have the knowledge, ability to recognize the symptoms of insomnia, factors contributing to it and proper practice of sleep hygiene activities.

Keywords: Insomnia, sleep hygiene activities, elderly, old age homes

Introduction

Insomnia is viewed as both a symptom and a disorder which affects a large set of population. The International classification of Disease-10 (ICD-10) gave guidelines to diagnose nonorganic insomnia by screening the individual for difficulty falling asleep or maintaining sleep. This criteria is also applicable when the individual has poor quality of sleep. These disturbances should occur at least three times in a week for a month and cause marked distress with normal activities of daily living. The individual may have preoccupations with the sleeplessness and excessive concern over the consequences of sleeplessness. The new version of ICD-11 released in June 2018, insomnia is classified under separate chapter sleep wake disorder. The major transformation noted in the new version is insomnia is listed outside the mental behavioural and neurological disorders with new definition for the clinical accuracy. According to ICD 11, ⁰Insomnia disorders are characterized by the complaint of persistent difficulty with sleep initiation, duration, consolidation,
or quality that occurs despite adequate opportunity and circumstances for sleep, and results in some form of daytime impairment. Daytime symptoms typically include fatigue, decreased mood or irritability, general malaise, and cognitive impairment. Individuals who report sleep related symptoms in the absence of daytime impairment are not regarded as having an insomnia disorder.

Old age is a part of human life cycle in which the elderly people are dependent on their family and children. In modern society elderly are thought to be less advantageous and face a lot of social problems as they are retired. Limited regenerative abilities, lack of social autonomy, unloved and being neglected by their family and friends pose them as a threat to live in the society. The global share of older people aged 60 years or above was 9.2 % in 1990 and it increased to 11.7 % in 2013. It is expected that the elderly population in the world might reach 21.1 % by 2050. In 1901, India had 12 million elderly population aged above 60 years, which was increased to 71 million in 2001 (Population Projection for India and states, 2006). By 2021, 10.7% of the total population will be elderly. A rapid increase in the number of old age population will give rise to various social, economic and health issues and problems. Traditionally, the family members has been the primary source of support and care for the elderly in India. The changes and the transition happened in the families and the structure of family forced the family members to shift the elderly to old age homes. Most of the times the present generation treated the elderly as a burden and in the absence of familial support, most of them prefer to stay in old-age homes. They are more vulnerable to health-related problems including disorders of sleep.

Poor sleep may increase many medical problems like pain, diabetes mellitus, and psychiatric conditions like depression, dementia, & anxiety disorder. Many medical conditions such as epiglottic cyst can also present like sleep problems in elderly. Insomnia is a major health issue that is observed in the elderly. Rao et al., (2012) conducted a cross-sectional study and found out that 13.04% of, elderly residing in old age home had insomnia and 50% of them had parasomnias.

### Prevalence of insomnia among elderly:
A study conducted by Bhattacharya in 2013 revealed that gender, age, psychiatric disorders among several others are risk factors for insomnia. The stress of modern urban life is the factors responsible for an increase in the prevalence of insomnia.

A study conducted by Panda S et al among 1050 healthy attendants/relatives of patients attending a tertiary care hospital in south India revealed that majority of them were between 35.1 ± 8.7 years of age. Insomnia was reported among 18.6% of the patients with 18% for initiation of sleep, 18% for maintenance and 7.9% with early morning awakening. Hypertension was noted in 42.6% of the subjects.

### Objectives of the Study
The objectives of the study were to determine the prevalence of insomnia and sleep hygiene activities practiced by elderly in selected old age homes

### Method
A quantitative approach with an exploratory survey design was used in the study. A non-probability purposive sampling technique was incorporated for the selection of participants. The primary outcome variable is insomnia and other variables includes factors contributing to insomnia, sleep hygiene activities practiced and socio demographic variables. The participants were elderly who were aged between 60 and 80 years, residing in selected old age homes of Udupi and Dakshina Kannada District. A total number of 181 elderly were participated in the study. Oral and written consent were taken from the participants and it is consistent with the guidelines issued by Institutional Ethics Committee of Kasturba Hospital and Kasturba Medical College (KMC IEC 53/2015).

### Materials
The data was collected through one to one basis by structured interview. The study encompasses data collection from the elderly using socio-demographic proforma and Insomnia Severity Index, sleep hygiene activities practiced and assessment proforma for factors contributing to insomnia. The validated tools were pretested and the items were comprehend and no difficulties present. The reliability of the tool on assessment proforma for factors contributing to insomnia and scale for sleep hygiene practiced were 0.96 and 1.00 respectively. The participants gave information on demographic data, severity of insomnia and sleep hygiene habits within one months preceding the inquiry. The Insomnia Severity Index was designed to assess nature, severity and impact of insomnia. The
dimensions evaluated are: severity of sleep onset, sleep maintenance, and early morning awakening problems, sleep dissatisfaction, interference of sleep difficulties with daytime functioning, noticeability of sleep problems by others, and distress caused by the sleep difficulties.

**Demographic Characteristics:** Among 181 participants, 69 were males and 112 were females. Out of all the participants 53% of the participants were between 60 to 70 years. There were 56.4% female participants and about 60.8% were married.

**Statistical Analysis:** Multiple logistic regression analysis was used to calculate the odds ratios for the socio-demographic and clinical variables as a potential correlates of insomnia, after controlling for the effects of other variables.

**Result**

**Insomnia among elderly:** Insomnia among elderly was assessed using Insomnia Severity Index. Insomnia is further classified into sub threshold, moderate and severe based on the obtained score. Out of 181 participants, the minimum score obtained was zero and the maximum score obtained was 21. The mean insomnia severity score was 11.28 ± 5.827 (95% CI 10.43-12.14%). In males, the mean Insomnia severity score was 12.59 ± 5.045 (95% CI 11.46-13.72%) whereas in females 10.26 ± 6.20 (95% CI 09.05-11.48%). To find out the prevalence, a cut of score of 10 was set by the researchers based on the findings of a previous study. The set cut off score has 86.1% sensitivity and 87.7% specificity for detecting insomnia cases in the community sample (9) it often remains unrecognized and untreated. Brief and valid instruments are needed both for screening and outcome assessment. This study examined psychometric indices of the Insomnia Severity Index (ISI). Out of 181 participants 122 (67.4 %) had scores at or above the cut off score which indicated insomnia. Meanwhile the insomnia severity scores are categorized into three types namely: no clinically significant insomnia (0-7), sub-threshold insomnia (8-14), clinical insomnia moderate (15-21) and clinical insomnia severe (22-28).

**Table 1: Frequency and percentage distribution of insomnia based on the classification of Insomnia Severity Index and cut off score**

<table>
<thead>
<tr>
<th>Severity of Insomnia</th>

<td>122</td>
<td>67.40</td>
</tr>
</tbody>
</table>

Around 12 participants (8.95%) were having sub-threshold insomnia but not grouped under the category of insomnia based on cutoff score due to the scores less than ten. So the overall prevalence of insomnia among the elderly ranges from 67.40% to 74.03 %. A gender wise analysis showed that among 69 male participants, 20 (29%) had cutoff score less than ten and 49 (71%) had cut off score more than ten. When comparing the data with their male counterparts, 73 (65.18%) of females had cut off score more than ten indicating clinically significant insomnia. The difference in the mean insomnia severity scores of male and female also indicate a statistically significant difference of 2.543 (t=2.909, p=0.004) (95% CI 0.82 to 4.27).

The socio-demographic and clinical correlates of insomnia are identified using multiple logistic regression analysis. The socio demographic and clinical correlates of insomnia are mentioned in the table 2.

Over the past one month 31 (17.18%) participants were taking Benzodiazepine for insomnia

**Discussion**

**Prevalence of Insomnia:** The present study reveals that out of 181 participants, 122 (67.4%) had insomnia. A study conducted at Ladakh also revealed that the prevalence rate of Insomnia was 15.2%. Altitude of residence and knee pain was significantly correlated with insomnia severity. It was also supported by the study conducted in Bangaluru where the older people had severe insomnia. Prevalence of Insomnia was 13.04% and there was no significant association with selected baseline variables

<td>129</td>
<td>71.3</td>
<td>52</td>
<td>28.7</td>
<td></td>
</tr>
</tbody>
</table>
The data presented in the table 3 shows that majority of elderly that is 75.1% were keeping their bedroom clam before going to bed, 71.3% of them kept their bedroom dark, 71.3% of elderly neatly arranged their bedroom before going to bed, 70.7% of elderly had avoided the consumption of coffee or alcohol 4-6 hours before bedtime, 66.9% of elderly are getting up from bed at same time every day, 61.9% of them avoiding day time sleep, 59.7% of elderly are using bed only for sleep. 48.6% of them avoided eating full stomach, 38.7% of elderly are following regular bed time, 35.4% of elderly are getting exposed to sunlight and 35.4% of them are relaxing by listening to music.

A cross sectional survey conducted among 70 elderly in a community area of NewDelhi revealed that increase in the level of stress was associated with poor sleep quality10

The results are contradictory to the study conducted by Bani, Hosanpur among 100 elderly in Iran where 70% of them woke up frequently at night, 5% got exposed to sunlight, 41% used the bed only for sleep, 37% kept bedroom dark, and 5% used to drink milk with honey11.

Conclusion

Insomnia was common among elderly residing at old age homes. Elderly should have the knowledge, ability to recognize the symptoms of insomnia, factors contributing to it and proper practice of sleep hygiene activities.

Conflict of Interest: Neither this manuscript nor one with substantially similar content under my/our authorship has been published or is being considered for publication elsewhere. Also we declare that there is no conflict of interest among the contributors

Source of Funding: We have not received any financial support or sponsorship

Ethical Clearance: The administrative permission was obtained from the Dean, Manipal College of Nursing Manipal. Permission was also obtained from the administrators of various old age homes in Udupi and Dakshina Kannada district to conduct the study. Ethical clearance was obtained from Institutional Ethics committee of Kasturba Medical College, Manipal and informed consent was obtained from the participants

ABSTRACT

Objective: To determine maternal risk factors and demographic profile of neonates presenting with persistent pulmonary hypertension in a tertiary care hospital, Odisha

Method: It was a hospital based study, conducted from June 2015 to December 2017 in Kalinga Institute of medical colleges and hospitals, Bhubaneswar, Odisha. All babies with gestational age > 34 weeks having respiratory distress and profound hypoxia were included in the study after confirmation of PPHN by Echocardiography.

Results: In our study population majority babies with PPHN were male (73%) and 90% babies were delivered by LSCS. Late preterm babies constituted 21% of total PPHN cases. Hyaline membrane disease (30%) and meconium aspiration syndrome (26%) were leading cause of PPHN in neonates.

Conclusion: PPHN is a serious and often fatal condition, associated with a high mortality (29%). Late preterm neonates constituted 21% of total population and 90% of PPHN neonates were born by LSCS. Hyaline membrane disease is the leading cause of PPHN suggesting a change in the demographic profile.

Keywords: Persistent pulmonary hypertension, meconium aspiration syndrome, hyaline membrane disease

Introduction

Neonatal respiratory failure affects 2% of all live births and is responsible for more than one third of all neonatal deaths. Persistent pulmonary hypertension (PPHN) of newborn is frequent complication of respiratory disease in neonates and is characterised by marked pulmonary hypertension resulting from elevated pulmonary vascular resistance (PVR) and altered pulmonary vasoreactivity, leading to right to left extrapulmonary shunting of blood across foramen ovale and ductus arteriosus, if it is patent. Incidence is 1 in 500 – 1500 live birth and mortality rate ranges from 4 -33%.

The pulmonary circulation in foetus is characterised by high vascular resistance and low blood flow, but after delivery of the baby lower vascular resistance is necessary for pulmonary gas exchange. In the normal transition at birth from foetal to neonatal circulation, pulmonary vascular resistance falls due to 8 -10 fold increase in pulmonary blood flow and the right to left shunting that occurs in the foetus through ductus arteriosus and foramen ovale, ceases after after birth. Several stimuli, including drainage and absorption of foetal lung liquid, rhythmic distension of the lung, increased PO2 and altered production of several vasoactive agents, including nitric oxide (NO), are known to contribute pulmonary vasodilatation at birth. The increase in NO production accounts for nearly 50% of the abrupt fall in pulmonary vascular resistance at birth in foetal lambs. NO mediates vasodilatation by stimulating soluble guanylate cyclase- induced cyclic guanosine monophosphate (cGMP) production.
is down regulated by phosphodiasterase 5 activity which is abundantly expressed in lung tissue during foetal life.7

PPHN is a clinical syndrome that is clinically associated with diverse neonatal cardiopulmonary diseases like birth asphyxia, sepsis, meconium aspiration syndrome, hyaline membrane disease or it can be idiopathic or primary.8 PPHN demographic profile can be broadly classified into three groups based on pathophysiology9 i.e.

Abnormally constricted pulmonary vasculature caused by parenchymal diseases:
- Meconium aspiration syndrome
- Respiratory distress syndrome
- Pneumonia

Hypoplastic pulmonary vasculature:
- Congenital diaphragmatic hernia
- Lung hypoplasia

Normal parenchyma with remodelled pulmonary vasculature:
- Idiopathic PPHN
- Congenital heart diseases
- Hypoxic ischaemic encephalopathy
- Others

A lot of studies were done all over the world about management and outcome of neonates with PPHN, but few studies were available in India regarding the demographic profile and risk factors of babies developing PPHN. Management and outcome of babies presenting with PPHN depends primarily on demographic profile. Hence we conducted the study “To determine maternal risk factors and demographic profile of neonates presenting with persistent pulmonary hypertension in a tertiary care hospital”

**Study Population:** All inborn and outborn neonates with gestational age more than 34 weeks admitted in NICU having respiratory distress and profound hypoxia were included in the study after confirmation of PPHN by echocardiography. PPHN was confirmed when a neonate with a echocardiographically confirmed structurally normal heart had:
- Severe hypoxemia, usually a PaO2 37.5 -45 mm Hg in an Fio2 of 1.0 and IPPV if necessary
- Evidence of right to left or bidirectional hemodynamic shunting at ductus arteriosus (Usually a Pao2 in postductal blood 7.5 – 15 mm of Hg lower than simultaneous preductal Pao2) or at patent foramen ovale
- Tricuspid regurgitation jet pressure of > 40 mm of Hg

**Exclusive Criteria:** Neonates with structural congenital heart disease and multiple congenital anomalies were excluded from the study.

**Sample Size:** Considering PPHN mortality (p) 31% in previous study by Roofthooft et al (9) and allowable error in p 10%, the calculated sample size was 890. Considering allowable error in p 50%, the calculated sample size was 35.

The sample size was calculated as per formula= \(4pq/L^2\)

\[ p = \text{positive character, } q=1-p, L= \text{allowable error in } p \]

Considering our study was an exploratory study, we had prospectively recruited the cases during the study period. In our study sample size was 84.

**Results**

There were sixty three male babies (73%) and twenty one female babies (27%) in this study and male: female ratio is 3:1. In our study eighteen neonates were preterm, sixty four babies were term and two babies were post term. Out of eighty four babies, sixty four neonates had birth weight more than 2.5 kg, sixteen babies had birth weight between 1.5-2.5 kg and only two neonates had birth weight less than 1.5 kg. Mean birth weight was 2.71 kg. Vaginal delivery occurred in eight (10%) cases and caesarean section in seventy six (90%) cases. Of the neonates enrolled in the study, 12% were in born and

**Method**

This was a prospective observational study conducted between June 2015 to December 2017 in Kalinga Institute of medical colleges and hospitals, Bhubaneswar, Odisha. There were total 1854 cases admitted into the NICU. Eighty four cases were diagnosed to have PPHN and were enrolled in the study. About 4.5% of babies admitted in the neonatal intensive care unit(NICU) were diagnosed as PPHN.
88% were out born. Out of eighty four babies, forty five (57%) babies were admitted within first 24 hours of life and total eighty (95%) babies were admitted within first 72 hours of life. Most of the babies developed respiratory distress immediately after birth. Being a tertiary referral centre, majority of admission were referral cases.

**Maternal risk Factors:** Eight babies (10%) had maternal history of premature rupture of membrane, two neonates had maternal pyrexia and meconium stained amniotic fluid in 26 (30%) cases. Maternal PIH was associated in eight babies. Meconium stained liquor was the commonest risk factor.

### Table 1: Comparison between preterm and term Neonates:

<table>
<thead>
<tr>
<th></th>

<td>7</td>
<td>23</td>
<td>0.78</td>
</tr>
<tr>
<td>No. Mortality</td>
<td>4</td>
<td>7</td>
<td>0.28</td>
</tr>
</tbody>
</table>

We found HMD was the most common cause of PPHN in preterm babies (p = 0.0002) and MAS was more common among term babies (p=0.032). Surfactant was significantly more used in preterm PPHN (P=0.0025), explained by more prevalence of HMD (P=0.0002). There was no significant difference in incidence of moderate-severe disease, requirement of HFOV, mortality among preterm and term babies.

The primary respiratory diagnoses were based on chest x ray. There were 22 (26%) cases of meconium aspiration syndrome, 25 (30%) cases of hyaline membrane disease (HMD), 8 (9%) cases of idiopathic pulmonary hypertension, 9 (11%) cases of pneumonia, 14 (17%) cases of congenital diaphragmatic hernia (CDH) and 6 (7%) cases of pulmonary hypoplasia included in our study as shown in figure-1. Hyaline membrane disease (HMD) and meconium aspiration syndrome were the most common causes of PPHN in neonates.

**Case distribution, based on severity of disease:** Oxygen Index(OI) was used to know the disease trends, severity, timing of initiation of NO. In our study population 30 neonates (35%) had severe disease (OI>25), 17 neonates (21%) had moderate disease (OI=15-25), and 37 neonates (44%) had mild disease (OI<15).

### Table 2: Distribution of severe PPHN(OI >25) in different etiology

<table>
<thead>
<tr>
<th></th>
<th>Number of Severe PPHN</th>
<th>Total Cases</th>
</tr>
</thead>
<tbody>
<tr>
<td>HMD</td>

<td>8</td>
</tr>
<tr>
<td>Hypoplasia</td>
<td>4</td>
<td>6</td>
</tr>
<tr>
<td>Pneumonia</td>
<td>2</td>
<td>9</td>
</tr>
</tbody>
</table>

The table-2 showed number of cases of severe PPHN (with OI>25) among different groups. In our study population among primary PPHN, only one neonate belonged to severe disease. About 57% cases (n=8) of CDH had severe disease. Distribution of cases, based on severity would affect the ultimate outcome of the baby.

**Discussion**

In this prospective observational study, we investigated the aetiology of PPHN in a large cohort of ventilated infants, in a level three neonatal intensive care unit. In our study 76(90%) neonates were delivered by LSCS and 8 (10%) neonates were delivered by NVD. Liston et al¹⁰ showed neonatal outcomes following caesarean delivery had two- to threefold increase in risk of neonatal respiratory conditions (p = 0.01). In a study by Elliot et al¹¹, the incidence of PPHN among elective LSCS was 0.39% and it was five times more compared to vaginal delivery. In a study by Hernandez et al¹² the risk for PPHN was seven times higher after caesarean section deliveries than after vaginal deliveries.

In our study, eight babies (10%) had maternal history of PPROM, two neonates had maternal pyrexia, which are known risk factors of early onset sepsis leading to lung parenchyma lesions. However Hernandez et al did not find increased incidence of PPHN in the presence of maternal fever, urinary, vaginal and respiratory infections, or use of antibiotics late in pregnancy.

In our study population, 30% cases had HMD and 26% had MAS. In Stack et al15 study, 43% of study group had RDS as the cause of respiratory failure in both near term and term neonates. In both Walsh Sukys et al5 and INONS study, meconium aspiration syndrome was the leading cause of severe respiratory failure and not respiratory distress syndrome, in both term and near-term neonates. The primary respiratory diagnosis in Walsh Sukys et al study was meconium aspiration syndrome (41%), idiopathic pulmonary hypertension (17%), pneumonia (14%), respiratory distress syndrome (13%), pneumonia (14%), CDH (10%), and pulmonary hypoplasia (4%). In INONS study MAS(42%) was the most common underlying diagnosis of PPHN, followed by primary PPHN(27%) and other diagnoses included RDS(17%), pneumonia or sepsis, pulmonary vasoconstriction from asphyxia, and pulmonary hypoplasia secondary to congenital diaphragmatic hernia (CDH) or oligohydramnios requiring NO.

The incidence of lung diseases associated with PPHN has changed over the last decade. The overall incidence of MAS has declined, coinciding with a decrease in the number of post term pregnancies worldwide. In contrast, RDS in preterm neonates, delivered by elective or indicated caesarean section at 34 to 37 weeks of gestation has become a more frequent cause of PPHN. In our study 21% neonates were preterm and needed surfactant as part of management of PPHN (P=0.0025), explained by higher prevalence of HMD (P=0.0002). These recent trends reflect the changing demographics of neonates who have PPHN, with important implications for their management and long-term outcome.

In our study, out of 84 cases, 14 (16%) neonates had diaphragmatic hernia. The high incidence of CDH is probably because of our NICU is the tertiary level three unit with a perinatal centre with a lot of intrauterine referrals. Daskhinamurti et al16 classified the pathophysiological mechanisms, of PPHN under three groups i.e. maladaptation, maldevelopment and underdevelopment.

**Conclusion**

- PPHN is a serious and often fatal condition, associated with a high mortality (29%).
- Late preterm neonates constituted 21% of total population in contrast to similar studies.
- Ninety percentage of PPHN neonates were born by LSCS, suggesting caesarean delivery may be associated with increased respiratory distress syndrome and PPHN.
- Hyaline membrane Disease was the leading cause of PPHN suggesting a change in the demographic profile.

**Conflict of Interest:** The authors declare that there is no conflict of interests regarding the publication of this paper.

**Source of Funding:** None

**Ethical Clearance:** Since it is a prospective observational study of babies admitted in NICU without any interventional work and without any disclosure of patient’s identity, thus having no ethical issues; ethical clearance was not considered.

Awareness of Cancer and its Symptoms among the Rural Population

Kalyan Ram S¹, Muthulakshmi Muthiah²
¹M.B.B.S, Final Year; ²Assistant Professor, Department of Community Medicine, Saveetha Medical College, Thandalam, Chennai

ABSTRACT

Background: Awareness and perception of cancer and its symptoms are low in rural population.

Objectives: To assess the level of awareness among rural people regarding cancer symptoms, the various treatment modalities available as well as preventive measures. To assess the difference in awareness levels with respect to sociodemographic variables.

Materials and Methodology: A community based cross sectional study was conducted from January 2018-October 2018 with the help of a self designed questionnaire. The subjects were chosen by non probability sampling technique. The sample size was 204. Collected data was entered into a spreadsheet and analysed with the help of Chi-Square test.

Results: Among the male population 65.26% and among females 69.72% had adequate knowledge about cancer. 80.46% of adequate knowledge was seen below 30 years and 58.12% was seen among 30 and above age group people. Among those who were educated above high school level, 79.87% had adequate knowledge about cancer and those who were educated below high school level, 34.55% had adequate knowledge about cancer. 68.62% of Hindus had adequate knowledge and 56.25% of non-Hindus had adequate knowledge about cancer.

Conclusion: The awareness was considered to be inadequate. Various health programmes and rural campaigns are to be undertaken to improve the knowledge about cancer.

Keywords: Neoplasm, cancer, India, rural, risk factor, awareness, knowledge, treatment, prevention, prognosis, warning signs.

Introduction

Non-communicable diseases are a group that are non-infectious and usually include cancers and lifestyle diseases such as diabetes, hypertension, obesity[1]. Mortality due to non-communicable diseases increase from 57% in 1990 to 65% in 2010. Cardio-vascular diseases account for the major fraction of these deaths followed closely by cancer.

Cancer is a blanket term covering a wide range of diseases that are characterized by excessive proliferation of the cells much higher than the normal limits[2]. These cells invade adjacent areas of the body and spread via lymphatics or blood vessels to distant places in the body. This is called metastasis. Cancer is a prime cause of mortality in almost all countries of the world[3]. Over the past years, the incidence of cancer has increased and scientists have predicted the incidence to rise further to approximately 26M new cases and 17M deaths by 2030[4]. Most deaths due to cancer are attributed to lack of awareness of early cancer symptoms which leads to delay in diagnosis, ultimately leading to poor prognosis[5].

According to the WHO, the main risk factors of cancers are age, alcohol, tobacco, smoking, obesity, radiation[6].

Not all cancers are malignant or dangerous. Some benign tumors do exist such as lipoma. Such tumors are limited only to a single site, do not invade the bloodstream and they do not metastasize. These are generally very harmless tumors and do not cause much symptoms or agony to the patient. These tumors have an excellent prognosis even when detected later.

The characteristic symptoms of cancer are persistent coarseness, nagging cough, increase in wart or mole, unexplained loss of weight or appetite, spontaneous bleeding from any site, excessive bleeding during menstrual periods and increase in size of swellings.

The global cancer burden is estimated to 18.1M cases and 9.6M deaths in 2018\(^7\). 1 in 5 men and 1 in 6 women develop cancer during their lifetime, and 1 in 8 men and 1 in 11 women die from the disease. The five year prevalence of cancer is estimated to be 43.8M.

In India the prevalence of cancer is calculated to be 2.25M and the deaths due to cancer in India amounts to 7,84,821. In men, most-common cancers are of the oral cavity, lung, stomach and colorectal carcinoma. In women the most common cancers are breast, cervix, stomach and oral cancer\(^8\) The incidence of cancer is rising steeply due to deterioration of lifestyle habits.

And Objectives of the Research Project

The aim of the study is to identify the level of awareness of cancer symptoms and knowledge about the diagnostic methods of cancer. The study also aims to establish the relation between socio-demographic variables such as age, religion, etc. and the level of awareness.

Methodology and Research Design

It is a community based, cross-sectional study conducted in the rural area of Thirumazhisai district, located near Chennai, Tamil Nadu, over a period of 6 months. Adults above the age of 18 were included in this study. Population below 18 years of age and those who did not wish to give informed consent were not included in the study.

Tool: The data was collected in the form of a validated self-structured questionnaire after referring to various literature pertaining to the symptoms, investigations and treatment modalities related to cancer. Questions were designed to determine the knowledge about the common cancers in their region, risk factors, signs and symptoms, treatment modalities, prognosis and source of information.

Sample Size: For calculating the sample size, the formula \(Z_{\alpha/2} \sqrt{P(1-P)}/l^2\) was used. From the research article the prevalence of knowledge was found to be 15% and substituting this value in the formula we arrived at a sample size of 204.

Procedure: Approval was obtained from the ethics committee regarding the study. The data was collected from the general population above 18 years through personal interview method. Out the total 27 questions, 16 were selected for evaluation. Each question was given a score of one and the total knowledge score was calculated based on the answers given by the participants willing to take part in the study. Participants having more than 50% of total score were classified as having adequate knowledge and the rest as having inadequate knowledge. Then chi square and odd’s ratio was done to find out the association between demographic factors and knowledge levels prevalent in the community.

Informed consent was obtained before data collection.

Sampling Technique: Non probability sampling method.

Statistical Analysis: All data will be analyzed using Statistical Package for the Social Sciences (SPSS), version 22. Descriptive statistics were calculated based on frequency and proportions. Analytical statistics was performed employing the Chi square test was used to find statistical significance. \(p<0.05\) was considered to be statistical significance\(^9\).

Notes:

* - p- value < 0.05 is statistically significant at 95% Confidence Intervals.

Out of the 204 study participants, males were 46.57% and females were 53.43%. 42.56% were below 30 years and 57.35% were above 30. Among this study population 73.04% were educated above high school and 26.96% were educated below high school level. Among the participants 96.12% were Hindus and 7.84% were non-Hindus.

Among the male population 65.26% and among females 69.72% had adequate knowledge about cancer. 80.46% of adequate knowledge was seen below 30 years and 58.12% was seen among 30 and above age group people. Among those who were educated above high school level, 79.87% had adequate knowledge about cancer and those who were educated below high school level, 34.55% had adequate knowledge about cancer. 68.62% of Hindus had adequate knowledge and 56.25% of non-Hindus had adequate knowledge about cancer.

After the analysis, we arrive at the findings, that there is no significant difference in knowledge levels between males and females and between Hindus and non-Hindus. There is a significant difference in knowledge levels between the two different age groups and between the education status.

### Discussion

In the study undertaken it was found that all of the participants(204) who consented to take part in the study, had a general awareness of the prevalence of cancer. A majority of the population(66.12%) understood it to be a dreadful fatal disease where there is uncontrolled, rapid proliferation of cells. They also had adequate knowledge about the general symptoms and risk factors associated with malignancy.

Almost all the participants(89.7%) concurred that smoking is a major risk factor for development of cancer. And among them, a good number (59%) were able to correlate smoking as a leading cause of lung cancer. Similarly majority of the study population (57.35%) were well informed that drinking any form of alcohol contributed to cancer pathogenesis, although they were unable to link it to a specific type of cancer. Surprisingly, a huge section of the respondents (67.65%) agreed that chewing of paan and betelnut significantly contributes as a trigger and accelerated the progression of cancer.

About one-third of the participants were aware of the not so commonly talked about risk-factors such as occupation(30.88), radiation(35.78%) and dietary(30.39%) relation to cancer etiology. Those who were aware, had little knowledge that diet also plays a significant role in the onset and development of the disease. However they could not pin point to any specific kind of diet which are suspected as a leading factor for cancer. Comparing this to a study conducted by Sarang Pedgaonkar et.al[10], which employed 525 individuals as the study subjects, it was found that majority(44.77%)
of subjects identified cancer as a dangerous, incurable disease with a very high mortality rate. Almost all (85.7%) of the people identified tobacco and smoking as the main risk factor followed by alcohol (73.7%). A low fraction of the subjects (17.22%) identified old age also as a risk factor. In another study conducted in the rural population of Wardha district by Rufina Binoy et al., it was found that people rightly identified smoking as a leading factor for lung cancer (23.46%) and oral cancer (22.44%). Very low (10.20%) associated smoking with cervical cancer.

Sparing a miniscule part of the population (0.49%), everyone possessed adequate knowledge about the warning signs of cancer. They believed that the most common warning sign is bleeding from any orifice of the body, seconded by presence of lumps or swellings that are visible externally. Knowledge about other warning signs such as change in bowel or bladder habits or persistent change in voice or hoarseness was present to a lesser degree. In a study conducted by Sarang Pedgaonkar et al., 109 (20.8%) thought that weight loss was the initial symptom, while 153 (29.1%) thought that a swelling in the axilla or groin was the initial symptom. On the contrary, 272 (51.8%) did not know the symptoms of cancer.

More than half of the study population (56.86%) believes that cancer prognosis improves greatly if detected early and are well informed of the various investigations for diagnosis. 40.2% believe that cancer is curable. There is an increasing trend in the positive outlook towards cancer patients. They are no longer cast out of their families as enough light has been thrown on the fact that cancer is a non-infectious disease and not transmitted form person to person.

In this study it was found out that the sources of information varied widely. A majority of the study participants (47.55%) cited friends and family as their source, while only few participants (7.35%) cited doctors as their source of information. Other sources of information were Television (23.53%), internet (2.45%) and Newspaper and Magazines (19.12%). Comparing to the study conducted by Sarang Pedgaonkar et al., the most common source of information of cancer was neighbours (34.45%) followed by media (24.79%) and friends (24.58%). Only 7.14% of the study population heard information directly from the doctors. The percentage of population who had never heard about cancer was only 9.33%. Also comparing to another study by Yogesh S. Kumar, 154 (84.6%) had an awareness of cancer and most of them (85.1%) could name a few cancers. The main source of information was friends and relatives (46.10%) followed by media (32.47%) and physicians (21.43%).

The study population was fully aware of the various options of treatment such as chemotherapy and radiation and only 2.45% were under the impression that cancer is not treatable. They were also aware of surgery as a treatment option. In a study conducted by Rai et al. in a hospital in Varanasi, among cancer patients 63.3% of patients with breast cancer and 41.1% of the patients with cervical cancer considered cancer as curable.

In a study conducted by Yogesh S. Kumar, many participants perceived cancer as curable (66.23%) and preventable (54.84%). The most important preventive method was found to be early diagnosis (59.3%). Only 35.06% had heard about cancer screening.

In a study conducted by Vidhubala among the urban population of Chennai, it was concluded that a majority of the respondents (83.5%) were aware that cancer is not contagious. And 79.5% concurred that it can be cured.

In the present study, age group less than 30 were found to have more awareness regarding cancer compared to age group > 30 years. This may be due to higher strive for education among the younger age group. Hence cancer awareness activities and initiatives should focus more on the older age group. This would narrow down the knowledge gap.

Nowadays, cancer is no longer believed to be a terminal disease and the general attitude of the public towards cancer management has vastly improved. This can be attributed to the sea of information present in the internet and digital media. In the city due to the technological boom and increase in the quality of life among all sections of the general population, there is unrestricted access to this goldmine of knowledge. Even lower sections of the population are able to afford internet services. There has also been zealous initiatives by the government for rural development and this has paved the way for provision of electricity and increased connectivity to the rural areas. This has slowly enabled the rural folks to gather knowledge from TV shows. Much emphasis has been placed on ‘Education for all’, especially for the girl population which is slowly starting to be followed in the villages. This has tremendously
increased the awareness among people. Doctors have greatly reduced the burden related to the misconceptions of cancer by providing scientifically backed-up facts and figures to disprove the countless myths and falsities portrayed by the general uninformed public.

**Conclusion**

This data may be considered as a preliminary step to assess the magnitude of awareness regarding cancer—its treatment and symptoms among the general population. This could be used to set a precedent for future cancer awareness campaigns. The differences in knowledge levels among the different sociodemographic variables would help in identifying target groups. This would increase the efficiency of the programme and would bridge the gap in knowledge. Curriculum based approach right from schools and colleges would help in increasing the awareness among the youth.

Prevalence and Antibiotic Resistance Profile of Coagulase Negative Staphylococci Causing True Bacteraemia in a Tertiary Care Hospital

Nipa Singh1, Srotaswini Hota2, Subhra snigdha Panda1, Dipti Pattnaik3, Ashok Praharaj3, Jagadananda Jena4

1Assistant Professor, 26th Semester MBBS Student, 3Professor, 4Professor and HOD, Kalinga Institute of Medical Sciences, Bhubaneswar

ABSTRACT

Background: As Coagulase negative Staphylococci (CoNS) are frequent contaminants of blood cultures, it is necessary to determine if CoNS in blood culture is due to clinically significant infection.

Aims: This study aims to determine the prevalence of true bacteraemia due to CoNS in our institution as well as the antibiotic resistance profile of these CoNS isolates.

Material and Method: A prospective study was done for a period of 7 months. True or significant CoNS bacteraemia was determined by a modified clinical and microbiological criteria.

Results: CoNS were isolated from 144 (16.6%) of the total 866 blood cultures. CoNS species were considered true pathogens in 38 (26.4%) cases. The most common species isolated was Staphylococcus haemolyticus, 15 (39.5%) followed by Staphylococcus epidermidis, 7 (18.4%). Highest sensitivity was to Vancomycin (100%) followed by Tigecycline (94.7%). Methicillin resistant CoNS (MR CoNS) was seen in 24 (65%) among the 38 CoNS isolates causing true bacteraemia. There is an overall high prevalence of resistance to non beta lactam antibiotics among MR CoNS as compared to MS CoNS with the difference being statistically significant for ciprofloxacin (64.1% vs 18.1%, P < 0.001), erythromycin (76.4% vs 45.4%, P= 0.034) and rifampicin (48.7% vs 13.6%, P=0.039).

Conclusion: It is necessary to determine if CoNS bacteraemia is to be treated to prevent unnecessary expenditure and increasing antimicrobial resistance.

Keywords: Coagulase negative staphylococci, bacteraemia, contaminants, antimicrobial resistance.

Introduction

Blood cultures are the one of the most important tests aiding in the diagnosis of serious infections. However, false positivity is a limitation which arises when contamination of blood cultures occur.[1,2]

Coagulase Negative Staphylococci (CoNS) are one among a group of organisms which can act both as a pathogen and a contaminant. The emergence of CoNS as a cause of bacteraemia may be attributed to increase in use of prosthetic devices and central venous catheters in hospitalized patients and increase in the number of immunocompromised patients.[3]

Coagulase Negative Staphylococci are the third most common cause of blood stream infection and are the most frequent cause of nosocomial blood stream infection.[4,5,6] Staphylococcus epidermidis is the most common among the CoNS species to be isolated from bacteraemia cases. Other species isolated are S. haemolyticus, S. lugdunensis, S. schleiferi, S. warneri, S. hominis, S. simulans and S. saccharolyticus.[7]

Treating contaminants as true bacteraemia results in additional laboratory tests, longer hospitalization and unnecessary antibiotic use (particularly of
vancomycin). Similarly, failure to recognize and treat true bacteraemia can lead to increased morbidity and mortality. Various studies have estimated the rate of true bacteraemia due to CoNS to range from 10 to 30% of the total CoNS isolated from blood culture samples.[8]

This study aims to estimate the prevalence and antibiotic resistance profile of CoNS isolates which cause true bacteraemia in our institution using an algorithm which combines both clinical and laboratory parameters.

**Material and Method**

This is a hospital based prospective study, conducted in a 1750 bedded tertiary care hospital for a period of seven months, i.e 1st July 2018 to 31st January 2019.

The study was carried out on Coagulase Negative Staphylococci (CoNS) isolates from blood cultures of patients who were admitted to our hospital during the period of study. CoNS isolates from the same patient were considered as a separate episode if CoNS was detected more than 8 days after the initial episode. CoNS isolates from outdoor patients were excluded. (The study was approved by the Institutional Ethics Committee prior to starting the study).

A total of 866 out of 6102 blood cultures were found to be positive. CoNS was isolated from 144 blood cultures.

Blood cultures received from indoor patients were incubated in an automated blood culture system (BacT/Alert 3D, Biomerieux) for a maximum of 5 days or earlier if the system indicated that the culture was positive. The positive blood culture samples were inoculated onto blood agar and Mac Conkey agar. The culture plates were incubated overnight at 37°C. After presumptive identification of CoNS by routine bacteriological methods, the identification and antibiotic susceptibility profile of the isolate was confirmed by VITEK 2 compact System (Biomerieux) by using identification card and antibiotic susceptibility cards by VITEK 2 technology (GP 21342 card for identification and AST –P 628 for antibiotic susceptibility).[9] The antibiotic susceptibility of the isolate was tested against the antibiotics as per CLSI guidelines. Information regarding cefoxitin resistance was generated by the system along with the susceptibility to the antibiotics mentioned above.[10]

The isolates identified as Coagulase Negative Staphylococci(CoNS) were included in the study.

True or significant CoNS bacteraemia was determined by a modified clinical and microbiological criteria derived from that described by Beekmann et al and also used by Singh et al.[8,11]This criteria has been chosen as it exhibits a combined sensitivity of 62% and specificity of 91% for determining the clinical significance of CoNS bacteraemia.[12]

According to this criteria, CoNS was considered a significant cause of bacteraemia if

i. The same CoNS strain was isolated two or more times from another blood culture sample of the patient within 5 days OR

ii. At least two of the three clinical parameters was positive (In case only one blood culture sample yielded growth of CoNS)

- Body temperature ≥38°C or <36°C, TLC >12,000/µL or <2,000/µL plus ≥10% bands or systolic blood pressure <90 mm Hg.

The clinical findings were taken into consideration for the patient if only one blood culture bottle grew CoNS isolate.

Relevant demographic and clinical data of the patient was recorded.

**Statistics:** The statistical analysis was done using Stata 15.1, StataCorp, Texas, USA.

**Findings**

Blood culture positivity was seen in 866 (14.2%) out of 6102 blood cultures. Coagulase negative staphylococci (CoNS) were isolated from blood culture of 144 patients, comprising 16.6% of the total (866) blood culture isolates. CoNS species were considered to cause true bacteraemia in 38 (26.4%) out of the 144 cases of CoNS isolated from blood. Of the 38 isolates of CoNS causing true bacteraemia, 27 (71%) were isolated from two blood cultures within a span of 5 days, the rest 11 (29%) were isolated from one blood sample and were considered to be true pathogens on the basis of clinical criteria. The vast majority 106 (73.6%) were considered contaminants.

The highest number of CoNS isolates, 48 (33.3%) was isolated from 61-70 years age The number of CoNS isolates causing true bacteraemia was highest in the age group of 61-70 years. (Table 1) Out of the 38 patients with significant CoNS isolates, 25 (65.8%) were males and 18 (47.4%) were from intensive care units.

CoNS isolates causing significant bacteraemia were highly sensitive to Vancomycin (100%) followed by Tigecycline (95%). Resistance was highest in Penicillin (100%), followed by Erythromycin (71%).

Increased body temperature, time to positivity ≤ 48 hrs and duration of hospitalisation >48 hrs was associated with 85% of cases of CoNS causing significant bacteraemia.

Table 3: Risk factors among patients infected with CoNS causing true bacteraemia

Methicillin resistant CoNS (MR CoNS) was seen in 24(63%) out of the 38 CoNS isolates which are true pathogens. There was an overall high prevalence of
resistance to non beta lactam antibiotics among MR CoNS as compared to MS CoNS with the difference being statistically significant for ciprofloxacin (64.1% vs 18.1%, P < 0.001), erythromycin (76.4% vs 45.4%, P = 0.034) and rifampicin (48.7% vs 13.6%, P = 0.039).

Conclusion

To determine if CoNS isolated is of significance, the repeated isolation of CoNS from blood cultures and clinical parameters should be considered.

According to this study, the percentage of blood culture positivity is 14.2% as compared to 9.7% and 19.5% in various other studies.[13,14] In Indian studies, the rates of positivity varies from 31.2% to 16.7%.[15,16] CoNS constituted 16.6% of all the blood culture isolates as against the findings of other workers which estimates the rate to be 7.1% and 31%.[7,11] In our study, CoNS were considered true pathogens in 26.4% cases, comparable to the findings of other studies where the rates were 24.1%, 26.7% and 27% but in contrast to the findings of Souvenir et al where the rate was 10-12%.[17,18,19,20] CoNS were identified as contaminants in 73.6% cases compared to 76.74% in another study.[21]

The majority of CoNS in this study were isolated from patients in the 61-70 years age group in intensive care units (Table 1,2) whereas Sidhu et al isolated the same from 31-75 years age group and from intensive care units.[17]

*Staphylococcus haemolyticus* (47.4%) formed the majority among all the species of coagulase negative staphylococcus (causing true bacteraemia). This is in concordance with previous studies from India.[11,22] In our study, majority of *S. haemolyticus* and *S.epidermidis* were isolated from ICUs (44%) and medicine wards (42.8%) whereas in the study by Singh et al the majority of *S. haemolyticus* and *S.epidermidis* were isolated from medicine (80%) and paediatric wards (70%) respectively.[11]

Body temperature, time to positivity and duration of hospitalisation was associated with 85% of cases of significant CoNS correlating with the findings of Sidhu et al.[17]

In this study, maximum resistance was observed to Penicillin (100%), followed by Erythromycin (71%), Cotrimoxazole (63.2%) and Ciprofloxacin (57.9%). This can be compared with the findings of Chavan SP et al where the resistance to penicillin was 92.25% and to cotrimoxazole was 73%. Another study by Mohan et al illustrates resistance to Erythromycin to be 64.6% and 66.2% to ciprofloxacin.[24]

Highest sensitivity was to Vancomycin (100%) followed by Tigecycline (95%), Daptomycin (92.5%), Teicoplanin (87.5%) and Linezolid (85%) in our study, similar to other studies.[23,25]

Methicillin resistant CoNS (MRCoNS) was seen among 63% of significant CoNS isolates. In different studies the prevalence of MRCoNS is 87.5%, 68.6% and 67.5% and 35%.[25,26,27,28]

There is an overall high prevalence of resistance to non beta lactam antibiotics among MR CoNS as compared to MS CoNS with the difference being statistically significant for ciprofloxacin (64.1% vs 18.1%, P < 0.001), erythromycin (76.4% vs 45.4%, P = 0.034) and rifampicin (48.7% vs 13.6%, P = 0.039), similar to the findings of Singh et al.[11]

Administration of anti pyretics or steroids and vasopressors may have interfered with our observation of body temperature and blood pressure and led to under-reporting of CoNS bacteraemia which are the limitations of this study.

Although blood culture contamination cannot be totally eliminated, proper collection of blood by trained health care worker will go a long way in reducing the rate of blood culture contamination due to CoNS.[29]
Conflict of Interest: None

Availability of Manpower Facilities in the Health Sector of Assam

Raju Saikia
Research scholar, Department of Economics, Gauhati University

ABSTRACT

Role of Manpower is the important factor in the health care facilities. Human resources in the health sector is considered to be the heart of the health system. The availability of human resources positively affects the quality of public health services and has a direct impact on health outcomes. The paper is based on the secondary data were qualitative and descriptive method are used. The paper tries to examine the status of Manpower Facilities in Assam wherein 85.6% of people live in rural areas. It attempts to analyze the status of health workers in rural health care facilities after the implementation of NRHM in 2005.

Keywords: Manpower, Health, Assam

Introduction

The Human resources health define as the stock of all individuals engaged in the promotion, protection or improvement of Population Health” (WHO, 2000), are “the heart of the Health System” Looking on the health system of a country the Human resources play a pivotal role in delivering healthcare services: they determine “what services will be offered; when, where, and to what extent they will be utilized; and as a result, what impact the services will have on the health status of the people” 1, hence the efficient functioning of the health system depends on having the adequate human resources with appropriate skill mix and equitable distribution. It is well recognized that availability of human resources positively affects the quality and efficiency of public health services and has a direct and positive effect on health outcome 9.

The knowledge about lack of Manpower facilities was taken into consideration in 2004 by the Joint Learning Initiative (JLI)- a network of global health leaders. The JLI’s report on human resources for health highlights that India has about 11.3 health manpower facilities (Doctors, Nurses and Midwives) per 10,000 people in 1998, and was regarded as the low health manpower density countries. The world health Organization Report 2006 estimated that the health manpower in India has a critical shortage and placed India at 57 countries (ranked at 52). The India’s Health sector has also been suffered Misdistribution of the healthy workers. The health workers are unevenly distributed across the state. The Economically backward states, such as, Bihar, Chhattisgarh, Jharkhand, Madhya Pradesh, Rajasthan, Uttar Pradesh, and the Northeastern States have lower density and less educated Health workers 4. Having glimpse on the above context paper tries to examine the status of Manpower Facilities in Assam wherein 85.6% of people live in rural areas. It attempts to analyze the status of health workers in rural health care facilities after the implementation of NRHM in 2005.

Data Sources and Methodology: This paper is based on both qualitative and quantitative method were the data has been taken from secondary sources-

(a) Bulletin on Rural Health Statistics 2011,
(b) National Health Profile 2011 (both published by the Health and Family Welfare, Government of India),
(c) Population Census2011 published by Registrar General, Government of India, and
Human Resource System in Rural India: The rural health resource system is comparatively critical in the rural areas as the distribution of health Manpower is overwhelmingly skewed in favor of the urban areas. Only about 40.8% of all health workers are in the rural areas, where about 70% of the population resides. The percentage of health Manpower residing in the rural areas by cadres is: 39.6% for doctors, 43% for AYUSH doctors, 39.6% for Nurses and Midwives, 20.4% for dentists, and 45% for pharmacists. (Fan, 2016).

