Performing simple gymnastic exercises in the optimal pulse mode has a positive effect on the patient’s entire body, contributing to his enrichment with oxygen, improving ventilation of the lungs, increasing the reserve capacity of the heart muscle, enhancing the blood circulation of eternal and peripheral vessels, training new motor functions and skills. Group aerobic exercises also expands the social contacts of the child, strengthens his motivations for recovery, creates a positive emotional background, and contributes to the process of socialization.

Another type of physical rehabilitation is massage. It is performed in the original supine position with a raised headboard of the couch. Massage the lower limbs, abdomen, arms, chest. Then the patient turns on his right side and his back is massaged. Stroking, rubbing, kneading and vibration are used.

Physical therapy in children with this diagnosis is used to reduce the oxygen starvation of the organs and tissues of the body, activate the processes of inhibition in the brain, stimulate the immune system, increase the overall tone of the body. As antihypoxic Method uses sodium chloride baths, which improve the functioning of the sympatho-adrenaline system. For the same purpose, oxygen baths are used to promote the supply of organs and tissues suffering from hypoxia with oxygen. Carbon dioxide baths are also used, whose carbon dioxide, acting on the respiratory center, entails a compensatory increase in the diffusion of oxygen in the lungs and an increase in its level in the blood. With a calming purpose, iodine-bromine baths are prescribed to the patient, which contribute to the normalization of the balance of the processes of excitation and inhibition of the cerebral cortex.

Conclusion

The features of the heart of children can be considered a relatively large mass of the heart and relatively large wide openings of the heart and the lumens of the vessels. This is a factor facilitating blood circulation in children. Congenital heart defects in children are formed in the process of intrauterine development under the influence of various adverse factors. They can be defects without cyanosis and defects with cyanosis. Physical rehabilitation for heart defects is used after surgical treatment in order to stimulate the heart muscle and adapt the child to normal life. The main types of physical rehabilitation in children with congenital heart defects are physiotherapy exercises with elements of recreational aerobics, therapeutic massage, and physiotherapy. Their appointment is always carried out individually.

Genotoxic and Teratogenic Effects of Mycophenolate Mofetil in Mice

Wajdi Sabeeh Sadeq¹, Ruida Watheq Neama¹

¹Biology department, College of Science, Tikrit University/Iraq

Abstract

Mycophenolate mofetil (MMF) or cellcept is an immunosuppressive drug which used to suppress immune system activity and reduce the risk of organ rejection in transplant patients. The present study investigates the cytotoxic, genotoxic and teratogenic potential of MMF in white mice. Genotoxic effects of this agent were evaluated using micronucleus test, and skeletal malformations were investigated according to dose concentration as treatment was with 16.6 mg. kg⁻¹ and 33.3 mg. kg⁻¹ MMF. A significant difference was observed in MNiPCEs in both treated groups than negative control, and 33.3 mg. kg⁻¹ concentration showed significant differences in MNi than negative control. A significant malformation was found in abnormal bones of cranial, ribs, pelvic girdle and shoulder girdle bones in 16.6 mg. kg⁻¹ cellcept group, while there were no significant differences in bone total number. There was a high difference in bones total number of thoracic and neck vertebrae of 33.3 mg. kg⁻¹ treatment, while a high significant show in abnormal bones of thoracic, neck, tail, sacral and lumbar vertebrae in 16.6 mg. kg⁻¹ group. In conclusion, MMF has cytotoxicity and/or genotoxicity action it possesses a high teratogenic potential, these effects increase with increasing dose.

Keywords: MMF, Teratogenic Effects, cellcept.

Introduction

Mycophenolate mofetil (MMF, Cellcept) an immunosuppressive drug, approved for clinical use in the prevention of acute allograft rejection following organ transplantation and hematopoietic stem cell transplantation [¹], and effective in treatment of autoimmune disease [²].

MMF is a noncompetitive, selective and reversible inhibitor of inosine monophosphate dehydrogenase, an important enzyme in the de novo synthesis of guanosine nucleotides in T and B lymphocyte [³], thereby blocking the de novo DNA synthesis pathway in these cells and providing effective immunosuppression in transplant patients [⁴].