The health care infrastructure in rural areas has been developed as a three tier system and is based on the population norms. The Sub-Centre (SC) is the most peripheral and first contact point between the primary health care system and the community. Each Sub-Centre is required to be manned by at least one Auxiliary Nurse Midwife (ANM)/Female Health Worker and one Male Health Worker. Primary Health Centre (PHC) is the first contact point between village community and the Medical Officer. A PHC is to be manned by a Medical Officer supported by 14 paramedical and other staff. Under National Rural Health Mission (NRHM), there is a provision for two additional Staff Nurses at PHCs on contract basis. It acts as a referral unit for 6 Sub Centres and has 4 - 6 beds for patients. Community Health Centre (CHC) serves as a referral centre for 4 PHCs and also provides facilities for obstetric care and specialist consultations. A CHC is required to be manned by four Medical Specialists i.e. Surgeon, Physician, Gynecologist and Pediatrician supported by 21 paramedical and other staff. It has 30 in-door beds with one OT, X-ray, Labor Room and Laboratory facilities.

Rural Health Care system in Assam: Health is an important component for the economic development. Good health is prerequisite for the well being of the people as well as augments labour productivity and stimulates economic growth. The national commission on Macroeconomics and health opines argues that ‘health is a creator and prerequisite of development” (WHO, 2001). Assam is the state were 85.6 % of people live in the rural areas as compare to the urban counterparts. The health workers are the heart of the health systems. Their availability is an important factor for the efficient functioning of the health care system. It is evident from the table that less than two-thirds of the PHCs in India have been functioning with only one doctor.

Source: Bulletin on Rural Health Statistics in India, 2011

One of the major problems confronting the rural healthcare sector of the region is shortage of health workers. Table 3 reports that India suffers shortage of 64.75 percent male Health workers, 37.8 percent female health assistants, 63.95 percent specialist and 53.92 Radiographers. Assam has also suffered from the shortage from one or other form of health workers. The state has largely faced the lack of male health workers, the large shortfall in male health workers and health assistants is a serious concern, which may result in poor male participant in family welfare and other health programmes and overburdening of the female health workers/ANMs, which further results in underperformance of the health workers.

The another reason for the shortage of health workers, is that the health care system in India is overwhelmed by large scale absenteeism and low level of participation in providing health care services among the existing health workers, especially in the rural areas. The acute shortage of health workers and large scale absenteeism among the existing health workers results in underutilization or non-utilization of the available health care infrastructure and facilities and therefore, affects access to adequate health care services. Therefore, a prior focus should be given to ensure availability of health workers in different health centers.

Conclusion

We found that there has been significant improvement on the rural health care facilities in the region, especially in case of the health centers after the implementation of NRHM in 2005. looking on to the existing population coverage norms in one or the other types of health centers they are still lacking behind with the manpower facilities. More importantly the region suffers from shortage of well trained health workers; be it specialist, male health assistant or Nurses. Even though there are various sanctioned post for the health workers, many of them are lying vacant, resulting in underutilization of facilities available in the existing health centre. Given these bottlenecks it can be said that the health care services in the rural areas of the state is not of high quality a rigorous effort should be given to strengthen the rural healthcare facilities in the region besides, the available health centers should be adequately staffed with well trained health workers.

Screening Urinary Methylmalonic Acid by Thin Layer Chromatography in Children with Suspected Inborn Errors of Metabolism

Saritha Kamath U1, Nalini Bhaskaranand2, Anjali Rao3
1Associate Professor, Department of Medical Laboratory Technology, Manipal College of Health Professions, Manipal, 2Former Professor, Department of Paediatrics, 3Former Professor, Department of Biochemistry, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Karnataka, India

ABSTRACT

Introduction: Inborn errors of metabolism (IEM) are a group of disorders due to deficiency of the enzyme. The symptoms are due to the accumulation of toxic substances or deficiency of products. Organic aciduria is a group of IEM which is due to errors in the metabolism of branched chain amino acids and lysine. Studies showed that methylmalonic aciduria (MMA), glutaric aciduria, branched chain aminoacidurias are more common organicaciduria. Many methods are used for detection of methylmalonic acid some of them are not affordable by developing countries.

Objective: To study the role of thin layer chromatography in detection of methylmalonic aciduria in children with suspected inborn errors of metabolism.

Method: Untimed urine samples were collected from 385 children with clinically suspected inborn errors of metabolism and analyzed for MMA by colour reaction and thin layer chromatography (TLC). Bromocresol green and Ortho dianisidine were the dye used for spotting MMA on TLC.

Result: Among 385 children who presented with developmental delay, seizures, hypotonia were worked up for underlying inborn errors of metabolism. Of them 52 children showed positive result for MMA by thin layer chromatography.

Discussion: Significant number of children showed positive result for MMA by thin layer chromatography hence the method may be useful for screening methylmalonic aciduria. Further studies required to confirm the diagnosis.

Keywords: Methyl malonic aciduria, thin layer chromatography, organic aciduria.

Introduction

Organic aciduria or organic acidemia is a rare group of inborn errors of metabolism mainly involving metabolism of branched chain amino acids and lysine(1). Due to rapid methodological advances in the field of laboratory diagnosis many diagnostic tools were introduced. Methylmalonic aciduria is the common organicaciduria detected in most of the studies worldwide(2)-(7). Techniques used to detect organic aciduria include different types of chromatographic methods such as thin layer chromatography, high performance liquid chromatography, gas chromatography mass spectrometry, tandem mass spectrometry, enzyme assay, tissue culture and molecular diagnostics (1),(8)-(11). In developing
countries advanced methods are not affordable hence many instances simple urine metabolic screening tests and clinical symptoms are utilized for diagnosis. Urine metabolic screening tests which includes simple colour reactions and thin layer chromatography are useful and gives valuable information about organicaciduria such as maple syrup urine disorder, homocystinuria etc. We planned to study urinary MMA in children with clinical symptoms suggestive of inborn errors of metabolism. The diagnostic tests included for the present study was colour reaction and thin layer chromatography for detecting urinary MMA.

**Materials and Method**

A total of 385 children with clinical symptoms suggestive of IEM were worked up for urinary MMA by colour reaction and TLC. Out of this 11 cases showed positive for MMA by colour reaction and 52 showed positive screening results for methyl malonic aciduria by TLC. The age wise distribution of MMA positive cases both by colour reaction and TLC are as follow

<table>

<td>5</td>
<td>5</td>
<td>17</td>
<td>12</td>
<td>13</td>
<td>52/385 (13.5%)</td>
</tr>
</tbody>
</table>

**Discussion**

Many studies have found that organic aciduria is comparatively common among disorders of inherited metabolism and methyl malonic aciduria is the commonest organic aciduria. We utilized simple colour reactions and thin layer chromatography in our study with which we could detect MMA in 52 cases. This shows that simple cost effective thin layer chromatography may be useful to initiate therapy to the affected children. TLC can be done in the laboratories with very minimal facility hence can be used as a basic screening tests in the centers when no other methods are available. MMA occurs either due to the enzyme deficiency or vitamin deficiency. Vitamin B12 deficiency is common in developing countries and affects all age groups. Moderate deficiency of vitamin B12 in children may cause neurological problems. Methylmalonic acid is the early indicator of this deficiency. It can be treated and neurological damage may be prevented if detected early.

**Conclusion**

Our study showed that simple cost effective, noninvasive urinary screening test with organic acid thin layer chromatography (TLC) gives valuable information and may be used in basic screening panel. However this has to be compared with confirmatory tests such as GCMS or MSMS which requires funding.

Lifestyle Practices and Glycemic Control among Type 2 Diabetic Patients in North Kerala

N. V. Fatimathu Zuhara¹, A. Thahira Banu², Najma Chokli³
¹Assistant Professor, Department of Home Science, KAHM Unity Women’s College, Kerala, India; ²Assistant Professor, Department of Home Science, Gandhigram Rural Institute (Deemed to be University), Tamil Nadu, India; ³Assistant Professor, Department of Home Science, KAHM Unity Women’s College, Kerala, India

ABSTRACT

In India, high prevalence of diabetes was reported in Kerala. The present study was conducted in North Kerala to explore the glycemic status and lifestyle practices of the diabetic patients. Around 179 diabetics were randomly selected. Information about their personal profile, diet, activity and awareness on diabetes was collected using a pre tested interview schedule. Fasting and post prandial blood sugar values of all the patients and HbA1c level of randomly selected 49 patients were recorded. The collected data was statistically analyzed. The mean age of the diabetics was 54.81 ± 10.42 years. Around 98.9% of them were non vegetarians. The mean Food Consumption Score was 75.75 ± 15.3. 86 percent of the diabetics consumed white rice based diet and 34.6% practiced no lifestyle modification. More than half of the diabetics were not aware of diabetes and its management. Most of them were sedentary workers. There was significant association between gender and exercise (p<0.05). The mean value of HbA1c was 9.74 ± 1.8%. The blood sugar levels were positively correlated with FCS. Uncontrolled blood sugar and poor lifestyle practices along with inadequate knowledge on diabetes and its control was observed. Effective education on diabetes management is the hour of need for the diabetics.

Keywords: Diabetes, Lifestyle, Diet, exercise, glycemic control.

Introduction

Diabetes is a non communicable disease affecting both the quality and longevity of the life of people. The prevalence of diabetes in adults has increased to 8.5% in 2014. It is the seventh leading cause of death in 2016. The percentage of deaths due to high blood glucose levels is higher in low and middle income countries. [1] In India, 8.8% of people in the age of 20-79 years possess diabetes in which a great majority of them have poor control of the disease. [2] This in turn lead to heart diseases, stroke, vision impairment, kidney diseases and nerve damage. In order to achieve good glycemic control, lifelong management of diet and physical activity is to be maintained as the heart of treatment along with medication. [3] In Kerala, the Indian state with high prevalence of diabetes, only 40% of the diabetics had optimum glycemic control. [4] There were very less studies reported on the lifestyle management practices of type 2 diabetics in Kerala. Thus, a population based study was conducted to study the lifestyle practices and glycemic status of type 2 diabetics living in North Kerala.

Materials & Method

A cross sectional study was conducted in the two villages randomly selected from the Kondotty taluk located in the northern part of Kerala. One ward from each selected village was further chosen for the study. Type 2 diabetics in the age group of 25 to 75 years, residing in the selected wards for the last three consecutive months were randomly selected. Thus, 179 adults who were diagnosed as type 2 diabetics and willing to participate were included in the study. Fasting Blood Sugar (FBS) level ≥126mg/dl and/or on treatment for type 2 diabetes was the criteria for diagnosis. [5] Informed written consent was obtained from each participant. Pregnant women, severely ill and or bedridden patients were excluded.
Patient profile and lifestyle behaviours: An interview schedule was developed to obtain information on the socio economic characteristics, details of disease and treatment, food frequency, dietary modifications, physical activity, exercise and awareness on diabetes and its management. The data was collected from each participant through a house to house survey using the pre tested interview schedule. From the food frequency pattern, Food Consumption Score (FCS) was calculated using FAO-WFP guidelines. The content of macronutrients was calculated with the help of Dietcal software (Profound Tech solutions, New Delhi).

Blood tests for the determination of glycemic control: Blood sugar values such as Fasting Blood Sugar (FBS) and Post Prandial Blood Sugar (PPBS) levels of all the diabetics were recorded using a Glucometer (Simple – One touch) or from their current or previous month’s lab reports. Blood samples of the randomly selected 49 patients were analyzed for their HbA1C level. The blood sugar values of each patient was further grouped under the three categories of glycemic control based on ICMR guidelines.

Statistical Analysis: The data was analyzed in IBM SPSS 23.0 version. Descriptive analysis was done to find out the means and standard deviation. Chi Square test was carried out to find the association between gender and the variables studied. Pearson’s correlation of coefficient was calculated to determine variables correlated with blood sugar values. These tests were done at 95% confidence level and p<0.05 was considered as statistically significant.

Findings

Baseline Characteristics: Among the 179 diabetics, there were 83 males and 96 females. Their mean age was 54.81 ± 10.42 years. Around 82.7% were Muslims while the rest were Hindus. Majority of them (80.4%) had education below higher secondary level and 61.5% of them were unemployed. 68.7 percent and 30.2% of diabetics belonged to the middle class and upper lower class families respectively.

Profile and treatment of diabetics: Out of the 179 diabetics, the duration of diabetes in 103 patients was 4 years and above. Nearly one fifth of the diabetics had less than one-year duration of disease. Majority of the patients followed allopathy treatment. Few diabetics took no treatment including diet therapy (Table 1).

Diabetes management among diabetics: As a part of management of diabetes, 65.4% of the patients practiced lifestyle modifications. 63 percent of the diabetics reported as following dietary modifications and nearly 14% of them practiced exercise (Table 2). Nearly half of the diabetics practiced dietary modifications along with medicines. Around 6% of the diabetics revealed that sugarless tea was their only dietary change practiced.

The mean FCS of the diabetic population studied was 75.75 ± 15.3. Nearly 99% of the diabetics were non vegetarians. Most of them consumed three meals in a day. 86 percent of the diabetics had rice based diet in all the three meals in a day. 48 percent of the diabetics consumed reduced quantity of food during dinner. Only a few diabetics applied changes in food selection and cooking methods (Figure 1). Most of the diabetics consumed sweets without any restriction (Figure 2).
Daily consumption of white rice was reported by 83.2% of the diabetics. Fish intake was more than thrice a week in 88.9% of the diabetics. Also, at least once in a week, 77.7% of the diabetics consumed chicken, 61.4% had meat and 65.4% included egg in their diet. 71.5 percent of the diabetics consumed fried foods daily. Bakery foods were consumed daily and more than thrice a week by 30.7% and 22.9% of the diabetics respectively. Daily consumption of fruits was reported by 44.1% of the diabetics while 46% included leafy vegetables at least once in a week. 95.5% of the diabetics used coconut oil in their daily diet. The daily intake of energy, protein and total fat of the diabetics was higher than their daily requirement while the intake of fiber was lesser (Table 3).

</tbody>
</table>

More than 40% of the diabetics recorded poor satisfaction on their own dietary practices. 96.6 percent of the diabetics had never consulted a dietitian. 12.3 percent stated walking as their exercise while 1.7 percent reported practicing yoga. The duration of walking was around 10-15 minutes. Exercise was strongly associated with gender (p = 0.019) with higher percentage of males practicing exercise (Figure 3).

Figure 3: Activity pattern of diabetics

Glycemic control among diabetics: Only around half of the diabetics used to monitor blood sugar level regularly. Majority (80%) of the diabetics had poor control of blood sugar (Table 4). The mean values of FBS and PPBS of the diabetics were 155.245 ± 37.5mg/dl and 242.66 ± 53.5mg/dl respectively. The mean HbA1c values of 49 diabetics (22 males and 27 females) was 9.74 ± 1.8%. Even though poor control of FBS and PPBS was found higher among male diabetics, glycemic control was not significantly associated with gender (p>0.05).
There was positive correlation between FBS, PPBS, HbA1C and Food Consumption Score. FBS was also positively correlated with the frequency of intake of poultry, meat and milk products and negatively correlated with the age of patients and age of onset of diabetes.

*only for 49 diabetics

**Awareness among the diabetics:** More than half of the diabetics (55.8%) agreed that they had poor knowledge of diabetes. None of the diabetic was aware about the concept of glycemic index of foods. A great majority of the patients believed that unhealthy food habits lead to diabetes.

**Discussion**

In the present study, most of the diabetics were in the age group of 45 to 60 years as documented in earlier studies. Similar to the previous findings, majority of the patients had secondary school education. The duration of diabetes in more than one third of the patients was 10 years and above. As indicated in the earlier study, a great percentage of patients followed allopathy treatment. Few patients took no treatment at all.

High values of FCS among the diabetics indicated wide variety of foods in their diet. A vast majority of the patients were non vegetarians as documented in the previous studies in Kerala. More than one third of the patients practiced no dietary modification to manage diabetes. An earlier study reported that around 13.7% of the diabetics never followed a healthy diet in any day of the week.

Among those practicing dietary modifications, the dietary changes were poor and inconsistent. Poor dietary practices among diabetics was earlier reported by several other studies. Lesser intake of food during dinner was the major dietary modification done. Most of them consumed rice based diet as documented in the previous study. Changes in the selection and preparation of foods were also less. Larger portion size was observed among the patients which further increased the intake of macro nutrients beyond their requirements. Same findings were reported in the earlier studies. But, the percentage of energy from carbohydrate, protein and fat were within the normal range as prescribed by ICMR, 2018.

Most of the diabetics consumed fried foods daily. Higher intake of fat and fried foods by diabetics was documented in the previous studies. The quantity and frequency of fish and meat intake were found to be high. Also, frequent inclusion of coconut in their diet further enhanced the fat and calorie intake. High intake of fat and carbohydrate foods was reported among the diabetics in the previous studies conducted at various regions of Kerala. Although the frequency of fruits and vegetables intake was adequate, their quantity was less. Similarly, poor consumption of vegetables and fruits was stated in the previous studies. The major dietary modification observed among the diabetics was sugar restriction in tea. Despite their disease, most of them had poor restriction on sweets intake. High intake of salt and sugar and decrease in fruits and vegetables intake were reported in the earlier studies.

Majority of the diabetics were sedentary workers and the habit of doing exercise was also poor as reported in previous studies. Most of the patients studied had not consulted any dietitian and as stated in an earlier study, the only source of dietary guidance was their doctors. Majority of the patients had poor knowledge...
on diabetes and its management. Also, similar findings were reported in few other studies. [14,16]

Poor glycemic control was reported in majority of the patients with much higher values of HbA1c. A cross sectional study conducted in 12 countries in Asia reported that 55% of the diabetics had HbA1c values higher than 8%. [17] FBS was positively correlated with FCS, frequent consumption of poultry and meat products.

**Conclusion**

Poor dietary modifications, sedentary behaviour and less exercise habits were observed among the diabetics studied. Poor knowledge on the necessary dietary and activity changes to be brought in their life resulted in poor glycemic control increasing the risk for complications. Hence effective education about diabetes and its management is essential for the diabetics in the study area to gain control over the disease.

**Acknowledgement**

We express our gratitude to University Grants Commission for providing UGC- FDP Teacher fellowship to Mrs. N.V. Fatimathu Zuhara for the completion of study.

**Conflict of Interest:** None

**Source of Funding:** Availed UGC-FDP Teacher fellowship.

**Ethical Clearance:** The ethical clearance for the study was obtained from the Institutional Ethical Committee of Gandhigram Rural Institute (Deemed to be University), Tamil Nadu.

ABSTRACT

Medical Tourism is a relatively new concept that is emerging at a rapid pace. It has a potential to give huge economic benefits if tapped properly. India is ranked amongst one of the top destinations for medical tourism. This is because of availability of quality services at an affordable price. This paper aims at identifying the factors with underlying variables that are responsible for causing customer satisfaction in this industry. Tamil Nadu has been selected as the sampling area as it is one of the best destinations of India for medical tourism where the tourists often frequent. Reliability of the sample data and validity of the questionnaire were checked. A model on Medical-Tourists-Satisfaction has been developed by structural equation modelling (SEM) through SPSS and AMOS. The findings imply that Indian healthcare industry needs to emphasize more on the identified critical factors in this study and the government needs to intervene to fully tap the potential of this industry.

Keywords: Medical Tourism; Healthcare Industry; Quality Services; Customer Satisfaction; Structural Equation Modelling

Introduction

National Health is considered as one of the most important factors that puts a direct impact on the economic growth of the country (Jackson & Barber, 2014). It is seen that India has been stuck in the vicious cycle around the poor economy as well as deteriorating health conditions of people. Healthcare industry has paved its way in becoming one of the largest industries in India, both in terms of employment generation as well as income. This industry is growing magnificently at a rapid speed and it has been possible because of quality services associated with the products, wide coverage of the industry, increasing expenditure made by the public, etc. Now, medical tourism is a very popular term which is responsible for fetching huge revenues for the organisations. In simple terms, it can be defined as the movement of a particular patient who is travelling from one place to the other for the purpose of seeking a pre-planned healthcare service (Glinos, et al., 2010). Thus, the concept of medical tourism could be considered by the various organisations across the globe in order to generate revenues through the utilisation of an effective marketing strategy.

Present Scenario of Healthcare Industry in India:

India has been successful in becoming a strong medical tourism destination wherein consumers can avail high quality medical services at a relatively lower cost. However, it must be noted here that all the states and cities of India are not prominent in these services. Though there are quite a few places which are good at
delivering quality medical services but the places which need to be mentioned are Bangalore and Chennai which are located in the states of Karnataka and Tamil Nadu respectively. Some of the famous healthcare providers in Bangalore are Apollo, Fortis, Columbia Asia, Manipal hospitals, etc. who are successful in getting medical tourists from all over the world. Similarly, some of the major healthcare providers of Tamil Nadu are Billroth, Apollo, Global Health City, Frontier Lifeline, The Madras Medical Missions, etc. Apart from Karnataka and Tamil Nadu, Delhi and Mumbai also attract many medical tourists from across the globe. It has been seen that the well known hospitals have their franchise in all the major cities and states of India. This is done deliberately in order to make these places the hubs for the affordable delivery of the healthcare services.

**Literature Review**

Medical Tourism has managed to become extremely popular amongst the common masses due to various parameters. One of these parameters is the hospital infrastructure which is a very important factor for the determination of the quality of the healthcare services provided by a particular organisation. Precisely for this reason, the Indian hospitals are looking for imbibing the latest infrastructure in their system in order to increase the quality of their services being provided to the customers (Sharma, 2013). By referring to infrastructure, it does not mean that only the building infrastructure is taken for consideration but it also includes a wide range of tests and diagnosis facilities which are made available in the hospitals across India, thus, making it a favourable destination for medical tourism (Muthyam, 2017). Medical Tourism is creating certain hype in the market because good quality medical services are made available at fair prices without compromising on the services being rendered to the population (Hopkins, et al., 2010). Research findings suggest that the good quality of tests and treatments are essential to increase the perceived value of the patients pertaining to a service provider. This is significantly important to promote the health tourism of a particular country (Haque et al. 2018). The good performance of qualified and experienced doctors as well as their capability for quick diagnosis of the diseases helps in attracting the customers towards a particular destination for medical tourism from all around the world (Kian & Heng, 2015). Not only the doctors but the nurses and staff also form an integral part of the hospitals. They maintain the maximum contact with that of the patient and hence, they are responsible for forming a huge perception in the minds of the patients regarding the service provider. The good performance of the nurses or the staff helps in increasing the perceived value of the patients regarding the particular service provider. Medical tourism destinations must offer affordable and comfortable stays. The local areas should be safe and secure for the tourists to wander (Majeed, et al., 2018). After the treatment is completed, the post treatments follow-up is very important for any healthcare provider. Telemedicine facilities could also be focused by the respective hospitals as well as good facilities must be in place so that the doctors of the hospitals should be contacted by the patients at the time of their need (Cheng et al. 2003). The patients who receive quality treatment from the healthcare providers are more likely to revisit the hospital for any kind of future treatment. Thus, the relationship between the client and the service provider is sustained over a long period of time. According to a research, the perceived performance of the service providers by the patients is success moderators for building the patient satisfaction (Aljumah et al. 2017).

**Objectives of the Study**

- To explore the determinants which have a profound influence on customer satisfaction level of medical tourists with reference to healthcare industry in Tamil Nadu, India.
- To find out the degree of influence of the determinants on customer satisfaction level.

![Figure 1: Hypothesized Research Model](image-url)
Research Methodology

In this study, hypothesized research model (Figure 1) has been prepared and established with the help of both secondary and primary data. A structure questionnaire was constructed with related variables from literature review for survey purpose. To bring rigor in research, it is therefore, essential for the researcher to first establish an evidence of reliability and construct validity before testing the model. 5 point Likert scale is used for measuring the responses of customers related with Tamil Nadu Health Care Industry, India. We targeted the sample elements for our study from 10 hospitals in Tamil Nadu through convenience sampling technique. After that, 192 responses (Patients/Patient-Party) were finally collected through simple random sampling from targeted 10 hospitals for this study. The survey period was from 1st February, 2019 to 20th April, 2019.

Analysis and Results

Structure equation modeling has been used here for developing the model and establishing the hypothesis by the help of AMOS 20.0 software. Validity and model fitness have been judged through measurement and structural model. Exploratory Factor Analysis (EFA) by the help of SPSS-21 describes the questionnaire validation through data reduction method. In this study, KMO and Bartlett’s Test shows sampling adequacy value of 0.782 with significance level (<0.001) which proves the appropriateness of Exploratory Factor Analysis (EFA). Cronbach alpha for all items which is 0.812 shows the satisfactory range of reliability. Variables with factor loading of above 0.5 have created 8 different factors which are extracted from Rotated Component Matrix (Table 1).

Path Analysis for Hypotheses Testing and Research Findings

H₁: ‘Hospital Infrastructure related Issues’ positively influences the ‘Perceived Performance on Service Attributes’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. If good infrastructure is available like advanced machinery and equipment for operation or surgery, various types of advanced testing machinery, various sophisticated x-ray machine, etc. then the doctors will be able to render the best possible services to the patients.

H₂: ‘Treatment Facilities related Issues’ positively influences the ‘Perceived Performance on Service Attributes’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. If proper treatment facilities in terms of proper diagnosis and remedial measures are available at a cheaper cost then it will obviously enhance the perceived performance on service attributes.

H₃: ‘Hospital Staff/Nurse related Issues’ negatively influences the ‘Perceived Performance on Service Attributes’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. If the attitude of the hospital staff and nurses is not good then medical tourist will not be attracted. Overall satisfaction of the patients depends on the attitude and behavior of hospital staff and nurses.

H₄: ‘Post Treatment related Issues’ negatively influences the ‘Perceived Performance on Service Attributes’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. Post care treatment should be given utmost importance in order to retain the existing medical tourists as well as potential medical tourists in the health sector. If post care treatment is not being taken care of then it will lead to dissatisfaction in the minds of medical tourists.

H₅: ‘Doctor related Issues’ positively influences the ‘Perceived Performance on Service Attributes’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. Doctors are the pillars of success of health industry. If efficient doctors are available then medical tourists will positively come. The success and failure of any hospital depends on the efficient as well as effective doctors.

H₆: ‘Local Environment related Issues’ positively influences the ‘Perceived Performance on Service Attributes’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. Local environment mainly includes cheap and best transportation cost, good weather, political stability, good accommodation facility, availability of food, etc. If these are available then it will positively influence the ‘Perceived Performance on Service Attributes’.

H₇: ‘Perceived Performance on Service Attributes’ positively influences the ‘Overall Customer Satisfaction’ in Tamil Nadu Health Care Industry, India.

Structural model supports this hypothesis. Overall customer satisfaction depends on various factors of service attributes like hospital infrastructure, treatment facilities, hospital staff/nurse, post treatment related issues, doctor related issues, local environment related issues, etc. If all the service attributes are better than overall customer satisfaction will be achieved successfully.

Implications of the Study: From our empirical study, it is very clear that the healthcare industry must consider the above stated factors in order to draw the attention
of medical tourists. It will help the healthcare industry in designing their strategies in order to draw the attention of medical tourists. From our present study, it is also observed that the attitude of nurse & staffs and post care treatment have negative impact on perceived performance. It implies that if the attitude of nurse & staffs are not right then the customers will not be satisfied. On the other hand, if the post care treatment is not given due importance then there will be negative perceived performance among the medical tourists. Therefore, the attitude of nurse & medical staff and post care treatment facilities should be given utmost importance.

**Conclusion**

Medical tourism is slowly and steadily becoming a phenomenon across the globe. Governments are trying their best to tap into this sector as it is capable of generating huge revenue as it is a service industry. The customer of medical tourism with optimum level of satisfaction mobilizes and generates goodwill to the business. The level of satisfaction is highly dependent upon perceived performance on service attributes. In our study, it is also observed from path analysis of structural model that ‘Doctor Related Issues’, ‘Treatment Facilities Related Issues’, ‘Hospital Infrastructure Related Issues’, and ‘Local Environment Related Issues’ having direct impact on overall customer satisfaction. Therefore, the healthcare industry must emphasis on the above stated four factors in order to draw the attention of medical tourists in Tamil Nadu, India. The study also concludes that if there is not efficient and adequate doctors then the medical tourists will be strongly dissatisfied. So, we can say that efficient and adequate doctors are the pillars of success for healthcare industry located in Tamil Nadu, India. However, it is essential for the government to take certain steps in order to develop this industry. In this manner, the gap between the private and the government health services could be reduced further in terms of delivering the quality services.

**Ethical Clearance:** Ethical approval for this study has been taken from selected hospitals of Tamil Nadu, India for carrying out the data collection procedure smoothly. Also Patients/Patient-Parties as our respondents have been assured for maintaining full confidentiality of their feedbacks related to this research.

To Evaluate and Compare the Microleakage in Class Five Cavities Restored by a Nanohybrid and a Nanofilled Composite Resin by Dye Penetration Method—An in Vitro Study

Chitharanjan Shetty, Namrata Khanna, Mithra N. Hegde

Aim and Objective: To evaluate and compare the microleakage in class five cavities restored by a nanohybrid and a nanofilled composite resin by dye penetration method.

Method and Methodology: Twenty premolar teeth were collected and standardized Class five cavities were prepared. The samples were divided into two groups, Group A and Group B. All the samples were then restored with the composite pertaining to that group (n=10). The samples were immersed in 2% methylene blue dye for 24 hours, post which they were sectioned vertically and the microleakage was assessed under the stereomicroscope.

Results and Statistical Analysis: The data for all the samples was obtained and subjected to statistical analysis.

Conclusion: Group B (Nano-filled composite resin) achieved superior results over the nano-hybrid composite resin group and exhibited lesser microleakage.

Keywords: nanofilled, nanohybrid, microleakage, composite resin, dye penetration

Introduction

The treatment of cervical defects is a prevalent clinical procedure in restorative dentistry. Fluoride accessibility and effective preventive programs and improved dental care has perpetuated the longevity of the treatment offered to patients. Preventive care has also led to a larger conservation of natural teeth in the population. Root caries and cervical lesions are still a challenge owing to aging and dentin exposure caused by gingival recession. Composite resins are a suitable alternative for the restoration of such lesions and provide aesthetics and satisfactory physical properties. Cervical restorations are technically demanding as the gingival margin is usually located in dentin or in cementum and this is a critical factor in establishing the adaptation of the margins. A strong bond strength is required for the durability of dental restorations defining its clinical success. Acid etching has certainly enhanced marginal adaptation and yet marginal gaps are a drawback. Regardless of their wide usage, composite resins put forth pertinent disadvantages such as inherent polymerization shrinkage, which explains the contraction gaps at the restoration/tooth interface leading to microleakage.

In an effort to achieve the minimization of unwanted effects of polymerization shrinkage and marginal leakage, an array of newer bonding systems have been introduced along with alternate placement techniques. However, all materials leak to some extent on dentin and cementum, and apart from fulfilling esthetic demands, improvements in the mechanical characteristics helped composite to be used as a posterior restoration as well.
Introduction of enhanced bonding and curing systems and reduction in filler particle size are a contributing factor in its advancement. Composite resins have developed from macro-filled to micro-filled and from hybrids to micro-hybrids and over the years, the dental market has also seen the evolution of the nano-filler technology along with packable and flowable composites.

Nevertheless, each resin based material is conferred with own favorable and unfavorable properties. Amongst these, the hybrid resin materials provide the best blend of adequate physical properties in high clinical demands for anterior as well as, posterior restorations. The nano-filler technology saw the employment of nanomer particles that are discretely 20-75nm in size and nano-clusters that are loosely bound agglomerates of the same. The combination of nanomers as nano-filled particles alone or with other filler-sized composite resins impart strength and showcase an improved polish retention.13

Microfills were thought to be the gold standard in esthetic restorations but their radiopacity and lack of strength and wear resistance limited their use to selected anterior teeth restorations only. Hybrid composite resins on the other hand provided a high filler loading but compromised on the esthetic qualities due to their average particle size being in the sub-micron range.

The two resin composites that were selected for this study were a nano-hybrid composite, Solare Sculpt, GC India Dental (Group A) and the nano-filled composite being Filtek™ Z350 XT Universal Restorative material, 3M™ ESPE, St. Paul, USA (Group B).

Filtek Z350 XT contains bis-GMA, UDMA, TEGDMA, and bis-EMA resins. The fillers are a combination of non-agglomerated/non-aggregated 20 nm silica filler particles and non-agglomerated/non-aggregated 4 to 11 nm zirconia filler particles and aggregated zirconia/silica cluster filler particles that comprise of 20 nm silica and 4 to 11 nm zirconia particles. The inorganic filler loading is around 72.5% by weight (55.6% by volume). Translucent shades and 78.5% by weight (63.3% by volume) for all other shades.14

GC nanotechnology has a unique homogeneous, pre-polymerized nano-fillers with uniform dispersion silane treatment technology and high density. 300 nm strontium glass fillers are homogeneously dispersed for high flexural strength and wear resistance.

Materials and Methodology

20 freshly permanent human premolar caries which were restoration-free without any visible cracks, extracted for orthodontic purposes, were selected. The roots of the teeth were scrubbed and soaked in hypochlorite solution for disinfection and stored in physiological saline solution at room temperature to prevent dehydration. The cemento-enamel junction (CEJ) of each specimen was demarcated with an indelible pen and the apices mounted in modelling wax up to 3 mm below the CEJ. Straight fissure diamond bur (Diamond fissure 330; SS White, Washington, USA) in a high speed handpiece and an air/water spray were used to prepare a standardized class V cavities (4mm mesiodistal width, 2 mm occluso-gingival height and 2 mm axial depth) on the buccal surfaces of each tooth. The occlusal margins of cavities were prepared at the gingival margins extending 1mm above the cementoenamel junction (CEJ). Each bur was used for five preparations. After cavity preparation, the teeth were randomly divided into two groups (n=10). Both groups were etched with 37.5% phosphoric acid for 15 seconds, and then rinsed with water jet for 20 seconds. Then, the teeth were restored with composite pertaining to the group they belonged to in normal consistency following the application of bonding agent used on the etched enamel and dentine. The teeth underwent thermocycling for 500 cycles in a water bath at 5° and 55°C for 30 seconds after which they were subjected to cyclic loading for 10,000 cycles.

The samples were immersed in 2% methylene blue dye for 24 hours, post which they were sectioned vertically and the microleakage was assessed under the stereomicroscope. The dye penetration in the specimens was evaluated for gingival surface based on the graded scoring system given by Araujo et al (2001) and Munro et al (1996) in Table 1.15 Each sample was observed and separately scored by two examiners blindly.

Statistical Analysis and Results

Results were expressed as means and standard deviations. Data was statistically analyzed by using independent t-test. SPSS version 20.0 was used with a significance level set at 5%.
Table 1: The scoring criteria used was that given by Araujo RM et al (2001), and Munro et al (1996)

Discussion

Microleakage can be defined as the dynamic clinical undetectable passage of bacteria, fluids, chemical substances, molecules and ions in between cavity walls and the restorative material used. Since the very beginning of dentistry, many research studies have been done to bridle the difficulty of microleakage in dental restorations, especially in cervical abrasions and class five cavities, but until today, there have been no dental restorative materials or techniques that can truly and completely eliminate microleakage.16,17
The sealing properties of the restorative material can be affected by improper adaptation of the restorative material to the cavity walls and margins along with how the material is condensed. In this study, dye penetration method was used to evaluate the microleakage because methylene blue dye penetration method provides the evaluators with a perfect and easy visualization of the prepared cavity and the digital images deliver a clear reference point from which scoring can be done. The dye also provides an excellent contrast with the surrounding environment.18

Microleakage is more critical in class V cavities as due to the majority of cervical margins these lesions are located in both dentine and/or cementum, which may lead to a weaker marginal seal than that at the enamel surface. However, it is essential to obtain a reliable dentin bond to the restorative material.19,20 The adhesion between composite resins and dentin is not as strong as with enamel; therefore the material can be dislodged toward occlusal during polymerization contraction, causing a bad adaptation of the restoration at the cervical margins.21

All tested samples exhibited dye penetration at the tooth-restoration interface. This could be attributed to the fact that dimensional changes in the resin often results from polymerization shrinkage of the restorative resin material and differences in coefficient of thermal expansion and contraction between the tooth and the restorative material. These changes in the material produce internal forces that results in gap formation at the tooth-restoration interface, which in turn causes microleakage. 22

While Group A resin’s composition consists of predominantly UDMA resin matrix AND pre-polymerised barium/strontium fillers (300nm) that are individually silanated and homogeneously distributed amongst the matrix for better wear resistance and reduced microleakage, group B achieved better results with respect to microleakage. This could be due to the zirconia/silica filler nanoparticles that exhibit a better polishing and resistance to abrasion. In case of the Group B composite resin, majority of TEGDMA is substituted with BisGMA and UDMA which are high molecular weight particles that considerably reduce shrinkage.

The various composite resins in the market with their varied filler technology provide a clinician an array of options to choose an appropriate restorative material catering to a particular case selection. The most widely used nano-filled resin being Filtek Z350XT is however the most popularly recognized resin from the nano-filler particle range. Nanohybrid resins may also provide matchable and desired results in comparison to the above and are an excellent alternative restorative material. Filler technology has been a boon in the reduction of microleakage as the smaller sized particles contribute to higher strength and lesser spaces between the adjacent particles automatically confers reduced marginal leakage of bacteria and contaminants.

**Conclusion**

Under the limitations of this study, Group B i.e. the Nano-filled composite resin showed lesser microleakage compared to Group A- Nanohybrid composite resin. However, more research is sought out to establish a decisive restorative material that can dominantly be indicated for such lesions.

A Clinical Investigation onto the Effect of Occlusal Interferences & Cognitive Behavioural Therapy in Temporomandibular Disorder Patients

Jinal Barochia1, Vignesh Kamath2, Konark Patil3, Roseline Meshramkar4
1BDS, MDS, (Prosthodontics and Crown & Bridge), Private Practitioner; 2Assistant Professor, Department of Prosthodontics, Faculty of Dentistry, Melaka Manipal Medical College, Manipal Academy of Higher Education, Manipal, Karnataka, India; 3Assistant Professor, Department of Prosthodontics, SDM College of Dental Science, Dharwad, Karnataka, India; 4Professor & Head, Department of Prosthodontics, SDM College of Dental Science, Dharwad, Karnataka, India

ABSTRACT

Purpose: The aetiology of temporomandibular disorder has been considered to be one of the most controversial issues in clinical dentistry. One of the conflicts that have attracted most attention has been the role of occlusal factors in temporomandibular disorder signs and symptoms. Therefore, this clinical investigation was done to evaluate the effect of occlusal interferences & cognitive behavioural therapy in temporomandibular disorder patients.

Method: The study was carried out on 60 dental students, age ranging from 18-25 years. The subjects were screened using Research Diagnostic Criteria for temporomandibular disorder. Further, the T-Scan was used to find the occlusal interferences and accordingly occlusal adjustments were made. These subjects were recalled after 2 weeks for screening and they were counselled under cognitive behavioural therapy for 3 sessions. They were screened again after the completion of 3 sessions i.e. after 6 weeks. At each visit, chewing test is carried out by calculating chewing strokes with test food.

Results: The majority of samples were in the range of 6-7 on pain scale at baseline, after 2 weeks in the range of 4-5 and after 6 weeks the intensity of pain was reduced to 3-4.

Conclusion: Occlusal adjustment can contribute to a positive treatment outcome in combination with other forms of therapy (counselling, splints, physiotherapy, etc).

Keywords: Temporo-mandibular disorders; occlusal interference; cognitive behavioural therapy; T-scan.

Introduction

Temporomandibular joint along with associated structures forms an integral part of stomatognathic system. Any imbalance in the harmonious relationship of temporomandibular joint with stomatognathic system leads to temporomandibular disorders. Temporomandibular disorders and their relevance to dentistry has been a highly debated topic as they include a wide variety of conditions associated with orofacial, head and neck pain dysfunction. Temporomandibular disorders present with a wide variety of symptoms and deleterious effects which adversely affects the patient’s social, professional, and economic life. [1]
The aetiolog of temporomandibular disorder has been considered to be one of the most controversial issues in clinical dentistry. One of the conflicts that have attracted most attention has been the role of occlusal factors in temporomandibular disorder signs and symptoms. Occlusal interferences cause muscle hyperactivity, which in turn can lead to muscle incoordination and dysfunction. Hence, the correction of the interferences eliminates the muscle dysfunction, relieves the pain and allows the muscles to return to normal balanced activity. (2)

Therefore, occlusion has an important place within the multifactorial concept of the temporomandibular disorder etiopathogenesis as well as in every form of dental treatment. Masticatory muscles and temporomandibular joints are directly connected with occlusal relations and temporomandibular disorders are traditionally linked with occlusal disorders.

Mastication is one of the main functions of the stomatognathic system and it may be hampered by temporomandibular disorders. As a result, limited masticatory function is one of the problems that patients with temporomandibular disorders encounter. Rehabilitation in order to improve the masticatory function is therefore one of the goals in the treatment of temporomandibular disorder. (3)

Hence this study was undertaken to investigate the effect of occlusal interferences & cognitive behavioural therapy in temporomandibular disorder patients.

**Materials And Method**

**Source of Data:** The study was carried out on 60 dental students, age ranging from 18-25 years at SDM College of Dental Sciences & Hospital, Dharwad.

Among all the different classification systems Research Diagnostic Criteria -Temporomandibular Disorders (4) is the most recommended diagnostic criterion as it includes an assessment of distress and disability, psychological and social factors. This dual-axis system grades and measures both physical and psychosocial components.

**Inclusion Criteria:**
- Pain and tenderness in the temporomandibular joint
- Tenderness of the masticatory muscles
- Mandibular deviation in occlusion

**Exclusion Criteria:**
- Any obvious other dental anomaly
- History of trauma
- Any other disorders like temporomandibular joint osteoarthritis or capsulitis
- Psychiatric disorder patients
- Subject not willing to accept treatment
- Mandibular deviation more than 3 mm

Informed consent of all the patients was taken and they were explained about the whole procedure.

Ethical clearance was taken from Institutional Review Board.

**Methodology**

The subjects were screened using Research Diagnostic Criteria for temporomandibular disorder. Further, the T-Scan was used to find the occlusal interferences and accordingly occlusal adjustments were made. These subjects were recalled after 2 weeks for screening and they were counselled under cognitive behavioural therapy for 3 sessions. They were screened again after the completion of 3 sessions i.e. after 6 weeks. At each visit, chewing test was carried out by calculating chewing strokes with test food which was a piece of raw carrot (1*1/2 inch) in dimension.

**Results**

For chewing tests, each subject was instructed to chew the portion of test food.

For estimating the masticatory performance, raw carrot with the (1*1/2) inch dimension was kept as test food.

**Discussion**

Occlusal therapy/equilibration is defined as ‘the modification of the occlusal form of the teeth with the intent of equalizing occlusal stress, producing simultaneous occlusal contacts or harmonizing cuspal relations.\(^6\)’ Permanent alteration of the occlusal condition is indicated for 2 reasons viz. the first and most common reason is to improve the functional relationship between the maxillary and mandibular teeth. The second reason for permanently altering the occlusal condition is as a treatment goal to eliminate a temporomandibular disorder and correct orthopaedic instability. Occlusal equilibration is appropriate only when alterations of the tooth surfaces are minimal so that all corrections can be made within the enamel structure.\(^7\)’ In the present study, there was a drastic reduction in the intensity of pain among the subjects after 2 weeks post occlusal equilibration. Forsvell H et al in 1987\(^8\) reported in their research work that the occlusal treatment had shown better results than placebo treatment. Vallon D et al in 1995\(^9\) found that occlusal adjustment is a treatment modality with a significant short-term effect on symptoms of craniofacial disorder of muscular origin.

Cognitive Behavioural Therapy (CBT) aims to enable individuals to better manage their difficulties by applying empirically researched principles of thoughts, feelings and behaviours. These principles translate into practical strategies, which can lead to changes in subjective and objective thoughts, feelings and behavioural states. Interventions in cognitive behavioural therapy include: goal setting, challenging negative automatic thoughts, relaxation and breathing exercises, cognitive visualisation exercises, behavioural coping strategies, stress management and assertion skills.\(^10,11\) In the present study, the subjects were counselled under cognitive behavioural therapy for 3 sessions. They were screened again after 6 weeks and reported a gradual reduction in the intensity of pain. Shedden Mora MC et al in 2013\(^12\) in their research demonstrated that biofeedback-based cognitive-behavioural treatment resulted in larger improvements in pain coping skills, and was well accepted by the patients, underlines the importance and feasibility of psychological treatments in the clinical management of temporomandibular disorder. Koop S in 1979\(^13\) reported that the counseling of patients had reduced their subjective symptoms and occlusal adjustment improved the clinical signs of mandibular dysfunction involving the temporomandibular joint.

In dental practice, articulating papers in various colours are most commonly used to visualize the contacts. Occlusal waxes or the computer-aided analysis of silicone check-bites are possible alternatives.\(^14\) One of the most innovative systems for quantitative occlusal analysis was developed by Maness. The Tek-scan system uses a sensor unit that records occlusal contacts on a thin Mylar film and relays the information to a computer. Through analysis of the occlusal contacts it is possible to determine the sequence and timing of which teeth contact with what degree of comparative force. Comparisons can be made for occlusal contacts in centric relation versus centric occlusion.\(^15\) The computerized occlusal analysis system is the only occlusal indicator that demonstrates the ability to provide quantifiable force and time variance in a real-time window from the initial tooth contact into maximum intercuspation. The reported advantages to accurately indicate occlusal contacts make the computerized occlusal analysis system a better occlusal indicator when compared with other non-digital conventional indicator materials available. The advantages of Tek-scan over other methods are pinpoint occlusal contacts and remove interferences with ease, enhance patient communication and education & eliminating the need for multiple
adjustment appointments. Garrido Garcia VC et al in 1997 found that the T-Scan system is a reliable method for the analysis and evaluation of occlusal contact distribution in maximum intercuspation. The goal is to obtain the maximum number of axially directed contacts that are equal in intensity. The pressure of even one tooth contact with greater intensity is sufficient to destroy the muscle harmony and activate a hyperactivity of the unbalanced muscles.

Masticatory performance is the most commonly used measure of masticatory function. It quantifies a patient’s ability to break down food based on the size of food particles after a specified number of chewing cycles. Numerous studies have shown that the masticatory performance is related to occlusal factors. In the present study, there was a considerable change in the number of chewing cycles from baseline to 6 week interval and observed 30 % improvement in masticatory efficiency (Figure 3). Henrikson T et al in 1998 found in their research that masticatory efficiency and ability were partly dependent on the occlusion and the symptoms of temporomandibular disorder had influenced the masticatory efficiency and ability.

The findings of this study are in agreement with the research work of Vallon, Koop and Henrikson and corroborate the conclusion that the occlusal therapy and counselling have shown better results than other measures.

Temporomandibular disorders and muscle disorders are common condition involving pain in the temporomandibular joint and/or associated masticatory muscles. The most recommended diagnostic criterion is the RDC/TMD in which assessment of distress and disability, psychological and social factors may be useful in providing an exact diagnosis. Treatment can range from simple homecare practices, splint therapy, occlusal adjustment, analgesics to psychotropic medication and rarely surgery. However, a simple occlusal adjustment may be defensible as an early treatment for temporomandibular disorders as it may reduce short-term symptoms. Cognitive Behavioural Therapy has been found to be effective in reducing pain and disability in temporomandibular disorders, particularly in combination with other treatment modalities, such as medication and biofeedback.