MMF treatment associates with high genotoxic effects in primary and secondary lymphoid tissues via reduction the antioxidant defense mechanism and increase oxidative stress and DNA damage[⁵].

The use of MMF in transplant patients has increased over time. In U.S., MMF is now used by nearly 80% of kidney transplant patients, and about half of liver transplant patients. Off-label use for autoimmune diseases such as systemic lupus erythematosus (SLE) and dermatology conditions such as psoriasis, may lead to even wider use, [⁶].

Of the live born reported to the National Transplantation Pregnancy Registry (NTPR), a higher incidence of structural malformations was seen with MMF exposure during pregnancy, compared to the overall kidney transplant recipient offspring. Three of the four defects included microtia (ear deformity) suggesting a pattern of malformations. However live born outcomes without structural malformations have also been noted in the MMF cohort. The structural malformations seen in the MMF exposure group appear to support the package insert recommendations of prospectively discontinuing MMF at least six weeks prior to conception [⁷].

In October 2007 the Food and Drug Administration and the Drug Manufacturer revised the pregnancy category of MMF to a pregnancy category D drug (positive evidence of fetal risk), acknowledging the increased risk of first trimester pregnancy loss and congenital malformations.[8]

Anderka et al (2009), stated, that the pattern of malformations and minor facial anomalies is sufficiently consistent to support MMF as a likely teratogen. In a fetus or infant who has been exposed to MMF, detection of this pattern malformations (bilateral microtia, orofacial cleft, coloboma, hypertelorism, micrognathia, conotruncal CHD, agenesis of the corpus callosum, esophageal atresia, digital hypoplasia) should prompt consideration of the embryopathy.[9]

Method

The study was conducted in white mice weighting 20- 25 g, 6- 8 weeks’ age. Animals were maintained under controlled ambient temperature 25 C°, and a 12\12 hrs. light\ dark cycle for two weeks prior to commencement the experiment.

The drug: MMF was a film coated tablets of 500 mg, which provided by Roche. It was freshly prepared before dosage via dissolving in adequate volume of sterile distilled water to obtain the desired concentration.

Micronucleus test (MN test): The first group of the animals was given 16.6 mg.kg\-1 and the second group 33.3 of MMF (cellcept). Mitomycin C (0.33 mg) was used as a positive control, while negative control was given distal mg.kg\-1 water, and 20 males were used 5 animals for each group. Treatment of animals in all groups continues for 5 consecutive days except positive control was single dose. After 18 hrs of the last dose, the animals were sacrificed. The experiment was conducted according to the method described by Schimed, 1975[10].

Teratogenic effects: In this test we used 20 females, the animals were mated with males in ratio 2 females:1 male, and left over night, in the next day females were examined to make sure there is vaginal plugs, which considered as the day 0 of pregnancy. Females were treated with MMF at 9, 10, 11 days of pregnancy, and incised in the 18 day to remove the embryos.

Treatment was as follow:

1. Negative control: 5 animals were treated with distal water,
2. Positive control: 5 animals were treated with 0.33 mg.kg\-1 mitomycin C,
3. 5 animals were treated with 16.6 mg.kg\-1 cellcept,
4. 5 animals were treated with 33.3mg.kg\-1 cellcept.

Fetuses were thoroughly skinned such as skin removal was to permit satisfactory penetration by the stain, the method was appliedthat described by Erdogan, 1995[11].

Result and Discussion

In the current study, no significant differences in polychromatic erythrocytes (PCEs) was found between negative and treatment groups, MNiPCEs and MNi count in MMF treated groups of mice. The Lowest concentration 16.6 mg. kg\-1 of MMF, showed no significant differences in micronuclei count in PCEs, while there were significant differences with higher concentration 33.3 mg. kg\-1, figure (1).

Fig. (1): Polychromatic erythrocyte of mice, A. 1 PCE B. MNiPCE. Arrow indicate MN.

MN frequencies consider as a biomarker of DNA damage for genotoxicity testing [12] Moreover, the micronucleus is composed either of small chromatin fragments which arise as a result of chromosome breaks after clastogenic action, or of whole chromosomes that do not migrate during anaphase as a result of aneugenic effects [13]. MN are produced from problem in cell division and their expression can occur after the DNA damage event at different stages of cell cycle[14], therefor increasing in MN frequency means increase the level of DNAdamage, with respect our study increase in MNi observed in the bone marrow cells of MMF exposed mice showed that this drug is genotoxic.

Chronic kidney diseases (CKD) patients are characterized by presenting higher genomic damage
than general population, and high genetic damage levels have been correlated with adverse health outcomes. The accumulation of changes at the genome level, due to both endogenous and exogenous factors, genomic instability and deficiencies in base excision repair were identified in CKD patients. This genetic susceptibility, together with potential exposure to genotoxic agents (including immunosuppresses), would explain the tendency to accumulate genetic damage in kidney transplantation (KT) patients over time, [15].

Cilião et al., 2016 concluded increased frequency of micronucleated mononucleated cells in relation to the transplantation time. Mycophenolate mofetil increased the MN frequency in mononucleated cells compared to the control group. The significant increase in MN frequency observed in this group suggest that the transplant patients have higher probability of developing cancer than the general population, [16].

With regard to teratogenic effects two concentrations of MMF were used and with increased the dose we expected increasing in the defects in mice embryos. The 16.6 mg.kg\(^{-1}\) MMF dose leads to high morphological phenotypes but did not appear a same effect in 33.3 mg.kg\(^{-1}\) dose as expected due to dead most of embryos and be lethal effects.

We found no significant differences in total embryos number, right horn embryo number and left horn embryo number compared with negative control. Many studies described teratogenic effects of MMF in both animals and case reports in human, and this support which we found in this study. Some unpublished studies referred to the possibility of increasing risk of miscarriage in pregnant rabbits and rats, [17]. NTPR observed that 14 pregnancies among 32 related to 23 women terminated in spontaneous abortions, [18].

NTPR also was reported about 6 non-renal transplant patients with 7 pregnancies who exposed to MMF. One pregnancy from one kidney/ pancreas transplanted and three from three liver transplanted and three from two heart transplanted. Between these seven pregnancies, four were spontaneous abortions and three were liveborn, [7]. Recent studies demonstrated that MMF exposure increase the risk of miscarriages. Results obtained by King et al., 2016 suggested that the miscarriages risk increased 9 times when the mother exposure to MMF during second-trimester of pregnancy compared with those who exposure during first-trimester of pregnancy or who discontinued MMF for 6 or more weeks prior to pregnancy. Discontinued cases for less than 6 weeks prior to pregnancy or discontinued during first-trimester increased the risk of malformation and fetal defects, [19].

Product information observed fetal loss and birth defects at doses 0.5 times the human doses for kidney transplant patients based on body surface area, [6]. we note from the morphological phenotype that the malformations concentrated in pelvic girdle, lower limbs and tail, the tail was short and turned and curved limbs, oligodactyly was described as in figure (2)

![Fig. (2) Embryos of mice. A. embryonic skeleton of negative control, B. embryonic skeleton of 1000 mg group, C. embryonic skeleton of 2000 mg group. 1. Missing bones 2. bone atrophy 3. stereospondylos 4. abnormal vertebrae 5. Synaptic ribs 6. Oligodactyly 7. Deforming skull 8. Abnormal bones.](image-url)
It was found a deficiency in total number of neckbones in 33.3 mg.kg$^{-1}$ group than negative control while there were no significant differences in total number in 16.6 mg.kg$^{-1}$ and positive groups in related to negative control, but there was a higher significantly in abnormal bones of the neck in 16.6 mg.kg$^{-1}$ group than negative control and not significant in 33.3 mg.kg$^{-1}$ group compared with negative control.