Moreover, Julian KC et al in 1996 reported that there is significant difference in masticatory performance among men, women, young boys and young girls. Therefore, further studies are required to study the effect of gender-based and age-related changes (body size) in masticatory function.

Conclusion

Occlusal adjustment can contribute to a positive treatment outcome in conjunction with other forms of therapy like counselling which incorporates patient education, encouragement towards self-management, reduce temporomandibular disorder related symptoms and disability.

ABSTRACT

All teeth are found to have variations in dental anatomy. For the success of endodontic treatment, clinician should have complete knowledge regarding the variations of the root canal anatomy. This case report demonstrates successful management of maxillary first molar with six canals: two palatal, two mesio-buccal and two disto-buccal canals. Such variation in anatomy exists and so the astute clinician should take a note of these anatomical considerations while treating a tooth.

Keywords: Maxillary first molar, anatomical variations, additional canals.

Introduction

Endodontic treatment aims at achieving three dimensional obturation of the root canal system which can be accomplished by the clinician who possesses thorough knowledge of the root canal anatomy and its variations. In his study on maxillary molars, Pecora et al found that three canals were there in 75% of maxillary first molars, 58% in second molars and 68% in third molars and four canals in 25%, 42%, 32% of first, second and third molars respectively. [1] Most common root canal anatomical finding in maxillary first molar is the presence of second mesiobuccal canal, whose incidence ranges between 18% and 96.1%.[2] Other uncommon variations include presence of one [3], four [4] and five [5] roots and also with unusual morphology within the root canal systems. Case reports with five [6] and six [7] root canals or with a C-shaped canal configuration [8] have also reported earlier.

In two separate case reports, six root canals were identified by Martinez-Berna’ and Ruiz-Badanelli, out of which three were in mesiobuccal roots, two in distobuccal and one in palatal roots. [9] Similarly de Almeida et al [7] and Bond et al [10] in their clinical case found two mesiobuccal, two distobuccal, and two palatal canals accounting to six canals. A case report by Maggiore et al [11] revealed six canals with two mesiobuccal, three palatal, and one distobuccal canals and Adanir [12] had four roots (mesiobuccal, mesiopalatal, distobuccal, and palatal) with six canals (one mesiobuccal, two mesiopalatal, two distobuccal, and one palatal canal). The incidence of two canals in distobuccal root varies between 1.90% - 4.30% [13,14,15] and that of two canals in palatal root varies between 2% to 5.1%.[16]

This clinical case report showcases a successful endodontic management of a maxillary first molar whose root canal anatomy exhibits an anatomic variation of two canals in all three roots resulting in a total of six canals in a single tooth.

Case Report

A 19 year-old young adult was reported to the Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Chennai, with a chief complaint of spontaneous toothache in his upper left back tooth region for past 2 weeks. Patient gave a history of increase in intensity of pain by thermal stimuli and on mastication. History also revealed an intermittent
pain in the same tooth with hot and cold stimuli for the past one month. Careful examination revealed maxillary left first molar was carious and it was tender to percussion. There was no mobility of the tooth and periodontal probing was within physiological limits.

Vitality testing of the involved tooth with heated gutta-percha caused an intense lingering pain, whereas electronic pulp stimulation (Parkel Electronics Division, NY) caused a premature response. A preoperative radiograph revealed radiolucency approaching the pulp space. Correlating the clinical and radiographic findings, the patient was diagnosed with symptomatic irreversible pulpitis with symptomatic apical periodontitis. Root canal treatment was planned and suggested to the patient.

Variation in canal anatomy could not be identified in radiographic evaluation [Figure 1]. Patient was administered with local anesthesia containing 2% lidocaine with 1:80,000 epinephrine. Under Rubber dam isolation, access opening was made [Figure 2], and four well-defined root canal orifices were located using a DG-16 explorer (Hu-Friedy, Chicago, USA) on the pulpal floor. One orifice for each of the buccal roots and two separate orifices for the palatal root were identified. A working length radiograph was taken which revealed two independent palatal canals joining in the apical portion, and the distobuccal file was not at the center of the canal [Figure 3]. Under magnification with dental operating microscope, dentinal lips around the mesiobuccal root was cleared and mesiopalatal canal orifice was revealed. Confirmation of working length was done with radiograph and an electronic apex locator (Root ZX; Morita, Tokyo, Japan) [mesiobuccal canal -17 mm; mesiopalatal canal, distobuccal canal and distopalatal canal -16.5 mm; and 21 mm and 20 mm for the two palatal canals]. Cleaning and shaping of the canals were performed in a crown-down technique using ProTaper Nickel-Titanium rotary instruments (Dentsply Maillefer). Distobuccal and distopalatal canals were found to be joined after canal preparation and enlargement. Irrigation was done using normal saline, 2.5% sodium hypochlorite solution and 17% EDTA with 2% chlorhexidine digluconate as the final irrigant. Absorbent paper points (Dentsply Maillefer) was used to dry the canals and obturated using cold lateral compaction of gutta-percha (Dentsply Maillefer) with AH Plus resin sealer (Maillefer, Dentsply, Konstanz, Germany) [Figure 4, 5]. Final restoration of the tooth was done with a posterior composite resin core. Full coverage porcelain crown was made and the patient was recalled after 3 months during which he was found to be asymptomatic.
Discussion

Scientific literature emphasizes on the fact that success of endodontic treatment of maxillary molars depends upon thorough knowledge of root canal morphology and its configuration. Existence of root canal anomalies is not an exception but awareness of its presence helps to treat cases with an unusual morphology. Cohen and Burns suggested the fact that the only reason why the canals are not treated is due to the failure of not locating it. [17] The clinician should make every possible effort to locate and treat the canal when he suspects it.

In the present case report during access opening after the removal of the coronal pulp and exploration of the canals, bleeding was present on the pulp chamber floor. On suspecting additional canals further exploration of the floor was carried out under magnification and this lead to the location of the two remaining palatal canals. The palatal root had two orifice openings with a single apical foramen whereas mesio buccal and disto buccal roots had two canals with two separate apical foramen. The success of identifying and negotiating canals requires proper access opening. The shape of access opening for maxillary molars is triangle shaped with apex pointing at the palatal canal and base formed by the buccal canals. But we have modified the access opening to a more trapezoid form in order to include all of the canal orifices. To facilitate cleaning and shaping of all the canals, combination of Hand files, Gates Glidden burs, and rotary Ni-Ti instruments were used.

If the clinician suspects any anatomic variations, he should recognize it by taking radiographs at different angles; by using 1% methylene blue dye to stain the chamber floor; “champagne bubble” test using sodium hypochlorite or by visualizing canal bleeding points. In addition, possibility of additional canals should be considered, if the clinician feels the endodontic files are not well centered in the canal on the radiograph. Microscope also aids in verifying the presence of morphologic variations. Occurrence of a second canal in the distobuccal and palatal roots is not frequent, but awareness of the existence of all possible anatomic variations aids the clinicians in the success of the root canal therapy.

According to Buhrley et al when he compared the groups of microscope, dental loupes and no magnification groups, he found that the frequency of MB2 canal detection in the maxillary first molars were 71.1%, 62.5%, and 17.2%, respectively. [2] In the present case, it was very difficult to predict the root canal anatomy on the basis of preoperative radiograph alone. Inadvertent search for extra canals without the aid of magnification could have led to perforations and excessive removal of tooth structure. Hence, clinicians should familiarize and incorporate dental microscopy in endodontic practice to get additional anatomic information. [18]

Conclusion

The present case report discusses the successful endodontic management of an unusual case of a maxillary first molar with three roots and six canals. It also highlights the role of dental operating microscope as an important analytic tool to ascertain root canal morphology which aids in the success of the treatment.

A Study on Issues on Environment Pollution and Health Hazard in Tamilnadu

R. Bright Reginold Raja¹, S. Antony Selvi²

¹Assistant Professor, Department of Management Studies, St. Xavier’s Catholic College of Engineering, Chunkankadai, Nagercoil; ²Professor, Department of Physiology, Rajas Dental College & Hospital, Kavalkinaru Junction-, Tirunelveli

ABSTRACT

In general, most of the diseases are caused by various mode of pollution. The awareness of the people and the impact of pollution, the causes of diseases may vary. In such circumstance, many social issues regarding environmental pollution have been agitated due to the effect of diseases and the awareness on such pollutions. The present paper portrays the health hazard, environmental pollutions and social issues on various modes of pollution in Tamilnadu during the decade of 2009-2018. Health hazard includes major diseases affected during the study period. Environment pollution consists of land, air and water pollutions. Social issues have happened in various places for the impact of environmental pollutions and the effect of diseases. The recommendations of the present paper will definitely give implication to the policymakers.

Keywords: health hazard, environment pollutions and social issues

Introduction

Society is one of the main pillars of the environment. National development is assured when the protections against health hazard, environmental pollutions, and social issues. The national economy is for providing facilities/services on defense, medical, education, and infrastructures. The economy of a country expected the sources of income from the major sectors such as agriculture, industry, and services. The industry is in the second place of its percentage of contributions to the Indian economy. Besides the environmental pollutions are in the first place. Hence, the protections against industrial pollutions on land, air, and water are significantly increased day-by-day. On the other hand, people affected due to pollutions are also increased subsequently. With the result, social issues have been increased against pollutions and its impact i.e., a health hazard. The awareness of the people is promoted by social media, political parties, public, government, and NGOs. The steps have taken against social issues by the court of law and government is the major implications on the part of the health hazard and environmental pollutions. The present paper enlisted the major issues on environment pollutions and the health hazard in Tamilnadu during the study period. The present paper also revealed the previous studies related to the health hazard, environmental pollutions, and social issues in Tamilnadu during the study period.

Environment Pollutions and its Issues in India: Many pollution issues are giving causations to India with several diseases. The main pollutions are air pollution, (land) garbage pollution, and water pollution. According to World Bank experts, from 1995 to 2010, India has faced and challenged environmental issues on par to other developed nations. Like India, many of the developed countries are facing the same situations. India will suppose to meet a big challenge and threaten in a few forthcoming years. At that time, India will cause of disease, health issues and long term adverse impact on livelihood through environmental issues.
**Water Pollution:** About 30 years back people in villages are used the pond water for their edible and even for drinking purpose. Most of the village people used the well, pond, river, and hand pump water for drinking. After entering the new companies into the Indian water market, they created the demand and unsafe for drinking above said sources of water due to various diseases affected. The packaged drinking water (without minerals) is created its demand even in remote villages. There is no remedy to cure water pollution by means of government, but they also prepared the packaged drinking water. Still, water pollution has been existing, when it is wiped-out or reduced?

**Water Resources:** NASA stated that the groundwater has been declining are highly on Earth between 2002 and 2008 in northern India. Politicians of India are concentrating the capital of India for the political benefits. But they are not for the development of agriculture and the protections against global warming. The people are obviously understood that the government is tried to fetch and sustain the next ruling period during their rule. Hence the survival of the people is a very big question for future water resources.

**Air Pollution:** Indian industry development is galloping its growth in the international arena. It results; the air pollution is stringently causing India. The technology alone will help to reduce air pollution. Because the industry and its usages are may not suppose to reduce or decline. The needs and wants of the commodity, goods and services will definitely be got the straight line growth. The research and development of the nation are responsible for increasing air pollution.

**Soil:** The soil is the main source of mineral in the world. Living organisms are living with the help of soil by means of basic needs. The human being has been polluted the soil unethically. The government is also injudiciously taking sand and other minerals from various sources to making money (politically) or funding the local body. There is no maintenance of water resources, drainage systems, and also collapsing the wastage/drainage water into the water resources. Totally, the government not does anything for the cultivation, rehabilitation of non-cultivatable lands, and agriculture economy.

**Health Expenditure:** The World Bank data have utilized to assess the per capita health expenditure incurred during the study period.

**Source:** World Bank Report

The per capita domestic health expenditure is average US$ 29.33. 75.9 percent of domestic health expenditure has been incurred and averagely the expenditure spent out-of-pocket is 69.01 percent. The value of covariance is very low in its percentage of private expenditure and the out-of-pocket. It shows that the consistency of its stability in the same position during the above tabulated period. As per the per capita, the growth has significantly increased by about 8.27 percent of domestic private health expenditure. Hence, the people of India spent their own money health care is significantly increased.

Source: World Bank Report

The per capita government health expenditure is average US$ 9.3. 3.12 percent of government health expenditure has been incurred and averagely the expenditure spent out-of-pocket is 69.01 percent. The value of covariance is low in its percentage of government expenditure as per the GDP %. It shows that the consistency of its stability in the same position during the above tabulated period. As per the per capita, the growth has significantly increased by about 11.66 percent of government health expenditure. Hence, the government of India spent money on the health care of people is significantly increased.

</table>
The air pollution is averagely 99.96 percent as per target 3. In target 2 is 99.16 percent averagely. But target 1 is attained at 89.16 percent averagely. The value of covariance is very low in its value. It shows that there is the stability of their positions prolong period and also slightly increased. As per the mean exposure of micrograms per cubic meter is got positive growth has significantly attained as 1.18 percent Hence, the air pollution is significantly increased.

### Finding
1. The expenditure spent out-of-pocket is 69.01 percent. The value of covariance is very low in its percentage of private expenditure and the out-of-pocket
2. The per capita domestic health expenditure is average US$ 29.33. 75.9 percent of domestic health expenditure has been incurred
3. The per capita, the growth has significantly increased by about 11.66 percent of government health expenditure. Hence,
4. The per capita government health expenditure is average US$ 9.3. 3.12 percent of government health expenditure has been incurred and averagely
5. The expenditure spent out-of-pocket is 69.01 percent. The value of covariance is low in its percentage of government expenditure as per the GDP %. It shows that the consistency of its stability
6. The air pollution is averagely 99.96 percent as per target 3. In target 2 is 99.16 percent averagely. But target 1 is attained at 89.16 percent averagely.
7. The value of covariance is very low in its value. It shows that there is the stability of their positions prolong period and also slightly increased.

### Conclusion
As per the findings of the above tables, discussions, review of the literature and environmental issues in Tamilnadu, the author concluded that the pollutions by land, air, and water are persisted. The government of India should concentrate on protecting the people from pollution impact on a health hazard. The expenditure against health care is increased by per capita, private, and government. But external expenditure alone has decreased. It shows that other sources like insurance are not responsible for the medication of people in general.

ABSTRACT

Background: Water is one of the most basic needs of life. 90% of the groundwater accounts for the world’s freshwater resources, used for irrigation, industry, and human consumption. Well water is considered as the sole source of drinking water in many regions. The water should be checked regularly to determine bacterial contamination in order to prevent water born bacterial diseases. This study was performed to evaluate the microbial quality of the water from the wells used for drinking purpose.

Method: In this cross-sectional study, twenty water samples from ten different wells around the agricultural area were collected in a 200ml capacity sterile container, transported to the laboratory and examined for presumptive coliforms by multiple fermentation tube test. The presumptive coliform count per 100 ml of water was determined using the probability table. Bacteria were then identified using conventional methods.

Results: All samples were contaminated with bacteria, and the most predominant bacteria isolated were Klebsiella pneumoniae (40%), followed by Pseudomonas aeruginosa (26%) and E.coli (13%). Of the ten wells tested, seven well water samples were found to be excellent, one satisfactory and two were unsatisfactory. No pathogenic bacteria were seen in any of the samples.

Conclusion: Before consumption of water, it should be adequately boiled, or filtered to prevent the incidence of water-borne diseases. Regular screening for bacterial contaminants is necessary in reducing the contamination and supplying safe drinking water.

Keywords: Well water, water contamination, most probable number, Presumptive coliform test, agricultural area, multiple fermentation tube, water borne diseases

Introduction

Water is one of the most basic needs of life¹. 90% of the groundwater accounts for the world’s freshwater resources and known as a vital global source of water for irrigation, industry, and human consumption². Visually, water should be clear, colorless, and free from all pathogenic organisms, their toxins, as well as poisonous minerals, and other organic substances³. In many of the regions well water is considered as the sole source of drinking water⁴.

Unsaturated zone and saturated zone are the two levels of water beneath the land surface. A saturated zone is filled with groundwater, and upper to that of the saturated zone is called a water table. Below the water table, the pressure is greater and that allows the water to enter into the well, thereby permitting groundwater to be withdrawn for human use. The depth to the water table varies seasonally and from year to year due to wide variation in the quantity, distribution, and timing of rainfall⁵.

Well is a hollow structure that is located in the ground by digging or boring mechanically or manually to access groundwater from the underground aquifers ⁶. Globally, contamination of well water is a problem that contributes to high mortality rates from water and food borne diseases⁷. In groundwater both the microbial and chemical contamination had been detected. There are numerous source of microbial contaminations which includes land disposal of waste outflow, slurry, septic
tank outflow, solid waste, agricultural mining, industrial practices and urban runoff. Water borne diseases such as cholera, hepatitis, typhoid fever, gastroenteritis are mostly caused by the usage of the untreated or inadequately treated ground water\(^8\). Consistent with the WHO, in developing countries, up to 80% of the health challenges are mainly due to water and sanitation related\(^9\).

In drinking water sources, pathogenic organisms are indicated by the presence of bacterial indicators\(^10\) like E. coli, total coliforms, thermo tolerant (fecal) coliforms, Clostridium perfringens and fecal streptococci\(^11\). E. coli are more common and widely distributed normal flora of humans and animal intestine\(^12,13\). Water samples should be regularly investigated to detect coliform bacteria E. coli (faecal indicator bacteria) according to the international ISO standards\(^14\) to check the quality of drinking water\(^15\).

**Materials and Method**

A cross-sectional study was conducted across Manipal, around the agricultural area, to determine the bacterial contamination of well water after obtaining the ethical clearance certificate form Institutional ethical committee, Kasturba Medical College and Hospital, Manipal Academy of Higher Education, Manipal. A total of ten wells used for drinking purpose were selected, and from each well two water samples were collected from two different sides. Informed consent was taken from well owners before the water collection.

World Health Organization guidelines were followed to collect well water samples. Water samples were collected by using 200ml of clean, heat sterilized bottles. An appropriate sized clean sterile stones were tied to the neck of the bottles using a piece of string. The bottles were unlocked and the mouth of the bottles was sterilized with cotton spirit. With no touching sides of the well and without beating the bottom or troubling any deposit, the bottles were lowered into the deep well. Total of 2 water samples from the same well at different sides were collected using two separate bottles. After filing a sufficient amount of water, bottles were removed by backpedaling the string. Nearly 20-30ml of water was removed from the bottles for adequate space to allow easy distribution of the bacteria in the water before processing. The bottles were properly labeled with complete details including source, site, address, date, and time of the collection. The water samples were delivered to the laboratory within 2 hours in a box containing ice packs. Four drops of aqueous thiosulphate solution were added to each of the bottles before sampling the water, to neutralizing chloride residue. Since the complete history of chlorination was obtained from the well owners, all the samples were neutralized with sodium thiosulphate solution soon after the collection\(^16\).

Water samples were processed in the laboratory by multiple tube fermentation test, to find the presumptive coliform count. Double and single strength of MacConkey broth bottles with Durham’s tubes were used and measured amount of water samples were added using graduated pipettes. One number of 50 ml volumes of water was added to 50ml of double strength MacConkey broth, five numbers of 10ml volumes of water added to 10 ml of double strength MacConkey broth and 5 numbers of 1ml volume of water added to the 5ml of single strength MacConkey broth (Table1). The tubes were incubated at 37°C for 24-48 hours. The presumptive coliform count per 100 ml of water was determined from the tubes showing acid and gas production using the McCrady’s Statistical table and interpreted the result \(^17\).

**Table 1: Sample volumes and number of tubes for multiple tube fermentation test**

Tubes those showed turbidity, along with the production of acid which is denoted by yellow color in the bottle, and gas that accumulated in the Durham’s tubes were sub cultured to MacConkey agar plate and incubated at 37°C overnight. Next day, colony morphology was studied and bacteria were isolated and identified based on Gram staining report, typical features like lactose fermentation on MacConkey agar, and biochemical tests such as Catalase test, oxidase test, motility test, Indole test, mannitol fermentation test, triple sugar iron (TSI) agar test, citrate utilization test, and urea hydrolysis test\(^18\).
Result

Of the ten wells tested, seven well water samples were found to be excellent, one satisfactory and two were unsatisfactory. No pathogenic bacteria like Salmonella and Shigella were seen in any of the samples, but all twenty water samples were contaminated with bacteria. The most predominant bacteria isolated were Klebsiella pneumonia (40%) Fig. 1, followed by Pseudomonas aeruginosa (26%), E. coli (13%), Klebsiella oxytoca (8%), Enterobacter species (5%), Coagulase-negative Staphylococcus aureus (5%) and Providencia alcalifaciens (3%). Total bacteria isolated from the well water near agricultural areas are shown in the Graph 1, the bacterial pathogens distributed in the two sides of the wells are shown in the Graph 2.

Discussion

Urbanization, overpopulation, environmental pollution and increasing demand of water pose a risk for the availability of safe drinking water. The guidelines set by WHO states that the existence of enteric coliforms especially E.coli makes the water samples unfit for the human consumption. The common phenomenon that has been reported in the developed and underdeveloped countries are the spread of diseases through the fecal contamination of the water sources.

Few studies showed that well water sources are as contaminated as surface water sources. We found large number of Gram negative bacteria in well water samples. The possible reasons for contamination of the water might be constructional defects on casing, concrete covers, railing, diversion ditches and other plumbing accessories. Apart from this, lack of regular care, disinfection and proper maintenance might also be a reason for the bacterial contamination of well water.

In the present study E.coli was present in four wells, according to the Guidelines for Hygiene Education in Community Water Supply and sanitation; it may due to the poor sanitation habit and hygiene education. The existence of coliform suggest insufficient treatment or post treatment contamination. The presence of fecal coliforms indicates recent fecal contamination of the well water, also propose that the presence of intestinal disease causing bacteria in well water, which is mainly due to the close proximity of the well to commercial toilet. Pseudomonas aeruginosa are the commonly occurring environmental pathogens and they can also be seen in faeces, soil, water and dirt, also seen in most of the wells in the present study. It can also multiply in the biological surfaces that are in contact with the water and also in the water environment. Particles from the surroundings may enter easily to the wells due to its openness and depth, might be a reason for the contamination of the well water by pathogenic bacteria. On the other hand due to poor hygienic state around the areas were such wells are situated or drawing waters from the wells in contaminated containers also a reason for the contamination of the well waters. Diarrhea, dysentery and typhoid fever are some of the unhealthy conditions seen from the enteric diseases in the country and is mainly due to the consumption of the contaminated well water.

Conclusion

According this study, increased incidence of contamination of well water by pathogenic organisms was observed. In order to drop the contamination of well water, it is recommended that the dug wells must be deep and closed properly. In and around the wells, suitable good personal and environmental sanitary practices must be followed. Before using for drinking purpose, water must be boiled or filtered properly which help in preventing the incidence of water-borne diseases. Regular screening of water for bacterial contaminants is required in reducing the contamination and supplying safe drinking water. High strength calcium hypochlorite could be used as disinfection of the contaminated wells.

ABSTRACT

Background: Dental calculus occurs in most adults worldwide. Dental calculus serves as an ideal substrate for sub-gingival microbial colonization and also initiates the inflammatory reaction in the gingiva that leads to periodontitis. Now research has been focused more on inhibition of crystal growth to reduce the formation of calculus. Thus, the aim of the present study is to assess the levels of Orthophosphate, Pyrophosphate, Pyrophosphatase and Citric acid in whole saliva with reference to Calculus groups and Plaque groups.

Materials and Method: 103 patients were randomly selected from Sree Balaji Dental College and Hospital, Chennai – 600100 for this current study. Depending on the calculus index score, individuals were divided into four groups: Group 1, calculus index score 0 to 0.6; Group 2, calculus index score 0.7 to 1.8; Group 3, calculus index score 1.9 to 3; and Group 4, plaque group where index varied from 0 to 3. The saliva was collected and biochemically analyzed for concentration of orthophosphate, pyrophosphate, pyrophosphatase and citric acid.

Results: The mean values of orthophosphate in group 1,2,3, and 4 were 4.7981,4.8683,6.1830 & 4.7904. The mean values of pyrophosphate in group 1,2,3 and 4 were 1.2056,1.1085,1.0879 and 1.2738. The mean values of pyrophosphatase in group 1,2,3 and 4 were 0.1592,0.1619,0.1803 and 0.1173. The mean values of citric acid were 0.1687,0.1753,0.1698 and 0.1816.

Conclusion: The result of the study shows that the components presented in saliva like orthophosphate, pyrophosphate and pyrophosphatase had a significant role with regard to calculus formation and inhibition. However, Citric acid requires increase in sample size to give satisfactory statistical analysis.

Keywords: Saliva, Calculus, Minerals

Introduction

Dental Calculus occurs in most adults worldwide(1). Dental calculus is calcified mineralized plaque which serves as an ideal substrate for sub-gingival microbial colonization(2). Large amount of calculus may hamper the efficiency of daily oral hygiene and initiates the inflammatory reaction of the periodontal tissue(3). Since many studies have shown that the combination of dental calculus, plaque and age is strongly correlated with severity of periodontal disease(3), now research has been focused more on inhibition of crystal growth through developing chemical approaches to prevent or eliminate calculus formation(2). On this basis, activity of Orthophosphate, Pyrophosphate, Pyrophosphatase and citric acid was studied in whole in calculus forming groups and plaque forming groups.

Materials and Method

Selection of Patient: 103 patients were randomly selected from Sree balaji dental college and Hospital, Chennai. All of the participants were informed in detail of the procedure and signed an informed consent form in advance of the procedure. Inclusion criteria includes both sex with age 15-35 years, Full complement of teeth, No history of antibiotics for past 3months, non-smoking, no systemic disease. Exclusion criteria include Patient undergone periodontal therapy within 1 year prior to the study, Pregnancy and Lactating mother.

Selected patients were divided into four groups by applying the Calculus index Simplified (Greene and Vermillion 1964)⁴ and Dental plaque scores (Schick and Ash index 1961)⁵. Disclosing agent used for identifying plaque for plaque index scoring. 26 subjects - Group I with calculus index score 0 to 0.6. 26 subject - Group II with calculus index score 0.7 to 1.8. 25 subjects - Group III with calculus index score 1.9 to 3. 26 subjects - Group IV with plaque index varied from 0 to 3.

Methodology

The 5ml whole un-stimulated saliva using passive drooping method is collected in the sterile container from the selected individual of each group. Transportation of saliva samples for biochemical analysis in an ice container. De-proteination of saliva is done by withdrawing 3ml of saliva collected from each donors with help of graduated pipette was transferred to a sterile centrifugal test tubes containing 5ml of 10% Trichloroacetic acid and centrifuged at 3000rpm for 15 minutes at room temperature to remove the salivary proteins.

The clear, supernatant saliva was analyzed for orthophosphate, pyrophosphate, citric acid and pyrophosphatase enzyme.

Estimation of Orthophosphate was done as per the procedure of C.H. Fiske and Yellapragada Subbarow method⁶.

Estimation of Pyrophosphate was done as per the procedure of Ruth M.Flynn, Mary Ellen Jones and Fritz Lipmann⁷.

Estimation of pyrophosphatase was done as per the procedure of John Josse method⁸.

Estimation of Citric acid was done as per the Colorimetric procedure for estimation of citric acid by G.Rajagopal⁹.

Results

Four parameters, ORTHOPHOSPHATE, PYROPHOSPHATE, PYROPHOSPHATASE AND CITRIC ACID were detected in the saliva sample collected from four groups (Group I Plaque group, Calculus group II, group III, group IV). The values were compared with all these four groups.

Mean values and Standard deviation of Orthophosphate, Pyrophosphate, Pyrophosphatase and Citric acid in Plaque group, Calculus group II (Mild), Calculus group III (Moderate) & Calculus group IV (Severe) were shown in table 1.

The result of the study shows that mean values of Orthophosphate in group 4 (Calculus severe group) is found to be high when compared with the other 3 groups(Table 1).

The result of mean values of enzyme Pyrophosphatase were found to be similar to orthophosphate with increased levels in Group 4 (Calculus group severe) when compared with other three groups (Table 1). The results of the study shows that the mean values of pyrophosphate is found to increased in group 1(Plaque group) when compared with other three groups (Table 1). The results of mean values of Citric acid were found to be similar to Pyrophosphate with increased levels in Group 1(Plaque group) when compared with Group III & Group IV (Table 1).

All four groups were compared for the values of Orthophosphate, Pyrophosphate, Pyrophosphatase and Citric acid by One-way Analysis of Variants. One-Way ANOVA (Analysis of Variants) illustrates that the mean values of Orthophosphate shows the statistically significant difference between all the four groups (p > 0.05) whereas the mean values of Pyrophosphate, Pyrophosphatase and Citric acid did not show any statistically significant difference between all the four groups (p > 0.05) as shown in table 2.

**Discussion**

The presence of dental calculus on the root surface is one of the major causes for the periodontitis(2). Over the past 50 years, a large number of clinical associated with laboratory studies have been performed to determine the efficacy of calculus prevention and removal from diseased root surface(2). The presence of various components in saliva like orthophosphate, pyrophosphate and pyrophosphatase itself is possibly responsible for the calculus formation and inhibition(3).

The super saturation of saliva with respect to calcium phosphate is highly responsible for the mineralization of dental plaque(10). This mechanism of dental calculus formation is unique with the formation of renal calculi(11). Since many studies have shown and proven that citric acid prevents renal calculi stones formation by inhibiting crystallization, this study made an attempt to estimate citric acid in saliva and its role in preventing dental calculus formation. Thus in the present study, Citric acid was also investigated in saliva with reference to calculus formation and Inhibition.

This current observation shows that the concentration of orthophosphate was directly proportional to the severity of dental calculus formation which was similar to the study made by A.R.Pradeep et.al (1), and Vincent J.Sawinski and Donald F.Cole (12) who also proved that the orthophosphate concentration in saliva was responsible for the formation of dental calculus. Enzyme alkaline phosphatase presented in saliva, in GCF and in plaque will increase the concentration of orthophosphatase which in turn reacts with calcium ions and lead to precipitation of insoluble calcium apatite crystals and formation of calculus(13). The roles of alkaline phosphatase activity in chronic periodontitis (13) and in chronic periodontitis in post-menopausal women (14) have also shown that it largely reflects on periodontal tissue inflammation.

The result of this study illustrates that concentration of pyrophosphate is directly proportional to the calculus inhibition. Pyrophosphate is naturally formed end product of cellular metabolism and plays an important role in various biosynthetic reactions.

Pyrophosphate, the anti-calculus component of dentifrice(15), is believed to resist and inhibit the crystal
growth of the dental calculus. Various studies have also proven the role of Pyrophosphate in inhibiting crystallization of dental calculus\(^2\). Besides anti-calculus effects of pyrophosphate, pyrophosphate\(^{15}\) also inhibits the growth of both gram positive and gram negative periodontal pathogens in supra-gingival and sub-gingival plaque. The upregulation/increased tissue non-specific alkaline phosphatase (TNAP) causes hydrolysis and deficiency of pyrophosphate by converting them into phosphate which is potentially responsible for the calcification, especially uremic vascular calcification\(^{16}\).

Charles O Neill et.al\(^{17}\), investigated the effects of Pyrophosphate in inhibiting uremic vascular calcification in rats and also found that exogenous pyrophosphate can inhibit uremic vascular calcification even in the presence of calcitriol without producing any adverse effects.

Bisphosphonates represent another group of synthetic pyrophosphate analog that interact strongly with minerals to prevent calculus formation by inhibiting crystal growth\(^2\). M.N.Haq Sikder et.al\(^3\), performed a study to examine the effects of TRK-530 in inhibiting the dental calculus formation. The results shows that TRK-530 in drinking water inhibit the precipitation of calcium phosphate and inhibit the dental calculus formation in a dose dependent fashion than subcutaneous injection of TRK-530.

John Hunter (1771) was interested in renal stone formation and recognized that there is a existing similarity between stone formation and the calcification in describing the formation of enamel of the teeth\(^{18}\). Various studies have shown that citric acid preventing urinary calculi, urolithiasis and nephrolithiasis by inhibiting crystallization. First of all, citrate forms an important complexer of calcium and thereby reducing calcium ion concentration and lowering the urinary saturation\(^{19}\). Secondly, citrate also decreases the calcium oxalate aggregation and also expected to reduce urinary osteopontin, which is the important component of urinary calculi. Thirdly, it increases urinary pH which is important factor for crystallization and uric acid stone formation\(^{19}\).

Ostberg (1931),Boothby and Adam,(1932), Kissin and Locks (1941), Scott et.al,(1943), Nordin (1963), reported that low levels of urinary citric acid is responsible for the formation of calcium containing renal stones\(^{19}\). Koji Tanaka (1989) also investigated the effects of citric acid on retained plaque and calculus of partly scaled root surface\(^{20}\). The result of the study shows that citric acid removes all debris and bacteria and decalcifies the superficial layers of residual calculus when compared with control group.

**Conclusion**

In our study, presence of orthophosphate and Pyrophosphatase in saliva is directly related to the mechanism of dental calcu-lo-genesis either by binding with calcium ions or by competing with pyrophosphate and altering their function based on the theories of calculus formation. Our study also investigated the role of pyrophosphate in saliva with regard to dental calculogenesis and from the interpretation of the results it is proven that pyrophosphate has a stronger inhibitory effect on plaque mineralization.

The aim of the experiment is to find out the role of citric acid in dental calcu-logenesis. Since it is proven inhibitor in renal calculogenesis, the experiment conducted in this regard in our laboratory in our patient indicate that there is a fall in salivary citric acid level in relation to dental calculi formation. However, the fall is not statistically significant. Futher research in large number of cases may indicate the significance and role of citric acid in dental calculogenesis.

ABSTRACT

Introduction: Cadmium (Cd) is an industrial pollutant that affects the human health. The purpose of present study was to investigate the protective role of Beta carotene on cadmium induced brain and kidney damage.

Materials and Method: The present study was conducted following approval from Institutional Bioethical Committee at Kasturba Medical college, Mangalore, MAHE and strict internationally accepted guidelines, for the usage of animals in experimental study were. Rats were divided into four groups with 6 rats in each. The Gr. I rats were administered with the single dose of normal saline intraperitoneally. Group II received Beta carotene (10 mg/kg bw) orally for 30 days. Group III received a single dose of 1 mg/kg bw cadmium chloride and Group IV received Beta carotene for 30 days prior to cadmium administration. After the desired protocol, rats were sacrificed and both the kidneys and brain were removed for biochemical and histopathological evaluation. The levels of lipid peroxides (LPO) and were detected in the tissue homogenates of the brain.

Results: In the present study, the level of lipid peroxidation (LPO) was significantly high (P<0.001) in cadmium treated rats compared to normal control. Pre-treatment with beta carotene showed a protective effect by decreasing LPO (P<0.001). The serum level of urea and BUN was high in cadmium treated rats, Pre-treatment with beta carotene showed a protective effect by decreasing serum urea and BUN. There was significant decrease in the neuronal count in cadmium treated rats and pretreatment with beta carotene showed an increase in neuronal count

Conclusion: Results of the present study showed the antioxidative role of beta carotene in protecting the brain and kidney from cadmium induced toxicity.

Keywords: ROS, Oxidative stress, Antioxidant, Lipid peroxidation, Beta carotene

Introduction

Cadmium is a heavy metal which is extremely toxic. Food and cigarettes are also a significant source of cadmium exposure¹. Blood and kidney Cd levels are consistently higher in smokers than nonsmokers. Inhalation due to industrial exposure can be significant in occupational settings for example, welding or soldering, and can produce severe chemical pneumonitis². Cadmium toxicity has been demonstrated in several organs. Cadmium induces tissue injury through creating oxidative stress³⁴⁵. Cadmium acts as a catalyst in forming reactive oxygen species. It increases lipid peroxidation, in addition it depletes antioxidants, glutathione and protein-bound sulphydryl groups⁶. Hence present study was aimed to study whether pretreatment with beta carotene will be helpful in reducing cadmium induced testicular damage. Prolonged exposure to Cd known to cause toxic effect due to its accumulation over time in a variety of tissues, including kidneys, liver, central

nervous system (CNS), and peripheral neuronal systems. Cd can be uptaken from the nasal mucosa or olfactory pathways into the peripheral and central neurons; for the latter, Cd can increase the blood brain barrier (BBB) permeability. Exposure to Cd also severely affects the function of the nervous system, with symptoms including headache and vertigo, olfactory dysfunction, parkinsonian-like symptoms, slowing of vasomotor functioning, peripheral neuropathy, decreased equilibrium, decreased ability to concentrate, and learning disabilities. As oxidative stress is one of the important mechanisms of cadmium-induced damages, it can be expected that the administration of some antioxidants should be an important therapeutic approach. As Cd pollution is generally widespread, this work aimed to study histologically and biochemically the possible protective role of beta carotene against the Cd induced changes in the brain and kidney of adult male albino rats.

Materials and Method

The present study was conducted following approval from Institutional Bioethical Committee of Kasturba Medical college, Mangalore, MAHE and strict internationally accepted guidelines, for the usage of animals in experimental study were followed. Inbred adult male rats of wistar strain weighing 200-250g were used in the present study. Animals were housed in polypropylene cages (4-5 rats/cage) under standard laboratory conditions and fed ad libitum with commercial rodent chow (Hindustan Lever Limited) and water. Cadmium chloride (CdCl2) (LobaChemie, India) was dissolved in normal saline. Beta carotene is dissolved in coconut oil and administered orally (10mg/kg bw). Animals were divided into four groups of eight rats in each group. In the normal control group (Group I) rats were administered with the normal saline intraperitoneally. In Group-II animals received beta-carotene (10mg/kg bw) for 30 days orally. In untreated experimental control groups (cadmium treated group) rats were administered with single dose of 1mg/kg bw (Group-III) cadmium chloride intraperitoneally. In pretreated groups rats were pretreated with beta carotene (10mg/kg bw) or 30 days orally and then injected with 1mg/kg bw (Group-IV) cadmium chloride intraperitoneally. In all the groups, rats were sacrificed under anesthesia 15 days after the final cadmium administration. Following the completion of the experimental protocol animals in each group were anaesthetized by injecting sodium pentabarbitone (40mg/kg bw) intraperitoneally under aseptic conditions. The brain and kidneys are quickly removed. Blood samples were collected by cardiac puncture and allowed to clot at room temperature and serum samples were separated by centrifugation at 3000rpm. Biochemical estimation of serum urea and Blood Urea Nitrogen were done by commercially available kits using spectrophotometer. Lipid peroxidation of the brain was estimated spectrophotometrically by thiobarbituric reactive substances (TBARS). Brain tissue is also preserved for histochemical analysis. Coronal sections of the formalin fixed specimen of prefrontal cortex and hippocampus which were embedded in form of paraffin blocks were prepared. The sections were stained with cresyl violet and quantitative analysis of neurons were performed under light microscopy (20X). The neurons in the prefrontal cortex, the dentate gyrus along with various hippocampal regions (CA1, CA2, CA3 and CA4) were counted.

Statistical Analysis: The data was expressed as mean ± SD. Analysis was done by using the unpaired t test. Statistical package SPSS version 17.0 was be used to do the analysis. P<0.05 was taken as significant

Results

The results of the present study showed that the levels of blood urea and blood urea nitrogen was significantly high in cadmium treated rats, but their values were significantly lowered in rats treated with beta carotene (Figure 1 & Table -1).

Discussion

Cadmium is widely distributed in the environment because of its many industrial applications. The health risk to humans from acute and chronic cadmium exposure has been well documented. Previously, Mueller (1986) reported that single-dose cadmium administration increased lipid peroxidation and decreased GSH in the liver<sup>12</sup>. Many investigators reported that the reduction of GSH levels leads to elevation of LPO<sup>12</sup>. The results of the present study showed an increase in lipid peroxidation in brain tissue indicating brain damage due oxidative stress by cadmium administration. The decreased neuronal count in the cadmium treated rats also supported the cadmium damage. Results of the present study also reported a increase in blood urea and BUN indicating kidney damage induced by cadmium administration. In the present study, pretreatment with beta carotene prior to cadmium administration showed a significant reduction in the levels of LPO compared to cadmium treated group. Results of our study showed that oral gavage of rats with beta carotene showed a beneficial effect by decreasing kidney damage induced by cadmium. The level of serum urea and BUN was significantly lower in beta carotene rats compared to cadmium injected rats.

Conclusion

In conclusion, present study showed that cadmium has damaging effects on the kidneys and brain and treatment with beta carotene has protective role in attuning cadmium induced kidney and brain damage.

ABSTRACT

Objective: To study the prevalence of bacterial vaginosis among antenatal women.

Design: Hospital based crosssectional study.

Setting: G.G.L. medical college,Rajahmundry. A.P.

Materials and Method: 500 antenatal women were taken at gsl medical college and examined.

Conclusion: Among 500 subjects, 14.4% prevalence of bacterial was found, high prevalence was among rural, uneducated and among low socioeconomic status was found.

Keywords: bacterial vaginosis, prevalence, ses, urban&rural.

Introduction

Bacterial vaginosis (BV) is a condition in which the normal, lactobacillus-predominant vaginal flora is replaced with anaerobic bacteria, gardnerella vaginalis, and mycoplasma hominis (Bacterial vaginosis has been associated with missed abortion, premature rupture of membranes, preterm delivery, intrauterine growth retardation, infection of the chorion and amnion, histologic chorioamnionitis, infection of amniotic fluid. Anaerobic Gram-negative rods, G.vaginalis, and M. hominis, have been linked to above complications. BV is detected by Gram stain (Nugent criteria) and accepted Gold standard criteria (Amsel’s composite criteria).

This suggests that it may be possible to prevent above complications by early detection and treatment for bacterial vaginosis and eradicating it early in pregnancy.

Background

Bacterial vaginosis is a common cause of abnormal vaginal discharge in a woman of reproductive age group. Until 1950’s the term bacterial vaginosis was referred to as ‘non-specific vaginitis’ because no causative organism was identified. In 1954, Gardener and Dukes proposed that this condition was caused by a bacteria,Hemophilus Vaginalis.. In 1963, this bacteria was reclassified and renamed as Corynebacterium vaginalis. In 1984, the term “BACTERIAL VAGINOSIS” was proposed to reflect the polymicrobial alteration in vaginal flora causing an increase in vaginal PH and sometimes associated with homogenous discharge but in the absence of demonstrable inflammatory response. Then onwards this conditions was called BACTERIAL VAGINOSIS. At the same time the diagnostic criteria determined by Amsel et al based on aggregate clinical findings were evaluated and accepted as the “Gold standard” for detecting the condition1.

The vaginal lining is composed of non-keratinized stratified squamous epithelium and underlying lamina propria. Below this there is a muscular layer, which consists of smooth muscle, collagen, and elastin. Beneath this muscularis lies an adventitial layer consisting of collagen and elastin (Weber and Walters, 1997). There are no vaginal glands. Instead, the vagina is lubricated
by a transudate that originates from the vaginal subepithelial capillary plexus and crosses the permeable epithelial layer (Gorodeski, 2005). Due to increased vascularity during pregnancy, vaginal secretions are notably increased. At times, this may be confused with amniotic fluid leakage.

During pregnancy the amount of glycogen is increased to maximum and the acidity of vagina is high [pH: 3.5-4.5]. During pregnancy there is copious, acidic vaginal secretion which normally consists of a curd-like product of exfoliated epithelium and bacteria. Lactobacilli species are removed from most pregnant women in higher concentrations than in non-pregnant women. These are the predominant bacteria of the vagina during pregnancy. During the puerperium and also in cases of leucorrhoea the acidity of the vagina is reduced and pathogenic organisms are then able to survive. After the menopause the epithelium atrophies and loses its glycogen. Doderlein’s bacilli are found in few numbers and the pH rises to a range of 6-8. Bacterial vaginosis involves an imbalance in the vaginal bacterial ecosystem, such that hydrogen peroxide producing lactobacilli are diminished and Gardnerella vaginalis, anaerobic gram-negative rods belonging to the genera Prevotella, Porphyromonas and Bacteroides and peptostreptococci, mycoplasma hominis and mobiluncus species are increased. Bacterial vaginosis is characterised by high concentrations (108-1011 CFU/gm of fluid) of G. vaginalis and a set of pathogenic microorganisms like Prevotella species, Peptostreptococcus species, Porphyromas species and Mobiluncus species. Species of lactobacilli are decreased in number or absent in bacterial vaginosis.

The changes in bacterial vaginosis include elevated pH, increased vaginal fluid concentrations of diamines, polyamines, organic acids and enzymes such as mucinases, sialidases, IgA protease, collagenases and non-specific proteases, phospholipase A2 and C, endotoxin, cytokines. PGE2, interleukin-1alpha and PGF2 alpha are also increased in presence of bacterial vaginosis. During pregnancy phospholipase A2 act on cervical mucus and non-specific proteases act on cervical and amniochorionic connective tissue and promotes the cervical ripening. It causes focal amniochorionic weakening. In addition phospholipases promotes the release of prostaglandin by activating arachidonic acid and leads to preterm birth.

The vaginal secretion in bacterial vaginosis is characterised by fishy odour. This is the basis for the Whiff test or KOH test.

**Predisposing Risk Factors**
- sexually active
- new sexual partner
- intrauterine device (IUD) use
- women who have sex with women
- smoking
- douching
- may occur without having sexual contact

In several large, prospective, longitudinal studies, the rate of bacterial vaginosis has ranged from 9% to 23%. BV has been studied most widely among women attending publically supported STD clinics, family planning and obstetrical clinics. Women seen in STD clinics have the highest prevalence of BV ranging up to 64%. In pregnant women, studies have documented similar prevalence rates to those seen in non-pregnant populations, ranging from 6% to 32%. BV has been linked to a number of obstetrical complications including spontaneous abortion, preterm labour, PPROM, chorioamnionitis and postpartum endometritis. Eschenbach et al and gravett et al were the first to implicate BV as a risk factor for preterm labour and low birth weight. The presence of BV in the mid trimester with a mean gestation of 32.6 weeks has been associated with increased risk for preterm labour and preterm PROM. PPROM accounts for 30% of spontaneous preterm labour and is associated with increased risk of preterm labor, intrauterine infections, neonatal morbidity and mortality. Cary J.C et al found that risk of preterm rupture of membranes, preterm labour and low birth weight was associated with T. vaginalis, M. hominis and Bacterial vaginosis.

**Diagnosis of Bacterial Vaginosis**

Various methods are available for the diagnosis of BV. These include culture, wet and dry microscopy, biochemical tests (gas-liquid chromatography) for metabolic by-products of vaginal bacteria, oligonucleotide probe-based hybridization for G. vaginalis, multiplex polymerase chain reaction for the identification of BV associated organisms, redox potential, and rapid or office tests. However the costs and complexity of some methods have restricted them for research purposes and not for routine diagnosis of BV.
Objectives

1. To study the prevalence of bacterial vaginosis among pregnant women.
2. To know the association of bacterial vaginosis with socio-demographic profile.

Materials and Method

Type of Study: Hospital based crosssectional study.

Place of Study: G.S.L. medical college, Rajahmundry A.P.

Study Population: All antenatal women attending to gynaecology op satisfying the inclusion criteria.

Duration of the Study: 1st December 2012 to 31st May 2014.(2 yrs 6 months).

Inclusion Criteria: All antenatal women attending gynaecological o.p.