There were significant differences in total number of thoracic vertebrae in 33.3 mg.kg$^{-1}$ group than negative control and there was a high significant differences in the number of abnormal bones in group 16.6 mg.kg$^{-1}$ than negative control.

Lumber vertebrae and sacral vertebrae showed no significant differences in total number bones in all groups compared with negative control, but showed significant differences in number of abnormal bones in group th 16.6 mg.kg$^{-1}$ than negative control.

Malformation in tail bones appear clarity in embryo there was a higher significant in group 16.6 mg.kg$^{-1}$ compared with negative control while no significant differences in 33.3 mg.kg$^{-1}$ group, and no significantly in total number of tail bones relative to negative group. The tail appear curvature prominently and quirky and this agree with results of Jiang et al, 2016 in Zebrafish embryos which show tail defects and quirky in angle compared with negative control,[20], see table 1.

Geranial bones give arise high significant in total number in group 33.3 mg.kg$^{-1}$ impaired with negative control, but there was a high significant in abnormal bones in both 16.6 mg.kg$^{-1}$ and positive group compared with negative control. Sternum bone did not show any differences never in total number or in number of abnormal bones in any group. As ribs did not show significant differences in total number in all groups, but there was a high significant in abnormal bones in 16.6 mg.kg$^{-1}$ and positive group than negative control.

As there were no significant differences in total number of shoulder girdle this mean there was no loss of bones in all group relative to control group, but when compared number of abnormal bones there was a higher significant in 16.6 mg.kg$^{-1}$ group compared with negative control, and no significant differences in 33.3 mg.kg$^{-1}$ group compared with negative control. There were no significant differences in total number of bones of pelvic girdle, but there was high significant in number of abnormal bones in 16.6 mg.kg$^{-1}$ and positive group than negative control, Table 2.

Many studies determined that the risk of birth defects increases with exposure to MMF in animal’s models. In rat’s malformation were exhibited at doses lower than or equivalent to clinical doses such as agnathia, anophthalmia and hydroencephaly,[21, 22].

Malformations observed in both human case reports and animal’s studies which may appear in heart, ocular, diaphragmatic hernia and kidney. Microtia is the most common anomaly in human but animals do not show the same response, [9] and rarely digital hypoplasia [17].
In one case report exposure to 0.5 MMF given twice per day for 12 weeks of conception, this liveborn exhibited microtia and hearing loss, [6]. MMF exposure during pregnancy may lead to a phenocopy of Fryns syndrome, which arise by genetic causes and CDH (Congenital diaphragmatic hernia) is the most important anomaly in this syndrome. But the information about mechanism of MMF action refer to MMF may yield to potential genetic syndrome, [17].

In a study made on woman had been take MMF 1g twice/day for eight months with prednisolone and hydroxychloroquine at the same time. MMF taking go on until 12 weeks of pregnancy. Ultrasound examination at 21 weeks revealed micrognathia, ocular hypertelorism, bilateral microtia, external auditory duct atresia and a nasal bifid anomaly, [8].

Toxic Effects of Acute Cadmium and Lead Exposure in Rat Blood, Liver, and Kidney

Wasan Najim Abdul-Sada

Department of Basic Science, College of Dentistry, University of Babylon, Babel, Iraq

Abstract

Background: The substances; Cadmium and lead are globally spread substances which are unchangeable and therefore harmful to the environment. They pollute the surroundings and are of considerable concern to individuals’ well-being. In real life situations, we have exposure to combinations of chemical substances as opposed to one form of chemical. It is hence of utmost significance in order to evaluate their toxic level. This experimentation was oriented towards studying the toxic consequences of acute cadmium in the blood and kidneys of rats. The former was also studied after being exposed to lead. In addition; the variations in the plasmatic hormonal profile, roles of the kidney and liver- from routinely being exposed to lead and cadmium, in cows, were also considered. The aforementioned was done by measuring proportions of cadmium in the livers and kidneys of rats. Alterations in the; hormonal, enzymatic and hematological state of rats, was also examined.

Keywords: Acute Cadmium, Lead Exposure, Kidney.