Exclusion Criteria: 1. Women in active labour
2. History of leaking per vaginum
3. Bleeding per vaginum
4. Antibiotic therapy in last one month

Data Collection Procedure: After obtaining Clearance from the Institutional Ethical Committee, the Data was collected by using a predesigned & pretested schedule which includes, a detailed history was taken regarding age, parity, period of gestation in weeks, medical history, history of vaginal symptoms like vaginal discharge, malodour, obstetric history of previous preterm deliveries, abortions, history of leak PV in the present pregnancy. Gestation age was calculated from first day of the last menstrual period and was confirmed by ultrasound examination.

Baseline parameters like pulse, BP, temperature were recorded. Weight and height of the patient were recorded. Presence of pallor, and pedal edema was noted. Cardiovascular and respiratory systems were examined.

Abdominal examination was performed to see height of uterus, presentation, position, lie of fetus, liquor volume, and fetal heart sounds were recorded. Speculum examination was done and any discharge and leak were noted. Length, position, dilatation of cervix, presence or absence of membranes were noted.

The vaginal pH was measured using pH strips. Cotton swabs were used to obtain the vaginal discharge from posterior vaginal fornix and smear was done on a slide. Amine test was done to know the presence or absence of amine odour by addition of 10% KOH for the characteristic fishy smell, also known as Whiff test. Smear was Gram stained and scores for BV as proposed by Nugent et al were assigned.

Data Analysis: Microsoft excels 2010 will be used for data entry, generating charts & diagrams, etc. Data analysis will be done by SPSS V 20 software. Data analysis will be done by applying Chi-square tests. P-value less than 0.05 will be considered as statistically significant. The results will be presented in the form of charts & tables and graphs.

Results

A total of 500 antenatal women participated in the study. Among them 14.4% (72) were diagnosed as Bacterial Vaginosis positive. The Prevalence of the Bacterial vaginosis (BV) was 14.4%.

Among study subjects,53(14.3%) were positive for bacterial vaginosis from rural area fallowed by 19(13.6%) were positive from urban area.

The association between area wise and bacterial vaginosis was found to be statistically significant.

**Discussion**

The Prevalence of the Bacterial vaginosis (BV) is 14.4%.

In Asia, the prevalence of BV during pregnancy is 13.6% in Japan and reported prevalence in Thailand is about 15.9%. The reported prevalence in pregnant women ranges from 14% to 21% in Western countries which are comparable to present study 8. In Iran 9 the prevalence of bacterial vaginosis (BV) ranges from 4 to 64%, depending on the racial, geographic and clinical characteristics of the study population.

In the United States, the National Health and Nutrition Examination Survey (NHANES)10, which included results from self-collected vaginal swabs from over 3700 women, estimated the prevalence of BV was 29 percent in the general population of women aged 14 to 49 years and 50 percent in African-American women,
where as in the present study most (70) of the study population diagnosed with BV belongs to 17-32 years of age group.

In this study bacterial vaginosis is more common in rural population 53 out of 72 women(73.6%) rather than urban population as most of the patients are from rural area. where as in a study conducted by Aggarwal et al 11 from Haryana, India, bacterial vaginosis was diagnosed in a high percentage (48.5%) of rural women which is quite low percentage when compared with our study.

In this study, bacterial vaginosis is more common in low socio-economic group(61.1%) compared to middle and upper class, Where as in a study conducted by Mariam Anjum et al 12 majority of the women suffering from bacterial vaginosis were of low socioeconomic class and the difference was found to be statistically significant (Table 2).

In this study bacterial vaginosis is seen in 32 (44.4%) cases of educated women as most of them have got primary education and 40(55.6%) women were uneducated, this is difference is found to be statistically significant (Table 3). This low incidence among educated women may be due to their good hygiene practices. But in a study conducted by Ibrahim et al 13 women who got primary education were more 37 (54%) out of 54 women and uneducated were 17(25%)out of 54 patients which was not in concurrence with our study.

**Summary & Conclusions**

A total of 500 antenatal women participated in the study. Among them 14.4% (72) were diagnosed as Bacterial Vaginosis positive. The Prevalence of the Bacterial vaginosis (BV) is 14.4% in our study. Prevalence of BV decreased with increasing age in the present study. Prevalence of BV is more in women belonging to low socio economic status in present study. Prevalence of BV is more in uneducated women. Prevalence of BV is more in women belonging to rural area when compared to urban area.

A Preliminary Study on Prevalence of Certain Risk Factors for Non-Communicable Diseases in a Rural Population of Karnataka, India

Sachidananda K1, Nanjesh Kumar2, Shahul Hammed3, Kurulkar P1, Ullal Sheetal D4

1Assistant Professor, Department of Community Medicine, A J Institute of Medical Sciences, Kuntikana, Mangalore; 2Associate Professor, Department of Community Medicine, K S Hegde Medical Academy, Mangalore; 3Associate Professor, Department of Community Medicine, Kanachur Institute of Medical Sciences, Mangalore; 4Associate Professor, Department of Pharmacology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education

ABSTRACT

Background: In India the burden of non-communicable diseases (NCDs) has overtaken that of communicable diseases. Since two-thirds of India’s population continues to live in rural areas which have limited health-care resources, studying the prevalence of non-communicable diseases and their risk factors in rural areas should take precedence in order to evolve a better health-care system.

Objective: To study the prevalence of certain risk factors for NCDs in a rural population.

Method: A detailed survey was conducted among adults above 25 years at Alike village in Karnataka. Information on behavioural risk factors like tobacco use, alcohol intake, physical activity and family history of hypertension, diabetes, ischaemic heart disease and stroke were recorded. Blood pressure was measured, BMI was calculated and categorised according to the Consensus Statement for Diagnosis of Obesity, Abdominal obesity and Metabolic Syndrome for Asian Indians. Descriptive analyses was done using SPSS version 21.0.

Results: The mean (± SD) age of the population was 50.9 years (± 11.4). 678 adults were surveyed of which 35.5% had a family history of either hypertension, diabetes, IHD or stroke. Current tobacco use (smoke or smokeless) was prevalent among 34.2% and alcohol intake was 10.3%. The prevalence of inadequate physical activity was 65.8%. One hundred and thirty eight (20.4%) subjects were underweight, 103 (15.2%) were overweight and 133 (19.6%) were obese. The prevalence of high blood pressure was 41.8%.

Conclusion: There is a high prevalence of risk factors for NCDs in this rural community. This necessitates the targeting of modifiable risk factors by improving awareness in the rural community.

Keywords: Non communicable diseases, rural, prevalence

Introduction

It is well established that non-communicable diseases (NCDs) are the leading cause of death in the world, responsible for 40 million of the 56 million global deaths that occurred in 2015. Almost half of these deaths (48%) in low and middle income countries were considered premature1. An estimated 80% of premature cardiovascular diseases and diabetes are preventable, if the risk factors are contained in time1. The burden of NCDs has overtaken that of communicable diseases in a developing country like India as well. In India, NCDs...
especially cardiovascular disease, cancer and type 2 diabetes mellitus, accounted for an estimated 63 per cent of all deaths in 2016, while the risk of premature deaths (before 70 years) is 23% (27% for males and 20% for females). Most of these NCDs share common risk factors such as family history, unhealthy diet, tobacco use, harmful alcohol intake, inadequate physical activity, obesity/overweight, high blood pressure and dyslipidemia. The behavioural risk factor of inadequate physical activity is at the highest at 33% among Indians of all age groups. Primordial prevention of occurrence of risk factors along with their early identification and management can help delay the progress of NCDs.

Since two-thirds of India’s population continues to live in rural areas which have limited health care resources, studying the prevalence of NCDs and their risk factors in rural areas should take precedence in order to evolve a better health care system. Substantial success can be achieved in reducing the modifiable risk factors like tobacco use, harmful alcohol intake, inadequate physical activity and unhealthy diet, simply by creating awareness. There have been few studies conducted in rural areas of Dakshina Kannada district hence this project was undertaken to study the proportion of certain risk factors of NCDs.

Method

A survey was conducted among adults above the age of 25 years at Alike village in Bantval taluk of Dakshina Kannada district in Karnataka. Alike village is located about 45km from the nearest city, Mangaluru. According to 2011 census, the population of Alike is 5840, of which 3206 are males while 2634 are females. Sample size was calculated based on the prevalence of hypertension in rural Tamil Nadu, with a 95% confidence interval, a power of 85% and a non-response rate of 20%, the sample size was calculated as 670. Convenient sampling was done to conduct the survey. Institutional ethics committee clearance was obtained. A written informed consent was obtained from each participant.

Information on behavioral risk factors like current tobacco use, alcohol intake, physical activity was collected using a preformed case record form. Any form of tobacco or alcohol use was considered as an NCD risk factor. Inadequate physical activity was defined as <150 minutes of moderate physical activity per week. Detailed history was also taken with regards to the participants’ current NCD status and concurrent medication for these conditions, if any. Data of family history of diabetes, hypertension, ischemic heart disease (IHD), and stroke were also recorded by interviewing the participants.

Height was measured using a portable stadiometer and weight was measured using a digital weighing scale. Body Mass Index (BMI) was calculated as weight in kilograms divided by height in meters squared and was categorised according to the Consensus Statement for Diagnosis of Obesity, Abdominal obesity and the Metabolic Syndrome for Asian Indians. Accordingly overweight was defined as BMI between 23–25.9 kg/m² and obesity as ≥25 kg/m².

Blood pressure was measured on the left arm using a mercury sphygmomanometer in the sitting position. A second recording was taken for participants who had a systolic blood pressure reading of more than 120mmHg and/or a diastolic blood pressure of more than 80mmHg. Hypertension was defined as a systolic blood pressure of ≥140 mm of Hg, or a diastolic blood pressure of ≥90 mm of Hg or the use of blood pressure-lowering medications for hypertension.

Descriptive analyses of the data was done using SPSS version 21.0. The results of the measurement were provided to each subject and those who required referral were referred to the primary health centre.

Results

A total of 678 individuals (48.4% men, 52.6% women) above 25 years participated in the study. The mean (± SD) age of the participants was 50.89 years (± 11.35) and the majority 71.7% (n=486) were between 36 to 60 years. One hundred and fifty five (22.9%) were illiterate and 523 (77.1%) had some formal education.

The details of certain NCD risk factors detected during the study are shown in table 1. Current use of tobacco was prevalent in 34.2% of the participants. Among the tobacco users 65.9% (n=153) were men and 34.5% (n=79) were women and among men 46.6% used tobacco and among women 22.6% used tobacco. Most of the women (95.5%) used smokeless form of tobacco.

94.3% (n=66) of the alcohol users were men. Inadequate physical activity was disclosed by almost 19% of the participants. Family history of either diabetes, hypertension or ischaemic heart disease/stroke was present in 35.5% participants.

Discussion

Our results showed a high burden of NCD risk factors in the study population belonging to rural coastal Karnataka.

Family history of NCDs was prevalent in 35.5% of the subjects. Very few investigators have studied the family history of NCDs as one of the risk factors for NCDs. Though it is a non-modifiable risk factor, individuals with a family history could be targeted early to modify their behavioural risk factors. Moreover, this subgroup of the population can be expected to be more receptive for preventive measures.

Behavioural risk factors: More than one-third (34.2%) of the participants used tobacco daily, which is similar to (32.5%) the daily average use of tobacco in rural India⁴. Almost 47% men and 23% women were daily users of tobacco which is again similar to the national average⁵. Smokeless form was used by double the number of individuals compared to smoke form of tobacco. In women the smokeless form was predominant (95.5%). This could be because chewing and snuffing tobacco is socially acceptable among local women, but smoking is not. In a study conducted in Shimoga district of Karnataka which only assessed smoked form of tobacco use, 63% of men were current smokers and 58% were current daily smokers; while less than 1% of women
A study conducted in and around Chennai found the prevalence of overall tobacco use in rural areas to be 23.7% and that of tobacco smoking to be 14.3%. In another study the prevalence of overall tobacco use in rural areas of Punjab was only 11.2%, much lower than the present study. The prevalence of inadequate physical activity at 19% was three times more than that in a previous study conducted in Trivandrum district. In another study conducted in Gandhinagar, Gujarat lack of physical activity was observed in 14.2% of the rural population. The prevalence of inadequate physical activity in India appears to vary regionally. However, in general, the overall prevalence is very high for a rural area where we assume people to be physically active. The reason for this finding could be an improvement in the transport system, availability of automated farming practises and lack of awareness of the importance of physical activity.

Overweight and/or obesity was observed in 35% of the participants which is overwhelmingly high for a rural population by Indian standards. The study conducted by Aroor et al observed a prevalence of overweight only among 11.9% of the rural population. The survey in rural Punjab reported the total prevalence of overweight and obesity as 38%, this despite following the WHO classification of BMI which considers BMI > 25.5 as overweight and >30 as obesity, whereas we followed the Consensus Statement for Diagnosis of Obesity, Abdominal obesity and the Metabolic Syndrome for Asian Indians according to which BMI > 23 is considered as overweight.

Prevalence of hypertension was 41.8% which too is high compared to WHO’s overall estimated Indian prevalence. A very similar prevalence was found in rural Punjab. In a study conducted among tribal labourers in Gujarat the magnitude of hypertension was found to be 16.9%. The proportion of patients with self-reported hypertension was only 19.3, which suggests that hypertension is largely undiagnosed.

The proportion of some selected NCDs (diabetes, hypertension, ischaemic heart disease and stroke) based on self-reporting was 26.5%.

This alarmingly high proportion of patients with already proven NCDs, obesity, low physical activity and tobacco use in a rural population calls for an immediate attention towards the health status of this population. Our study has a few limitations: in depth assessment of behavioural risk factors, including tobacco use, and the reasons behind such a high prevalence of the risk factors of NCDs could not be addressed.

**Conclusion**

NCD risk factors studied in this rural population are considerably high. This necessitates the targeting of modifiable risk factors by improving health promotion activities and easily accessible early diagnosis and treatment facility in rural areas.

Perspectives on Mental and Physical Distress and School Counselling Based Interventions for Sexually Abused Adolescents

Saleena M.1, Suja M. K.2
1PhD Scholar; 2Thesis Advisor and Chairperson, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

ABSTRACT

Adolescence is a stage in life for acquiring new skills, attaining mastery over environment, adapting to handle new responsibilities and gaining control over one’s emotions and thoughts. It is believed that emotional difficulties may clear up completely only with adequate support. At present abusive and violent behavior by adolescents is increasing due to pressures from various walks of life.

In the case of children who are sexually abused, children as young as 3 years of age are the victims. Sexual abuse of school going children is an area that was until recently neglected. The victims continue to be victimized in the process of getting justice. Victim blaming is the norm of most societies. Sexually abused children face many mental and physical problems. In depth study of the child sexual abuse cases and its intervention strategies is the need of the hour. The researcher’s experience during the last 8 years as a school counsellor in the School Counselling Centre of Psycho Social Service Scheme for Adolescence, Department of Women and Child development, Government of Kerala has made her understand the importance of counselling in schools as the key element to prevent child sexual abuse and provide protection and care to the victims. This case study is from the eight years experience of the researcher as a school counsellor.

Aim: The aim of the study was to understand the mental and physical problems undergone by the sexually abused children and the interventions provided by the school counsellor. Sexually abused children face so many physical problems and mental health problems. The researcher understood that they show sleep disturbances, sudden behavioural changes, emotional distress, fear of loneliness, social withdrawal, depression, suicidal tendencies and suicide ideation, anxiety, clingingness, running away and lack of concentration in studies. It was noticed that some abused children wait for over a year to reveal their problems due to fear and shame. School counselling has been of great support to many students who suffer from emotional and physical disturbances, due to sexual abuse.

Keywords: Adolescents, Sexual abuse, Mental distress, physical distress, school counselling, intervention.

Introduction

Estimating the prevalence of child sexual abuse has been difficult because many of the cases go unreported. In a study by The National Society for the Prevention of Cruelty to Children (NSPCC), 2010, it is said that around a quarter of young adults who were subjected to sexual abuse (either contact or non-contact) during their childhood was by an adult person or by a peer. The Girls are higher risk than boys of being abused by a family member and while strangers abuse boys more than girls.

Neglected children and children who do not have many friends are targeted by abusers because they are more likely to get attracted to the attention shown by the abuser. Children with disabilities are three times more vulnerable than normal children. Alexander in the year 2011 explains how sexual abuse cause years of negative impacts on the victims and says sexual abuse is a “chronic neurologic disease”. Around 40% of the victims of sexual abuse don’t show long-term negative consequences. The after effect of abuse include depression, eating disorders, post-traumatic stress disorder and very low ability to cope with emotions and stress.

Social justice department of Kerala (2008) has been implementing psychosocial services for adolescent girls for addressing the issues faced by adolescence. The project is called as psychosocial service scheme for adolescent girls. Earlier it was known as school counselling scheme.
for adolescent girls. The project started in 2008 as part of ‘KishoriShaktiYojana’, an already existing project under Ministry of Family and Child Welfare, Government of India. Later, the school counselling project was undertaken by Social Justice Department, Kerala and continued as the Psychosocial Counselling Service for adolescent girls till 2013. The project was implemented in 163 schools earlier and now extended to 1000 schools throughout Kerala. In 2013 the scheme was again redesigned and service is extended at the community level through schools and Anganwadies. Now the project is known as Psycho Social Service Scheme for Adolescent Girls and is under the Department of women child development, Government of Kerala. The main objectives of the project are; to provide social and psychological support to adolescent girls in the community, to undertake activities to enrich and empower adolescents through life skill training and another community based programs, to mobilize and support community based responses on identifying social disintegrating factors that affect development of adolescents, to spread among adolescents about physical mental and social health, to address gender related issues of adolescents.

In this study adolescent means, the children in the age group of 10-19 years those who are studying in the school. Sexual abuse is inappropriate sexual behaviour with a child. It includes fondling a child’s genitals, making the child fondle an adult’s genitals, sexual assault (intercourse, incest, rape, sodomy), exhibitionism and pornography. To be considered child abuse, these acts have to be committed by a person responsible for the care of a child or related to the child (for example a baby-sitter, parent, neighbour, relatives, extended family member, peer, older child, friend, stranger, or a day-care provider).

The mental stress and the physical or biological difficulties that is faced by the children who have undergone physical or sexual violence is deep and negative. School counselling is the services given to students to promote their holistic development. It provides on-going prevention and offers personal counselling to students. In this study intervention means to intentionally become involved in a difficult situation in order to improve it or prevent it from getting worse.

**Methodology**

The present study was conducted in a school counselling center of Kerala. Case histories of 27 sexually abused children during the period February 2009 to December 2017 at school counselling centre was used for the analysis of this study. School counselling centre is a project under the psychosocial service scheme of the department of women and child development, Kerala government. Case study design and detailed explanatory method was used for knowing more about the mental and physical distress of victims and also about the interventions by school counsellor. Six case studies are presented here:

**Case Study 1:** Twelve year girl from middle class family, studying in 7th standard was noticed to be inactive, sitting alone and was unable to concentrate in her studies. The class teacher referred her to school counselling centre. The girl emotionally complained about her father’s misbehavior. Her father was using alcohol and other narcotic substances. He always quarreled with her mother. She was molested inside her home. He forced the child to take part in sexual activity. Once when her mother had gone outside and she was alone at home, her father came and forcibly showed her pornographic videos. All of a sudden he hugged her and started to kiss her. While she was struggling to escape, her father forcefully pushed her on to the bed. She told that she would inform the incident to her mother. Then the father said that if she shared the incident with anybody, he would commit suicide. The same pattern continued and she did not inform to anybody because of fear.

**Intervention by school counsellor:** Counsellor provided psycho social support to the child. Counsellor believed the child and gave reassurance to her and explained about the existence of legal, family and social support system. She listen carefully and had concerns associated with disclosure.

The counsellor through ‘family intervention’ provided counselling to her mother and close family members. Counsellor called the father. Initially he denied all the allegation raised by his daughter. After giving clear picture about the laws, he told the truth. The counsellor tried to refer him to an expert psychologist. But he didn’t cooperate. Very next day girl came to the counselling centre and informed that her father verbally harassed and made up arum or that she had a love affair with a boy. She felt helpless about the situation. Mental harassment of father increased day to day.

The girl was able to get a safe place shelter with her maternal grandmother living alone in their ancestral home. She decided to stay with her grandmother.
Counsellor gave parental counselling to grandmother. Legal Support: with the permission of school Headmistress and family members, Counsellor and girl reported all these to district child welfare committee. Then the Police arrested the father. After that the school counsellor had regular follow up of the girl. The girl became very assertive and came to school very happily and was focusing in her studies.

**Case Study 2:** This is a case of a 13-year-old, mentally challenged student studying in 8th standard who was sexually abused by her neighbour. She reported the incident to school counsellor. She cried and told that she felt pain in private part. After talking with her, counsellor identified that several times this man exhibited his sexual organs in front of her. On the way to school, he caught and raped the girl. Her private parts were wounded.

**Intervention by school counsellor:** Counselling provided emotional support to her. Counsellor immediately informed Head mistress and her parents and referred the child for medical examination with her parents. Counsellor explained the legal aspects to parents and they were willing to seek legal support. Counsellor reported the case to child line with the permission of school authority. They filed the case and the accused man was arrested. Through continuous follow up counsellor provided mental support to girl and taught her to become assertive.

**Case Study 3:** A group of girls studying in 9th and 10th standard came to counselling centre and complained that one male teacher unnecessarily touches their bodies and gave some medicine. He told that the medicine helps to improve their beauty. At the pretext of providing Reiki therapy to girls, he touched their body parts and always looked at them in an indecent manner. The teacher was also touching the students inappropriately as a part of physical punishment for bad behavior. The students were afraid when sitting in his class. They tried to avoid that teacher’s class by using various excuses.

**Intervention by School Counsellor:** School counsellor documented all the incidents with the signature of girls and informed the school authorities. The complaint against the teacher for misbehavior towards the students was taken up very seriously. According to the school counsellor’s decision, the Headmistress warned the teacher and advised him to behave properly. After some time the girls complained that the teacher have reverted to his old behavior. Counsellor informed it to school authorities and school management committee with the permission of students and their parents.

Counsellor taught assertiveness to girls and gave an insight to legal and social support for them. Students themselves reported all the incidents to child line. Then police came to school and an FIR was filed. Teacher (abuser) got punishment transfer from the education department. After that issue some staff members showed negative attitude towards the school counsellor and the students who had complained. With the help of parent teachers association, Principal and Headmistress the counsellor conducted a training for teachers by inviting an expert resource person. After participating in the training, the teachers were sensitized about how to behave well with the students. They got thorough knowledge about The Protection Of Children from Sexual Offences Act (POCSO Act) 2012 and this brought a positive change in the knowledge, attitude and behaviour of the teacher’s towards students.

**Case Study 4:** Sixteen year old girl, studying in plus two showed school refusal. When she came to school, she always had breathing difficulty and complained that she had headache and stomach pain. The girl was brought to counselling center because she fainted during class. During the counselling session, she emotionally expressed that her uncle misbehaves with her. She was sexually abused by him for the last one year. The girl disclosed this to her mother who ignored it. After this the girl felt insecure and showed the above mentioned symptoms.

**Intervention by school counsellor:** Counselling and reassurance to child was provided. Counsellor called her parents and gave them awareness on the mental status of child and the legal aspects of that incident. Counsellor reported it to police with permission of child. Police and respective authorities have taken necessary action towards the uncle. Through several follow up sessions the child came back to the normal state and concentrated on her studies. Parents also became supportive.

**Case Study 5:** 15 year old boy studying in tenth standard had problems in interacting with others. He was also facing difficulty to answer questions raised in class. He showed poor performance in other extra curricular activities and had very few friends. His mother reported that her son was an introvert. Through counselling sessions he told that once his neighbour lady tried to
hug him and touch his private part. He became so scared and escaped from there. After this incident he couldn’t concentrate in studies and became anxious about future.

**Intervention by school counsellor:** Counselling was given by school counsellor, she also provided awareness about the situation which the child faced. Counsellor provided insight therapy, assertiveness training and methods to cope with stress. After several sessions of counselling the boy became better in personal and academic life.

**Case Study 6:** One night a twelve year old girl was sexually abused by her 15 year old relative. After that incident he always tempted her to have sex with him. Gradually she was interested in this activity and was sexually used many times by her relative with her permission. She was in a fantasy world and she told all these experiences to her friends with great interest.

**Intervention by counselor:** Counselling was provided to her and created awareness about the consequences of her acts. With her permission counsellor called her mother and gave an insight about her daughter’s situation. The mother positively cooperated with counsellor. After that the counsellor met her relative boy and also provided counselling to him. Through several sittings they positively changed their risky behavior.

**Major Findings:** The study reveals that there are high levels of mental and physical health problems seen in the victims of abuse. This has affected the adjustment and coping behavior of children with their peer groups. These children also show introvert nature and least interest in studies and other school activities.

Out of the 27 victims, 12 victims faced sexual abuse from their relatives, 9 faced from outside people, 4 from their own teachers and 2 from their peer group. This statistics shows the insecurity of children within the family itself. Lack of sex education and the lack of awareness about safe touch and unsafe touch are the main reasons that these children are victimised. The abuse is seen more in children coming from a poor socio economic background and where parental care is less. Here school counselling services promote the holistic development of students by providing ongoing prevention and intervention services and offering personal counselling to students, parents, teachers and significant others.

From the case studies researcher understood that sexually abused children show sleep disturbances, sudden behavioural changes like withdrawal. They also have feeling of insecurity, emotional distress, fear of loneliness, social withdrawal, violence in class room, depression, suicidal ideation, self harm, anxiety, clingingness, phobia, eating disorder, soma to form disorder, running away, lack of concentration in studies and exam fear, post traumatic stress disorder, behavior problems, sexual anxiety and risky sexual behavior. Male victims show more anti social behavior and use drugs and alcohol for coping previous traumatic memories and emotional problems.

The victims show many physical disturbances like breathing difficulty, headache and stomach pain. In many cases urinary infection and injuries to reproductive parts are also seen. Childhood and adolescent sexual abuse is associated with negative mental and physical health outcomes. It is also seen that some abused children wait for over a year to reveal their problems due to lack of awareness and fear.

School counsellor have a vital role in child sexual abuse cases. Individual counselling has been of great impact on many students who suffer from emotional disturbances. Students say that the greatest benefit of counselling is the chance “to get things off their chest” and understanding that they themselves have the ability to change their lives for better. Many students who responded to the researcher said it was as if a “weight had been lifted.” Parents and children said that counselling made them feel “less alone.” School counselling had changed the way they looked at Sexual Abuse they were able to walk away from disturbed situation and start their life again. Many teachers and parents were satisfied with school counselling programme as they have a facility to offer a quick professional response to distressed students. The school counsellor provides crucial support to students who cannot access help in any other way. In child sexual abuse cases school counsellor provides emotional support, family interventions, legal supports and referral to the victims and their families. School counsellor also provides individual counselling, group counselling, awareness classes, training programmes to parents, children and teachers.

**Discussion and Conclusion**

Issues of child sexual abuse are gaining importance because of the increase in the number of cases reported.
School counsellor have vital role in child sexual abuse cases. Children from low economic background and mentally challenged are more prone to CSA. Reporting of cases from girls is higher than boys. Sexually abused children have several psychological, physical and emotional ill effects. School counselling and interventions provide the abused child and their parents with a ‘safety net’ where they can voice their fear and concerns without being judged. It also helps children to regain their mental stability and work towards better future.

Assessment of Oral Health Status and Comparative Evaluation of Different Methods of Oral Health Education in Children with Special Health Care Needs

Supriya A.1, Rekha Shenoy2, Praveen Jodalll3, Laxminarayan Sonde3, Imran Pasha4
1Post Graduate Student, 2Professor & Head, 3Reader, 4Senior Lecturer, Department of Public Health Dentistry, Yenepoya Dental College, Mangalore, Karnataka, India

ABSTRACT

Introduction: Oral health is an important aspect of health for all children, and is all the more important for children with special health needs because, severity of medical conditions and perceived general health are significantly associated with dental health status.

Methodology: It is a non-randomised intervention study conducted among 510 children with special health care needs aged 7-18 years attending 5 special schools in Mangalore city. The oral health status among these children was assessed using the OHI-S (1964) at baseline, midway and at the end of 9th month of the intervention. The oral health education continued every month till the 9th month of the study.

Results: In the present study it has been observed that majority of the children had fair oral hygiene i.e 69.4% in the baseline, which increased to 70.0% in the mid intervention period which further increased to 70.6% at the end of 9th month.

Conclusion: The children who received training to brush their teeth with the help of pictures showed slight improvement in their mean OHI-S scores (2.27 to 2.22) at the end of 9th month.

Keywords: Oral health, toothbrushing, health education, special health care needs, Audio-visual

Introduction

Oral health is an important aspect of overall health, which contributes to each individual’s physical and mental well-being, appearance, and interpersonal relations.1 Oral health is not only limited to healthy teeth, but also healthy gums are also equally considerable, as they can have a major impact on people's daily activities as they experience pain, distress and also cause difficulties with eating, as well as in socializing.2

In India, children comprise 40% of the rapidly growing population, but the provision of health care, especially dental health services is poor and dental health services at rural schools are almost nonexistent. Children with Special Healthcare Needs (SHCN) constitute a high-risk group; hence, their health is of significance for the overall improvement of the society. Children with SHCN have considerable oral pathologies because of disability itself, other medical, economic or social reasons and or incapability of caretakers to carry out proper daily oral hygiene.(e.g.,cariogenic effect of medicines with high sugar content, bruxism). Disabilities could be physical, mental, or social. The Maternal and Child Health Bureau (MCHB) has defined children and adolescents with SHCN as those “who have or are at increased risk for a chronic physical, developmental, behavioural, or emotional condition and who require health and related services of a type or amount beyond that required by children generally.”3 Children with special health care needs may have great limitations in oral hygiene performance due to defect in coordination, sensorium and intellect, and so are prone to poor oral health2 Developmental disabilities may be
due to a variety of conditions like cerebral palsy, Down’s syndrome, mental retardation, autism, seizure disorders, hearing and visual impairments, congenital defects and intellectual deprivation. It has been reported that some of the common dental problems such as caries and periodontal diseases has higher prevalence among people with special needs when compared with normal people of same age, due to accumulation of bacterial plaque, and also genetics, muscular and nutritional disturbances were also considered to influence the cause. This group of individuals may also not understand or show interest towards preventive oral health practices.

Since children with disabilities frequently experience heavy plaque accumulation, controlling dental plaque in these individuals is an important issue in preventive healthcare programs. It is well known that toothbrushing is the principal, simple and effective method for reducing levels of plaque/gingivitis, and controlling and preventing periodontal disease; it is a behaviour that should be inculcated quite early, during the primary and secondary socialization of the child.

Schools may provide most effective long term oral health education as they offer communication for many years. Dental health education is the first step in the prevention of oral diseases and also helps in equal distribution of oral health services, thus promoting ideas necessary for the improvement of the population’s quality of life.

Therefore this study was designed to assess the oral health status of children with special needs and to compare and evaluate the different methods of oral health education in improving the oral health status of these children.

**Methodology**

A Non-randomised intervention study was conducted among 510 children with special health care needs aged 7-18 years attending 5 special schools in Mangalore city, to assess the oral health status and to compare and evaluate the efficacy of different methods of oral health education for children with special health care needs. The protocol for the study was presented before Yenepoya (Deemed to be) University Ethics. The ethical clearance was obtained on 5/12/2015 with reference number 2015/260. Permission to examine and impart education on oral health to children with special health care needs was obtained from the authorities of the respective special school. Consent was duly obtained from the parents of the study participants. Uncooperative children, Children who were on use of anti-epileptic drugs and children who have systemic diseases like asthma, haemophilia and HIV infection and who are on long term medication were excluded from the study. After obtaining the informed consent from parents and school authorities, the examiner had visited each school every month for a period of 9 months. The demographic details such as name, age and sex of the patient were recorded in the study proforma. The oral hygiene status was assessed using the Simplified Oral Hygiene Index OHI-S (1964). The OHI-S has two components, the Simplified Debris Index (DI-S) and the Simplified Calculus Index (CI-S). The criteria for the debris and calculus indices are shown in Tables 1 and 2. The DI-S and CI-S scores were calculated separately by summing the attributed scores and then dividing the results by the number of examined surfaces. The total sample was divided into 3 groups based on number of children in each school. (170 in each group). On each visit health education was provided as follows:

**Group I:** Audio-visual: In this group, a video of a peer model, filmed while he is demonstrating the brushing technique with audio clip in the language known to the children was be shown in their schools.

**Group II:** Pictorial activity and individual cast instruction: In this group, a sequentially arranged series of laminated pictures demonstrating the tooth brushing technique, was shown to the children and the correct brushing technique was demonstrated on a study cast.

**Group III:** Training special care children to brush their teeth: This group of individuals received acquisition training that included verbal instruction, demonstration and physical assistance.

The oral health status among these children was assessed at midway through the intervention.

The oral health education continued every month till the 9th month of the study. At the end of 9th month, the oral health status was again assessed among the special care children using OHI-S (1964). At the end of the study, a comparison was made between the efficacy of 3 methods of oral health education based on the OHI-S scores.

Statistical Analysis: Data analysis was done using SPSS 22.0 (Statistical Package for Social Sciences). Descriptive statistics were used for the analysis of data and distribution of study variables. Chi square test was used to find the association between the OHI-S scores and the video, pictorial activity and individual instruction group. The level of significance was set at p< 0.001.

Results

The present study was conducted to assess the oral health status and to compare and evaluate the efficacy of different methods of oral health education among 510 children with special health care needs in Mangalore. The mean age of the participants in the video group, picture group and individual instruction group were 13.63 ± 2.64, 12.89 ± 2.64 and 12.12 ± 3.04 respectively. The distribution of study participants based on gender. The study comprised 332 males (65.1%) and 178 females (34.9%). (Table 3)

Table 4 shows distribution of study participants based on Baseline OHI-S scores. In the video group 13.5% of them had a good oral hygiene, 62.9% had a fair oral hygiene and 23.5% of them had a poor oral hygiene. In the picture group 1.2% of them had a good oral hygiene, 70.6% had a fair oral hygiene and 28.2% of them had a poor oral hygiene. In the individual instruction group 4.7% of them had a good oral hygiene, 74.7% had a fair oral hygiene and 20.6% of them had a poor oral hygiene and this difference was statistically significant (p<0.001).

When OHI-S scores were recorded midway through the study, in the video group 13.5% of them had a good oral hygiene, in the picture group 2.4% of them and in the individual instruction group 5.9% of them had a good oral hygiene and this difference was significant (p<0.001). (Table 5)

The data presented in Table 6 shows distribution of study participants based on final OHI-S scores recorded at the 9th month of the study. In the video group, good oral hygiene was seen among 14.7% of the participants, in the picture group 2.9% of them had a good oral hygiene, and in the individual instruction group 6.5% of them had a good oral hygiene and this difference was statistically significant (p<0.001).

Discussion

The present study was conducted to assess the oral health status and to compare and evaluate the efficacy of different methods of oral health education for children with special health care needs. In the present study there were 65.1% males and 34.9% females. These findings are almost similar to a study conducted by Mokthar MS et al.\textsuperscript{10}

The findings of the present study revealed that majority of the children had fair oral hygiene i.e 69.4% in the baseline, which increased to 70.0% in the mid intervention period which further increased to 70.6% at the end of 9\textsuperscript{th} month. These findings are comparable to a study conducted by Teixeira SA et al.\textsuperscript{11} The dental plaque can be removed only when an individual has the dexterity to use a toothbrush. However, the efficient brushing or flossing of teeth may be a difficult task for those individuals with physical and mental disabilities.\textsuperscript{11}

In the present study the mean OHI-S scores in the baseline for the video group was 2.10, for the picture group it was 2.27 and for the individual instruction group it was 2.16. These findings are comparable to a study conducted by Rao D et al.\textsuperscript{1} Snyder et al. pointed out that the lack of manual coordination in disabled children is a factor in the difficulty of their oral hygiene maintenance. Tooth brushing ability, is related to coordinated muscular movements, innate skills, ability to understand instructions, and age of the individual.\textsuperscript{1}

From the results obtained from this study, it was observed that there was a significant decrease in the mean OHI-S scores of all the three groups after teaching the brushing technique. The mean OHI-S scores of all the groups depict that the maximum drop in the OHI-S scores at the 9\textsuperscript{th} month of the study was seen in the picture group (with a drop in mean OHI-S scores from 2.27 to 2.22) when compared to the video group and individual group.
Many studies have highlighted poor oral health status of children with special health care needs in terms of higher calculus deposition, more caries prevalence, and a higher prevalence in malocclusion, emphasizing the need for receipt of timely preventive dental care. Sheehy et al. suggested the use of a Communication Board and picture communication symbols to supplement management in a pediatric dental setting for individuals who have limited or no functional speech because of severe physical, neuromuscular or cognitive deficit. Darwis and Messer used aided augmentative communication system (COMPIC: Computer Pictographs for communication) to manage children with cerebral palsy in a pediatric dental setting. It proved to be a promising adjunct for the care of the child with communication impairment, offering valuable and active management of behavior. 

Conclusion

This study revealed that majority of the children had a fair oral hygiene (70.6%), followed by (21.4%) of them who had poor oral hygiene and only (8%) of them had good oral hygiene. When health education was provided with the help of videos, pictures and individual instruction, the children who received training to brush their teeth with the help of pictures showed slight improvement in their mean OHI-S scores (2.27 to 2.22) at the end of 9th month. The reasons for poor oral hygiene in differently abled children may be due to lower level of concentration and lack of motor skills.

Evaluation of the Baby Friendly Hospital Initiative Programme in Two Hospitals Designated “Baby-Friendly” in Kirkuk City, Iraq

Fakher Abobaker Ahmed Gli1, Dale Spence2, Linda Johnston3, Finoa Lynn4, Richard Tubman5, Ziad Mohammad Sadiq6
1College of Nursing, Kirkuk University, Iraq; 2Senior Lecturer, Queen’s University Belfast, UK; 3University of Toronto, Canada; 4Lecturer, Queen’s University, Belfast, UK; 5Consultant Neonatologist, Belfast Trust, UK; 6College of Medicine, Kirkuk University, Iraq

ABSTRACT

Background: Although the Baby Friendly Hospital Initiative (BFHI) was implemented in Iraq since 1992, a remarkable regression in exclusive breastfeeding has been highlighted by UNICEF (2011). Kirkuk province has experienced the lowest rate of breastfeeding initiation in the first hour of life, with higher neonatal and under five years mortality rates. International organizations have recommended a focus on breastfeeding practices and strengthening the implementation and monitoring of BFHI program in Iraqi provinces.

Method: Two-phase study was carried-out in two-designated Baby-Friendly hospitals (Azadi Teaching Hospital and Kirkuk General Hospital), using a standardized questionnaire. Monitoring BFHI tools utilised to measure the compliance with BFHI. Carolina B-KAP survey questionnaires were used to assess knowledge, attitudes, and practices of clinical and non-clinical staff and to measure the components of Organisational Readiness for Change (ORC) theory through practical and theoretical knowledge of hospitals processes. The Chi-square test of independence was performed to test for group differences in the responses to the Carolina B-KAP questionnaire.

Results: There was compliance in both hospitals with step 1,7 and 10 of the Ten Steps to Successful Breastfeeding, and the International Code of Marketing Breastmilk Substitutes (the Code). However, a non-compliance with step 3, 4, 5,6,8 and 9 were present. KGH also showed non-compliance with step 2 (training on BFHI). A total of 143 participants (124 clinical and 19 non-clinical) responded to the survey. ATH were more likely to have greater knowledge of infant feeding, than respondents working in KGH (p<0.05). Responses indicated that (61.7%) of participants reported that healthy full-term newborns within their care had started to breastfeed within 60 minutes after birth. In terms of matching infant feeding with appropriate clinical support plans, the results show that respondents agreed or strongly agreed on the need for additional guidance and training (78.3%).

Conclusion: Increased compliance with the BFHI programme can have positive impact on breastfeeding initiation, duration and exclusivity. Maternity departments in Kirkuk hospitals must fully implement Baby Friendly Hospital Initiative to support an increase in exclusive breastfeeding rates. Also, implementation of Baby Friendly Community Initiative (BFCI) can provide community support for breastfeeding.

Keywords: Baby Friendly Hospital Initiative (BFHI), the Ten Steps to Successful Breastfeeding, International Code of Marketing Breastmilk Substitutes (the Code), Organisational Readiness for Change (ORC).

Introduction

The Baby Friendly Hospital Initiative (BFHI) is evidence-based practice programme initiated in 1991 by the United Nations Children’s Fund (UNICEF) and World Health Organisation (WHO), and its designated to
increase the rates of initiation, duration and exclusivity of breastfeeding worldwide.\textsuperscript{1} BFHI consist of the Ten Steps for Successful Breastfeeding, and the International Code for Marketing of Breastmilk Substitutes which is a key element of the international standard for promoting, protecting and supporting breastfeeding.\textsuperscript{2} The BFH assessment process, otherwise known as the BFH designation process or accreditation, consists of a set of tools initiated in 1991 and revised and updated in 2006 to 2009. This process was designed based on the BFI quality cycle (Figure 1).\textsuperscript{3} Changing staff attitudes continues to be the greatest challenge to those hospitals that wish to achieve Baby-Friendly certification.\textsuperscript{4} Organisational readiness for change (ORC) is key factor in the effective implementation of new strategies, programs and practices in healthcare facilities.\textsuperscript{5} ORC embodies two important principles for the implementation of change, collective efficacy and collective commitment.\textsuperscript{6,7}

The BFHI was first implemented in Iraq in 1992, including the city of Kirkuk.\textsuperscript{8} The Multiple Indicator Cluster Survey (MICS4) conducted by UNICEF\textsuperscript{9} indicated a marked regression in breastfeeding since 2004 with record low rates of exclusive breastfeeding and duration of breastfeeding at 19.6\% (as compared with 30.9\% in 2004) and 13.8\% (as compared with 15\% in 2004), respectively. Kirkuk province had lower initiation rate of breastfeeding within one hour (10\%) than in any other Iraqi province, while the mortality rate for children under five (51 per 1,000 live births) was higher in Kirkuk than in any other Iraqi provinces and the neonatal mortality rate was 32\%.\textsuperscript{9} The evidence-based report by the U.S. Agency for International Development (USAID)\textsuperscript{9} stressed the importance of conducting a study into breastfeeding practices in health institutions and communities in Iraq, and proposed a further evaluation of the BFHI in Iraq.\textsuperscript{8} This also recommended by a report by the International Baby Food Action Network (IBFAN).\textsuperscript{10}

Two main gaps have been identified through the literature review. First, there is a dearth of studies which apply Organisation Readiness for Change (ORC) theory to assess clinical and non-clinical staffing levels required to deliver the BFHI programme. Second, few researchers have sought to understand how the organisational cultures of individual hospitals influence compliance with the Ten Steps to Successful Breastfeeding and the Code. The aims of this paper, therefore, are as follows:

1. To determine if the two BFHI designated hospitals in Kirkuk have sustained adherence to the Ten Steps to Successful Breastfeeding and the Code.

2. To assess the levels of support reported by clinical and non-clinical staff to successfully deliver the BFHI programme.

![Figure 1: Baby Friendly Initiative quality cycle.\textsuperscript{3}(p.5)](image-url)
**Material and Method**

A quantitative approach was carried out in the maternity departments of two public hospital, Azadi Teaching Hospital (was accredited as a Baby Friendly Hospital in June 2014) and Kirkuk General Hospital (was in the final stage of accreditation), in the city of Kirkuk, Iraq. Both hospitals had high birth rates (13,000 and 15,000 births respectively in 2014).

The standardized instrument Monitoring Baby Friendly Hospitals tools, gathered hospital level data regarding the implementation of BFHI. This mechanism was used to confirm the hospital’s commitment to Step 1 (policy) and Step 2 (training) of the Ten Steps to Successful Breastfeeding and the Code. The questionnaires for breastfeeding mothers [interview of 60 postpartum mothers (experienced vaginal birth or caesarean section birth) across the two participating hospitals through stratified sampling on random basis] were used to confirm the hospital’s commitment to the Steps 3 to 10, of the Ten Steps.

A survey utilized Carolina B- knowledge, attitudes and practices (Carolina B-KAP) questionnaires Nickel 11 were used to assess these aspects in clinical and non-clinical staff (were 125 employees in ATH and 105 in KGH by using self-selecting convenience sample) in relation to the BFHI, and to measure the components of Organisational Readiness for Change (ORC) theory through practical and theoretical knowledge of hospitals processes.

**Data Analysis:** Descriptive statistics were utilised as per the UNICEF/WHO guidance for data analysis. Summarising the data and interpretation of the finding of the Monitoring Baby Friendly Hospital tool, including the questionnaire for breastfeeding mothers, was undertaken to identify the level of the hospital’s adherence with BFHI steps. The data from Carolina B-KAP questionnaires were entered and analysed by the researcher using SPSS program.

**Findings**

The results of Monitoring Baby Friendly Hospitals tool revealed a partial commitment to providing maternal and infant health services under the BFHI program in Azadi Teaching Hospital (ATH), (Table 1) and Kirkuk General Hospital (KGH) (Table 2).

Survey Results

The response rate was 62% across both hospitals with 143 participants in total (124 clinical and 19 non-clinical staff).

Knowledge of infant feeding: The results in (Table 3) show that for items 1-3 and 6, respondents working in ATH were more likely to have greater knowledge of infant feeding, as they responded correctly to these items, than respondents working in KGH (p<0.05).

Practices in mother-baby care: Only clinical staff (n=124) responded to the 11 items relating to practices in mother-baby care, which included questions about counselling and clinical practice. Most of the respondents (77.4%, n=96) always recommend breastfeeding to the mothers in their care who have not decided how to feed their babies. Responses indicated that (61.7%, n=58) of participants (out of 88 participants involved with Labor and delivery care) reported that healthy full-term newborns within their care had started to breastfeed within 60 minutes after birth.

Attitudes toward commitment and ability in the workplace: The participants responded to 15 questions which measured the components of Organisation Readiness for Change (ORC) across five categories. The first category related to their opinion about clinical staff in the maternity facility where they work and whether they needed additional guidance (Table 4). In terms of matching infant feeding with appropriate clinical support plans, the results show that respondents agreed or strongly agreed on the need for additional guidance or training (78.3%, n=112).

Discussion

Increases in exclusive breastfeeding rates are associated with high compliance with BFHI practices. Participated hospitals in this study showed non-compliance with many steps of the Ten Steps to Successful Breastfeeding. Specifically, a non-compliance in KGH in relation to step 2 was due to the low proportion of clinical staff who had participated in...
the training courses, which was below the required rate set by the UNICEF and WHO guideline.

There was a non-compliance in both hospitals with Step 3. Given that the total number of births in both hospitals for 2014 exceeded 28000, a small prenatal clinic in both hospitals cannot be expected to cover Step 3. This finding is consistent with the result obtained by Zakarija-Grkovic as a minimum compliance with the same step was reported.