Introduction

The crust of the earth and soil being exposed naturally to: significant amounts of lead, anthropogenically conducted processes (e.g. burning of combustible materials such as coal and mineral oils, extracting metal from its ore by burning/melting, excavating to obtain coal or other minerals from a mine, process of alloy, painting activities in the industrial sector) are significant reasons for lead and cadmium in animals in the surroundings of industries. Moreover, various manufacturing processes have been identified as reasons for the contamination of the hunt of animals. Additionally, increased amounts of blood lead and cadmium were found in livestock whose habitats were located by these manufacturing divisions[1].

After absorption, Cadmium and lead are distributed in the organisms via red blood cells or proteins. A major amount of Cd in erythrocytes can potentially cause high-molecular-weight proteins, while a minor amount is bound to hemoglobin. However, when lead goes into the cell, most of it is bound to hemoglobin rather than the membrane of red blood cells. The hematopoietic system is amongst the most sentient of systems and blood symbolizes both the mode of transport and the critical toxicity goal of Cadmium and lead. Both metals may lead to anemia by various mechanisms. Cadmium and Pb are transported to the liver, in which they can cause damage and disturbed function. Liver damage can be confirmed by histopathological findings and is often accompanied by increased blood enzyme levels and reduced protein synthesis. Toxic effects on kidneys are represented through the structural damage of kidneys and changes in the excretory function[2].

Research into the sub-chronic oral toxicity with varying Cd and Pb doses indicated that the dominantly targeted organs were; the blood, liver, and kidneys. After 15 days of administering the peritoneum (i.p.) of a Cd and Pb combination[3], identified that Cd reacted more amongst the two metallic substances, while[4] suggested a possible antagonistic effect between Cd and Pb. Clearly, the interactions between the two metals in a combined mixture are complex and warrant further investigation.

We decided to investigate the toxicity of a Cd and Pb combination in a model organism after a single exposure. An investigation was conducted into the consequences of being exposed to single metallic substances and their combinations on hematologic and biochemical frameworks. The status of redox in the plasmatic substances, liver, and kidneys of rats (that were given treatment) was also studied. Furthermore, the
distribution of metals and bio-elements was investigated in selected tissues, as well as their histopathology.

**Materials and Procedure**

**Chemical substances:** Each substance utilized in the chemical analysis and the relevant chemical substances were of analytical grade quality (i.e. extremely pure). Cadmium chloride (CdCl2xH2O, Merck, Germany) and lead acetate (Pb(CH3COO)2x3H2O, Centrohem, Serbia) were used for oral administration solutions. Solutions which contained a precise concentration of the following elements; Cd, Pb, copper (Cu), and zinc (Zn) (Merck, Germany) were used to create calibration curves for toxic metals and bioelements analysis, while cHNO3 (65%, Merck, Germany) and H2O2 (30%, Sigma-Aldrich, Germany) were used for tissue mineralization. All chemical and reagents for the examination of antioxidant status were purchased from Sigma-Aldrich Chemie (Germany).

**Animals:** Laboratory rats (masculine Wistar rats) were bought from the Military Medical Academy (Belgrade, Serbia). These rats weighed roughly 250 grams. They were kept in conditions with standard control (degree of heat intensity 25 ± 3 degree centigrade, comparative humidity of 35 percent to 60 percent, twelve-hour circadian rhythm). Laboratory rats (masculine Wistar rats) were bought from the Military Medical Academy (Belgrade, Serbia). These rats weighed roughly 250 grams. They were kept in conditions with standard control the Ethical Committee on Animal Experimentation of the University of Belgrade, Faculty of Pharmacy [5].

**Study Design and Experimental Procedure**

After 2 weeks of being acclimatized, a process of random division of the rats into three different categories. This included a control group and two experimental groups.

**1-Control group:** was only given access to water.

**2-Cadmium treated groups:** 25 rats were given one treatment of an aqueous solution of CdCl2 and/or Pb(CH3COO)2 in dosages: 15 milligrams of cadmium per kilogram of body weight (b.w.) (Cd15 group),

**3-Lead treated groups:**

25 rats: received 150 mg Pb/kg b.w. (Pb150 group).