The knowledge of participated hospitals staff was varied according to the hospitals as there is a gap in knowledge to support breastfeeding, respondents working in ATH were more likely to have greater knowledge of infant feeding. This can be linked to lack of training in KGH when that hospital showed non-compliance with step 2 of the BFHI. A study on BFHI confirmed that lack of health training affects the rate of correct answers on breastfeeding knowledge.14

The rate of initiation of breastfeeding (within first hour of birth) in accredited (BFHI) hospitals is greater than those of non-accredited. Based on the opinion of staff working in labour and delivery care, our findings showed that up to 61.7% of healthy, full-term newborns initiate breastfeeding within the first hour of birth. This rate is significantly associated with respondents from KGH (p<0.05). A survey in the District of Shaqlawa, Erbil, Iraq, found a statistically significant relationship between delivery in BFHI hospitals and initiation of breastfeeding.17

Readiness in healthcare organisations is required before implementing evidence-based interventions. Changing staff attitudes requires time and remains the greatest challenge for those wishing to attain Baby Friendly certification. Our findings indicated that the clinical staff require more guidance, training and skills in terms of matching infant feeding plans with appropriate clinical support plans (78.3%). This result was significantly associated with the respondents working at KGH, and those in the age group 31-40 years (p<0.05).

Conclusion

Maternity departments in Kirkuk must fully implement Baby Friendly Hospital Initiative. Organisational Readiness for Change is vital in successful implementation of the BFHI. Training on BFHI develops the knowledge and skills of staff concerned. Community support of optimal breastfeeding practices in Kirkuk is needed through implementation of the Baby Friendly Community Initiative (BFCI) to increase the rates of exclusive breastfeeding at six months.

Conflict of Interest: Nil

Source of Funding: This study was funded by the official representative of the Iraqi Ministry of Higher Education and Scientific Research (MOHESR) in the UK and Ireland.

Ethical Clearance: Ethical approval and permission to access participants was obtained from the School of Nursing and Midwifery Research Ethics Committee, Queen’s University Belfast and the Ministry of Health in Iraq.

The Combinatory the Effect of Healthy Educational Programs with Kinect Simulation Device on Learning Some of Basketball Skills

Mohammed Shihab Ahmed1, Mayyadah Khalid Jasim1
1Department of Physical Education and Sport Sciences, Faculty of Basic Education, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

The problem that led to this research is derived from neglecting the use of alternative modern methods of learning that simulate the intellectual capabilities of the ones who learn, which urged the researcher to shed the light on this dilemma and try to find the optimal solutions. The researcher had used the experimental approach; as the research sample was represented by the first year students of Physical Education and Sports Sciences, College of Basic Education- Al-Mustansirya University for the academic year (2016-2017). The research’s sample was selected randomly, and the sample divided into three halls, where hall no. (1), represented the second experimental group, whom were taught by using the educational program made by the researcher, while hall no. (2) held the research sample that been taught the skills via the educational program combined with the kinetic simulator device while hall no.(3) held the control group which being taught using the old routine. After the set of the educational units of each skill that being studied for the experimental groups according to the specificity of the educational program along with the simulator device. Each group was examined pre and post testing. The data were collected and analyzed statistically via SPSS

Keywords: Simulator Kinect, Basketball. Health programs.

Introduction

The world is of a fast development in various fields, this had built a burden of accumulation of responsibilities and duties. Which results in a noticeable increase in the numbers of those who participate sport activities, one of those activities is basketball that considered of one of the most popular sport around the globe due to its physical, intellectual, and skillful properties, nevertheless the presence of excitement and thrilling elements for the players and the audience as well.

Accordingly it requires concentration on good planning for educational process hence preparation of great educational curricula related specified to each game that basketball demands special requirements depending on a modern alternative educational methods that simulate the intellectual capabilities of the learners, one of these effective methods is the kinetic simulator device which is considered as the basics of learning, therefore the research use the device along with a specially set educational program proposed by the researcher. As such educational alternative method is crucial in learning skills, especially those of basketball, that they are exhibited as fast rhythm characterization and transition between the attacking and defensing positions, therefore it calls for the use of methods produce diversity in performance

As a sum of all the above, came the importance of proposing this research in preparing an educational program base on the use of simulator device to learn some of attacking skills in basketball that is hoped to be as an aid in teaching process in the future.

The main goal of the kinetic learning theories in every game is to elevate and develop the learning process, which in normal cases relay on the alternative modern
methods of learning therefore, an adherence to proper scientific methodology in learning process is a necessity that reflects the improvement level during learning process. As long as basketball is one of the most popular sports and gained a wide world attention including Iraq, it was essential to define the errors associated with the learning process of its skills and eliminate them.

**Objectives:**

- Identifying the effect of the educational program, which was made by the researcher, on the learning of some types of attacking skills’ in Basketball.
- Identifying the effect of combining the educational program with kinect simulator device in learning some of attacking skills in basketball.
- To identify the effect of the learning technique on types of basketball attacking skills.
- To identify the effect of the best educational programs in learning some of attacking basketball skills.

**1-3 Hypotheses:**

- There are significant statistical differences between the results of pre and post tests while learning some of the attacking skills for the first experimental group favoring the post test results.
- There are significant statistical differences between the results of pre and post tests while learning some of the attacking skills for the second experimental group favoring the post test results.
- There are significant statistical differences between the results of pre and post tests while learning some of the attacking skills for the control experimental group favoring the post test results.
- There are significant statistical differences between the results of post tests result for the research groups.

**Research Domains:**

**Human Field:** Students of Physical Education and Sports Sciences-College of Basic Education- Al-Mustansiriya University.

**Place Domain:** Closed Sports Hall - College of Basic Education-Al-Mustansiriya University.

**Time Domain:** 12/2/2017 to 12/4/2017

**Methodology**

The experimental approach was used to design three groups suitable for the nature of the research.

**Community and Sample Research:** The research community is represented by students of the first grade/Physical Education and Sports Sciences, College of Basic Education.

Al-Mustansiriya University. After excluding of those who failed or those who are experienced, the total number of students was 48 male students. Which divided randomly into three groups, as each of the first and second group consists of 10 students while the control group held 10 students as well, therefore the search sample was 62.5% of the total community.

**Tools and Instruments for the Information Collection:**

**Tools, Devices, Means of Information Collection:**

**Search tools and devices:** For the purpose of conducting the research procedures, the following tools and devices were used:

1. Basketball court
2. Stop watches (2 watches).
3. Basketballs (15 balls) type (Molten).
4. Adhesive colored tape (width 5 cm).
5. Textile measuring tape (15 m).
7. Plastic cone (12 cones).
8. Laptop (Dell).
9. Kinect simulator device
10. TV screen

**Sources of Information Collection:**

1. Arabic and English resources.
2. Performance tests.
3. Registration forms to confirm test scores.
4. International Information Network (Internet).

**The Research Tests (7: 95)**

**Selection of passing ball using one hand over the shoulder (long passing)**

**Purpose of selection:** Measure the accuracy of the bassing with one hand above the shoulder on target.
Accuracy Test of layup shot post dripping

Objective of the test: As this test is one of the tests that show the motor and skillful coordination between the work of arms and legs, therefore it aims to assess the level of accuracy of layup shooting.

The scientific basis for the technical tests:

A. The Truth: It is the order by which the object of test is being measured (4: 64); one of the methods of proving truth is via self-honesty, as mentioned in table (1) that shows the honesty of varies tests.

B. Stability: (it means the reproducing of the results over the repletion of the test on the same group of participants), (1: 70).

Retesting method was conducted to measure the stability coefficient of the test on a group of first grade students other than the research sample.

C. The Objectivity: Objectivity, refers to non bias condition as being referred by (WajihMahjoub), whom defined it as “the subjective judgments are not affected by the experimenter and that objectivity is available without bias and self-intervention by the experimenter) (5: 64). Experts had proven that each skill requires certain selection of proper tests therefore there is no difference in judgment by the experts on certain experiment or on a particular subject) (2: 64), accordingly the tests being used in this research were selected to be known, clear, understandable and easy. And each aspect of each test was clarified including the tasks to accomplish.

In order to identify the objectivity of the selected tests, (Pearson) correlation coefficient was being used on data of the first and second judgment, to gain a value of highly objectivity hence the tests are considered highly objective. Table (1) summarizes that:

<table>
<thead>
<tr>
<th>Tests</th>
<th>Stability</th>
<th>Self honesty</th>
<th>Objectivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ball passing above the shoulder (long passing)</td>
<td>0.85</td>
<td>0.92</td>
<td>0.87</td>
</tr>
<tr>
<td>Lay up shot</td>
<td>0.8</td>
<td>0.89</td>
<td>0.83</td>
</tr>
</tbody>
</table>

Preliminary Testing: It is a preliminary empirical study intended to select research methods and tools) (6:79).

Therefore, the researcher conducted two surveys in 8/2/2017 on Sunday on a group of students of the first year Department of Physical Education and Sports Sciences/College of Basic Education (6 students), whom were excluded from the research sample. The purpose of the experiments was:

1. Demonstration of tests and explain them to the students.
2. Identifying the time required for testing.
3. Identifying the time required for each exercise within the program used in the search.
4. Identifying the obstacles that may hinder tests or educational processes.

Research Field Procedures:

Preliminary Lectures: The researcher presented a lecture for the three groups of research whom were not familiar with these skills before, as the lecture included a demonstration of ball passing above the shoulder and lay up shooting skills.

Pre Tests: The researcher carried out the pretests in 12/2/2017 on the three research groups of the above-the-shoulder ball passing skill and the skill of layup shooting. In the court of Physical Education and sport Sciences at the Faculty of Basic Education, Al-Mustansiriya University.

Educational Program: The researcher designed a special educational program for the exercises associated with the use of Kinect simulator device and was carried out on the first experimental group. While the second experimental group carried out the same educational program without using the simulator device.

This program was employed in the process of learning the long ball passing from above the shoulder and lay up shooting skills as shown in the table below:
The research groups consist of eight units, as one educational unit was given per week, (90 Min.) divided into preparation part (20 Min.); the sum of all units was (160 Min.), and the main part time (60 Min.) per each unit. And the sum of them was (480 Min.), the final part (10 Min.) per unit and (80 Min.) as sum of the units.

The mechanism of applying those skills was through the practical part as the researcher prepared set of skilling exercises concentrating on the skills being studied, for the first experimental group as the early repetition, especially in the first and second educational units, on the skill performances in constant distances and angles to provide the focusing element to the learner thereafter through the late educational units there was a diversity in the motor behavior by using different angles and distances besides using exercises similar to those being practiced by learners with simulator device that being used during the educational units, as the learner was practicing some repetitions of those exercises on the playground, then switch to practice those exercises the simulator device with certain routines, later on the learner will practice those exercises on field. On the other hand the second experimental group the learning process was maintained via the performances of the same exercises being taught in the educational program with increasing the number of repetitions yet without the simulator device, as the repetitions will compensate the time and the device

Post-Tests: Post-tests results for the skills being studied were conducted in 12/4/2017 under the same conditions of performance as the pre tests were established.

Statistical Analysis

The researcher relied on the processing of statistical data using (SPSS)

Discussion

Discussion of the pre and post tests results for three groups concerning the long ball passing above the errand layup shooting skills in the Basketball: The results presented in Tables (2, 3), Show the existence of significant statistical differences for the two experimental groups.

This is due to the harmonization of the given exercise with the research sample, as the set educational program and the given exercises had given enough space to the learner that fit with his ability to adapt and learn while changing the environment of exercise, which is essential for better learning of skills for beginners

Nevertheless the results had shown that there is no significant statistical differences for the control group while practicing the long ball pass over the shoulder, due to insufficient practicing style for such skill as it is not harmonized with their abilities, on the other hand the control group had shown a significant statistical difference with the other skill due to the suffice learning process gained from the educational program and the over repetitions of that skill

Therefore the educational program had proven to be harmonized with the capabilities of learning and produce great results

Posttests results of the three research groups of the long ball passing above the shoulder and the layup shooting skills in basketball: The results of the tables (4, 6) showed that there is a significant difference in the learning of the attacking skills in the basket among the three groups. Which is mainly due to the use of the educational program accompanying the Kinect simulation for the first experimental group while for members of the second experimental group, the educational program was used solely

The results of the LSD test had showed that experimental group 1 has the least significant difference while learning those skills, due to the nature of the exercises that were efficient under changing the environment which create an applicable kinetic program can be used in different circumstances of practicing, nevertheless the kinetic simulating device had a major role in learning those skills by combination effect between the virtual and practical worlds, by adding the thrilling and excitation effects to the learning process which made the learner enthusiastic to learn and practice

Conclusions

The results showed the effectiveness of the educational program prepared by researcher combined with the use of Kinect simulator device for learning long passing from above the shoulder and lay up shooting skills. The results showed the effectiveness of the educational program prepared by the researcher to learn long passing from above the shoulder and lay up shooting skills. The results showed the effectiveness of the method used in learning my skills (long handling
from the shoulder, peaceful correction). The results showed the preference of the educational program prepared by the researcher when accompanied by the Kinect simulator in learning long passing above the shoulder and lay up shooting skills on the educational program prepared and the approach used.

**Recommendations**

The need to connect the virtual and the practical world in the preparation of the educational curricula of learning the skills of basketball. Provide substantial and moral support for teachers and trainers in order to provide such devices to serve the educational process. The researcher recommends conducting similar studies on a different sample from the research sample as well as other skills of basketball and other sports games. The researcher recommends all the specialists in the educational process to keep up dated with what is the latest in the field of simulators and try to employ it in learning sports skills.

ABSTRACT

Smoking considered as bad habit that has negative reflection on person’s health, society and economic. Civil society organizations and governments were aware about the risk of smoking phenomenon, in Jordan which motivates the government to issue regulations and laws that contribute to put limitations for smoking in public places and sites. Also, it generates many health awareness campaigns to put limit for smoking phenomenon in cooperation with education institutes and civil society organizations in order to urge people to quit smoking. In spite of that, Jordan is still suffering from increasing number of smokers. Because of that, the objective of this study is to investigate the effect of health awareness campaigns in influencing people behavior to stop smoking. Sample of 369 smokers were selected, and the questionnaire composed of the following five dimensions:

Awareness campaigns through media; factors that motivated smoking quit; frustrating factors to quit smoking; Reference groups and smokers response to awareness campaigns.

Study results show that there are motivation factors in the environment that smokers live in, and there is strong relation between antismoking factors and smokers’ response to health awareness campaigns; where the connection factor between them is 0.634. Awareness campaigns could not face the abortive factors to stop smoking and to influence on smokers in spite of the fact that 33% of the sample individuals are planning to quit smoking in the future and the fact that there are three clinics in Amman for assistance to quit smoking and a specialized pharmacy, but the problem is that most people do not have any information about it. It shows, clearly, the failure of health awareness campaigns related to quit smoking. The sponsors must draw suitable strategy that coincides with Jordan reality and suitable to effective factors of smoker behavior.

Keywords: Awareness Campaigns; Smoking; Media tools; Health; Amman

Introduction

Tobacco products, nowadays, are responsible for the death of more than three million yearly around the world; which represents about 6% of the total deaths [1].

However, it is expected that this percentage will increase to 10.9% by the year 2020 or early 2030, related to all deaths of the growing (developing or less developed) countries and up to 17.7% in the more developed (Industrial) countries [2].

This is a major indicator that smoking causes death more than any other single disease. Smokers in growing countries are about 800 million or more than 70% of populations [3].

The age average, that people start smoking, is between the age 12 and 15 years and 90% of the smokers smoke regularly before the age of 21. For that, health awareness campaigns (to quit smoking) must focus on people of age 11, in schools, and these campaigns should continue in universities [4-6].

The workers in awareness campaigns, to quit smoking, work on identification of damages, harms, hurts and disadvantages of smoking to the smokers.
The workers must increase awareness about these risks and to work on performing negative attitudes towards smoking and push smokers to quit smoking by publishing and broadcasting information, conduct seminars, conferences and urge governments to put laws and regulations that stop or reduce smoking process [8].

Jordan is located in advanced position concerning the number of smoker because smokers, in Jordan, represent 65% of the population in a middle of scaring expectation that it will raise up to 88% among males. Specialized authorities are working to apply the national strategy to control smoking through implementation of forbidden smoking in public places. Their efforts were clear in issuing the modified health law (47), 2017, forbidding smoking in public and closed places, where fines are determined and jail penalty to people who break the law [9].

The reason behind that is the fact that smoking becomes a very dangerous phenomenon in Jordan, and the late statistics indicate that tobacco is behind the cause of death for 12% of the total deaths in Jordan between people whom their ages are above thirty years old. Jordan suffers from 29 death cases, weekly, caused by smoking [10].

Objectives

The wide spread of smoking phenomenon pushes us to prepare this study and to investigate the effect of health smoking campaigns on quit smoking through media, reference groups, effect of motivated factors on smoker behavior to quit smoking, and frustrating (abortive) factors to quit smoking.

Study Problem: The indication of Faris Alhawari, Cancer disputing office manager, Al Hussien Center, that number of smokers in Jordan represents 65% from the country population, among expectations that it will increase between males, within few years, to reach 88%. Also, 50% of death cases, in Jordan, are related to smoking. He pointed, as well, to the importance of the implementation of Smoking disputing national strategy, because forbidding of smoking in public places reduces smokers percentages in the Kingdom by 4% within a year [10].

For all of that, the problem that faces the society needs more and more studies to determine and identify reasons for smoking, the proper treatments and medications to reduce number of smokers in Jordan.

Previous Studies: Nurulfarahin et al, mention that quitting smoking is hard as people who stop smoking often start again because of weight gain, stress and withdrawal symptoms. So it is imperative to strengthen the enforcement on regulations advertisement, and develop more activities on motivation among smokers and their families, which may be organized by government or non-government organizations [11]. Unal E., M.E. et al, they mentioned that all the advertisements were more effective for adolescents who had never smoked compared to ex-smokers and current smokers [12].

Bednarski et al, explains that smoking tobacco decreased in many countries due public health campaigns, anti-smoking programs, anti-smoking policies and banding smoking advertisements [13]. Chandra, A., et al, says that health awareness campaign can be implemented through distributing booklets, handbooks, presentation of posters, provide door to door information and the public reacting with the team assigned to awareness campaign [14].

The objective from health awareness campaigns is to educate smokers and non-smokers against smoking by broadcasting and spreading awareness, knowledge and make changes in their beliefs and attitudes, in order to affect their behavior [15]. Also to continue their work spreading awareness to control smoking because continuous awareness campaigns gain and bring more results than short ones or through occurrences separated by long periods. In fact there is a big direction from governments, in the whole world, to support awareness about smoking health warnings [16].

Health awareness campaigns that are anti-smoking must concentrate on all people, where smokers’ friends, their families and attitudes that support smoking have role in encouraging smoking [17].

Workers with anti-smoking health awareness campaigns must stress on smoking damages and harms where smokers suffer for many years from bad health beside the early death [18].

Study Objectives: The study objective is to know how far smokers are responding to health awareness campaigns to quit smoking; through media tools, reference groups and price effect.
Hypotheses of This Study

Ho: There is statistical, not significance (α ≤ 0.05), of the health awareness campaigns, motivated factors, frustrating factors that they play an effective role in driving smokers to quit smoking, and reference groups through media tools

Methodology

This study is implemented on the youth faction (sector) and includes seven independent factors (variables): Television, radio, posters, and seminars, quit smoking Clinics, reference groups and price. The dependent variable is quit smoking.

The questionnaire is designed, formulated and consists of 28 questions in order to gather, analyze data and to reach the conclusions and recommendations based on results of this study.

The study is an experimental research, using a descriptive and analytical approach.

Data Collection

Data collection, manners of analysis and programs used in the current study are based on two sources:

1. Primary Source: the questionnaire that was designed to reflect study objectives and questions. The selected sample was, from youth age, 480 youths. The valid returned questionnaires for the statistical analysis were only 369, which is 77%.

2. Secondary Sources: books, journals, articles and previous theses to write the theoretical framework of the study

Study Model: The following diagram (Figure 1) represents the study model which is based on the study problem, objectives and hypotheses [19-25].

</table>

The results show that individuals of the sample do not proceed to follow-up advertisements that encourage quit smoking on radio, see advertisements that encourage quit smoking in local newspapers, and participated in seminar that encourages to quit smoking, this indicates the ineffectiveness of health awareness campaigns against smoking in this area.

Also the results indicate that the mean for all the second dimension questions was greater than the average unit of measurement (3), except the Health awareness campaigns, for quit smoking, contribute to aware smoker that his productivity will be greater when he quit smoking.

On the same hand, results indicate that the factors frustrating to quit smoking took the highest averages, encouraging them to continue smoking, especially question 15, “You feel that seeing a person smoking will make you wish to smoke”; where the value of the mean is the largest value among all questionnaire questions. Based on the results, we reject the null hypothesis.

The results indicate that the health awareness campaigns to quit smoking, affected family members to urge smokers to quit smoking, but did not affect behavior of their co-workers, which push them to encourage him to quit smoking.

Summary and Conclusions

The results indicate that (234) respondents tried to quit smoking by (63.41%), but they had failed to continue quit smoking.

The failure of many attempts to quit smoking needs to provide psychological support, medication and treatment with the proper costs and make space for the opportunity to quit smoking [26-27].

The study reveals that there are about (125) smokers who are planning to quit smoking in the future with percentage of (33.88%) against (244) smokers who are not planning to quit smoking in the future with percentage of (66.12%), which is very high percentage and an indicator to the failure of health awareness campaigns to quit smoking and to affect in smokers behavior; at the same time,

The frustrating (abortive) factors to quit smoking have great effect on the failure of awareness campaigns where the correlation factor represents the highest value which is (0.63). This indicates that there is strong relation between these factors and the case that smokers do not quit smoking.

Recommendations

Health awareness campaigns must be efficient and effective. They have to concentrate on increasing awareness about health, psychological damages and harms caused by smoking and work to change people motives and attitudes towards smoking by providing them with information, present films and arrange awareness seminars.

Also, they must help smokers to put their own plans and provide psychological support for them that will help them to quit smoking.

Such campaigns must be condensed and continuous and all related authorities have to take part in them, like organization of civil society, education organizations,
health departments and work on issuing laws and regulations that push and motivate people to quit smoking.

The work must be on producing awareness campaigns with clear targets, through media tools, and must have an impact on smokers and non-smokers behavior, taking in their consideration to deepen the people awareness about smoking risks that include health, social and economic risks.

For that, specialized authorities, concerned with health awareness campaigns, must put successful plan based on study of environmental factors that smokers live in and the factors that affect their behavior so that they can put efficient programs to help smokers to quit smoking.

ABSTRACT

Aim of the Study: to assess the prevalence of active eye involvement in Iraqi patients with BD and to evaluate the potential relationship between active eye disease with sociodemographic and clinical characteristics.

Method: A cross-sectional descriptive study was conducted at 64 patients with Behçet’s disease diagnosed according to the International Study Group for Behçet’s disease. Sociodemographic and clinical characteristics were recorded. Comprehensive ophthalmological examination was to assess ocular involvement.

Results: Mean age of patients was 32.3(8.9) years. Males were 81.3%. Active ocular involvement by Behçet’s disease was 27 patients (54%). The risk of having active ocular BD was significantly increased 29,265 folds in male patients, (p= 0.033). genital ulcers increased risk of having active ocular involvement by 19.971 folds (p=0.05). Smoking increases the chance of having active eye involvement in BD by about 3.438 folds (p>0.05).

No significant association between active ocular BD and age of the patient, HLA-B51 status, BMI score, family history of BD, duration of the disease, presence of oral ulcers, headache, joint involvement, skin rash, erythrocyte sedimentation rate(P>0.05).

Conclusion: Active ocular involvement by Behçet’s disease was relatively common and correlated directly and significantly with male gender. This indicate that late diagnosis and treatment might cause these active eye manifestations.

Keywords: Behçet’s disease, active ocular involvement, eye manifestation.

Introduction

Behçet’s disease (BD) is a chronic, relapsing, inflammatory vasculopathy of unknown etiology. (¹,²) The key clinical manifestations are oral and genital aphthosis as well as ocular inflammation. (³) Although ocular involvement is not commonly the presenting feature of Behçet’s disease, it is a major source of serious morbidity. (⁴) Ocular Behçet’s is classically manifested as a bilateral non-granulomatous panuveitis and a retinal vasculitis. However, uveitis may remain unilateral for many years in some patients (⁵). Uveitis can be anterior, intermediate, posterior, or panuveitis (⁶).

Ocular involvement occurs in 60–80% of patients with Behçet’s disease and it is sight threatening. (⁷,⁸). Vision loss in Behçet’s disease usually results from long-standing inflammation and consequent sequelae in the posterior segment, macular lesions, vitreous hemorrhage, and neovascular glaucoma. (⁹). Visual loss also can be due to optic nerve and chorioretinal atrophy, ghosting and attenuation of retinal vessels and those are considered end-stage ocular disease. (¹⁰)

Anterior uveitis occurs with or without hypopyon. A transient, facile hypopyon can be seen by the patient
herself or his family. Hypopyon is explosive in nature, onset occurs within hours and can resolve with or without treatment. Posterior uveitis is the most common form of uveitis across age groups. It includes an obliterator necrotizing retinal vasculitis of both arteries and veins. Vascular sheathing with Cystoid Macular Edema (CME) is one of the manifestations of posterior uveitis. Retinal ischemia with Neovascularization of the iris can also occur. Acute vasculitis may be associated with multifocal areas of chalky white retinitis. With repeated episodes of vasculitis, vessels can become white and necrotic. Vasculitis affecting the arterioles of optic nerve leads to progressive optic neuropathy. This study aimed to assess the prevalence of active eye involvement in Iraqi patients with BD and to explore the possible relationship between active eye disease and socio demographic and clinical characteristics.

Patients and Method

Study Design: A cross-sectional, descriptive study was conducted at Rheumatology Unit in Baghdad Teaching Hospital from July 2015 to July 2017. Ethical approval was taken from College of Medicine, Department of Medicine and patients consent was recorded.

Participants: Sixty-four Iraqi patients enrolled in this study. All were classified as Behçet’s disease by fulfilling criteria of the International Study Group for Behçet’s disease. All included patients agreed to participate in the study. Patients were excluded from the study if they did not fulfill the inclusion criteria, if they had a history of an ocular disease other than Behçet’s or if they had undergone ocular surgery other than cataract or if they suffer from proved inflammatory bowel disease.

Data Entry, Collection, and Measurements: We used a pre-constructed questionnaire sheet. The questionnaire included age, gender, body mass index, smoking history, family history of BD, age of onset and disease duration were reported. We defined the onset of BD as the age of the patient when the initial manifestation of BD presented. The duration of BD was calculated as the time interval between the onset of BD and the age at the last visit of the patient to the hospital.

Patients were examined by an expert same ophthalmologist including external ocular examination, slit lamp biomicroscopy for anterior uveitis, defined as an Anterior Chamber (AC) reaction and/or the presence of hypopyon, or other possible sequelae like synechiae or cataract.

A detailed fundus examination using indirect ophthalmoscopy and slit lamp with aiding lenses (condensing lenses Volk 90, 78) was done to determine vitritis, retinitis and/or retinal vasculitis, these findings defined active uveitis in the posterior segment of the eye.

The definition of retinal vasculitis was based on the observation of inflammatory or gliotic sheathing of the vessels or on the fluorescein angiographic findings of staining, leakage, and/or occlusion of the retinal vasculature.

The intraocular pressure (IOP) was measured using an applanation tonometer. Patients who develop optic atrophy, occluded vessels that look like white cords, and diffuse retinal atrophy with variable scarring and pigmentation were defined as having end-stage eye disease.

Erythrocyte sedimentation rate (ESR) and HLA-B51 were measured. ESR was found using a traditional Westergren method in the hospital laboratory.

Statistical Analysis: Statistical analysis was done using statistical software SPSS 23. Descriptive statistics were reported as numbers(percentiles) for categorical variables and mean(SD) for normally distributed continuous variables. Multiple logistic regression analysis was used to assess predictors of active eye involvement. P<0.05 was considered statistically significant.

Results

Table 1 shows that the mean age of the studied group was (32.3 ± 8.9) years. Males constituted 81.3% of patients. Positive family history was reported in only 2 patients (3.1%). The age of onset ranged between 13 and 43 years with a mean of (28.3 ± 8.4) years. The duration of disease was ≤ 5 years in 49 patients (76.6%), and more than 5 years in the remaining 15 patients, (23.4%). More than half (53.1%) were current smokers, and 43.8% were non smokers, two patients had a previous history of smoking. Body mass index was normal in (42.2%), while (39.1%) were overweight and (18.8%) were obese. Within the last four weeks of the assessment, oral ulcers were present in 50 patients (78.1%), while (76.6%) of patients had joint involvement in the form of arthralgia &/or arthritis. Forty-seven patients (73.4%) had headaches. Skin rashes, genital ulcers were reported in (48.4%) and (70.3%), respectively.
Fifty patients out of the total 64 had ocular involvement. Out of these fifty patients, active ocular Behçet’s disease was reported in 27 patients (54%) at the time of the assessment as shown in figure (1),

Table 2 shows that out of the 27 patients with active ocular BD, nine patients (33.7%) had anterior uveitis, 11 patients (40.7%) had posterior uveitis and 7 patients (25.9%) had panuveitis.

Raised intraocular pressure was increased in 86 of the total 128 examined eyes (67.2%), Anterior chamber reaction was present in 27 (21%) of the total examined eyes. Hypopyon was seen in only eight examined eyes, (7.8%) of the total. Cataract and synechiae were seen in 42(32.8%), 43(33.6%) respectively of the total examined eyes as shown in (table 2). Vitritis, retinitis, retinal vasculitis were seen in 36 (28.1%), 18 (14.1%), 18 (14.1%) of the total 128 examined eyes, respectively. Optic atrophy is seen in (8.5%) of the total examined eyes.

In Table 3, the risk of having an active ocular BD was significantly increased 29,265 folds in male patients, (p value 0.033). Active ocular involvement also correlated significantly with the presence of genital ulcers within the last four weeks prior to assessment, with a p value of 0.05 and an increased risk of 19.971 folds. Current smoking increases the chance of having an active eye involvement in BD by about 3.438 folds, however this was not statistically significant, (P value = 0.226, non-significant) No statistically significant association was found between active ocular BD and age of the patient, HLA-B51 status, BMI score, family history of BD, duration of the disease or mean ESR value (P>0.05). Also the presence of oral ulcers, headache, joint involvement, skin rash during the prior four weeks of assessment did not significantly raise the risk of having active eye involvement, (P>0.05).

Discussion

This study revealed active ocular involvement was relatively common in Iraqi patients with BD and significantly directly correlated with males.

Active eye inflammation was 54% of patients at time of the assessment. Anterior chamber (AC) reaction was 21.9% and Hypopyon 7.8%. Al-Rawi et al (1) reported hypopyon was found in 12%. This difference may be related to change in disease severity in the three decades with a better awareness and advances in treatment.

In the posterior segment, Vitritis was 28.1 % in contrast to a previous study in Tunisia was 84.7% (2) and Jorden about 50% had uveitis (3) and this may be explained by different study design and inclusion criteria.

In this study, each of retinitis and Retinal vasculitis were 14.1 %. while Al-Rawi et al. reported only 3% patients (1) This may be due to different sample size and treatment.

The increased IOP was 67.2 %. Cataract 32.8%. Synechia 33.6%. Optic atrophy 8.5% this differ from another study in which IOP 8%in cataract 31.5%, synechia 32.4%, optic atrophy 13.5% (2). This difference possibly due to difference in time of assessment, disease severity, management approach, follow up and compliance to a better treatment.

In the current study only males increased the risk of an active eye involvement by (29.265) folds (p = 0.033). As shown in previous literature, male has a worse ocular outcome and its associated with a worse course of the disease (4).

This study has some Limitations: Shortage of resources and time led to a small sample size included in our study, additionally the lack of some investigations (like C-Reactive Protein) that would provide an insight about a more thorough laboratory findings association with active ocular Behçet’s. The temporary unavailability of tissue typing HLA-B51 for few months during the period of the study led to limiting the number of selected patients.

In conclusion, Active eye involvement were relatively common in Iraqi patients with BD and correlated with male gender. This suggest the need for high index of suspicion for early diagnosis and, prevention, and treatment. Further larger sample size studies with longer duration are recommended.

Conflict of Interest: The authors declare that there is no conflict of interests among them.

Source of Funding: The source of funding was by authors.

Effect of Using Simulation (Electronic Media) in Learning of Some Basic Skills in Technical Gymnastic for 2nd Grade’s Female Students

Abeer Ali Hussein1, Bashaer Hashim Abdul-Wahid1, Nidhal Obaid Hamzeh1
1The College of Physical Education And Sport Sciences, University of Karbala, Iraq

ABSTRACT

The research aims to know the effect of using simulation (electronic media) in learning some basic skills in technical gymnastic for the 2nd grade female students and knowing the best group from the two groups (Experimental and controlling) for the skills of research. Research sample was divided into two equaled groups randomly, (16) female student as controlling group and (16) female students as experimental group, controlling group took learning lessons by the classic method of teaching while the experimental group took that by simulation (electronic media). Harmonizing the sample and equalizing the two groups of research that influence the accuracy of results of research and to restricting the differences of influence to the independent variable only. In order to start the research, the two researchers divided the research sample which is (32) female students, controlling group practiced learning exercises according to the curriculum of 2nd grade female students, college of physical education and sport sciences of University of Karbala, for (12) educational unit, while experimental group was divided into two equaled sub-group as (8) female student per each, in order to organize the educational curriculum, female students of the two groups learnt the new skill (front hand jump on mat of ground movements) then practicing on it using and developing using lap top computer and data show screen a skill that they have already learnt it (standing by hand on balance beam), the two groups compose the main experimental finally, educational curriculum lasts for (12) educational unit, each lasts for (90) minutes as two units a week due to the differences of learning environment, decreasing time of learning and exciting female students enthusiasm. One of the most conclusions of the research is the preference of using the technology of electronic simulation in developing and improving the level of learning of some skills in gymnastic devices for female students.

Keywords: Simulation, Basic Skills and Technical.

Introduction

Using computer becomes necessary in our life, what we have witnessed of such tremendous and fast development in technology of computer urges us to activate it in the field of teaching by innovative way, as there is no field that doesn’t include important role of computer. Computer is the backbone of educational, economic and social process..etc, and it is the main and fast tool in processing data, not only spectacular scientific and technical developments are the most discriminative characteristics of our time but furthermore the accelerating in average of that development, and extent of effect upon the educational process. Therefore, the student can’t ignore effect of technical and scientific development especially those that relate with technology of information in all fields of life. Computer is employed in all specializations and job fields. Hence computer becomes so important, and learning how to use it’s diverse programs in all fields including teaching, our educational system is a developed one and keep up with development that our world confronts in field of using computer, this system has been updated and enhanced by technology of information and electronic media to become a main element in this system to improve and develop it, directing it to be compatible with new orientations, hence the two researcher decided to use the electronic simulation in explaining main concepts for some gymnastic skills and explanation of them in a best way.1

Because of that the two researchers are working in college of physical education and sport sciences, they observed that there is a difficulty in practicing some basic skills in technical gymnastic for female students
(front hand jump on mat of ground movements, standing on balance beam) as they need more physical potential by female students, and take longer time as they required muscular power, gracefulness and flexibility for female students. In spite of that it is a practical method for teaching these skills but we have faced a difficulty in teaching these skills due to the difficulty of performing these searched skills by female students due to relying on applying the practical, students confronted a difficulty, that urges the two researchers to tackle with this study.

Material and Method

Population: The two researchers used the experimental method with equivalence groups style because this type is adequate with nature of the research’s problem that requires a solution, population was represented by female students of 2nd grade (day time study), college of physical education and sport sciences – Karbala University, year of (2017-2018) who are (42) students.

Subjects: Post exclusion (10) female students from the population to achieve harmony condition in the sample of learners, sample individuals become (32) student, the sample was divided into two equaled randomly groups, (16) female students as a controlling group, (16) female students as experimental group, controlling group takes lessons by the followed teaching method while the experimental group takes lessons by using simulation (electronic media). Groups have the same teaching sessions specialized to learn (Skills which are in process or researching in technical gymnastic for female students). It has been harmonizing the sample with the equivalence of two groups of research that influence the accuracy of results and to return differences of influence to the independent variable only, that is using simulation, therefore it is important to verify the harmony and equivalence of research sample in the variables that are similar to the skills of research as shown in table (1).

Tools and devices used in the research.

Tools and devices:

The two researchers used the following tools and devices:

1. Personal computer.
2. Ground movement mat.
3. Data show.
4. Wooden boxes.

Means of collecting information.

1. Internet.
2. Arabian and foreign references.
3. Observation and experiment.

Field research procedures:

Specifying the two skills of research: The two skills were specified according to technical gymnastic method for 2nd grade in college of physical education and sport sciences to be adapted with the research subject and educational method prepared for it.
**Surveillance experiment:** Surveillance experiment was implemented on (28/2/2017) on the sample of population who were (8) female students from those who didn’t take part in the main experiment, for many aims some of them are:

1. Organizing the work and adjusting time of educational unit’s procedures with all divisions.
2. Knowing how much the tests are adequate with the sample.
3. Knowing the obstacles that may emerge during implementing the tests and educational method and finding solutions for them.
4. Adjusting timings and required recurrent.

**Pretests:** Pretests were implemented for the both groups controlling and experimental on (9-10/3/2017) post finishing two identifying educational units (**), by giving an educational unit for the skill of hand front jump on ground movement mat on (9/3/2017) including explanation of the skill with assistance by pictures and related drawings of such skill, then showing that on a lap top by a special program, then research sample have applied that, at the end of the educational unit, it has been implementing the post test for the sample to assess the technical performance and accuracy of the skill itself.

In the next day on (10.03.2017), giving another educational unit of the skill of standing on hands on balance beam includes same steps of the unit belong to the first skill in term of explanation, showing and application.

Using an accredited skill in assessment of these skills (‘) by giving (10) marks per each skill, this degree is donated by a three - referee committee, then choosing the best degree for each referee via determining the arithmetic mean for the best three degrees to calculate final degree per female student.

**Educational method:** Pre starting implementing the educational method we must illustrate the relation between the styles that aim to find a bunch of aims and make use of electronic simulation in learning some skills of technical gymnastic of students.

Aims of using electronic means are: developing relation between the teacher and student notably developing the student and increasing his personal independency, we noticed that the goal is the harmony, regulation, accuracy, response and controlling in warming-up part of the lesson and concentrating education, that is the reason behind using electronic means.

In order to startup of research procedures, the researcher organized the work of two groups (controlling and experimental) as follow:

- Dividing the research sample which is (32) students by lottery into two groups (controlling and experimental), (16) students per group.
- Controlling group : practicing learning exercises up to the followed educational method for the 2nd grade students in college of physical education and sport sciences of Karbala University base on (12) educational unit.

**Experimental group:** This group has been divided into two equaled sub-groups as (8) students to manage the educational method, female students of both groups trained on learning a new skill of hand front jump on ground movement mat, practicing on it, develop an electronic device (Lap Top), data show and a previous learnt skill of standing by hand on balance beam, these two group compose the main experimental group.

Educational method takes (12) education unit as each one lasts for (90) minutes based on two units per week due to the change of education environment, shortening the learning time and exciting the endeavor of female students.

**Post Tests:** Post finishing applying of educational units experimental and controlling groups, posttest has been implemented to assess the technical performance for the skill of standing by hands on Tuesday (27.04.2018).

On Wednesday (28.04.2018), posttest has been implemented to assess the technical performance of human wheel. Researcher concerned about circumstances to be similar for Pretests in term of (place, time and referees).

**Results**

**Showing, analyzing and discussion the results:** Showing the results for research groups, analyzing and discussion them.

Discussion of Results

The two researchers confirm, through statistic results, that the followed educational method by the teacher of material has influence upon students’ learning of basic skills over ground movement mat and balance beam in technical gymnastic that depends the educational style relied by material’s teacher to the appropriate recurrences that accompanied educational units, plus to performing the continuous exercises considering its adaption to abilities and capabilities of students in addition to the graduation in difficulty level for movements and skills that ensure performance by all participants, that goes with what was mentioned by (Najah Mahdi Shalash and Akram Mohammed, 2000), as they wrote “Practicing and paying efforts in training and frequent recurrences are so important in process of learning and earning skills, also training is a main factor in process of individual interaction with skill and controlling his movements and achieving
harmony between movements that compose the skill in an intact consecutive performance and appropriate time beside it increases learning of a skill and profession of it”. In order to enable the two researchers to discover the differences between post and Pre differences to the individuals of experimental group, they apply processing data statistically and determining values of arithmetic mean, criterion deviation for all variables of the research as shown in table(4), that confirms that there is a significant effect of educational method in learning some basic skills over ground movement mat and balance beam in technical gymnastic which is applied by the two researchers because the training units include a group of different movements for the back, arms, legs and head, also fast and slow diverse movements up to the time of movement, recurrence and the distance, in addition to using a technology by electronic simulation represented by using a monitor (Data Show) and lap top, all of that helps in learning and earning a good level of legal and scientific knowledge for the material technical gymnastic of the students in addition to the skills of (front hand jumping over ground movement mat and standing by hands over balance beam).

The reason behind this learning and earning skills is the response of students for all learning requirements via educational units considered as the most prominent active means to show the powers, keeping best levels and achieving aims, (Nazar Altalib and Kamil Louis, 2000) referred to that “The athletic who endeavor toward a specific aim will be a motive for him in his work, work without an aim is a fruitless and neglected job so the sport instructor should help the athletic to apply an appropriate goal for him to be able to achieve to create a value for the exercise and to let the athletic knows how much he progress”.

Also (Ed.Lisa Yount) refers that “Using learning technology in training is better because it diminish risks of injury and help hearing-problems student to focus and learn the main skills then study materials more exciting, hence students will become more subjected to remember what they have learnt, economically, VR technology will be cheaper than other means”. The two researchers see that using electronic simulation create an ideal environment for learning notably in gymnastic whereas isolating all external influences on the student and help him to concentrate his learning also to update with nowadays development and increasing thrill and exciting for student to break the routine during practicing exercises in lecture.

Education units included a bunch of different movements for back, arms, legs and head in addition to different movement fast and slow up to the movement time, recurrence and distance besides using virtual reality technology via data show screen, all of that help in learn and earn the searched skills.

That ensures the used exercises in education units with window of virtual reality have participated in learning and earning basic skills (On the movement ground mat, jumping beam, parallel beams and hinge devices) for students, researcher attributed that for the response of students for all learning requirements via educational units considered as one of the most active means to show powers, keeping good levels and achieving goals, researcher sees that showing the skill through screen is a keeping up with the modern development that happens in all fields of science, many universities lack this modern method.

Achieving to the aim of the study including knowing the excellence of differences between using environments of electronic simulation and used method by the teacher in improving performance level for some skills in devices technical gymnastic for female students.

Conclusions

1. Using electronic simulation technology has an active effect in developing and improvement of learning level of some skills on gymnastic’s devices for female students.

2. Results showed that there is an excellence in using electronic simulation technology in developing and improving learning level of some skills on gymnastic’s devices for female students

Body Image and Physical Perception of Children with Precocious Puberty in Baghdad City

Adraa Hussein Shawq¹, Eqbal Ghanim Ali²
¹Instructor; ²Professor, Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq

ABSTRACT

Study Aim: To valuate children physical perception toward their early body maturation and their body satisfaction.

Methodology: A cross-sectional study, of (63) children from both genders, > 7 years diagnosed with precocious puberty, attending endocrine clinics in Baghdad city. Consent form taken from children and their guardians to participate in the study. Tanner scale image and Child Body Image Scale CBIS were used, the discrepancy between children selection reflect their physical perception and body satisfaction. SPSS programme version 23 used for data analyses.

Result: children with precocious puberty were occupied in their earlier body maturation; they showed physical awareness toward these changes, and this earlier maturation caused unaccepted body image for them.

The researchers recommended details psychological assessment for children with precocious puberty during their routine physical examination and provide suitable psychological support for them and their parent.

Keywords: physical perception, body image, precocious puberty

Introduction

Normal onset of puberty characterized usually by development of secondary sexual characteristics between (8-14) years for girls and (9-15) years for boys, while earlier onset of puberty than expected described as precocious puberty (1,2). Precocious puberty is more common in girls than boys, approximate 10:1 with no explanation (3&4), attention needed for diagnosis with precocious puberty that result from tumor or other disorder (5), it is consider stressful period for those children (6). Early physical changes and growth spurt caused by premature activation of hypothalamus-pituitary axis, lead to mismatch between their physical maturation and psychosocial immaturity can cause peer differences, behavioral problems, and unaccepted body changes (7,2,1). Accepted body image is affected on children’s self-esteem, social relations, and academic performance positively (8,7,4). Evaluate children psychosocial condition is helpful to prevent children psychological trauma and faced their challenges positively (9,8,1).

Method and Materials

Method

Research design: A cross-sectional study used, data were collected from first of May tile the first of November 2018.

Setting: study was carried out in outpatient endocrine clinics at pediatric teaching hospitals and specialized centres in Baghdad city.

Instrument of the study and procedure: Tanner scale image and Child Body Image Scale were widely used in previous children studies and showed highly validity and reliability. Tanner scale with five pubertal developmental images, gender specific, developed by Marshal and Tanner (1973) used to assess puberty stage, represent the secondary sexual characteristics development during...
period of maturation. Children were asked to select one that closest to their early body changes as they percept. Children assessment compare with physician assessment regarding their puberty stage, the similarity between children and physician assessment reflect children awareness toward their early physical maturation.

Child Body Image Scale is a pictorial scale, with seven image (1= scrawny, 2 & 3= typical image, 4 & 5= overweight, 6 & 7= obese), used to assess children body satisfaction, the approval taken directly from the ownership. Children asked also to select one image that represent their actual body image and select another image that they desire to be. The discrepancy between children actual and desire body image; reflect their body dissatisfaction.

Statistical Analysis: The statistical package for social science (SPSS) version 23 was used for data analysis. The descriptive statistical measures of frequency, percentage, mean, and standard deviation were used. T-test was used to investigate the differences among groups.

In this table, (33.3 %) of children assessed their puberty stage in stage (2 and 3) for both of them respectively, compare to (27%, 49.2%) of pubertal physician assessment in stage (2 and 3) respectively.

In these figures, mean age of children diagnosed with precocious puberty is $(8.41 \pm 2.7)$, most of the sample (88.5%) at school age (6-12) years, (85.0%) are girls.

In this table there is significant association between children and physician puberty assessment by Tanner scale $(p = .000)$, while no association between children actual and desire body image $(p > 0.005)$.

Figure 3: Comparison between children actual and desired body image
In this figure, (38.15, 23.8%) of children actually select obese and overweight image respectively, while (61.9%) of children desire typical image.

**Discussion**

The result of the study support previous finding that, (85%) of children was girls, (88.5%) at school age (figure, 1). This result supported by Al-Shuwailli (2017) and Hammeh (2015) in their study in Baghdad about precocious puberty that majority of children was girls and mostly were > 6 years (6, 9).

The finding showed higher percentages of children and physician assess puberty development at stage 2 and 3 according to Tanner scale. In addition, figure (2) showed (60.3%) of children assessment similar to physician assessment regarding puberty changes, and in table (2) a significant association between children and physician means was at (p. = .000). This finding concerned that children aware toward their body changes; majority of children at school age, their identity and cognitive development was developed.

Different researcher used Tanner scale to assess children puberty development such, a study by Ernst et al. (2018) about self-assessment of pubertal development with 715 child aged 8-16 years showed that children with late stage of puberty can assess their development correctly (10). Another study by Chan et al. (2008) about reliability of pubertal self-assessment in Hong Kong children that with 354 children aged 8-18 years documented that, Tanner pubertal self-assessment scale can reliably estimate for sexual maturation status (11).

Those children experience also body dissatisfaction; figure (3) revealed most of children selection for actual body image was different to their desired one, and table (2) showed no association between children selection (p > 0.005). Because majority of the sample was girls and their body mass index and sexual characteristics was different and developed earlier than peers; mostly lead to unaccepted body image. This may affects negatively on children well-being later, also low educational level and early marriage and may be associated, especially for girls.

This consistent with a study by Williams et al. (2018) about reviewing and evaluation psychosocial studies concerning children with precocious puberty (pp) that, most studies revealed those children experience body image disturbance, low self-esteem, and negative expressive outcomes about their bodies than normal developing children (12).

Choi & Kim (2016) coincide with the present finding in their study about body image and depression of (82) girls diagnosed with pp that, early puberty mostly lead to negative body image, low self-esteem and usually correlated with negative feeling and behaviours about themselves (13). In addition, their awareness about the degree of sexual maturation body was correlated with body dissatisfaction and depression signs, especially late pubertal stage (3- 5) (13).

Michigan Medicine school (2011) reported in their study about children with precocious puberty that, being different from peers especially in body shape make children in stressful situation, children with early maturing body experience teasing, negative body image, and low self-esteem (14).

**Conclusion**

Children with precocious puberty were occupied with their body changes and showed awareness toward their early sexual characteristics development. These earlier body changes affects negatively on their body satisfaction.

**Recommendations**

Assess children psychosocial profile during routine physical examination. Provide emotional and social support for those children and their parent to avoid psychological trauma.

**Conflict of Interest:** The researchers report no conflict of interest.

**Source of Funding:** This study did not receive any funding from any agency.

**Ethical Clearance:** A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Baghdad

ABSTRACT
Health workers are expected to be a role model, especially in healthy behavior, but the concepts and instruments to assess these roles are still few and not specific. This research purposed to describe the concept and develop an instrument of roles as healthy model. The study was conducted for 22 months in Pontianak and Yogyakarta, Indonesia with two stages of research. The four concepts of health workers roles as healthy models are to have a good knowledge, attitudes and behaviors regarding healthy behavior and have an ideal physical appearance. The results of the construct validity was obtained 60 valid items with Cronbach’s alpha was 0.89. The roles as healthy models have gone through the stages of validity and reliability needed in making instruments.

Keywords: Health Workers, Roles, Healthy Model, Concept, Instrument

Introduction
The role as a role model is considered to be a person’s needs at the highest level, to actualize themselves and self-esteem as health workers. Professionalism behavior will be created on health workers who can become a role model that will ultimately affect the patient’s trust in medical action, adherence and satisfaction with health services 1. Confidence in providing therapy to patients is also affected 2. Based on the health professional code of ethics there are four areas that health workers must have to apply their role as role models of health educators, becoming a mentor, becoming role models in responding to differences, showing performance as a teacher, and gaining trust from society 3.

Several studies that assessed the role model of the health workers in their area had used assessment instruments. Based on the literature search found an instrument that has been developed to assess nurses as role models for health promotion 4, other role model instrument is on the physical therapist 5. Nonetheless, from these literature have never been found that developed instruments for evaluating the role of health workers in several health professions and informant groups specifically regarding the role of health workers as role models for healthy living behaviors.

Method
The research process is carried out in two stages starting from May 2017 until March 2019 in Pontianak City, West Kalimantan. This research had received ethical approvalal from the Medical and Health Research Ethics Committee Faculty of Medicine, Public Health and Nursing Universitas Gadjah Mada number KE/ FK/0528/EC/2017 with continuing review approval KE/ FK/0435/EC/2018.

Stage 1. Concept development: The first phase of this research was conducted to develop the concept of the role of health workers as a role model for healthy living behavior, carried out from May 16, 2017 to August 14, 2018, in Pontianak, West Kalimantan, Indonesia.
The study was conducted with exploratory qualitative methods, data collection using in-depth interviews with 26 informants with the background of health personnel from six stakeholders with criterion sampling method. Table 1 shows the criteria for informants used in the study and the number involved in the study.

Data collection was carried out in various places and times agreed upon between informants and data collectors, explanations of research and objectives were carried out from the beginning of the introduction and requests as informants accompanied by the signing of informed consent. Interviews were carried out in only one meeting, with an average time of 60 minutes/informant, data analysis was carried out by transcribing the results of sound recordings, making coding, categories and themes. This process is carried out 2 times for quality control by all authors, in addition to increasing the validity of the results, the expert test is conducted

</table>

Experts have a doctoral education background in nursing with experience conducting qualitative research and qualitative training, meeting with experts is done twice face to face and once via email. To maintain the confidentiality, each informant will be given a code namely PHO (O1-O3), head of PHC (H1-H3), community (P1-P3), medical student (S1-S5), clinical practitioner (L1-L6) and health lecture (L1-L6).

Stage 2. Instrument development: Research in the second phase was carried out to make the instruments roles as healthy model, from four variables based on the results of the theme in stage one. The process of making instruments is carried out from September 2018 to March 2019, starting from setting the type of answer choices with a 5-point-likert scale-strongly disagree, disagree, neutral, agree, strongly agree, determining closed question types, compiling answer instructions and instrument formats.
In the initial stage, 172 pool of items were made where in the first variable to third each was 50 items and the last variable was 22 items, the next stage is content validity with five experts, consisting of three experts representing each health professional organization in Yogyakarta and understand the code of ethics of the role of health workers as role models for healthy behaviors. Others experts expertise in the qualitative field and making instruments with educational doctoral backgrounds in the nursing. The experts were asked to provide an assessment of representativeness and clarity on each item using a 4-point Likert scale-not represent/clear, major revision, minor revision, represent/clear 9. Analysis with Aiken’s V for each item based on the responses of experts 7.

The 105 represent questions are proceed to the trial phase 1, validity criterion test. This stage was carried out on 44 health workers in the hospital of Tanjungpura University Pontianak, RS. Abdul Azis Singkawang and the Faculty of Medicine, Tanjungpura University. Analysis with Pearson product-moment (r >0.2973) and alpha reliability >0.7. Phase 2 trials were conducted on 140 respondent’s postgraduate students of Medical, Public Health And Nursing Universitas Gadjah Mada (FKKMK-UGM). At this stage using the confirmatory factor analysis (CFA) test with the aim of testing construct validity by assessing convergence and discriminant of each item. Analysis using Lisrel 8.80 software results from the evaluation was seen from the evaluation of goodness of fit (GOF), namely chi-square (p-value >0.05), root mean square of approximation (RMSEA) <0.08, standardized root mean square residual (SRMR) <0.08, comparative fit index (CFI) >0.90, in addition to testing between items received by looking at the number of factor loading >0.5 and alpha value >0.75 8,9.

Findings

Stage 1. Roles as Healthy Model Theme: Exploration of the opinion of health workers regarding their role as a role model for healthy living is done by involving 2 health education institutions and 5 PHCs in the Pontianak City area. Based on the results of qualitative analysis it was found that the role of health workers as role models of healthy behavior was defined as behavior patterns, values, attitudes, knowledge that must be possessed by health workers as an example for themselves, the community and other colleagues in applying physical activity, patterns balanced eating, smoking behavior and having an ideal physical appearance, which are grouped into 4 criteria: someone who has good knowledge of healthy living behavior, has an attitude as a role model for healthy living behavior, has a healthy lifestyle and has an ideal physical appearance.

These criteria means health workers have to a good abilities and expertise in applying healthy living behavior as an initiator, promoter and informer of health in the community. Doing physical activity, increasing vegetables and fruits consumption, no-smoking behaviour and having an attractive appearance, fit, energetic and rarely ill was a trends, desire and readiness as health workers to increase public trust and behavior and implementation of health programs.

Stage 2. Instrument development of Roles as Healthy Model: At the content validity test stage, expert qualifications determine the results of the instrument assessment, so the selection of experts is also important. Based on the results of the expert assessment with the Aiken’s V test of 172 items tested, 67 questions were not representative and 82 unclear questions, this was because the item had ratings of less than 0.87. Unclear but representative questions have been corrected according to expert input and used at the trial stage.

The sample at the first trial stage was 14 respondents work as doctors, 16 nurses and 14 nutritionists, respondents have worked for approximately 7 years, with education between diplomas to doctoral degrees. At this stage, 74 valid questions were obtained from 105 questions with coefficient alpha 0.933, questions that were invalid and did not affect the objectives of the variables to be measured, omitted and not used at a later stage.

At the second trial stage, 330 questionnaires were distributed to potential respondents divided into five postgraduate study programs at FKKMK-UGM, but only 140 questionnaires (42.4%) were returned and complete. 66 respondents work as doctors, 59 nurses and 15 nutritionists, besides, 73.6% of respondents are women, aged less than 40 years. In table 2, it can be seen the results of construct analysis where 60 questions have a loading factor >0.5 with the reliability level of each criterion >0.75. 14 Invalid items in each criterion are considered inappropriate because they have a small loading factor of <0.5, which in the end the item is discarded.

*: invalid items; italic: unfavorable item.

At the beginning 172 items was developed from 4 variables roles as healthy model, after evaluating content by expert, there were 105 items that had a high rating. In the test phase of the validity criteria 31 questions were invalid and eliminate at the next test phase, so that the remaining 74 questions to be tested at the content validity test stage. The final result of the instruments roles as healthy model is 60 questions with alpha coefficient 0.89. The standard GOF measurement model is obtained in the roles as healthy model variable, namely the chi-square value = 0.25, df = 2, p-value = 0.88348, RMSEA = 0.000, so it can be concluded that the measurement model on the role model variable has been designed based on theory fit with data in the field. Roles as healthy model instrument available on request.

Discussions

The roles as healthy model are the results of the development of themes from qualitative exploratory results, which as far as it is known researchers have never made an instrument to assess the role of health workers as a role model for healthy behavior in the community before. This instrument has gone through several stages of testing to produce a valid and reliable instrument to be used in a diverse healthcare profession, especially doctors, nurses and nutritionists. Furthermore this instrument was also developed based on information from informants with different workplaces, namely in hospitals, health centers, and educational institutions, in addition to the different fields of work, namely at the
head of the PHC, administrators of health organizations, practitioners in health centers, user communities health services and teaching and medical students.

Health workers are considered as a role model for the community in a healthy lifestyle because they are considered to have extensive knowledge about health, so the role as a role model is attached to health workers as health educators in the community [3,10]. “Practice what they preach” is one of the responsibilities of a health worker who in this study not only in the community but also in themselves and health colleagues [11,12]. The responsibility as a role model is a competence and an unwritten contract with the community, besides that it is considered as the most powerful learning model to share knowledge and skills with others. So that the role as an example must be realized by health personnel, maintaining behavior at all times and places [13]. Awareness of behavior as a role model will increase trust, perception and closeness of relationships with patients, besides that health workers will find it difficult to provide health promotion if they never apply and have experience doing healthy behaviors [14,15]. As a health promoter, implementing a healthy lifestyle will increase his credibility, which will affect the compliance of the treatment and the patient’s beliefs when consulting. In the end, this increased credibility will also increase self-confidence as a health worker who is considered to have good knowledge and abilities [15,16].

When compared with the concept and role model instruments on health workers that have been formed before, several similarities were found such as the concept of responsibility, practice what they preach and accepting themselves as an agent of change. Another concept that is almost the same is that health workers are also a human being who in acting is not always perfect, as well as being a role model of living behavior, even if seen from the social norms, health workers must adopt healthy behaviors as an example and become an example for yourself, the community and colleagues [3,17]. Being a role model is also considered to affect the trust of health workers, patients will pay more attention to the advice given [14,18,19].

The difference in variables formed by concepts and other instruments is the assessment of the ideal physical appearance of health workers. Physical appearance is considered to affect the first impression of the community on health workers, besides that it will also affect self-confidence in doing work and in social life in the community [20]. Positive appearance is an attribute that must be possessed by health personnel in addition to interpersonal skills, ability to be a leader and commitment to the right actions [21,22].

**Conclusion**

Health workers must have behavior, values and knowledge as a role model for themselves, society and colleagues in healthy behaviors such as applying physical activity, balanced diet and no smoking behavior also having an ideal physical appearance. 60 items Instruments roles as healthy model are developed, namely knowledgeable about good health behavior, have good health behaviors, have healthy life behaviors, and have an ideal physical appearance. This instrument still has weaknesses because the number of samples was too small to assess instruments, besides this research is carried out only in 2 regions in Indonesia so that it still has the opportunity to be developed in other regions.

Assessment of Serum Glucose and its Correlation with the Pregnancy

Alaa Umran Musa
Karbala maternity teaching hospital, Karbala, Iraq

ABSTRACT
Gestational diabetes is a temporary (in most cases) form of diabetes in which the body does not produce adequate amounts of insulin to regulate sugar during pregnancy. The aim of the present study, to evaluate the correlation between the serum glucose levels and pregnancy complications in gestational Diabetes Mellitus (GDM) and healthy individuals. In this case control study, pregnant women with GDM (n=30) and healthy (n=30) visited in the Karbala maternity teaching hospital were enrolled in the study. The women showing a fasting blood glucose (FBG) ≥105mg/dl were considered in the group of gestational diabetes (GDM). The GDM women showed significantly (p≤0.0001) higher area under the curve and the fetus birth weight as compared to the healthy women. This increase in the fetus birth weight results in the C-section delivery. About 83.34% GDM women undergone C-section delivery, while only 16.66% normal delivery occurs. The fetus birth weight is positively correlated with the presence of GDM i.e. insulin resistance. Serum high glucose level was positively correlated with the pregnancy complications such as C-section delivery, premature birth, increased in fetus weight etc.

Keywords: Gestational diabetes, C-section delivery, fasting blood glucose, fetus weight

Introduction
Gestational diabetes is a temporary (in most cases) form of diabetes in which the body does not produce adequate amounts of insulin to regulate sugar during pregnancy. It may also be called glucose intolerance or carbohydrate intolerance. The thrifty phenotype hypothesis state that the low neonatal weight is correlated to an increased level of blood sugar or higher peripheral insulin resistance. This low birth weight may leads to an intrauterine programming process retardation which in turn negatively affect organ maturation.

In normal pregnancy, insulin resistance is similar to type 2 diabetes. This syndrome worsens in the third trimester and leads to gestational Diabetes Mellitus (GDM). Changes in insulin resistance occur to transport glucose across placenta that is needed for normal growth of the fetus. When glucose is transported across placenta it stimulates pancreatic insulin secretion. Insulin is also an important hormone required for growth apart from its role of just maintains glucose homeostasis. In GDM there is increased risk of macrosomia which is increasing birth weight of infant >4kg or >4.5kg, induction of labor and cesarean section. GDM is associated with long term adverse outcomes for mother and also for offspring like obesity and cardiometabolic risk. Carbohydrate intolerance often results in high serum glucose levels i.e hyperglycemia during pregnancy. Hyperglycemia during pregnancy is less severe than in type 2 diabetes. But still, it can lead to adverse pregnancy outcome. Carbohydrate intolerance in pregnancy who are without Gestational Diabetes, also leads to adverse maternal and even fatal outcomes. Thus, fetal morbidity is prone at a very lower glucose level in pregnancy, i.e. <140mg/dL. The American College of Obstetrics and Gynecology (ACOG) had laid a few recommendations for GDM patients. The cutoff capillary glucose value must be, Preprandial glucose <95 mg/dL (5.3 mmol/L), 1-h postprandial glucose 130–140 mg/dL (7.8 mmol/L) and 2-h postprandial glucose <120 mg/dL (6.7 mmol/L). Hyperglycemia during pregnancy is generally detected...
between 24 to 28 weeks. It results in poor pregnancy outcome and must be managed properly. Obesity, pregnancy at old age, multi-parity, weight gain during pregnancy, short stature, family history of diabetes, polycystic ovarian syndrome (PCOS) are a few of the risk factors for hyperglycemia during pregnancy. Therefore, diagnostic criteria were conventionalized for 24–28 weeks of gestation including glucose values during an oral glucose tolerance test (OGTT)\(^{10}\). With this background, we aim to study the correlation between the serum glucose and its pregnancy in Iraqi women.

**Material and Method**

This study included 60 pregnant women enrolled to the Karbala maternity teaching hospital in January 2019 to April 2019. They were successively performed a 100g/3hr oral glucose tolerance test (OGTT) between the 24th and 26th gestational week. The test was performed at Karbala maternity teaching hospital according to recommended guidelines of the American Diabetes Association\(^ {11}\). According to this protocol, a full 100-g 3-h OGTT should be performed in all women and their glucose clearance as measured. In the present study, pregnant women with reported diabetes were screened for their further complications.

Fasting blood (n=30) was collected by a single puncture form the diabetic patients and healthy participants after obtaining informed consent. Gestational diabetes mellitus (GDM) patients consider the age group between 19–40 years with fasting plasma glucose (FPG) ≥ 110mg/dl (As per the ADA guidelines). The parameters like child birth weight, type of delivery and duration of pregnancy was recorded.

The fasting blood was collected (2ml) in the plain vacutainers from the vein after getting participant oral consent. The samples were kept at room temperature for 30min. Followed by the centrifugation at 3000rpm for 15min. The serum was separated and kept at 20°C for further study. The post prandial blood sugar was estimated after 1 and 2hr.

Serum sample was used to evaluate serum glucose by using commercially available kits (Coral Clinical Systems, Goa, India).

**Statistical Analysis:** The data were subjected to statistical analysis using GraphPad Instat (3.0, Trial Version). Results were presented as Mean ± Standard Error (SE). Dunnett Multiple Comparison Test and one way Analysis of Variance (ANOVA) was done to estimate the statistical significance.

**Results**

The women showing a fasting blood glucose (FBG) ≥105mg/dl were considered in the group of gestational diabetes (GDM). Other, women were included in the normal group (FBG ≤105mg/dl). The OGTT was performed for all women. The fasting and postprandial glucose levels are depicted in the Table 1.

| Table 1: Blood glucose (mg/dl) levels of women enrolled in the study |
|----------------|----------------|----------------|
|               | Fasting        | Postprandial 1hr | Postprandial 2hr |
| GDM group     | 116.64 ± 0.91  | 172.09 ± 2.00    | 148.48 ± 1.56    |
| Healthy group | 101.5 ± 0.93   | 141.09 ± 2.24    | 112.51 ± 1.22    |

**Area under curve (AUC) for the OGTT:** The GDM women showed significantly (p<0.0001) higher area under the curve as compared to the healthy women. The AUC of GDM and healthy women were found to be 1094520 ± 8418.0 and 885300 ± 4956.3, respectively. The value reflects the significantly higher insulin resistance in the GDM women as compared to healthy women.

**GDM women showed increased in the fetus weight:** GDM women showed significant (p<0.0001) increased in the fetus weight as compared to the healthy women. The birth weight of the fetus is shown in the Figure 1. This increase in the fetus birth weight results in the C-section delivery. About 83.34% GDM women undergone C-section delivery, while only 16.66% normal delivery occurs.
Average weeks of child delivery were found to be about 36.65 and 39.34 weeks in GDM and healthy women, respectively. The presence of GDM leads to the premature delivery.

The fetus birth weight is positively correlated with the presence of GDM i.e. insulin resistance. Serum high glucose level was positively correlated with the pregnancy complications such as C-section delivery, premature birth, increased in fetus weight etc.

**Discussion**

Sugar is released into serum quickly and causes the blood sugar level to rise. In response to this there is a rapid release of insulin, which is required to normalize blood glucose. But instead of maintaining a steady state of energy throughout the day, it results in tiredness. The low level of sugar maintains a constant energy level. High glucose level in pregnancy leads to weight gain in pregnancy, causes gestational diabetes, pre-eclampsia and baby being overweight in later life. Serum glucose plays a major role in fetal growth. But the normal levels of glucose must be clearly defined in pregnancy and its effect on fetal growth must be evaluated.

Perinatal morbidity and mortality is often affected by blood glucose levels during pregnancy. Serum glucose level during pregnancy affects the infant birth weight. Hyperglycemia and Adverse Pregnancy Outcomes (HAPO) study reported that previous diagnostic cut offs for diabetes in gestation has predictive value for fetal hyperinsulinemia and LGA. Thus, International Association of Diabetes in Pregnancy Study Group and the American Diabetes Association (ADA) revised these cutoffs and later recommended new lower criteria for gestational diabetes diagnosis. But, there are many women whose glucose values are within therapeutic range but still deliver macrosomic infants.

Previous reports have documented that serum glucose influence amniotic fluid glucose concentration. A positive correlation exists between maternal serum glucose and amniotic fluid glucose level. Maternal hyperglycemia affects amniotic fluid glucose and results in elevated glucose levels. Negative correlation is reported between glycemic control and vitamin D levels in serum of gestational diabetes patients. It is speculated that high blood glucose level in pregnancy raises the risk of baby’s congenital heart defect. According to a study led by researchers at the Stanford University School of Medicine it is reported that women with diabetes are likely to give birth to babies having heart problems. Significant correlation was also found between glucose and sonographic parameter which were estimated during gestation. In our study, we found the correlation between the glucose and child birth weight.

In gestational diabetes, blood glucose level becomes high and is associated with increased fetal insulin and fetal size. It results in adverse obstetric outcome. In the pregnancy volume of blood volume, plasma is increased. During the third trimester the female suffers from anemia due to increase in demand of nutrition for the baby. Hemoglobin levels become lower during the third trimester as compared to first trimester in pregnant women. Also, the hematocrit decreases with increase with advancement in gestation. It is well reported that serum glucose concentration increases from first trimester to third trimester. In later stages of pregnancy insulin secretion is is increased by 2-3 folds by the nutrients. This effect is due to binding of receptors to insulin which is altered by hormones released by placenta mainly, human placental lactogen (HPL), estradiol, progesterones, and free cortisol. In pregnancy serum glucose is elevated by appears more prolong in the post prandial state. Hyperglycemia and Adverse Pregnancy Outcomes (HAPO), was important study that highlighted the association between maternal serum glucose level and its prenatal complications. The study reported significant and increasing association between fetal macrosomia, need of caesarean section for delivery, neonatal hypoglycemia, etc. One more study by Riskin-Mashiah et al demonstrated the similar association of fasting glucose in the first trimester and the occurrence of complications in pregnancy. Our finding are accordance with these reports.
Conclusion

From the above study, we can conclude that the fetus birth weight is positively correlated with the presence of GDM i.e. insulin resistance. Serum high glucose level was positively correlated with the pregnancy complications such as C-section delivery, premature birth, increased in fetus weight etc. The serum glucose should be monitored strictly so that it will leads to the healthy or normal delivery.

Ethical Clearance: The blood was collected from the Karbala maternity teaching hospital after their investigation. Oral consent was taken before enrolled the patients in the study.

Building and Applying the Personal Values Measure for the Administrators of Sports Clubs and Clubs for People with Disabilities from the Point of View of the Players of Some Games

Amal Adulameer Tuama¹, Methaaq ghazi¹

¹Faculty of Physical Education and Sports Sciences, University of Thi-Qar, Iraq

ABSTRACT

The research community was identified with disabled players of some games in the provinces of southern and Middle Euphrates Iraq. There were 228 disabled players who constituted 97.36 % of the research community.

The researcher built and applied a measure of personal values to (110) players and the scale was applied to (100) players. The sample was divided into six levels. The highest proportion focused on the levels; excellent and good and good.

The scale entertained some validity, construct and reliability coefficients (0.89). The researcher concluded:

1. The scale designed by the researcher is able to reveal the level of personal values for administrators of sports committees and clubs for people with disabilities.

2. The creation of standard scores and levels of the personal value scale as the objective evidence for the administrators of sports committees and clubs in assessing the level of the player for the group to which he/she belongs.

Keywords: personal values, administrators, disabilities and players.

Introduction

Values are considered an important axis for personality and a criterion for judging the normality and abnormality of behavior for values determine the scope of success obtained by individual and organizations in the achievement of objectives. Many organizations underwent a lot of problems that needed new working techniques to overcome such problems. It is to be noted that organizations and governments can coexist with renewing and increasing financial, economic and political crises, that is why management has to look for new and modern techniques to address such problems for it is impossible to deal future difficulties with outdated methods for applying old pattern of management would lead to the extinction and disappearance of organizations due to their inability to adaption. Studies and researches introduced a new management pattern, which in turn limits the problems of the management. The value-based system was introduced as a contemporary introduction of management. Therefore, authors and researchers were required to go through the value system through which the theory of value-based system will be developed, and the nature of values diagnosed in the way that it can effect on personnel, and determine to how far these values can improve administrative work in general.¹

Among the important areas of the sports institution is the sport of those who need special care for they make the pillars of society building and an active part in the process of its development. The building of such community requires concerted efforts, including individuals who suffer from physical disabilities. The states of the world have recently given serious interest to the disables’ sports as considered a vital part of society which needs to be provided with an opportunity to play an active role in various walks of life, including the sports field represented by the investment and development of their remaining abilities and talents. The selection has to be performed according to special disciplines taking into account the voluntary aspect that stems from the faith in certain values that take care of the society and...
its interaction with the individual subjective values and this is not enough if the privacy of the administrative work and method of modern scientific management are considered. There should be personal and administrative values to constitute a successful basis for the work, similarly as other organizations do in the society.\(^2\)

Personal values express the individual’s self-beliefs, as seen from his point of view considered as a fundamental element of the culture of the organizations constituting individual personality and contributing to the defining of his goals within a proper normative framework. The personal values provide individuals with diverse options that determine their behavior and modify it and help in the prediction of the individual’s behavior. Personal values greatly affect the individuals’ private and practical lives as considered one of the basic components of the personality. The impact covers individuals’ behaviors, trends, attitudes and relationships, and thus provide an important framework to direct individual’s and groups’ behavior and organize it within and without the organizations. The importance of the research lies in the collection of accurate information on the personal values of the administrators of disables’ sports committees and clubs from the point of view of players of some games.\(^3\)

**Methodology of the Research**

The researchers adopted the descriptive methodology, which is an accurate description of the mutual relations between society, trends, desires and development in a way that the research reflects the living reality and devises parameters, and builds future expectations.

**The community and sample of the research:** The research community was determined by the disabled sports players in some gaming teams in the southern and middle provinces of Iraq; they are 228 in number at 97.36% of the research community. The sample included 110 disabled players for the building sample and 100 disabled players for the sample of application. Six of the total number of the players were excluded for the forms were not filled and Table (1).

**Means, tools & appliances used in the Research:**

**Means of collating data:**

- Arabic & foreign sources.
- Personal interviews.
- Questionnaires.

- International electronic information.

**Tools and Appliances:**

- Hp computer (2).
- Manual electronic calculator (Casio) stationary and office tools.
Field procedures of the Research: For the purpose of conducting of the research, the researcher had to build a scale for measuring the personal values of the administrative staff of the sports committees and clubs of the disabled athletes from the viewpoint of the players of certain games in the southern and middle provinces of Iraq as per the following steps:

Measures of building of the measure scale of the personal value:

Drafting of the primary formula of the measure:

1. Reviewing the literatures related to the personal values and identifying articles and schemas of the measurement values.

2. The researcher worked out a questionnaire and distributed it to the experts and specialists in the field of general psychology, cognitive psychology, sport psychology, administration, organization, tests and valuation.

3. The researcher conducted a series of personal interviews with some of specialists in general, and sports psychologies, in international economics, management and organization, business management and administrative systems so as to obtain larger amount of information which helps the process of determination of the measurement values and its norms.

The primary scale of measurement consists of 35 formulated paragraphs. There were also a set of methods pursued by the researcher to form the paragraphs of the measure in a way that each paragraph shall have one idea and its language shall be simple and direct with avoidance of using negation which may embarrass the respondent. The researcher used every day language in the paragraph formulation.

The final analysis about the validity of the domains (values) of measuring personal values resulted in the acceptance of 5 domains out of 6 domains with the exclusion of religious values as shown in Table (2).

Table 2: Shows the percentages and values of (Chi square) of the experts’ views about the validity of the domain (personal values)

Application of the scale to the building and standardization sample: The scale was applied to the building sample from 19/7/2018 to 10/8/2018. The sample of the building included (110) players representing (22) teams from (8) provinces of Iraq situated in the south and the Middle Euphrates. After answering was completed, the forms were checked to ensure that all paragraphs were answered.

Correction of paragraphs of the measuring scale: The scale of measuring personal values of the administrative personnel from the disabled players’ viewpoint consisted of (29) paragraphs distributed into 5 domains as shown in table (3).

</tr>
</tbody>
</table>

The researcher adopted the pentatonic stepladder after being observed by the experts.

Internal consistency coefficient for scale paragraphs: The internal consistency value of this index was extracted by using the simple correlation coefficient (Pearson) between the score of each paragraph and the total score of the scale, which resulted in the acceptance of all the paragraphs.

Table 5: Shows the values of correlation coefficient of the internal consistency of the paragraphs of the personal value scale

Table (6) shows that the excellent level was represented by the raw grades (109.34 and on), which corresponds to the standard grades (81-100) and 27 players with percentage of (27%). The level very good was represented by the raw grades (67, 109.33-92) corresponding to the standard grades (61-80) with 58 players and having the percentage 58%, which corresponds to 13.59%, which is higher than the normal value. While the level good was represented by the raw grades (76-92.66), which corresponds to the standard scores (41-60), where the number of players was (11) player obtaining the percentage of (11%), which corresponds to (34.13%) which is less than the normal value. The level average was determined by the raw grades (58.34-75), which corresponds to the standard grades (31-40) where the number of players was (4) with percentage of (4%), which was less than the normal value (34.13%), whereas the fair level was represented by the raw grades (41.67-58.33), which corresponds to the standard scores (21-30), where the number of players and the percentage were zero, and the poor level was determined by the raw grades (41.66 and down), which corresponds to the standard grades (1 - 20) where the number of players and the percentage were zero. Based on table (6) it was observed that the highest percentage of the research sample was concentrated on the level (excellent), followed by (very good), (good), and (average). 6

The researchers attributed that to the administrators of sports committees and clubs due to importance of personal values and beliefs adopted by the manager or administrator in the organization and its role in activating the administrative process, 7 and found that the more positive values of the administrative leaders increase, 8 the more they impact on the efficiency of administrative procedures, through the understanding by the leaders of their subordinates values and thus taking care of their feelings and concerns in a way that reflect the best impact on their psyche and vice versa as well as the employee who contrasts with his group values or with his superiors’ or with the values of the organization in which he works, he would act differently, 9 creating a conflict that generates divisions and separation among the working individuals of the institution. 10 The levels (fair) and (poor) did not score any proportion on the scale of personal values and the researcher believed that this was attributable to the degree of awareness of the sample which placed them at the fair and poor levels, mainly they did not score any proportion in the levels. 11

**Conclusions**

Based on the presentation, analysis and discussion of the results, the researcher reached the following:

1. The scale designed by the researcher was able to reveal the level of personal values for administrators of sports committees and clubs for disabled people.

2. The founding of standards and levels of the standard measure of personal values that serve as objective evidence for the administrators of sports committees and clubs in assessing the level of the player for the group to which he belonged.

3. The sample was distributed naturally in the level of personal values for administrators of sports committees and clubs for disabled people, and the personal values scale was divided into six levels ranging from poor to excellent.

4. The variation of the sample members in their obtaining different grades, levels and percentages through the application of the measure of personal values, the highest level of proportion was at the level excellent followed by the very good and good levels.

ABSTRACT

In order to control population growth, Indonesian National Family Planning develop Family Planning (KB) Village Program. The implementation has found some obstacles, in terms of cross-sector/partnership integration reached around 25%. Especially in formal legal aspects and funding which are suboptimal. It is qualitative research with explorative studies. Data collected from in-depth interviews, field observations and analysis. It was conducted in October - November 2017 in KB Village of Bulu Meduro Village, Banjar District, Tuban Region and KB Village of Kota Lama Sub-District, Kedung Kandang District, Malang City. There were 55 participants recruited. The results showed that the implementation of the KB Village Program in Tuban Region had formal legal aspects from the Regional, District and Village Governments, cross-sector partnership had been going well, the Regional Government to the Village Government have allocated budget to support it although limited. Whereas the Implementation of the KB Village Program in Malang City has not received the support of a comprehensive formal legal aspect yet from the level of the City, District and Subdistrict Governments, so that cross-sector integration and financial support still encounter many obstacles. The conclusion is the implementation of the KB Village program needs improvement with the stronger commitment or political will of policy makers at various levels ranging from the Regional Government to the Village Government to provide total support for each planned program.

Keywords: family planning village, cross-sector partnership, local government, formal legal aspects

Introduction

Increased population is a prominent problem experienced by many developing countries, including Indonesia. The total amount and rate of population growth that is not matched by good welfare conditions are still the main problems in Indonesia. The current population of Indonesia is rapidly growing and causing high unemployment and poverty. Based on that situation, family planning programs were created to develop the community. Maximizing the implementation of family planning programs are certainly an absolute choice for the current government. According to the regulation number 52, year 2009 about population growth and family development as the basis for implementing Family Planning Population and Family Development Program.
One of the mandates of the law, specifically in family development is to establish Family Planning (KB) Village which strengthen The Family Planning Population and Family Development Program (KKBPK) that carried out by compiling activities that directly effect the community by providing beneficial activities for the community and also achieving the targeted objectives. KB Village requires the support from government and private group to work in accordance with the needs and conditions of the local, and also implemented at the lowest level which is neighborhood.2

KB villages are expected to be one of the strategic innovations to be able to implement the KKBPK program’s priority activities in full in the field in realizing the Priority Agenda 5 (five) of the 9 government priority agendas for 2015 - 2019 namely “Improving the Quality of Indonesian Human Life” through Family Planning Population and Family Development Program. Moreover, BKKBN itself has compiled the 2015-2019 Strategic Plan with 6 (six) predetermined strategic targets, namely: (1) reducing the average Population Growth Rate (LPP) from 1.38% per year in 2015 to 1.21% per year in 2019, (2) the decrease in the Total Fertility Rate (TFR) from 2.37 per woman of childbearing age (WUS) in 2015 to 2.28 in 2019, (3) the increase of Contraceptiive Prevalence Rate (CPR) of all methods from 65.2% of total fertile age couples (PUS) in 2015 became 66% in 2019, (4) the decline in family planning needs was not served by unmet need from 10.6% in 2015 to 9.91% in 2019, (5) the decrease in the Age Specific Fertility Rate (ASFR) of 46 per 1000 women in the age group 15-19 years in 2015 to 28 per 100 women in the same age group in 2019, (6) the decrease in the percentage of unwanted pregnancies from WUS from 7.1% in 2015 to 6.6% in 2019.2

Data collection techniques that is used are primary data collecting with questionnaires, in-depth interviews, and direct observation. The validity of the data in this study uses source triangulation. Analysis of the data used in this study are data collection, data reduction, data presentation, data analysis and conclusion drawing.

Result

Results of interviews with Sub-District Head, Village Head, Village Midwife, Head of the Prevention of Narcotics Abuse in BNN, Education Agency and National Population and Family Planning Board (BKKBN) related to KB village program implementation in Malang City and Tuban Region are as follows:

There is no Camat Decree for KB Village. Partnerships that have been cooperated through Branch Leadership Deliberation (muspimcab): Military District Command (Danramil), sectoral police (Kapolsek), Islamic teachings and pre-marital directives (KUA), Family Welfare Development (PKK), Cadres, Health Office (for Health), Department of Population and Civil Registration (Dispendukcapil) that giving services in sub-districts. KB Village funds is taken from the District PKK. Data collection in sub-districts is not available, but available in each village. The KB Village specific meeting did not yet exist at the sub-district level. However, there are cross-sectoral meetings every 3 months attended by the head of sub-district, police chief, military command, all the village heads, PKK, and BNN
Activities such as the Elderly Posyandu, twice a month in coordination with the Social Service, and Health Office. Youth activities are actively carried out. Then there is the marriage dispensation (related to the time-consuming marriage management), especially the Madurese.

Whereas in Tuban City the implementation of the KB village is as follows:

The establishment of the KB Village is legal formal, an Instruction letter from the Head of the village, followed by instructions to the village. So the eagerness to enter its budget through the village income and expenditure budget plan (APBDes) could arise. Not merely support through the budget. However, the situation and conditions in the institution often change, for example the Family Planning Field Officer (PLKB) staff from the BKKBN joins the Health Office and then joins Bapemtas, then joins the Center, the numbers are less so weakening. But what strengthens is that the support of the regional head is very strong. Coordination and advocacy from the district level to the lower level must be strengthened.

In Malang City: Frequent activities with KB villages, namely being invited to community groups is the next plan. If there is a meeting, in the sub-district by inviting youth, cadres, KB Field Officer (PLKB), Bhayangkara Fostering Community Security and Order. The status of the working group in Malang City is still needs to be known and should inviting the head of the Technical Implementation Unit (UPT)s to jointly carry out the activities. Especially through Planned Generation (GenRe) activities. The budget provided for activities is usually described in the work plan.

The benefits of the KB Village Program implementation:
According to Puskesmas Midwives in Malang City and Tuban;

After the KB village program is implemented, there are two KB safari services. For acceptors with low income may be served more through KB cadres. The form of family planning (KB) Safari that conducted in Community Health Centre (Puskesmas) is collaboration with PLKB, especially for Intra Uterine Device (IUD)s and Implants.

In Tuban Regency, about the benefits of the KB Village:

After there KB village is established, the residents slowly leaving their habits to defecate in the sea, then build and use their own latrines. KB Village meetings often use a newly constructed building. The Village KB Team Decree was signed by the Head of the Village, but for the KB Village Team decree it still involved its Regent District Head.

Differences before and after the KB village is that after a family planning village has a family planning participation increased, activities about family planning and health care have increased, community awareness about family planning has increased. Physically a special room has been built for KB Field Officer (PLKB) activities, Posyandu rooms, meeting/extension rooms, construction of the gate at the time of launching. There is also a building, accompanied by BKKBN activities.

How is the Budgeting for the KB Village Program Implementation:

There is no special budget for the implementation of KB village programs in each village. However, the budget that has been used so far is Village Budget. During this time the main obstacle in implementing KB villages in each village was the lack of a budget. This is because not all villages have made KB villages a priority for the program.

The obstacles of the implementation of the KB village program:

The obstacle in the implementation of KB Village activities is funding or the budget for KB. The biggest challenge is the community. Do they realize that these drugs damage intelligence. there is no crossing between sector and everything depends on the leader. The challenge is the unique community, because the majority of people are Madurese and difficult to regulate. The strategy that needs to be done is to continue to intensify the KB Village program with other sectors.

Suggestions for implementing the KB village for the future:

Shared commitment that village KB activities must be frequent (because frequency become obstacles) and need mutual care from all parties, especially funding for frequent activities. It is hoped that the Regional Device Organization (OPD)s can open themselves to KB villages. For the majority, KB activities should be promote even more.
The expected results from this study are the increasing use of MKJP, the majority of the community already has latrines, the creativity of adolescents increases, there is no early marriage, and toddlers and the elderly are getting healthier. The challenge of implementing the KB village is the funds that goes for KB village activities that have not been given perfectly.

Discussion

To achieve the success of KB village program, there are at least 6 main factors that need to be improved, those main factors as follows:

1. Strong commitment from stakeholders at all levels (City, Sub-District, village): Support from partners at the provincial level with strong advocacy. One of the most basic things from the success of the KB village is political will or commitment from the head of the region or stakeholders at all levels. This commitment must be clear so that each program in KB Village can run well with budget support. In addition, this commitment is needed to bridge various sectors that must take part in implementing the KB Village program. The reason is that the implementation of the KB Village program was not carried out by the OPD related to family planning but instead required synergy from various existing OPDs.

2. Gather partners donors to help those who have not been able to immediately make latrines: The factors that influence empowerment in human resource development among them are the existence of self-resources and self-abilities in the form of modeling, motivation, and support. There needs to be support and model for village level community members in the provision of healthy latrines.

3. Establish standard procedures at the district level for a grace period for disbursing funds and donors: The family planning program has been recognized as the most effective factor in intervening health problems globally. The need for clear collaboration between the Government and the relevant BKKBN establishes standard procedures at the district level for a grace period for disbursing funds and donors.

4. Integration of the KKBPK program and cross-sector integration: Principle of the KKBPK Program is to embodies a happy and prosperous small family by implementing eight family functions. Cross-sector development and partnerships involve the role of various parties such as the private sector, providers, and other stakeholders. Cross-sector integration is in the form of integrated services between sectors that are community needs, such as family planning services, deed-making services, road and bridge construction, ID card making, reading books, posyandu, Early Childhood Education Programs (PAUD), Program for Increasing the Role of Women Towards Healthy Families (P2WKSS) and others.

5. Enthusiasm and dedication of the KKBPK program managers in field: Family planning is a program that has the most simple yet practical meaningful quantity in improving the family’s social and economic welfare. The success of the important KB Village Program is supported by an increase in public awareness and participation in managing family planning programs carried out by Rural Community Institutions, NGOs, private sector, community leaders and other relevant government institutions.

6. Active Community Participation: Active participation from community leaders, religious leaders and traditional and community leaders in the management and implementation of all activities that will be carried out in KB villages is a basis prerequisite for the establishment of KB villages to improve the standard of living of all communities in the region. In addition, the involvement of the private sector in developing the Development Program in KB Village was very important as a form of mutual cooperation from all parties.

Conclusion

KB village is a strategic innovative program in supporting The Family Planning Population and Family Development Program (KKBPK). Because KB Village is a model or miniature development that involves all sectors in the community. Based on results of the study conducted in 2 locations of KB villages it can be concluded that the existence of KB villages since its inception in 2016 contributed to a number of indicators. The weakness of implementation of the KB Village program needs improvement with commitment.
or political will of policy makers at various levels ranging from the Regional Government to the Village Government to provide total support for each planned program. In addition, eliminating sector ego is an important key to the success of the KB Village program.

ABSTRACT

This study aimed to assess the effect of peer intervention models on nutrition educator intervention in an effort to change behavior in decreasing of overweight at Islamic Elementary School of Makassar. The design of this study was quasi-experimental with non-equivalent control group design. The subjects were selected by proportional random sampling. The intervention did for six months with mentoring of peer nutrition educators and module administration, obesity prevention management leaflets, peer education for 25 minutes each week and evaluating using questionnaires and measuring body mass index of children using WHO’s Anthro Plus. Data processing was analyzed by univariate and bivariate analysis with Independent t-test, Mann-Whitney test and Paired t-test and multivariate with Hotelling test. The results show that there were differences in nutritional knowledge, attitudes toward nutrition, physical activity and significant snacking habits for overweight children before and after peer education by peer nutrition educators (p = 0.000 <0.05). This proves that there is an influence on the peer assistance model of nutrition educators on change in nutritional behavior in an effort to control the lifestyle of overweight children after they are given peer nutrition education. This study expected to implement an integrated peer nutrition education in physical education learning in schools for obesity prevention.

Keywords: Overweight, Obesity, Nutrition Educator Peer, Nutritional Behavior, Physical Activity

Introduction

The prevalence of overweight and obesity are one of the public health problems that occur in school-age in various countries. The world health department has stated that obesity is one of developing determinant factor for diabetes mellitus, hypertension, and heart disease1. Globally, other research conducted in Singapore shows that the prevalence of obesity increased from 9% to 19%. This perspective would continue increasing to reach a prevalence estimate of 9.1% by 20202. Obesity is the cause of various risk factors for disease and death3. Based on the Republic of Indonesia’s basic health research (2018), the prevalence of overweight children aged 5-12 years 11.8% overweight and 9% obese, and the prevalence of overweight in South Sulawesi province according to body mass index per age of 13-15 years as many as 13.6% obese and 21.8% obesity4. The prevalence of overweight and obesity in Indonesia occur mostly in school-age children and is a threat to Indonesian children5.

A preliminary study conducted by the researchers in 16 Integrated Islamic Elementary Schools in Makassar by anthropocentric measurements and calculating body mass index per age of children and then entering into the standard deviation values based on sex and age of children, of the total children 2,177 children, who has nutritional status consisting of very thin 2.53%, thin 4.92%, normal 62.15%, overweight 13.92%, obesity 16.49%. The results of this survey show that school-age children prefer to buy food and eat snacks that are always over-served triggered by urban lifestyles. This is a fact of the high trigger of overweight and obese children. Overweight and obesity are part of the result of an unhealthy diet. The epidemic of overweight and obesity in children caused by bad diet including fewer consumption fruits and vegetables and consuming more high-fat foods but less physical activity\(^6,7\).

The finding on overweight and obesity are due to unhealthy diet behavior and lack of physical activity, thus an intervention strategy that is used in the prevention of obesity that is to assist peer nutrition educators. Nutrition educator peers are reinforcing factors that can influence the behavior of school-age children including eating behavior. Peer groups can have a negative or positive influence on school-age children. Friends of the same age can become peer nutrition educators, as one of the health education strategies\(^8\). Efforts to prevent overweight and obesity in school-aged children are focused on efforts to improve healthy eating patterns and reduce relaxed activities through peer nutrition educator approach in schools. Overweight and obesity is a nutritional problem when adults can be repaired and prevented when children so prevention of obesity in school-age groups can be effective. The peer intervention model of nutrition educator is applied to change nutrition behavior, increase physical activity so that it can prevent overweight and reduce the prevalence of obesity. This study aims to prove the influence of peer intervention models for nutrition educator intervention in an effort to change behavior in decreasing the incidence of overweight.

### Material and Method

The study uses a quasi-experimental approach with non-equivalent control group design with the aim of proving the influence of peer nutrition educator intervention models on behavior change prevention of obesity in the Integrated Islamic Elementary School of Makassar conducted for 6 months. A sample of 80 children consisting of 40 children received intervention in the form of assistance, modules + leaflets and discussions through peer group sharing and 40 children only received modules and leaflets. The research subjects were divided into two namely the treatment group and the control group. Then measurements were taken before and after the intervention (pre-post test) in both groups. The Research had taken two times for measurement of weight and height of school-age children, one time before and after the intervention. Because each school has a different number of overweight children, the proportional random sampling of each child in the selected school is conducted. Data collected were nutritional behavior and physical activity carried out through direct interviews using questionnaires, anthropocentric data including body weight and height, nutritional status assessment determined by WHO’s Anthro Plus 2007 software for school-age children 5-18 years. Before and after the intervention, the child’s eating pattern as measured by the Food Recall form is 24 hours. Analysis of differences in nutritional behavior, diet, physical activity between the treatment and control groups after the intervention were used chi-square test, independent t, t paired, Wilcoxon, Mann Whitney, T² Ho telling.

### Results

This research was conducted in the Integrated Islamic Elementary School of Makassar from September 7, 2018, to February 27, 2019. Distribution of children’s characteristics can be seen in table 1 as follows:

### Table 1: Characteristic of Participant

Table 1 shows that children in the intervention group had more female sex (52.5%), class IV (70.0%), average body weight 39.3 kg with height 137.8 cm. Children in the control group had more female sex (60.0%), average body weight was 35.9 kg with a height of 152.0 cm. The results of the chi-square test and the independent t-test obtained p > 0.05, which means the condition of sex, class, weight, and height of the intervention group children with the same control (homogeneous). Changes in obesity prevention behavior before and after intervention can be seen in the following table:

p*: Wilcoxon test p**: Mann Whitney test

Table 2 based on the Wilcoxon test results showed that all children had knowledge about nutrition, nutritional attitudes, physical activity and eating habits that increased when post 1 and post-test 2 were compared at pre-test (p = 0.000 < 0.05). This shows that there is an influence of the provision of modules and mentoring peer nutrition educators on increasing children’s knowledge, nutritional attitudes, physical activity, and snacking habits. Increased knowledge of nutrition, nutritional attitudes, physical activity, and snack eating habits were higher in the intervention group compared to controls and decreased nutritional status (p = 0.000 < 0.05). The difference in the influence of peer nutrition educators on changes in nutritional behavior and physical activity towards prevention of obesity can be shown in the following table:

Table 3 based on the results of the statistical test with the Hotelling’s T test obtained the value of $F = 2888.82$ and $p = 0.000 < 0.05$. This means that there are differences in nutritional behavior and physical activity of children who receive peer nutrition educators with no peer nutrition educators. Nutrition educator peers influence nutrition knowledge, nutritional attitudes, physical activity and snack eating habits ($p < 0.05$).

**Discussion**

Change of eating habit in school-age children causing of overweight and obesity are low knowledge of nutrition. Knowledge of child nutrition is very influential on food selection\(^{(9)}\). The result of the study prove that all children have knowledge about nutrition which increases when post 1 and post-test 2 compared to the pre-test. This can be seen from the results of the Wilcoxon test which shows a difference in students’ knowledge about nutrition between before and after the post-test 1 and 2. This assumed in the treatment group that with a six-month intervention using peer nutrition educators can improve children’s nutrition knowledge. The result means that there is a difference in the nutritional knowledge of the children in the treatment group before and after nutritional education with a mean change in value higher than the control group. This assumed to increase nutrition knowledge after intervention through modules, leaflets and peernutrition educators. It results in line with the research of Sulisnadewi et al. (2012) showing that family health nutrition education is effective against the family’s knowledge ability to keep diarrhea in children in the treatment group\(^{(10)}\). It shows that after health education with the application of peer nutrition educators to overweight prevention is very effective. After health education is with the application of peer nutrition educators. Good knowledge of children’s nutrition strongly supported by self-efficacy having high confidence to change to be better in controlling a healthy lifestyle in children. Knowledge of good nutrition of children is also in line with the knowledge that has increased from the first month to the sixth. Knowledge of children’s nutrition results in a decrease in body weight or a child’s body mass index. Increased knowledge of nutritional treatment groups from month to month changes. This was due to the fact that at the beginning of the visit, the children had been given a module then given a peer intervention nutrition educator every visit all children were well-informed in preventing and controlling behavior in overweight and obese children.

The attitude of school-age children to overnutrition also plays a role in preventing negative nutritional behavior where the attitude is readiness or willingness to act and not an implementation of certain motives. The positive actions of school-age children on nutrition have a direct effect on children’s eating behavior to be positive, but negative actions on nutrition almost certainly have an impact on nutritional attitudes and behavior\(^{(11)}\). This shows that there are differences in attitudes at the time after post-test 1 and 2 in both treatment and control groups. Nutritional attitude scores were higher in the treatment group than controls and proved in the treatment group that with a six-month intervention using peer models, nutrition educators could improve the nutritional attitudes of overweight children. Thus, the nutritional attitude of a good child will also have sufficient ability to control the child’s lifestyle.

Nutrition education in educating children using modules, children are sure and very useful to obtain nutritional information from peers so that they can improve their nutritional attitudes in choosing healthy foods. This is due to the treatment group in the form of peer nutrition educators, while the control group only obtained modules and leaflets without peer nutrition educators. This statement is justified by other studies suggesting that peer nutrition education plays a major role in children’s attitudes and adherence to a diet. Nutrition educator peer needs an individual peer approach that aims to help individuals gain a better understanding of the over-nutrition problems faced and help to make decisions in overcoming these over-nutrition problems. Education through peer groups is more effective if children are gathered with their peers or their classmates so that children feel more comfortable.
and free in discussions so that they can optimally improve their understanding of healthy snacks. Ayaz, et al. (2015) obtained results through their research that pre-post test scores on students showed a significant value (p < 0.05) higher in students who attended a school that applied peer group learning compared to schools that applied ordinary learning exercises.

Overweight children move a little activity than children with normal weight. Physical activity is needed by children. From there the child learns to enjoy physical activity. Increased physical activity was higher in the control group than in the treatment group. Based on the results of the analysis there were differences in physical activity of children after intervention in the treatment and control groups, changes in activity showed that there was an increase to 93.2% in the sixth month while the physical activity of the control group children decreased. This proves that there is an influence of peer nutrition educator intervention on children’s physical activity. Increased income of people in certain socioeconomic groups, especially in urban areas, causes changes in dietary patterns and patterns of activities that support an increase in the number of obese people. Overweight occurs in children who have a lighter level of physical activity than children with heavy activity.

The decrease in snack eating habits was higher in the intervention group than in the control group. School-age children like to eat snacks such as fried foods, banana chips, cassava chips, sweets, sweets and others that are sold freely in the cafeteria while eating fruits and vegetables is rare so their diet is low in fiber. Snack foods can reduce appetite so that children who consume too much snack foods will usually eat more frequency and fewer portions, often not eating. The behavior of children consuming snacks followed by a sedentary lifestyle (sedentary behavior). Eating snacks while playing games, watching television and rarely moving can lead to overweight. It should be a major concern that to solve the problem of obesity a multi-factor and cross-sector approach is needed. Changes in nutritional behavior and increased activity are a good first step. Low-fat foods, rich in fruits and vegetables and limiting consumption of snacks are the right combination for children who want to maintain a normal nutritional status to prevent obesity.

**Conclusion**

The application of peer nutrition educator assistance and the use of peer nutrition education modules and leaflets affect the prevention behavior of obesity and the reduction in over-nutrition status of children.

Association between Maternal Iron and Vitamin D with Risky Development of Autistic Children

Ashraf M Osman¹, Hanan M Kamel¹, Emad A Abdel-Naem², Aliaa M Higazi², Noha Mahmoud Abdullah³

¹Professor, ²Assistant Professor, ³Assistant Lecturer, Department of Clinical Pathology, Faculty of Medicine, Minia University, Minia, Egypt

ABSTRACT

Autism is one of neurodevelopmental disorders that shows increase in prevalence for last two decades. It was noticed many risk factors associated with development of autism. Here in our study, we were focusing about mothers risk factors that predisposing to get children with autism. We selected mothers that have autistic children and measured serum levels of maternal iron and vitamin D. It was found that iron and vitamin D levels were decreased among mothers with autistic children. Additionally, more reduction in iron and vitamin D levels associated with severity of autism.

Keywords: iron, vitamin D, mothers, Autism, ELF A, CTMA

Introduction

Autism Spectrum Disorder (ASD) are incorporated into a group of diseases concerned about neurodevelopmental disabilities. The rate of incidence of both ASD in the pediatric population was significantly increased. In 2018 the Centers for Disease Control (CDC) determined that approximately 1 in 59 children is diagnosed with an ASD. This estimate is a 14% increase in 2016 and a 47% increase in 2012. Also, the prevalence of autism associates with the greater severity of learning disability or lower verbal IQ. These facts make ASD the most interesting and challenging areas of research. Due to the progress in the incidence of autism in recent decades, a wide range of studies have been done to identify the risk and etiological factors that predispose or underlay autism. It has been suggested that a number of environmental and risk factors could anticipate to the development of ASD. The matter is not only one but a collection of environmental risk factors regarding father, mother and child could participate in the incidence of these disorders. Iron and Vitamin D considered as the most common risk factors for development of autism. Iron deficiency affects 40%–50% of pregnancies. Iron is necessary for early neurodevelopmental processes that are affected in autism spectrum disorder (ASD). Furthermore, the vitamin D is best known for its importance on bone mineral density. However vitamin D are also required for brain function, via its role as neurotrophic and neuroprotective actions, neuronal differentiation, maturation and growth. We conducted this study to detect the association of maternal Iron and Vitamin D with risky development of autism.

Subjects and Method

This study was conducted on 65 mothers divided into 2 groups, control one that containing 20 mothers with apparently healthy children selected from those regularly attending the follow-up at outpatient pediatric clinic for monitoring of their growth. While another group containing 45 mothers with children suffering from autism, they were selected from patients attending the pediatric neuropsychiatric clinic, Pediatric Hospital, Minia University, Minia, Egypt as well as from Kayan charity for education and rehabilitation of ASD, Minia Branch, Egypt. About eight ml of venous blood was collected from each mother by sterile venipuncture under complete aseptic conditions. This sample was divided...
as follow: Two ml in ethylene diamine tetra acetic acid (EDTA) containing tube for CBC and Six ml into one plain tube for iron and vitamin D. Iron was determined by Colorimetric CAB Method in which the Iron reacts with chromazurol B and cetyltrimethyl-ammonium bromide (CTMA) to form a colored ternary complex (Spectrum Diagnostics, Cairo, Egypt). Vitamin D was determined by detecting the level of 25 OH Vitamin D using the ELFA technique (Linked Enzyme Fluorescent Assay) by (Mini Vidas, Biomerieux, France).

Results

Comparison between studied groups regarding laboratory data of mothers: laboratory data of the included mothers found that those with children suffering from autism spectrum disorders had low levels of vitamin D3 as there Mean ± SD was (9.8 ± 4.04). So, there was statistically significant decrease in vitamin D3 levels among mothers with autistic children when compared to the control group (p=0.001) (table 1)

Table 2: Comparison between ASD subgroups as regards laboratory data of the mothers. group GIa; mild autism spectrum disorder (ASD), GIIb; moderate ASD, GIIc; severe ASD, SD; standard deviation, Hb; hemoglobin, Vit D3; Vitamin D3, N; number, *p value ≤ 0.05 = significant

Comparison between severity of ASD as regards laboratory data of the mothers: our data showed reduction in levels of hemoglobin, iron and vitamin D3 among mothers of autistic children associated with severity of autism. Mean ± SD of hemoglobin levels for mothers with mild autism was (12.5 ± 0.8), moderate autism was (12.2 ± 1.1) and severe autism was (11.3 ± 1.1). There was a statistically significant decrease in mothers of severe autism hemoglobin levels when compared to mild form (p=0.002) and in mothers with severe when compared to moderate (p=0.03). Also, mean ± SD of iron levels in mothers with mild autism was (60.5 ± 19.8), moderate autism was (51.9 ± 12.8) and severe autism was (47.2 ± 15.8). There were a statistically significant decrease in mothers with moderate autism iron levels when compared to mild autism (p=0.01) and in mothers with severe autism when compared to mild (p=0.03). Additionally, mean ± SD levels of vitamin D3 in mothers with mild autism (12.8 ± 4.2), moderate autism (7.6 ± 1.3) and severe autism (6.9 ± 0.3). There was a statistically significant decrease in mothers with moderate autism vitamin D3 levels when compared to mild form (p=0.001) and in mothers with severe autism when compared to mild (p=0.001) (table 2), (Fig. 1,2)
The prevalence of autism was increased in last years. we studied most common risk factors associated with autism. Our data recorded that mothers with chronic iron and vitamin D deficiency, having children with autism. Furthermore, severe deficiency of maternal iron or vitamin D responsible for severity of autism. As iron play an important role in fetal brain development, it was noticed that perinatal iron deficiency leading to developmental delay and cognitive deficits (5). S. Basu et al, 2018, recorded a progressive decrease in concentrations of both neonatal hippocampal volumes and cord blood (brain-derived neurotrophic factor) BDNF with severe maternal iron deficiency(6). Additionally, the association between advanced maternal age and low iron intake had a 5-fold increased ASD risk(5). These previous studies are similar to our finding. About vitamin D, researchers reported vitamin D receptors in most areas of the brain. It appears to protect neurons and promote neural growth (7). Vitamin D deficiency has been associated with cognitive pathology, including ASD(8,9). Zaky et al. 2015, reported that 25% of children with rickets also have ASD (10).

Other studies that supported our results were cried out among Swedish and Australian women. With Swedish female there was association between maternal vitamin D deficiency (< 10 ng/ml) and risk of ASD, especially those with intellectual disability(11) While Australian women with low vitamin D levels (< 10 ng/ml) in mid-gestation had two times risk to have a child with autistic traits compared to those with vitamin D levels >20 ng/ml (12). Meta-analysis was done and supported evidence that increased prenatal exposure to vitamin D was associated with improved cognitive development and decreased risk of attention deficit hyperactivity disorder and autism (13). In trying to find relation between vitamin D and development of autism, first study was done for parental and child vitamin D pathway gene variants and autism by Schmidt Rj et al. 2015. They reported that child GC vitamin D binding protein (VDBP) AA-genotype/A-allele was associated with autism and they suggested a role for (VDBP) and lower plasma vitamin D in autism(14).

Conclusion

The current study supported that mothers with chronic iron and vitamin D deficiency associated with autism risk. Additionally, more progression for both maternal iron and vitamin D deficiency have relation with severity of autism.

Incidence and Risk Factors of Hypocalcaemia in Post Thyroidectomy Patients in Tikrit Teaching Hospital

Ayoub M. Zedan
Assist. Prof., College of Medicine, Tikrit University, Tikrit, Iraq

ABSTRACT

Hypocalcemia stands for a well-recognized problem of thyroid surgery. It is frequently transitory event that happens after widespread thyroid resection that may require calcium or vitamin D supplements to alleviate or prevent the symptoms. This study aims to determine the hypocalcemia incidence beyond to thyroid surgery and realize the involved risk reasons regarding the patient gender, age and muscular built, clinical analysis, extent of surgery, ligation of the inferior thyroid artery, and pathology report. This paper has been performed on 50 patients who experienced thyroid surgery for numerous thyroid illnesses at the surgical department of Tikrit Teaching Hospital between January 2016 to January 2017. The results of this occurrence of post-thyroidectomy hypocalcemia are 30% and in most cases (24%) is transient.

On the other hand, it is permanent in just (6%) of cases and has occurred mainly after total thyroidectomy and in cases with ligation of the inferior thyroid artery. We concluded that post-thyroidectomy hypocalcemia is a comparatively mutual complication, but it is transient in most patients. Its incidence is linked with the surgery extent and can be reduced by the use of the correct surgical procedures.

Keywords: hypocalcemia, thyroidectomy, complications, risk factors.

Introduction

Theodor Kocher is accredited with refined methods of thyroidectomy and decreasing the frequency of postoperative hemorrhage. He as well determined the preservation significance of parathyroid glands 1.

Postoperative hypocalcemia represents an effective complication of thyroidectomy, and its occurrence is very common beyond to full thyroidectomy as compared with another more conformist thyroidectomy. The testified transient hypocalcemia incidence is ranged from (1.6% - 9.3%) after subtotal thyroidectomy and from (6.9%- 42%) after full thyroidectomy. On the other hand, permanent hypocalcemia was testified in (0.2 -3%) of patients beyond to subtotal thyroidectomy and in (0.4-29%) of patients later to full thyroidectomy 2,3,4.

It typically shows itself in the 1st 24 hours postoperatively or within the 2-5 days after an operation. Nevertheless, very seldom the onset is overdue after 2-3 weeks5.

In the majority of patients, it is transient that resolves naturally, and only a few patients can be developed to permanent hypocalcemia 6.

In 80% of cases, it resolves in about 12 months7. The risk of these difficulties relies on the surgery extent, the characteristics of the primary disease and the familiarity of the operating surgeon. Additionally, particular surgical difficulties have come across recurrent thyroid disease, huge goiter, anatomical variation, retrosternal or even mediastinal position and injury with respect to the parathyroid glands 8.

Other causal mechanisms that have been concerned in the pathophysiology of post-thyroidectomy hypocalcemia are uptake of calcium by bone for patients with thyrotoxic osteodystrophy, parathyroid suppression from augmented calcium reinstated from the bone of patients with hyperthyroidism, transient post-operative hemodilution with raised renal excretion of calcium, augmented calcitonin release due to thyroid manipulation 9,10.
The 1st clinical symptom of hypocalcemia can be less usual including numbness and tingling sensation nearby the mouth and in the distal edges 11.

Intravenous calcium gluconate can be given 10-20ml of 10% solution slowly until the symptoms disappear, then 50 ml of 10% calcium gluconate can be added to 500 ml of 5% dextrose solution and administered by intravenous drip at a rate of 1 ml/kg/h 12.

**Aims of the study**

This study aims to investigate the incidence of hypocalcemia after thyroid surgery and to find out the complicated risk factors leading to hypocalcemia regarding the patient age, gender and muscular built, clinical diagnosis, the extent of surgery, ligation of the inferior thyroid artery and pathology report.

**Patients and Method**

This study has been conducted on 50 patients who suffered from thyroid surgery for numerous thyroid diseases at the surgical department of Tikrit Teaching Hospital from January 2016 to January 2017.

The patients included were only those who underwent subtotal, near full and full thyroidectomies.

The date form included patient age, gender, muscular built, clinical diagnosis, thyroid function status, type of surgery, ligation of the inferior thyroid artery, and pathology report.

Each patient had serum calcium, phosphate and total serum protein measured preoperative and at day 1,2,3,4,5 postoperatively. Patients who had postoperative hypocalcemia were followed up as outpatients and had serial checking of their serum levels.

A calcium level of 8 mg/dl (2mmol/L) on at least 2 consecutive measurements was considered as a threshold value of hypocalcemia, besides, experiencing symptoms such as perioral and digital paraesthesia and having chvostek’s and Trousseaus sign was also included in a definition.

It has been considered transient if it resolves within 6 months and permanent if it stayed after 6 months, and the patients are maintained on supplementation therapy after calcium and vitamin D. Patients who had clinical evidence of hypocalcemia (circumoral and acral fingers and toes) paraesthesia, and carpopedal spasm were given such as calcium gluconate,10-20ml of 10% solution until the signs and symptoms disappear. Some patients require the dose to be given 2-3 times per day.

Patients who had permanent hypocalcemia were given oral calcium and vitamin D supplementations and were followed up on regular outpatient checking up visits.

The histopathological report was reviewed, and the result was compared with the state of hypocalcemia.

It was not feasible to perform a parathyroid hormone level assay because this test was not available at our hospital lab.

**Results**

A total of 50 patients aged between 20 to 70 years old underwent thyroidectomy in the period between January 2016 to January 2017 at the surgical department of Tikrit Teaching Hospital. About 46 were females, and 4 were males. The majority of patients (70%) had a simple multinodular goiter, (12%) had Grave’s disease, (8%) had a toxic nodular goiter, (6%) had thyroiditis, and (4%) had cancer as shown in Table (1). Total thyroidectomy was performed for (10%) of patients, near-total thyroidectomy for (22%) of patients and subtotal, thyroidectomy for (68%) of patients as shown in Table (1).

Fig. 1: The incidence of Hypocalcaemia concerning patient genders

About (33.3%) of the patients who had transient hypocalcaemia were between 31-40 years of age, 25 between 20-30 years of age, (16.7%) were between 41-50 years of age, (16.7%) were between 51-60 years of age, and finally (8.3%) were between 61-70 years as stated by Table 5.

(66.6%) of the patients who had permanent hypocalcemia were between 31-40 years of age, (33.3%) were between 20-30 years of age. Mean age of hypocalcemia patients is 39 years as shown in.
Discussion

Postoperative hypocalcemia is a relatively common complication of thyroid surgery and is known as a major cause of postoperative morbidity, but most often it is a transient event that occurs after extensive thyroid surgery.

The results of this study showed that the incidence of hypocalcemia is 30% and it was transient in the majority of the cases.

Regarding the age, most of the patients who had transient hypocalcemia (33.3%) belong to the 31-40 years age group, and most of the patients who had permanent hypocalcemia (66.6%) belong to that age group also, which is nearly similar to other studies.

Regarding the gender depicted in Fig.1, most of the patients who had transient hypocalcemia (91.66%) were females, and most of the patients who had permanent hypocalcemia (66.66%) were females also, which is similar to Thomuusch et al. study.

Regarding the type and extent of the surgical procedure, the research found that the incidence of transient hypocalcemia was (60%) after total thyroidectomy while it was (36.3%) after near-total thyroidectomy and it was only (14.7%) after subtotal thyroidectomy.

The incidence of permanent hypocalcemia was (20%) after total thyroidectomy while it was (9%) after near total thyroidectomy and only (2.9%) after subtotal thyroidectomy.

These results are agreed with those reported in other studies (Ishtiaq Ahmed et al.) and (Wingert, 2006), that showed that the extent of resection and surgical has a more significant impact on the rate of post-thyroidectomy hypocalcemia.

Regarding the ligation of the inferior artery, we found that (66.6%) of the patients who underwent bilateral ligation of that artery had post-thyroidectomy hypocalcemia, while (33.4%) of the patients who underwent a unilateral ligation of that artery had hypocalcemia, so making that procedure as an important risk factor.

These results are consent with those reported in other studies (Ishtiaq Ahmed et al.) and (Wingert, 2006). This result was due to the inadvertent excision of parathyroid gland in total thyroidectomy and for the interference of blood supply of the parathyroid gland in case of the method of inferior truncal thyroid a ligation.

Regarding the clinical and the pathological diagnosis, we found that all the patients with CA had post-thyroidectomy hypocalcemia, while (66.66%) of patients with thyroiditis had hypocalcemia and only (33.33%) of those with Graves disease had hypocalcemia and (50%) of those with toxic nodular goiter had, and only 20 of those with simple multinodular goiter had hypocalcemia.

These findings are in agreement with other studies (which is similar to Thomuusch et al. study) and (Sippel Rs.), which showed that the thyroid cancer is a risk factor for inadvertent parathyroid excision.

This was due to the radical removal of thyroid tissue, excessive dissection and truncal ligation of inferior thyroid. All of these factors might lead to unintentional removal of the parathyroid gland and subsequent hypocalcemia.

Conclusion

It was concluded that post-thyroidectomy hypocalcemia is a relatively common phenomenon, especially after extensive thyroid surgery but it is transient in the majority of the cases.

Its incidence is related to the extent of the surgical procedure especially if this was associated with ligation of the inferior thyroid artery and the use of correct surgical procedures can only reduce it.

The Correlation between Knowledge and Experience of Nurses toward Triage Decision Making at Lombok Nusa Tenggara Barat

Baiq Fitrihan Rukmana¹, Ahsan², Kuswantoro Rusca Putra²
¹Master Program of Nursing, ²Lecturer, Faculty of Medicine, University of Brawijaya

ABSTRACT

Triage is important to do at emergency unit. It is used to determine priority of emergency state action so medical team can promote treatment for patients who need urgent and accurate treatment to improve life opportunity of them. Triage process is started when a patient gets into ICU where the nurses assess based on subjective and objective findings which are done quickly and accurately. However, execution of triage needs sufficient knowledge and experience to find out priority of the patient. This research has purpose to find out the correlation between knowledge and experience toward triage decision making at emergency unit of Lombok Nusa Tenggara Barat hospital. This research is an analytic observational by using cross sectional with 135 respondents. The findings show that there is correlation between knowledge and experience toward the decision making with each p value is 0.000. Linear regression shows knowledge becomes the most correlated variable in decision making of triage. Knowledge and experience of working become the most important variables of nurses in making decision so medical service can be improved.

Keywords: Triage, Life Opportunity, Emergency Unit

Introduction

Triage is an important component to do at emergency unit(1). It is a way to classify patients based on types and levels of emergency state treatment to improve the treatment and to prioritize cases in handling emergency state condition(2). Triage assessment on patient is the first – main step in providing emergency state treatment as indicator of further action to be given(3).

Triage system is implemented in classifying priority of emergency state treatment so medical team can promote medical treatment to patients who need urgent and quick treatment in order to increase his life opportunity. Triage process is started when a patient gets into emergency unit where its nurses assess based on subjectively and objectively reviewed findings to have quick and appropriate treatment(4). Process of triage is done by one medical treatment, a nurse(5).

Nurses at triage have obligations to position the patients appropriately based on emergency level. The nurses will label the patients based on the conditions suffered from red for emergent patients, yellow for urgent patients, green for non-urgent patients, and black for death patients. After labelling, the nurses bring the patient to treatment room based on the order and emergency state priority. Then the nurses provide appropriate treatment(6).

High rate numbers of patients visiting ICU causes nurses must be able to sort its patients quickly and accurately based on injury level of emergency state condition occurred or suffered(7). Mistake in assessing patient’s condition will lead to overwhelming numbers of patients and length of inpatient at ICU(8). Ferero et al states that mistake in triage will cause to increasing number of length inpatient and waiting lists of patients at ICU(9).

DOI Number: 10.5958/0976-5506.2019.02502.6
Thus, triage nurses are demanded to have sufficient experience and knowledge. They will make the nurses to be able to review and to cover complex and pressured conditions\textsuperscript{(10)}. In facing this condition, the nurses must act professionally to overcome appearing stressor in determining step related to severe condition of the patient and their families\textsuperscript{(11)}.

The interruption can be occurred due to lack of knowledge of the nurses which lead to inappropriate triage decision, incomplete symptom’s identifications, and incomplete assessment\textsuperscript{(12)}. Lack of experience and knowledge of the nurses affect toward less response of the nurses and delay of the nurses causing increasing rate of morbidity and mortality. When the nurses cannot do triage, it can decrease quality of the treatment and negative impacts for the patients\textsuperscript{(3)}. Based on the conditions, it is not easy for the nurses to do triage\textsuperscript{(13)}.

Based on preliminary study done on October 31, 2018 that at hospital Lombok has problem in decision making on triage process. Researcher observed 30 nurses directly and found that most of them did not do triage when they had new clients. Some of them did triage when the clients were in front of ICU’s door or when the patients just arrived in ICU although they were not in emergency state condition. Some of the nurses also inaccurately assessed triage when the patient categorized as green but they were categorized into yellow and incomplete documentation of triage such as lack of giving check list of the triage patient on medical record and incomplete physical checkup which affect decision making upon triage patients. It has negative impacts on giving service in emergency unit. The purpose of this research is to find out the correlation of knowledge and experience toward triage decision making at emergency unit of Lombok Nusantara Tenggara Barat Hospital.

Methods and Material

This analytic observational research with cross sectional approach. The respondents are 135 participants from five hospitals in Lombok by using total sampling. To measure knowledge and triage decision making, they are done by using questionnaire. Each questionnaire has been validity and reliability tested by using alpha Chronbach 0.806 for its knowledge variable and 0.869 for triage decision making. Working experience is gained through questionnaire related working experience of the nurses. Bivariate analysis by using spearman rank and multivariate analysis are done by using multiple linier regression. This research is done after having ethical clearance from commission of ethics of Universitas Mataram, number 13/UN18.F7/ETIK/2019.

Results

Table 1: Characteristics of the Respondents based on Age, Working Experience, Knowledge and Triage Decision Making

<table>
<thead>

</tbody>
</table>

Based on the table, it is known the youngest patient is 22 year old and the oldest one is 45 year old with average age 31.23 year old. The longest working experience is 22 years and the youngest one is 1 year with 8.24 years in average. Highest score of respondents’ knowledge is 8 while the lowest one is 4 with average 5.56. Highest score of decision making is 90 and the lowest one is 48 with average 71.23.

The table shows the dominant is male with 73 respondents. Meanwhile, the most dominant education is first degree + Ners with total 71.

Table 3: Correlation of Knowledge toward Decision Making of Triage

<table>
<thead>
<tr>
<th>Variable</th>
<th>Triage decision making</th>
</tr>
</thead>
<tbody>
<tr>
<td>Knowledge</td>
<td>r = 0.69, p = 0.000, n = 135</td>
</tr>
</tbody>
</table>

The table shows $p = 0.000$ ($p<0.05$) so it is concluded that there is correlation factor between knowledge toward triage decision making at the emergency unit. The $r$ score is 0.69 showing positive correlation with strong strength of the correlation where higher score of the knowledge also has higher triage decision making score of the nurses.

Table 4: Correlation between Working Experiences toward Triage Decision Making

<table>
<thead>
<tr>

Table 5 shows knowledge variable can explain that variety of the decision making of triage is 43.7%. The rest of them are affected by other uninvestigated factors. Based on the table, then knowledge becomes the most dominant variable correlating to triage decision making with coefficient score B 6.423.

Discussion

Findings of the research explain correlation between knowledge to triage decision making at emergency unit of Lombok Nusa Tenggara Barat hospital with $p = 0.000$. Score of $r$ is 0.69, showing that there is strong positive correlation. It explains that higher knowledge has higher triage decision making of the nurses. Linier regression test shows variable is the most dominant to triage decision making.

This research is in line with Aloyce et al in 2014 showing that higher knowledge of nurses dealing with triage can improve nursing accuracy in triage decision making at emergency unit. Highest knowledge of the nurses can help to categorize triage appropriately according to patients’ condition so it improves nurses’ performance and better outcome (14).

Triage is autonomous nursing role focusing on patient survival and efficient treatment execution. Clinical decision made by triage nurses needs complex cognition. Triage nurses must show ability to think critically in limited, incomplete, and ambiguity data environment. Process of effective and efficient decision making depends on broad knowledge and experience dealing with various disease and patterns of injuries (15,16). In a study done by Roudbari & Mirhaghi 2010, it stated that lower ability of nurses in doing triage is caused by their lack of knowledge and incapability to review patient’s condition (17).

Emergency Nurse Association in 2011 also recommends that knowledge to be mastered by nurses in doing triage are triage taking process, triage documenting process, law of health service, abdomen emergency state, hearth emergency state, trauma, respiratory emergency state, psychiatric emergency state, fast track, musculoskeletal, special condition, and child emergency state (18). By the existence of these recommendation dealing with needed knowledge by nurses dealing with triage, then triage can be done quickly and appropriately so it improves services at the hospital.

The findings also explain that there is correlation between working experience to decision making of triage
at the emergency unit with $p = 0.000$. Score of $r = 0.289$, explaining that low positive correlation causes higher working experience to have higher triage decision making.

It is in line with Duko et al 2019, stating that nurses whose lengthy working experience decide triage decision at emergency unit. Higher experience of nurses will be something to learn for them to categorize appropriate triage according to conditions of patients so it will improve treatment performance and better outcome(19).

Benner (1982) stated that becoming expert nurses need to develop ability and understanding related to patient management at whole time in which can be learnt by having many experiences(20). Benner groups abilities into 5 levels namely novice, advance beginner, competent, proficient, and expert.

Triage nurses are expected to be competent in which they can handle and consider as well as create needed plan to face current situation in future time. This stage symbolizes that a nurse whose had similar jobs or situation for 2 or 3 years will grow when they find out that their action reach into the target, or consciously they have planning within their action. Consistency, ability to predict, and time management become description of competent stage. Competent nurses can perform their responsibilities dealing with conditions of patients, more focus, and being able to perform critical thinking ability(6,21,22).

Conclusion

It can be concluded that there is relationship between knowledge and working experience of nurses to triage decision making at Lombok Nusa Tenggara Barat hospital. The most correlative variable in decision making is knowledge. By identifying this factor, it is expected can contribute to suggest all parties of the hospital to improve knowledge and nursing experience dealing with appropriate triage decision making.

**ABSTRACT**

In this study 30 clinical isolates of *Staphylococcus haemolyticus* were isolated from blood cultures of neonate patients at a hospital in Baghdad and during period extended from January, 2015 to February, 2016. The of antimicrobial sensitivity test results showed the most effective antibiotics on *S. haemolyticus* isolates were linezolid, quinupristin and moxifloxacin which had 100% sensitivity rate, while the all isolates showed a high level of resistance to oxacillin and benzylpenicillin (100%). Phenotypic detection test of methicillin resistance to *S. haemolyticus* isolates showed all 30 *S. haemolyticus* isolates under test were methicillin resistance and the results of PCR assay for detection of *meca* gene showed from 30 isolates of methicillin-resistant *S. haemolyticus*, 28(93.3%) isolates were positive to *meca* gene with 258-bp, while only 2(6.7%) isolates were negative to *meca* gene.

**Keywords:** *Staphylococcus haemolyticus*, methicillin resistance and *meca* Gene.

**Introduction**

Coagulase-Negative Staphylococci (CoNS) species are the most frequent cause of nosocomial blood stream infections (1). *Staphylococcus haemolyticus* (S. *haemolyticus*), is a part of skin normal flora of the humans (2). *S. haemolyticus*, is a well-known opportunistic pathogen, and it is the second-most frequently isolated Coagulase-negative staphylococci from human blood cultures (the first is *Staphylococcus epidermidis*) (1, 4). So, it plays an important role in the hospital-acquired opportunistic infections related to implanted medical devices. Infections that caused by *S. haemolyticus* can be systemic or localized, and those infections were often associated with the insertion of the medical devices (5).

There had been a dramatic increase in the emergence of the antibiotic resistant bacterial isolates, which has made the antibiotic choices for the infection control increasingly limited and also more expensive (6). The highly antibiotic-resistant and also the ability of *S. haemolyticus* to form biofilms make *S. haemolyticus* a difficult pathogen to treat (3). *S. haemolyticus* bacteria have the highest level of antimicrobial resistance among all species of CoNS (7). Methicillin- Resistant Staphylococci (MRS) cause hard to treat infections, due to the resistant of MRS to the most types of the antibiotics such as macrolides, aminoglycosides and beta-lactam antibiotics (8). So this limits the therapeutic options available and also makes the *Staphylococcus haemolyticus* infection a serious threat (9).

The resistant to methicillin is conferred by *meca* gene, which it carried on the staphylococcal cassette chromosome mec element (SCCmec). So, the increase in the frequency of methicillin resistant *S. haemolyticus* isolates as the causal agent of hospital infections and also the possibility of the emergence of resistance to the other types of antibiotics demand trustworthy characterization of these isolates and to an investigation of clonal spreading within the hospitals (10).
The accurate and rapid diagnosis of antibiotic resistance genes in the treatment of *Staphylococci* infections is extremely important in preventing the spread of infections. For the determination of antibiotic resistance genes, the PCR-based molecular methods are often preferred (11).

This study was aimed to detect the presence of the *mecA* gene in the methicillin-resistant *Staphylococcus haemolyticus* isolates which were isolated from neonatal blood cultures. Phenotypic and molecular methods were used to study 36 methicillin-resistant *Staphylococcus haemolyticus* clinical isolates.

**Materials and Method**

**Study Period:** Thirty six clinical isolates of *Staphylococcus haemolyticus* were isolated over a period of study extended from January, 2015 to February, 2016 from blood cultures of neonatal which they were suffering from bacteremia and lying at a hospital for pediatric and obstetric in Baghdad/Iraq.

**Identification of *Staphylococcus haemolyticus***: *Staphylococcus haemolyticus* isolates were identified at species level by using the Vitek-2 system (Bio-Merieux, France) with the using ID-GP cards according to the manufacturer’s instructions.

**Antibiotic Susceptibility Test:** The antibiotic susceptibility test towards different classes of antibiotics was done by Vitek-2 system (Bio-Merieux, France), with the using AST-P580 cards and according to the manufacturer’s instructions.

**Phenotypic Detection of Methicillin Resistance:** Phenotypic detection of methicillin resistance was done by detection the resistance to methicillin which was performed with Vitek-2 automated system (Bio-Merieux, France), and according to the manufacturer’s instructions with using of AST-P580 cards that have cefoxitin screen test as methicillin resistance indicator.

**Genotypic detection of *mecA* gene**

**Extraction of DNA:** The bacterial DNA was extracted according the boiling method by suspending 2-3 colonies of each *S. haemolyticus* isolate which grown on overnight culture brain-heart infusion agar plates in (500 μL) of nuclease-free water (Promega, USA) and then heated at 90°C for 10 min using a water bath. Samples after that centrifuged at 10000 rpm for (10 min). Those samples were used as the DNA template for PCR assay (Endimiani et al., 2009).

**Detection of *mecA* gene by polymerase chain reaction (PCR):** Polymerase chain reaction (PCR) was used to amplify the *mecA* gene. Primer sequences for *mecA* (258-bp) were chosen according to the method described by (Kawano et al., 1996): the forward sequence of *mecA* gene is (5-AGATTGGGATC ATAGCGTCA-3) and the reverse sequence of *mecA* gene is (5-GAAGGTATCAT CTTGTACCC-3). The forward and reverse primers were synthesized by (Alpha DNA, Canada). PCR was performed in the DNA Thermal Cycler (Agilent (8800), USA). The mixture of PCR for the *mecA* gene was set up in total volume of 25μl included: (2X Master mix (12.5μl) (Promega, USA), 1μl of each primer, template DNA (4μl) and sterile D.W. (6.5). The negative control contained all the materials except DNA, D.W. was added instead of DNA.

The program used to amplified *mecA* gene was: The initial denaturation at 94°C for 5min; (denaturation at 94°C for 1 min, annealing at 55°C for 2 min, extension at 72°C for 3 min) for 26 cycles; and the final extension at 72°C for 7 min (12).

**Agarose Gel Electrophoresis:** The PCR products were detected by using gel electrophoresis and the visualized was done with the aid of RedSafe dye (INtRON, Korea) and UV transilluminator documentation system (13).

**Results and Discussion**

**Period of Study and Bacterial Isolates:** Thirty isolates of *Staphylococcus haemolyticus* were isolated during the period from January, 2015 to February, 2016 from the blood cultures of neonate patients at one hospital in Baghdad. All 30 *S. haemolyticus* isolates were isolated from neonate patients within the age group less than one month. The results showed that the incidence of infected with *S. haemolyticus* isolates was higher among males 18(60%) than that of females 12(40%).

**Antibiotic Susceptibility Test:** The antimicrobial sensitivity test for 30 *S. haemolyticus* clinical isolates which isolated from neonatal blood cultures to various antimicrobial drugs were shown on Table-1.
Table 1: The results of antimicrobial sensitivity test for 30 *S. haemolyticus* clinical isolates under study

</table>

The results showed that the most effective antibiotics on clinical isolates of *S. haemolyticus* were linezolid, quinupristin and moxifloxacin which had 100% sensitivity rate followed by tigecycline and levofloxacin which had 96.7% sensitivity rate then vancomycin and nitrofurantion which had 93.3% sensitivity rate. On the other hand, the isolates were shown a high level of resistance to oxacillin and benzylpenicillin (100%) followed by Erythromycin which had 60% resistant rate.

**Phenotypic detection of methicillin resistance** *S. haemolyticus* isolates: According to cefoxitin screen test that including within the cards of Vitek-2 system (AST-P580 cards), all 30 clinical isolates of *S. haemolyticus* under study were methicillin resistance (Figure-1).

**Figure 1: Positive result of Cefoxitin screen test that done by Vitek-2 system with the use of AST-P580 card**

**Genotypic detection of mecA gene by polymerase chain reaction (PCR) assay:** The results of PCR assay for detection of mecA gene showed that, out of 30 isolates of methicillin-resistant *S. haemolyticus* clinical isolates, 28(93.3%) isolates were positive to mecA gene with 258-bp band as shown in Figure-2, while only 2(6.7%) isolates were negative to mecA gene. Detection of mecA gene was done on (1%) agarose gel at 5 V/cm for 1.5 hr. which stained with RedSafe dye and visualized on UV transiluminator documentation system.

**Figure 2: Detection of mecA gene by monoplex PCR assay; Lane M, 100 bp DNA ladder; lanes 1-11, amplification of mecA (258bp); lane C, Negative control**

**Discussion**

Isolates of *Staphylococcus haemolyticus* are the second of most frequently isolated bacteria from the human blood cultures among the coagulase-negative staphylococci (CoNS) (14), and have the highest level of antimicrobial resistance (7). Methicillin resistance of *S. haemolyticus* is conferred by the mecA gene which carried on the staphylococcal cassette chromosome mec (SCCmec) (15, 16).

Our results showed that all 30 *S. haemolyticus* isolates were resistant to oxacillin and benzylpenicillin (100%) and all the isolates were susceptible to linezolid and moxifloxacin. All the *S. haemolyticus* isolates were methicillin resistance phenotypically. Our results demonstrated that the majority of *S. haemolyticus* clinical isolates under study were positive for molecular
detection of the mecA gene by PCR. Barros and his co-workers (10) determined that by PCR of the mecA gene, 87% were found to be methicillin resistant.

Oko Mama Culture Betel Nut Consuming Habit in Kupang District and its Effect toward Salivary Ph and Flow Rate

Christina Ngadilah¹, Hari Basuki N.², Rika Subarniati T.³
¹Doctoral Program of Health Sciences, Faculty of Public Health, ²Faculty of Public Health, Airlangga University, Indonesia; ³Head of Public Health Department, Faculty of Medicine, Wijaya Kusuma University, Indonesia

ABSTRACT
Public health always associated to culture and lifestyle. Lifestyle itself constitutes a concept that commonly used to define “The way people live”, reflecting the whole social value, attitude, and activity. One of long-term culture that become personal habit is chewing betel nut. Oko Mama culture is the local culture of the Timorese tribe who consider it as the symbol of philosophy, dignity, enjoyment, beauty, also as a means of communication in society, political means, and delaying hunger. Several studies revealed several unbeneficial of chewing betel nut, such as acute betel nut toxicity, cardiovascular disease, respiratory disorder, and congenital defect. Besides, betel nut may also alter oral health. This study is aiming to analyse the correlation of habitual chewing betel nut toward salivary pH and flow rate. This was an observational analytic study, by means of cross sectional design involving both on male and female aging 17-50 years old in 4 sub-district, consisting of 2 remote areas and 2 urban areas. The correlation between variables was analysed using path analysis by means of Smart PLS 3.2.7. The analysis revealed a positive correlation between Oko Mama culture toward behaviour (p=0.316) and intention (p= 0.454), also a negative correlation between the culture toward oral hygiene knowledge (p=-0.185) and the effect of chewing betel nut knowledge (p=-0.111). A positive correlation also recorded toward perceived norm (p=0.931). While intention had a positive correlation toward behaviour (p=0.429). Regarding oral health, chewing betel nut had negative effect toward salivary pH (p=-0.167) and salivary flow rate (p=-0.210).

Keyword: community habit, betel nut, salivary pH, flow rate.

Introduction
Public health is an integrated matter with the local culture. The society in each region have their own concept of health, as the important part of the culture. Betel nut chewing denotes an old habit of the society in Kupang. A prior study revealed that in Oelnaineno, sub district Takari, Kupang, 94% people aged 17-60 years old chew betel nut. The betel nut usually areca nut, lime. In other country sometimes the other ingredients were added tobacco.

The Oko Mama culture, that used betel nut in various occasion in daily life, thus, it can be found in every household in Timor. Oko Mama is the Timorese tribes culture, that chew the betel nut as the symbol of philosophy, dignity, enjoyment, beauty, also as a means of communication in society, political means, and delaying hunger. This culture denotes the factor that drives the society to chew betel nut to date (2).

Studies revealed that chewing betel nut might induce oral precancerous lesion which highly tend to become cancer. The areca nut itself has been classified as class I carcinogenic agent by the International Research Agency for Research Cancer (3). Areca nut only, has significant impact toward health, thus, tobacco addition may rise worsen health consequence, even death. After chewing betel nut, several symptoms may appear, such as headache, tachycardia, hot sensation and sweating, epigastric discomfort, hyperventilation, thirst and

Corresponding Author:
Christina Ngadilah
Doctoral Program of Health Sciences, Faculty of Public Health, Airlangga University, Indonesia
Email: christinangadilah62@gmail.com
hunger diminish, relax, and overexcited \(^{(1)}\). Areca nut contain arecolin, that possibly toxic toward periodontal tissue, thus, may worsen the periodontal status \(^{(4)}\).

The betel nut is addictive to its chewers. The tint from betel nut can penetrate into oral mucosa, and teeth, yet may disappear if strongly rubbed by areca skin \(^{(5)}\). The tooth discoloration due to betel nut chewing may prevent tooth demineralization. Several studies had proved that betel nut could reduce the caries prevalence \(^{(6)(7)(8)}\).

Considering the high number of betel nut chewers and its effect toward health, thus, it is important to analyse the Oko Mama culture, related to the habit of chewing betel nut and its effect toward caries. It is expected to be able to help the attempt to reduce betel nut chewers in Kupang, East Nusa Tenggara Indonesia as it is dangerous to their health, especially their dental health. This research aiming influence someone behavior and it's effect toward salivary pH and salivary flow rate.

**Material and Method**

This observational analytic study employed a cross sectional design. The sub district South Amfoang and Takari, denotes remote areas, while the urban areas were sub district Nekamese and Kupang Centre. Those selected areas had the most population. The subject of this study were the inhabitants aged 17-50 years old. As much as 363 peoples were randomly chosen from 146.597, calculated using estimated proportion population formula.

The criteria for the respondents were male and female who chewed betel nut, and those who did not from those 4 selected areas. The respondents were asked to fill a questionnaire. The acquired data were analysed by means of path analysis by PLS 3.2.7 to find a correlation among variables. We hypothesized eleven theories; 1) there is a correlation between attitude and intention; 2) there is a correlation between perceive norm and intention; 3) self-efficacy affect the intention; 4) Oko Mama culture affect intention; 5) Oko Mama culture affect behaviour; 6) intention affect behaviour; 7) oral health knowledge affect behaviour; 8) disease knowledge affect behaviour; 9) habit affect behaviour; 10) behaviour affect salivary flow rate; 11) behaviour affect salivary pH.

**Results**

The respondents participated in this study consisted of 51.5% female and 48.5% male. The total of betel nut chewers was dominated by female (52.8%). Among the population, the betel nut chewers (79.9%) were more than those who do not chew betel nut (20.1%). Mostly respondents were aged 41-50 years old (43.8%), while the respondents aged less than 20 were the minority (11.3%). The younger the respondents, the less they chew betel nut. Most of the respondents were farmers (82.6%), with the last education was elementary school (59.2%).

The habit of betel nut chewing more than 5 times a day were done by 37.5% of the respondents. The average frequency of betel nut chewing was twice a day. A portion of 51.8% the respondents has been chewing betel nut for 10 years or more, with 58.1% of them chewed betel nut with lime and areca nut. The majority from their parent (96.9%).

Similar to TRA/TPB, the most important predisposing factors in Integrated Behaviour Model (IBM) is intention. Intention defined as individual decision indicator to do a certain behaviour. Without intention, behaviour will not be built. The intention itself was determined by attitude, perceived norm, and self-efficacy to start doing betel nut chewing as habit. This study used 4 variables based on the IBM that affect the intention to chew betel nut, that are attitude, perceived norm, self-confidence and Oko Mama culture. Based on the result from table 1, there were 2 rejected hypotheses, that are 1) oral health knowledge have no effect toward behaviour (p>0.05), and 2) disease knowledge have no effect toward betel nut chewing (p>0.05).

Attitude had significant correlation toward intention as much as 0.278 (p<0.05), while perceived norm also had significant correlation toward intention as much as -0.191 (p<0.05). Self-confidence significantly affect intention as much as 0.417 (p<0.05). Intention had significant effect toward betel nut chewing as much as 0.429 (p<0.05). Oko mama’s culture significantly affects the intention to consume betel nut at 0.454 (p value 0,000). The Oko mama culture significantly affects the Behavior of consuming betel nut by 0.316 (p value 0,000). The habit of consuming betel nut significantly affects the salivary pH of -0.167 (p Value 0,000). The habit of consuming betel nut significantly affects the salivary flow rate of -0.210 (p value 0,000). The Behaviour Hypothesis influences the Saliva Flow Rate in the habit of consuming betel nut analysed by looking at the Path Coefficients (table 1). This hypothesis is accepted significantly because Path Behaviour to the Saliva Flow Rate has a p-value of 0,000 and the value of t-statistics 3,933 and Path Coefficients -0,210. The hypothesis is accepted because p-value is less than 0.05 and t statistic is more than 1.96. From these results it can be concluded that the Behaviour has a negative effect of -0.210 on the salivary flow rate.

**Discussion**

The behaviour of chewing betel nut affects salivary flow rate, may possibly due to the reduce in salivary secretion or salivary properties changes while they are not chewing betel nut. This condition may contribute to several oral and dental diseases, that directly affect the quality of life. Several studies stated that the normal unstimulated salivary flow rate is 0.3-0.5 ml per minute \(^{9,10}\), while stimulated salivary flow rate is 10 ml per minute \(^{11,12}\). The significant changes of salivary flow rate affect dental and oral health \(^{12}\). The functional changes of salivary gland, is related to oral cavity, throat, oesophagus, neoplasm, nutrition metabolism, inflammation, genetic disease, auto-immune disease, and nervous system damage. The varied salivary flow rate also depends on the time of measurement. Those variations in 24 hours depends on the circadian rhythm. Besides, other factors also contribute, such as age and gender.

Several studies recorded that unstimulated normal salivary pH ranged from 5.5 to 7.9, the higher pH, the higher salivary flow rate \(^{12,13}\). Salivary pH is controlled by carbonate/bicarbonate acid system, phosphate system, and protein system. A study revealed several rate of salivary flow from chewing 4 kinds of betel nut mixture, and raw areca nut only, which resulted the highest mean of salivary flow rate recorded was 4.18ml in 10 minutes \(^{(11)}\). A decrease of salivary secretion or changes in saliva properties may also contribute to several oral and dental problems, that directly affect the quality of life. Some of those problems are speak and eat difficulty, taste perception changes, increase plaque formation, increase risk of caries, tooth erosion and periodontal disease, increase of plaque formation, mucosal irritation, halitosis, and candidiasis, also decrease the retention of full denture. Those aforementioned oral and dental problems may also affect general health, since the affected individual may experience lost appetite, that leading to malnutrition \(^{(14)}\).

There is a significant correlation between chewing betel nut with salivary flow rate. A study revealed unstimulated salivary flowrate in betel nut chewers was basically same to those who do not, yet the when stimulated, the chewer group had a higher flow rate \(^{(15)}\). This is possibly caused by the increase of sensitivity and
salivary mechanism due to areca nut and tobacco. There is an opinion, that this also probably due to salivary gland hyperplasia, and masticatory muscle hypertrophy in long-term betel nut chewer (16). Besides, oral mucosa also become more sensitive due to toxic effect of betel nut (11)(15). However, those changes do not affect masticatory efficacy (15)(17). Another study showed that the salivary flow rate and pH of the carious and free-caries subject were not significantly different (18). Also no significant differences of salivary flow rate between those subjects. Enamel demineralization may occur in pH <5.5 (19). The mean pH of the respondents chewing betel nut was 6.6, while those who don’t was 6.78 (18).

There was a significant correlation found between betel nut behaviour with the salivary pH (p=0.000; t-statistic 3.617 and path coefficient -0.167). Behaviour had negative correlation to salivary pH (-0.21). The current study found changes of salivary pH and flow rate in betel nut chewer, which may lead to various oral diseases (20). Betel nut chewing denotes socio-cultural expression (Oko Mama), which significantly affect the perceived norm (0.931). The importance of culture affect how the society will behave. Besides, betel nut chewing also noted as social identifier, to be considered as cultured and ethical individual. Some individuals do betel nut chewing in order to be recognized as the member of society (21).

That the areca nut availability promotes betel nut chewing behaviour. Since betel nut is easily found in every household, makes it easier to consume and mostly the chewer firstly learnt from their parents (22). That in several cases, betel nut chewing was done due to the social pressure, and the desire to be recognised (21). WHO summarized that betel nut is correlated to oral cancer prevalence (23). Oral carcinoma due to betel nut chewing denotes aggressive malignancy that required intensive treatments (24). While the society have not fully understood about cancer, thus, this need a long-term attempt of prevention. Betel nut chewing was not an oral and pharynx potentially malignant disorder (OPMD) only, but also may be the predisposing factors of other diseases. The high prevalence of betel nut chewing increase the incidence of hepatic cancer. Besides, betel nut chewing also affect cardiovascular, nervous system, digestive system, metabolism, respiratory system, and reproductive system (25).

To date, there has not any global policy regarding betel nut chewing. Multidisciplinary research is required to control this phenomenon, and further studies to get a better understanding in basic biology, mechanism, and epidemiology of betel nut chewing. This may encourage the prevention, also, stop the betel nut chewing for a better health. Those attempts are betel nut uses monitoring, continuous educate the society to stop the habit, by utilizing advertisement board, and increase areca nut tax.

**Conclusion**

Oko Mama culture affects intention to chew betel nut, and also affect the behaviour to chew betel nut. The betel nut chewing behaviour affects salivary pH and flow rate. The habit of betel nut chewing shows a change in salivary pH and flow rate. Those changes contribute in the occurrence of oral diseases. Complex behaviour of betel nut chewing is reflected in varied salivary pH and flow rate.

ABSTRACT

Benzene is a volatile liquid aromatic hydrocarbon. Benzene is also used in industries related to oil processing, one of which is fuel. According to the Agency for Toxic Substances and Disease Register (ATSDR), toxic chemicals contained in oil includes Polycyclic Aromatic Hydrocarbons (PAHs), Total Petroleum Hydrocarbon (TPH), benzene, ethylene and toluene. Of all these toxin substances, benzene is the most dangerous chemical and exposure to benzene has a serious impact on human health. As a form of control effort, determining the safe duration of exposure (Dt) for benzene exposure based on the value of RfC (Reference of Concentration) using NOAEL (No Observed Adverse Effect Level) of white mice (Rattus norvegicus) is needed. This study aimed to determine the value of No Observed Adverse Effect Level (NOAEL) of white mice (Rattus norvegicus), safe limits of toxin dosage for the community or Reference of Concentration (RFC), Risk Quotient (RQ) and safe duration of exposure (Dt) in laboratory workers. This was a cross sectional, observational, and descriptive study with 51 samples of PT Pertamina RU IV Cilacap laboratory workers. The object sample used in this study was the air in the work area of the main laboratory section and the petrochemical and gas laboratory of PT Pertamina RU IV Cilacap. The results of this study indicated that safe duration of exposure (Dt) was 19 years; under normal safe duration of exposure for workers. The safe duration of exposure (Dt) can be a reference for the relevant company to consider the workers’ working period and reduce the exposure duration with benzene to prevent significant health impact on workers.

Keywords: Benzene, safe duration, laboratory workers, petroleum processing industry

Introduction

Benzene, C6H6, is a volatile liquid aromatic hydrocarbon. Benzene’s properties are colorless, volatile, flammable, and distinctive odors. PT Pertamina is an industry in Indonesia that provides fuel to meet the consumption of the Indonesian people. The products include pertamax plus, pertamax, pertalite, and premium which have benzene levels of around 1% - 5%. Toxic chemicals contained in oil content include Polycyclic Aromatic Hydrocarbons (PAHs), Total Petroleum Hydrocarbon (TPH), benzene, ethylene and toluene. Of these toxins, benzene is the most dangerous chemical and exposure to benzene has a serious impact on human health.

DOI Number: 10.5958/0976-5506.2019.02505.1
A previous research by Dewi Kartikasari, Nurjazuli, Mursid Rahardjo (2016) determined the value of RfC (Reference of Concentration) based on established by IRIS (Integrated Risk Information System) of US-EPA by 0.03 mg/m³ or equivalent to 0.0085 mg/kg/day. The previous study still using references from research in America or Europe so that they cannot be used as a reference in determining risk in Indonesia so that previous study did not obtain RfC value using NOAEL (No Observed Adverse Effect Level) of white mice (Rattus norvegicus). Saridewi and Tualeka (2012) determined the value of RfC by using the formula for calculating RfC with NOAEL of white mice (Rattus norvegicus) and RfC value of 0.004mg/kg was obtained.

Based on previous studies, it is obvious the safe duration of toxin exposure in an industry cannot be taken based on the results of research elsewhere. Therefore, in this study, the determination of safe duration of benzene exposure based on RfC by using NOAEL of white mice (Rattus norvegicus) is explained. The aims of this research is to determine NOAEL benzene using of white mice (Rattus norvegicus), average height and weight of workers in Indonesia, Reference Concentration (RfC) and safe duration of exposure (Dt).

**Material and Method**

This is an observational, cross sectional and descriptive study. The subjects in this study were all 85 workers in the Laboratory section who worked in the Main Laboratory of PT Pertamina RU IV Cilacap. The object used in this study was ambient air working area Laboratory PT Pertamina RU IV Cilacap. The sample size was 51 workers, while the object sample used in this study was air in the work area of the Main Laboratory and Petrochemical and Gas Laboratory of PT Pertamina RU IV Cilacap.

The variables of this study were the concentration of benzene in the work area in the laboratory, body weight of workers, height of workers, respiratory rate of workers, duration of exposure in a day, body surface area of workers, weight of white mice (Rattus norvegicus), body surface of white mice (Rattus norvegicus), highest dose of toxin without effect on experimental animals (NOAEL), Km factor in animals (Animal Km), Km factor in human in (Human Km), safe limit of dose of toxin for the community or Reference of Concentration (RfC), Risk Quontient (RQ) and safe duration of exposure (Dt) in laboratory workers.

The RfC formula used in this study is $^5$:

$$
RfC = \frac{\text{NOAEL}}{\text{Animal Km} \times \text{Human Km}}
$$

**Explanation:**

RfC: Reference Concentration (mg/kg)

NOAEL: No Observed Adverse Effect Level (mg/kg)

Animal Km: Km factor on animal

Human Km: Km factor on human

Data analysis was carried out quantitatively to determine the safe duration of benzene exposure in laboratory workers.

**Findings**

A. Characteristics of Experimental Animal and Surface Area of the Experimental Animal (Rattus norvegicus): The general toxicity of a compound can be interpreted as a potential chemical that causes damage when entering the human body$^6$. Toxicity test was carried out using white mice (Rattus norvegicus) as the research objects or experimental animal. Based on the weight of white mice (Rattus norvegicus), the body surface area of the animal can be calculated using the following formula:

$$
\text{Animal BSA} = 0.09 \times W^{0.67}
$$

**Explanation:**

BSA: Body Surface Area (m2)

W: Weight (kg)

<table>
<thead>
<tr>
<th>Experimental animal (Rattus norvegicus)</th>
<th>W (kg)</th>
<th>BSA (m²)</th>
</tr>

B. Characteristics, Body Surface Area and Worker’s Respiratory Rate: The characteristics of workers included in this study were body weight, height, working period and worker breathing rate in 51 workers of PT Pertamina RU IV Cilacap laboratory. Based on Table 2, the average body weight is 67 kg. The average height of workers is 159 cm. The surface area of the body and the respiration rate of the workers were 1.72 m² and the average breathing rate was 0.596 m³/hour.

Based on data on workers’ weight and height, the body surface area and worker breathing rate can be calculated using the following formula:

A. The average body surface rate of the worker

\[
BSA = \sqrt{\frac{W \times h}{3600}} = \sqrt{\frac{67 \times 159}{3600}} = 1.72 \text{ m}^2
\]

Explanation:

BSA: Body Surface Area (m²)
W: Weight (kg)
h: Height (cm)

B. Respiratory rate

\[
BR = \frac{5.3 \times \ln W - 6.9}{24} = \frac{5.3 \times \ln 67 - 6.9}{24} = 0.596
\]

Explanation:

BR: Breathing Rate (m³/jam)
W: Weight (kg)

D. Animal Km and Human Km

1. Animal Km: Determination of safe dosage of toxin for workers begins with the calculation of Animal Km. Animal Km is obtained by using the following formula:

\[
Animal \ Km = \frac{W}{BSA \ animal}
\]

Explanation:

Animal Km: Km factor on animal
W: Experimental animal body weight (white mice or Rattus norvegicus) (kg)
BSA: Surface area of experimental animals (m²)

Table 4: Calculation of Animal Km in Experimental Animal of White Mice (Rattus norvegicus)

<table>
<thead>
<tr>

</tr>
<tr>
<td>Average</td>
<td>0.1407</td>
<td>0.024165</td>
<td>5.82</td>
</tr>
</tbody>
</table>
2. Human Km: The Human Km calculation is performed by using the following formula:

\[
\text{Human Km} = \frac{W_{\text{human}}}{\text{BSA}_{\text{human}}}
\]

Explanation:

Human Km: Km factor in humans
W: Human Weight (kg)
BSA: Body Surface (m²)

<table>
<thead>
<tr>
<th>The number of sample</th>
<th>W (kg)</th>
<th>BSA (m²)</th>
<th>Human Km (W/BSA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>67</td>
<td>1.72</td>
<td>38.95</td>
</tr>
</tbody>
</table>

E. NOAEL (No Observed Adverse Effect Level):
No Observed Adverse Effect Level (NOAEL). NOAEL benzene is 0.022 mg/kg, obtained from the calculation of the following formula:

\[
\text{NOAEL Benzene} = 3 \text{ mg/m}^3
\]

\[
\text{NOAEL} = \frac{3 \times 0.00013 \times 8}{0.1405} = 0.022 \text{ mg/kg}
\]

F. Reference Concentration (Rfc): Reference concentration according to Shaw et al (2007) in Saridewi and Tualeka (2017) uses the following formula:

\[
\text{Rfc} = \frac{\text{Animal Km}}{\text{Human Km}}
\]

Explanation:

Rfc: Reference Concentration (mg/kg)
Animal Km: Km factor in white mice (Rattus norvegicus)
Human Km: Km factor on workers

Based on the formula above, the Rfc calculation results obtained from NOAEL, Animal Km averages, and the Human Km averages are:

\[
\text{Rfc} = 0.022 \times \frac{5.82}{38.9} = 0.003 \text{ mg/kg}
\]

G. Risk Quotient (RQ): Health risk characteristics are expressed as risk levels or risk quotient (RQ) for carcinogenic effects \(^8^{89}\). RQ calculations are obtained by the following formula\(^1\):

\[
\text{RQ} = \frac{\text{Ink}}{\text{Rfc}}
\]

Explanation:

Ink: Intake the amount of risk agent that an individual receives (mg/kg/day)
Rfc: Reference Concentration (mg/kg)

For the characteristics of non-carcinogenic risks, the risk agent intake received by individuals is determined by the following formula:

\[
\frac{\text{C} \times \text{Br} \times tE \times fE \times Dt}{\text{Wb} \times tAvg (\text{non carcinogen})} = 0.09 \times 0.596 \times 8 \times 265 \times 12.55 \times 67 \times 30 = 0.019 \text{ mg/kg/day}
\]

H. Safe Duration Of Exposure To Benzene:
The safe duration can be determined using the following formula:

\[
\text{Dt (safe)} = \frac{\text{Rfc} \times \text{Wb} \times \text{tavg}}{\text{C} \times \text{Br} \times tE \times fE}
\]

Explanation:

Dt (safe): Safe duration of exposure for workers (years)
Rfc: Reference Concentration (mg/kg)
T avg: Average time period (days/years)
C: Concentration in air (mg/m³)
Br: Breathing rate/working breathing rate (m³/hour)
tE: Length of exposure time (hours/day)
fE: Frequency of exposure (day/year)
Then $D_t$ (safe) calculation is as follows:

$$D_t \text{(safe)} = \frac{0.003 \times 67 \times (30 \times 365)}{0.09 \times 0.596 \times 8 \times 265} = 19 \text{ years}$$

The results of this calculation can be used as a reference for the relevant companies to control benzene exposure so that it does not have a health impact on their workers.

**Discussion**

Based on research conducted by Swan et al (2010) states that NOAEL benzene is 3.0 mg/m$^3$ or its value is equivalent to 0.022 mg/kg. Based on the results of this study, the calculation of NOAEL benzene value in white mice (*Rattus norvegicus*) is 0.022 m/kg. Thus, the results of this study are safe for human.

The present study used inhalation route that the response dose for the non-carcinogenic effect used was the Reference Concentration (RfC) value. Benzene RfC value in this study was carried out by using NOAEL of white mice (*Rattus norvegicus*). The research conducted by Tualeka AR, Wibrata DA, Ahsan A, et al (2019) indicated that NOAEL could experimentally determine doses where there was no statistically significant indications of toxic effects or biological problems. The study conducted by Saridewi and Tualeka (2012) obtained a benzene RfC value using NOAEL of white mice (*Rattus norvegicus*) is 0.004 mg/kg. Based on the results of this study, the calculation of benzene RfC values in white mice (*Rattus norvegicus*) is 0.003 mg/kg. The value of Benzene obtained in the present study was smaller than those of Rendy’s (2012) obtained a benzene RfC value is 0.01 mg/kg. It is also smaller than the results of a study conducted by Dewi Kartikasari, Nurjazuli, Mursid Rahardjo (2016) obtained a benzene RfC value is 0.0086 mg/kg. Thus results of this study are safer for humans by using NOAEL of white mice (*Rattus norvegicus*) as a calculation of RfC.

Toxins with potential to produce non-cancerous or non-carcinogenic effects, the health assessment ratio is stated by Risk Quotient (RQ) where RQ $> 1$ is categorized as unsafe or risky $^4\text{to}^\text{10}$. In the calculation, RQ less than 1 (RQ $< 1$) does not affect the body, but RQ value of more than 1 (RQ $> 1$) is dangerous.$^1\text{1}$. Therefore, it is necessary to control the effect by determining the safe duration of exposure ($D_t$) value. Based on the results of this study, the value safe duration of benzene exposure in PT Pertamina RU IV Cilacap laboratory work environment was 19 years.

**Conclusion**

a. Benzene concentration in the laboratory work area at PT Pertamina RU IV Cilacap was 0.09 ppm. This is below the threshold value that allowed in Indonesia according to Permenakertrans No.5/MEN/X/2018 on Threshold Value of Physical Factors and Chemical Factors in the Workplace of 0.5 ppm.

b. NOAEL Benzene in the laboratory work area of PT Pertamina RU IV Cilacap was 0.022 mg/kg.

c. Reference Concentration (RfC) in the laboratory work area at PT Pertamina RU IV Cilacap was 0.003 mg/kg.

d. The level of risk was unsafe with RQ value $> 1$

e. The safe duration of exposure to benzene in the laboratory work area of PT Pertamina RU IV Cilacap was 19 years.

**Recommendation**

The safe duration of exposure to benzene for non-carcinogenic laboratories at PT Pertamina RU IV Cilacap was 19 years. This figure was smaller than the normal workers safe duration of exposure of 30 years. To normalize safe duration of exposure, the concentration of toxin must be minimized to adjust the safe limit of toxin concentration for workers and daily exposure duration was also smaller than 8 hours/day.

**Conflict of Interest:** All author have no conflicts of interest to declare

**Source of Funding:** This is an article about “Determination Safe Duration Of Exposure To Benzene In Workers Of Petroleum Processing Industrial Laboratory In Indonesia By Using NOAEL Of White Mice (*Rattus Norvegicus*)” of Occupational Health and Safety Departmen that was supported by Faculty of Public Health, Airlangga University.

**Ethical Clearence:** The study was approved by the institutional Ethical Board of the Public Health, Diponegoro University.

Assessment the Relevance of Dental Aesthetic Index, Smile and Desire for Orthodontic Treatment among Iraqi Teenagers

Esraa S. Jasim¹, Zainab M. Kadhom², Noor F.K. Al Khawaja³
¹Assistant Professor; ²Assistant Lecturer; ³Lecturer, Department of Orthodontics, College of Dentistry, University of Baghdad

ABSTRACT

Purpose: This study aims to assess the psychological effects of the malocclusion on the emotional state of Iraqi teenagers through comparison of Dental Aesthetic Index (DAI) to certain aesthetic questionnaires and assessment of the malocclusion severity for them.

Materials and Method: 248 Iraq students, of 14 and 15 years old from secondary school in Iraq were selected for this study. The students were interviewed and the clinical data of oral examination were collected by specialist orthodontist under natural day light using dental vernia taking into account the Research Ethics Committee rules. The collection of DAI parameters was performed together with aesthetic self-perception data by ten aesthetic questionnaires.

Results: Of the total sample 37.1% are highly desirable and of mandatory treatment need. The students who were satisfied with the appearance of their smile reported to be about 84%, while about (13%) of them were willing to wear braces.

Conclusions: Dissatisfaction with dental appearance has been noted to be more frequent than the desire for treatment. The DAI correlate significantly with the subjective assessment that is concerned with dental appearance and orthodontic treatment need.

Keywords: Dental Aesthetic Index; Dental appearance; Self-perception.

Introduction

The previous studies found that malocclusion is associated with the dissatisfaction with the appearance for a great extent, and negatively affect the quality of life. Moreover, the self-perception of the level of attractiveness or “The positive” feelings toward the dentofacial complex is a more important factor the contribution to self-conception in teenagers than the self-perceived severity of the malocclusion alone. Malocclusion influences the quality of life and is a highly prevalent public health problem. Particular types of malocclusion seem to affect satisfaction with one’s dental appearance, facial appearance, general appearance, and perceived attractiveness. Measuring and recording the severity and prevalence of malocclusion can be used as an epidemiological tool for preventive procedures or for training orthodontic specialists.

In the 1960s, the occlusal indices were first introduced to help epidemiological studies. DAI is one of orthodontic treatment need indices. Although the DAI indicate the relative employment and social acceptability of dental appearance, it is preferable to include the patient’s own psychosocial view. The demand for orthodontic treatment in many populations is related to their desire to improve their degree of attractiveness and their appearance. Most of the orthodontic needs questionnaires which have been developed in recent years are used as result measures. The patient’s perception in many researches has been shown to be not favored with the orthodontist’s point of view; therefore the

DOI Number: 10.5958/0976-5506.2019.02506.3
differences may be found between esthetics perceptions of laypersons and the orthodontists. The aim of this study was to assess the psychosocial influence of malocclusion on the emotional state of Iraqi teenagers through comparison of the DAI carried out by orthodontist on certain ten questionnaires answered by the individual her/himself for evaluation of dental appearance, satisfaction with smile and desire for orthodontic treatment, In addition to the assessment of the frequency and severity of the malocclusion among Iraqi teenagers.

**Materials and Method**

The sample of this study involves Iraqi students of 14 and 15 years; and the research was confirmed by the Research Ethics Committee. Ten from 260 secondary schools were chosen using simple random technique for selection. Of the total of 248 students, 148 males (60%) and 100 (40%) females were interviewed and examined. A specific privacy for each student was accomplished.

Students with mental or physical impairment, with previous history of or currently undergoing orthodontic treatment were excluded. Clinical data were collected through oral examination. The examiner used disposable mask, gloves, dental mirrors, periodontal probes and dental vernia under natural day light through the window. The subjects were asked about their self-perception of malocclusion using organized questionnaire, noting that interview agenda was piloted before. The DAI used in the assessment of the malocclusion and treatment needs. It includes ten parameters of dentofacial structures:

\[
\{\text{visible missing teeth \times 6} + \text{Crowding} + \text{Spacing} + \text{Diastema} \times 3 + \text{Anterior maxillary misalignment} + \text{Anterior mandibular misalignment} + \text{Anterior maxillary overjet} \times 4 + \text{Anterior mandibular overjet} \times 4 + \text{Anterior vertical open bite} \times 4 + \text{Anterioposterior molar relationship} \times 3 \} + 13
\]

The formula classifies dental malocclusion as mild occlusion, definite occlusion and severe or very severe occlusion as explained in Table (1). While aesthetic self-perception data was collected through ten questions regarding concerns of self-perceived oral appearance which was based upon previous researches investigating self-perception questionnaire. The questionnaires are listed in Box (1).

**Box 1: The Questionnaire**

1. Do you have a pleasant smile? Yes/No
2. How much do you like the appearance of your smile?
   i. Very much
   ii. Quite a bit
   iii. Not much
   iv. Not at all
3. Do you like the way your teeth look? Yes/No
4. How much do you like the way your teeth look?
   i. Very much
   ii. Quite a bit
   iii. Not much
   iv. Not at all
5. Are your front teeth straight? Yes/No
6. How would you consider your teeth as compared to your entire face?
   i. One of the nicest features of your face
   ii. Better than average feature of your face
   iii. Below average feature of your face
   iv. One of the poorest features of your face

Conted Box 1…
7. Are your teeth good looking?   Yes/No

8. Compared to your classmates and friends how do you think your teeth look?
   i. Among the nicest
   ii. Better than average
   iii. Below average
   iv. Among the worst

9. Do your teeth need straightening?   Yes/No

10. If it were possible would you want to wear braces to straighten your teeth?
    i. Definitely No
    ii. Probably No
    iii. Probably Yes
    iv. Definitely Yes

**Statistical Analysis:** The SPSS computer based software version 25 was used for descriptive data analysis. Comparison of males and females with DAI scores was done using t-test. Questionnaire results and DAI scores were compared by Chi-square test.

P value considered to be:
   Statistically insignificant (NS) at p > 0.05
   * Significant (S) at 0.05 ≥ P > 0.01
   **highlySignificant (HS) at p ≤ 0.01

Intra-examiner calibration to ensure the reliability of the results was accomplished, and the kappa value was 0.67, which indicating good agreement ⁶.

**Result**

As shown in figure (1): about 29% of the total sample needs no treatment, 33.9% need elective treatment and 37.1% are highly desirable and of mandatory treatment need, males of highly desirable treatment need are more than the females in response to the questions put forth in the questionnaire, 84% of the students reported to be satisfied with the appearance of their smile, almost 46% of them agree that their teeth need straightening, also 53% of them stated that they have better than average of teeth appearance when compared with their classmates, the students who felt their teeth to be better than average and who felt that their teeth to be below average feature of their face is equal (37%) and about 13% of the students were willing to wear braces in order to improve their smile. The students who were demanding orthodontic treatments were about (13%) table (3).

As Shown in table (2): no statistical difference between the answers of males and females in (Q1, Q6 and Q9) while there was a statistical difference between answers of males and females in (Q3,Q4,Q5,Q7and Q8) and very highly significant difference in (Q2) and highly significant difference in Q10. The data from table (3) Compares DAI with the questionnaire and show no statistical difference except in (Q3, Q5, Q9 and Q10). That means the DAI correlate significantly with the questions that concern the dental appearance and also with the questions that deal with orthodontic treatment need.

Discussion

The recommended treatment cut off point for DAI was 31; any value below it considered as minor malocclusion severity and there is no definite need for treatment. The age selected for our study are considered to be a pertinent age for perception of personal dental appearance since the realization of body image and awareness of facial aesthetics increases with the age and takes priority during late adolescence15, 23. Our results revealed that 84% of students feel comfortable and satisfied with their smiles; while it was 83.5% in India25, and about 23.3% were hiding their teeth while smiling in Turkey1. There was no significant difference between DAI and self-satisfaction with smile; this agree with Nayak et al.23 and come in contrast to the Cons et al.8. Also, there is no significant difference between DAI and self-satisfaction with dental appearance as in Yeh et al.28; but it disagree others23,24. In our study the subjects who were satisfied with the appearance of their teeth are more than of subjects who were dissatisfied, this come in agreement with many studies24,28, but in disagreement with the Mugonzibwa et al.23.

In contrast with our results, the females in some studies were more dissatisfied with the appearance of their teeth as compared with males19, 23,29. At the same time, they were more dissatisfied with their smile as compare with males as in Hamarmci et al.13 The idea is that the self-estems of females could be affected from physical injuries more than that of males30. Simultaneously, the males believe that their teeth need straightening more than the females and about 65.6% of them want to wear braces, this disagrees with Birkeland et al.5.

Our findings showed that there is no significant difference in the relationship between DAI and self-assessment of relative appearance of teeth by the subjects as compared to their entire face and between this index and self-assessment of dental appearance as compared to classmates and friends which comes in agreement with Josefsson et al.17. There was a significant correlation between DAI and all the questions concerning individual self-perception23; while the DAI correlate significantly with questions that concern dental appearance and the need for orthodontic treatment.

The cultural differences are one possible reason for different results in these studies, as well as racial factors, religion, individual characteristics, and unrealistic anticipation21.

Different studies reinforced the concept of occlusal problems effects on the adolescent’s life and the
importance of subjective measures to identify the impact of negative self-perception of dental appearance which increased a lot with the severity of malocclusion⁵,⁷; So if we compare the results of our study with previous Iraqi study², we found that 37.1% of total sample have a severe malocclusion which need mandatory orthodontic treatment while about 27% had severe malocclusion and treatment was highly desirable²⁷, in contrast to 10.3% of the previous Iraqi study results which is an unfortunate outcome after a decade of years of recent advances in dentistry. This could be due to poor health education programs by the Iraqi Ministry of Health, large displacement of people from rural areas to the capital in recent years. The demand for orthodontic treatment was 29% among United States students⁹ and 35% among Indian²³, while in our research it was 13% as shown in table (3) that is related to reduction in the level of education and health awareness about orthodontics in some Iraqi communities.

Conclusions

1. Dissatisfaction with dental appearance has been noted to be more frequent than desire for treatment.
2. The subjective assessments of dental appearance and orthodontic treatment need correlate significantly with DAI.
3. In this study the subjects’ dissatisfaction does not necessarily mean they need orthodontic treatment but they have enough conviction about their aesthetic and dental appearance with little health awareness about orthodontics.

ABSTRACT

Background: Tonsillitis is considered one of the most otolaryngological diseases. It might lead to tonsillectomy if not treated properly.

The Aims: The aim of the current study is to determine the prevalence of chronic tonsillitis caused by bacterial infection among different age groups of both sexes at Kirkuk City. In addition, find out the bacterial load in the tonsillitis cases, as well as their susceptibility pattern to some common antibiotics.

Method: Two hundred and ten throat swabs were taken from patients with signs and symptoms of chronic tonsillitis. The swab samples were cultured on different culture media. The isolates were diagnosed using laboratory methods for identification of bacteria.

The Results: Revealed a high prevalence of chronic tonsillitis in Kirkuk city and it was more predominant in female (55.63%). The female to male ratio was 1.2:1. The most affected age group was (1-10) years old, constitute (35%) of all participants. There are 160 samples produce positive bacterial growth. The results showed that Streptococcus pyogenes was the most infectious bacteria associated with chronic tonsillitis which constitute (41.9%) of bacterial isolates, followed by Staphylococcus aureus (35.6%), Streptococcus parasanginus (7.5%), Streptococcus mitis (6.3%), Streptococcus agalactiae (5.6%), and Streptococcus mutans (3.1%). The results of antibiotic sensitivity test, disc diffusion method revealed that the most isolates under investigation were found to be multidrug resistant. Since all isolates were resistant 100% to Ampicillin, followed by high rate resistant to penicillin (82.58%), with moderate resistance to Erythromycin (59.92%), Amoxicillin-Clavulanic acid (59.68%), and less resistant to Cefotaxime (47.70%), Ceftriaxone (38.08%). However, most of them were highly sensitive to Ciprofloxacin, and Imipenem.

Conclusion: The knowledge about the most likely local infectious microorganisms and their susceptibility to antibiotics can reduce the chance of chronic tonsillitis.

Recommendation: It is recommended to control throat infections and tonsillitis, this required the availability of primary care with adequate dose, and course of appropriate antibiotics treatment, which play important role in the prevention of chronic tonsillitis and its long term squeal.

Keywords: Tonsillitis, Antibiotics, Bacteria, Tonsillectomy, Streptococcus pyogenes.

Introduction

Tonsillitis is the term refer to inflammation of tonsils, which are organs of the immune system, this tissue naturally act as a defense against infection. The tonsillitis considers one of the most otolaryngological diseases, which might lead to tonsillectomy operation for many patients. It is usually indicated when there are six
attack or more per year for two successive years. Other indications of tonsillectomy include; obstructive sleep apnea, Quinsy, and suspicion of malignancy. It has the potential when performed for the proper requirement, as infectious indication. The etiological agents of tonsillitis might be viruses, as Epstein-Barr virus, rhinovirus, adenovirus, parainfluenza, influenza type A, and B. Most viruses likely have a role in the development of tonsillitis, crypt obstruction, and secondary bacterial infection. The most prevalent bacteria involved in tonsillitis were *Streptococcus pyogenes* that cause sore throat, *Staphylococcus aureus*, *Haemophilus influenzae*. The less frequent microorganisms encountered were different Staphylococcus species, Streptococcus species, and other oral microflora. Also some species of intestinal bacteria were detected by some investigators which might be attributed to oral fecal contamination. Multidrug resistant emerged among most of these microorganisms, which may be due to injudicious, and over use of antibacterial therapies without following proper antibiotic policy. The aims of the present study is to determine the prevalence of chronic tonsillitis caused by bacterial infection among different age groups of both sexes at Kirkuk City. In addition find out the bacterial species in the tonsillitis cases, as well as their susceptibility pattern to some common antibiotics.

**Patients and Method**

Two hundred and ten throat swabs were tacked from patients with signs and symptoms of chronic tonsillitis, who were attending Azadi Teaching Hospital at Kirkuk City during a period of the 1st of January to the end of December, 2017, their genders and ages, were recorded. The tonsillar swab was inserted into tonsils’ region for each patient, carefully rotated there, and then withdrawn avoiding contaminated with mouth and transported immediately to laboratory under aseptic condition.

**Bacteriological Study:** The swab samples were cultured on Brain heart infusion broth (transport media), Nutrient agar and MacConkey agar, then incubated at 37°C for 24 hours. Also, they were cultured on chocolate agar then incubated anaerobically in a candle jar at 37°C for 24-48 hours. The growing colonies were further cultured on other media as Mannitol salt agar. The pure colonies were tested with the gram staining, and biochemical tested for identification of bacteria according to Bergey’s manual of determinative bacteriology [8], then the results confirmed by Api, Staph. and Api Strep. System (BioMérieux, France).

**Antibiotic Susceptibility Test:** All the isolated bacterial species were submitted to eight antibiotic discs using the disc diffusion method. The antibiotics including Ampicillin (AM) 30 mg, Penicillin (P) 10mg, Amoxicillin-clavulanic acid (AMC), Cefotaxime (CTX) 30 mg, Ceftriaxone (CRO) mg, Erythromycin (E), 30mg, Ciprofloxacin (CIP) 10mg, and Imipenem (IMP) mg, (Oxoid Company). A single colony was transferred to 5ml nutrient broth then incubated at 37°C for 24hr. The inoculum was adjusted to 0.5 McFarland turbidity standard solution, then spread evenly with sterile swab on the surface of agar. The standard antibiotic discs were placed at some points in the same Petri dishes then they were stand for 45minutes. Later incubated at 37°C for 24hr. The diameter of zones of inhibition were measured and interpreted according to.

**The Results and Discussion:** Table (1) demonstrates the distribution of tonsillitis according to gender and age groups. It revealed the high rate of chronic tonsillitis in this city. Also it showed that the chronic tonsillitis was more predominant in female with frequency of 89 (55.63%) than male which include only 71(44.38%) of total participants. The male to female ratio was 1: 1.25. Regarding the age, it had been found that the most affected age group was (1-10) years old with the frequency of 56(35%) patients. While the less age group were (41-50) years old.

The result of present study was in agreement with Jamal who found in a study on tonsillitis including 200 patients, in which the percentage of females was higher (56.6%) than the males. Also other investigators in Baghdad reported the children under fifteen years were more susceptible to tonsillitis than other ages.

These results might be attributed to increased activity of children at this age group which enhance the exposure to infection than other ages. In addition to contacting children with each other in kinder garden and school beside, intrafameliac transmission of infectious agents that cause the disease.

Table (2) illustrates the frequency and percentages of bacterial species isolated from infected tonsils. From the two hundred and ten throat samples, 160 samples produce positive bacterial growth. Accordingly only these samples included in the study. Out of 160 samples exhibit positive bacterial growth 67(41.9 %) of isolated bacteria were S. pyogenes, followed by S. aureus 57(35.6%), S. parasanginus 12(7.5%), S. mitis 10(6.3%), S. agalactiae 9(5.6%), and S. mutans 5(3.1%). This finding indicated that Lancefield Group A Beta Hemolytic Streptococcus GABHS (S. pyogenes) was the most infectious bacterium associated with tonsillitis. These results were in accordance with that conducted by Al-Mousawi who showed that 43.69% of his total isolates were S. pyogenes from throat swabs of 250 cases of tonsillitis in Najaf governorate. While the results of current study was higher than other investigator, who were found 37.3% of their total isolates were S. pyogenes from throat infection of patients with tonsillitis in Yemen. This result might be due to many virulence factors produced by this bacteria, in addition to climate variation. More over easy transmission of these bacteria by droplet spread, thus close contact between children in school or in large families can increase the risk.

S. aureus found to be the second most bacteria isolated in the present study. This result was in accordance with that reported by Bakir and Ali who revealed that this bacteria was the most frequent microorganism, which constitute 37.7% of their total isolates from tonsillitis cases. This finding due to the fact that S. aureus were posses many virulence factors that attributed to their invasiveness and pathogenicity as well as their resistant to multiple antibiotic agents.

The percentages of S. parasanginus and S. mitis were (7.5, and 6.3)% respectively. This finding was less than that reported by [13] who diagnosed (34.3 and 11.9) % of their total isolates from children with tonsillitis in Baghdad was S. parasanginus and S. mitis respectively. The less frequent bacterial species encountered through present research were S. agalactiae and S. mutans which constitute (5.6 and 3.1) % respectively of total isolates. These finding were relatively higher than that dictated by other authors who observed only (4.2 and 0.7) % of their isolates were belong to these two species S. agalactiae and S. mutans respectively. The finding of varies bacterial species with different frequency in this study may be due to the presence of these microorganisms as normal flora in the upper respiratory tract, moreover most of them were opportunistic and can cause disease especially in immune compromised patients.

Table (3) demonstrates the results of antibiotic sensitivity (disk diffusion method. It showed the most isolates under investigation were found to be multidrug resistant because they were resistant to more than three antibiotics. All isolates were resistant 100% to Ampicillin, followed by high rate resistant to Penicillin with moderate resistant rate to Erythromycin and less resistant to Amoxicillin-Clavulanic acid, Cefotaxime, and Ceftriaxone. Furthermore, there are some resistant of isolates were emerged to the other aminopenicillin as Amoxicillin despite its combination with inhibitor agent called clavulanic acid which increase its activity. These results were consistent with previous study conducted by Bakir and Ali who showed that the most Gram positive bacterial isolates from tonsillitis cases were highly resistant to Penicillin, and Ampicillin, more over most of these bacteria were β-lactamase producers. These results revealed the that the bacterial isolates under investigation were confer resistant to Beta-lactam (β-lactam) antibiotics which include Penicillin, Ampicillin, Amoxicillin, Cefotaxim, and ceftriaxone.
This finding might be due to the production of β-lactamase enzymes which hydrolyze β-lactam ring of β-lactam antibiotics. In contrast other investigators reported that there were no β-lactamase enzymes had been produced by their isolates which include 67 bacteria belong to β-hemolytic group C and F streptococci from patients with acute pharyngitis at Hilla city. They suggested the resistant of their isolated bacteria to antibiotics attributed to other causes as Alteration of β-lactam target enzymes, especially penicillin binding proteins. Moreover, Penicillin less effective in eradicating GABHS which found to be the most frequent bacteria in the current study because Penicillin have the capacity to eradicate the normal oropharyngeal flora, especially α-hemolytic Streptococci which provide an ecological barrier to GABHS infection by producing bacteriocin.

Concerning the moderate resistant of the studied isolates to Erythromycin in the present study, it might due to irregular and overuse of this drug without performed routine culture and sensitivity of microbes to the drug. This might lead to genetic mutation and acquire resistant gens to antibiotic. Other researchers investigated the molecular screening of erythromycin gene of seven strains of S. pyogenes. They improved all isolates did not contain the resistant genes, so they concluded that the resistant to erythromycin could be due to other causes as structural modification of erythromycin by glycosylation, phosphorelation, or lacton ring cleavage by erythromycin esterase.

There are many mechanisms by which bacteria confer resistance to the antibiotic agents including intrinsic impermeability, as well as acquired resistance as mutations, plasmids, and transposons. Furthermore, the tonsils with chronic inflammation, and adenoid contain more scar tissues following each infection. In turn causing an impairment of antibiotic penetrating into the core and become more resistant to antibiotic therapies.

Regarding the Ciprofloxacin and Imipenem, most isolates were found to be sensitive to these drugs with resistant rate of (2.49 and 2.92) % respectively. This finding was in agreement with other researchers who found the most effective antibiotics, and less resistant against his isolates from tonsillitis cases were Ciprofloxacin and Imipenem with resistant of (14.9 and 17.5) % respectively. Hence they could be used as drugs of choice for treating tonsillitis.

It have been concluded that the disease was predominates among female, and (1-10) years old age group. The major pathogenic bacteria was S. pyogenes. Furthermore Most isolates were multidrug resistant. It is recommended to control throat infections and tonsillitis, this required the availability of primary care with adequate dose, and course of appropriate antibiotics treatment, which play important role in the prevention of chronic tonsillitis and its long term squeal.

### Conclusion

The chance of chronic tonsillitis can be reduced by increase the knowledge about the most likely local infectious microorganisms and their susceptibility to antibiotics.

ABSTRACT

Study was conducted in Um-Khashim region (middle of Iraq) during the year 2018 by using 360 local buffaloes (180 daughters and 180 dams) in different parity to determine the relationship of daughters performance with their dams for reproduction and newborn mortality. Regression coefficient was estimate by determine the daughters regression on their dams for number of insemination, abortion rate, dystocia and mortality rate at first three months after calving. Heritability was also calculated depending on regression coefficient. Results showed that vary heritability estimates of the traits that studded, the highest heritability of the insemination number was in the 1st parity (0.38) while the least heritability was in the 4th parity (0.07). Due to the abortion rate, the highest heritability was noticed in 4th parity (0.39) compared with the least heritability which noticed in 7th parity (0.12). Dystocia heritability estimate was 0.38 in the 2nd parity while decreased to reach to 0.07 in 6th parity. Heritability of mortality rate in 1st month after calving was also differed by parity, the highest estimation was noticed in 1st parity (0.42) and decreased gradually to reach 0.08 in 5th parity.

Keywords: Buffalo, heritability, reproduction performance.

Introduction

Buffalo is characterized as the main source of dairy in many countries especially in Asia because more than 95% of global buffalo are found in this continent. Buffalo were found since a very ancient time in Mesopotamia region (Iraq) and was domesticated by Sumerians and Assyrians people, nowadays there are two species (Reverine and Marshes buffalo) which differ morphologically, milk production ability and chromosomes number¹². There are many challenges that prevent the buffalo breeding to blossom in Iraq such as the deficiency of food and absence of governmental supporting³.

Many studies around the world mentioned to reproductive difficulties in buffalo such as silent estrous, dystocia and early or late abortion, ⁴⁵ indicated that the reproductive problems in buffalo caused by varied environmental factors and lead to heavy economic losses. One of reproductive problems is abortion which classified as ovular and fetal. Dystocia is the other important problem which caused by many factors and lead to fetus lose⁶. Some of studies referred that the reproductive problems are resulted from maternal effects, ⁷ indicated that the maternal effects are more important than direct gene effects especially in postnatal period. ⁸ indicated that the buffalo are known to have grater incidence of maternal dystocia than the other ruminants while ⁹ referred to the poor reproductive efficiency of buffalo daughters depending on their dams performance. The major aim of this study is to focus on the maternal effects on reproductive problems in Iraqi buffalo such as high number of service per conception and abortion or dystocia through estimation the regression coefficients and heritability of these traits for daughters on dams and exploit the results as a guidelines in the improving of reproductive performance under farming conditions.
Maternal and Method

Data were made available from 360 buffaloes (180 daughters and 180 dams), in different parity and reared in classical system in the year 2018. The region of study is known Um-Khashim which is located in AL-Najaf province –middle of Iraq.

Experimental Animals: Animals were reared under farming conditions as a herds with different size. Natural insemination is used and the herds are fed on concentrate rations contains from wheat barn and quern cereals. Roughage food contains mainly from rice hay in addition to green food such as alfa alfa or clover according season. In summer, animals were fed on water plants such as cane and bulrush as a cheap and bulk food. Vaccines and veterinary process were made routinely and the milking buffaloes were milked manually twice a day.

Number of inseminations per conception, abortion rate, dystocia rate and mortality rate in first three months after calving were determined for both dams and daughters. Statistical Analysis System was used to estimate the regression coefficients of daughters performance on dams performance were calculated by the formula:

\[ b = \frac{\sum XY - (\sum X)(\sum Y)}{n} \]

\[ \frac{\sum X^2 - (\sum X)^2}{n} \]

where :
- \( x \): Dams performance
- \( y \): Daughters performance

Heritability for all traits that studded was estimated:

\[ h^2 = \frac{2b}{\sum Y - (\sum X)} \]

Results

Results represented in (table -1) showed a significant estimates (P<0.05) of regression coefficient of insemination number during the first three parities namely, 0.19, 0.17 and 0.13 respectively while the regression coefficients were not significant in 4 th – 7 th parity.

* (P<0.05)

Regression of abortion rate was significant in the first four parity namely 0.18, 0.15, 0.19 and 0.20 respectively while no significant regression in the 5 th, 6 th and 7 th parity. Regression of dystocia of daughters on their dams was significant in 1 st and 2 nd only (0.16 and 0.19) compared with the other parities. Results showed that a significant regression coefficients (P<0.05) of mortality rate the 1 st month after calving in 1 st, 2 nd, 3 rd, 4 th and 7 th parity namely, 0.21, 0.20, 0.18, 0.15 and 0.14 respectively and a significant regression in the 2 nd month after calving for all parities except 7 th parity (0.18, 0.15, 0.18, 0.20, 0.18 and 0.16 respectively) while a significant coefficient in 3 rd month after calving in the 1 st to 5 th parities namely, 0.17, 0.19, 0.15, 0.18, 0.16 respectively. Results in (Table -2) shoed the heritability estimates of the traits studded, the highest heritability of the insemination number was in the 1 st parity (0.38) while the least heritability was in the 4 th parity (0.07). Due to the abortion rate, the highest heritability was noticed in 4 th parity (0.39) compared with the least heritability which noticed in 7 th parity (0.12). Dystocia heritability estimate was 0.38 in the 2 nd parity while decreased to reach to 0.07 in 6 th parity. Heritability of mortality rate in 1 st month after calving was also differed by parity, the highest estimation was noticed in 1 st parity (0.42) and decreased gradually to reach 0.08 in 5 th parity.

</tbody>
</table>

In 2nd month after calving, heritability estimate of mortality rate was 0.39 in 4th parity compared with 0.24 in 7th parity. The heritability estimates of mortality rate in the 3rd month after calving was in the same direction, the highest value was noticed in 2nd parity compared with the 7th parity namely 0.38 and 0.10 respectively.

**Discussion**

The results of present study indicated that the genetic relationship of dams and daughters are strong in the beginning of life and trend to decline with the progress of age. The results came hormonal with others past studies that referred to the decrease of maternal effect with age progress. 11reported that the estimate of heritability based on daughters regression on dams performance for reproductive traits were high in early parity compared with late parity in Egyptian buffalo. 12,13showed that the regression estimation is an efficient tool to estimate the genetic effect of dams on daughter performance. 14,15reported that the maternal effect are modulate offspring performance through the causal influence of dam genotype on her daughters. Results showed a that the abortion rate and newborn mortality in daughters are correlated with dams status therefore, we can predict of daughters status depending on their dams and select the best individuals to be dams in next generation. Most of studies referred that the abortion or calve mortality are resulted from environmental causes such as diseases, poor food and bad management16 and ignore the genetic relationship between dam and daughter. Many studies reported that we can exploit the genetic parameters such as heritability for selection and improving but the accuracy of estimation depends on the amount and quality of primary data17. Therefore, we can find a vary estimates of heritability in different studies for the same traits.

**Conclusion**

The results of current study providing the link between maternal effect and some of reproduction problems in Iraqi buffalo and we can exploit this relationship to improve animals under farming conditions.