The selection of experimental doses was based on our previous research, as well as literature data (Buha et al., 2012). Every rat was given a treatment with a volume of 1 mL/kg b.w. that was administered by force. They were sacrificed twenty-four hours following being treated. This was conducted under light anesthesia.

**Sampling:** An aggregate of fifty specimens of; livers, kidneys and thigh muscles (twenty of everyone) were accumulated at random from the carcass of each rat. These were investigated in clinical observation.

Blood specimens (twenty from every farm) were obtained from the jugular vein. Blood (prevented from coagulation using disodium-EDTA (2.5 milliliters) was utilized for complete blood count (CBC). Seven point five (7.5) milliliters was shifted to a serum separator tube for later blood metabolite examination. Additionally, ten milliliters of blood were stocked in tubes (to which heparin was added to prevent coagulation)in order to identify metallic substances’ concentration. Every tube was kept instantly over frozen water and shifted to the lab. Blood (prevented from coagulation) was examined soon. This was following the accumulation for quantification of hematocrit (PCV), total leukocyte count (WBC), and hemoglobin (Hb) by microhematocrit, cyanmethemoglobin, and routine hand-operated procedures, in the afore-mentioned order[6]. A polarogram was obtained following a scan of the potential from −980 to +30 megavolts. An observation of the highest point was made at −560 and −380 megavolts for cadmium, and lead. Systematic correctness was identified with the usage of CRM of the Community Bureau of Reference standard for trace constituents in bovine blood. 2 blanks with no blood and two specimens for referencing purposes were in each batch of fifteen blood specimens. The acceptance of analysis was on the condition that the range of recoveries was in-between 90 % and 110 % of the certified values.

**Results**

Results in Table (1) show that the cadmium levels vary quite notably (P < 0.01) this was followed by liver (0.172 ppm/wet.wt) and the least level observed in the muscle (0.007 ppm/wet.wt).
Results in Table (2) show that the lead levels vary notably (P < 0.01) amongst the various organs studied. The greater lead level found in the kidney (0.610 ppm/wet wt.), followed by liver (0.604 ppm/wet wt.) and the least level observed in the muscle (0.299 ppm/wet wt.).

The contaminated flesh and inner body parts of slaughtered livestock, with cadmium and lead, are a significant source of meat in Egypt. Henceforth, the amount of slaughter of cattle is significantly greater than that of other creatures. Following slaughter, they are generally moved from the slaughterhouses in open trucks. This poses a great risk to the meat. It can become contaminated because of the harmful gases let out from vehicles (that have a high content of lead and cadmium).

The contaminated flesh and inner body parts of slaughtered livestock, with cadmium and lead, are a significant source of meat in Egypt. Henceforth, the amount of slaughter of cattle is significantly greater than that of other creatures. Following slaughter, they are generally moved from the slaughterhouses in open trucks. This poses a great risk to the meat. It can become contaminated because of the harmful gases let out from vehicles (that have a high content of lead and cadmium).

The present study identified that the approximate high and mean level exposures to Cd of each specimen that went under examination (equal to 1 μg/kg bw/day) were in between or insignificantly greater in comparison to the TWI stated by WHO. In 2009, EFSA issued its scientific view on Cd in food and set up a reassessed TWI for Cd of 2.5 μg/kg bw (equal to .36 μg/kg bw per day). The average dietary contact across European republics was assessed to be 2.3 μg/kg bw per 7 days, with great levels if exposure approximated to be 3 μg/kg bw per 7 days. In spite of the fact that unfavorable consequences on kidney function are not likely to happen at exposures two times larger than the TWI, the EFSA has come to a conclusion that exposure to cadmium at the population level must be lessened. On considering the latest values of TWI for Cd, it is evidently identifiable that the intake of offal has the potential to put forth a public health hazard.

High and mean level everyday consumption of lead for both sheep and cattle specimens did not exceed tolerable levels set up by WHO on everyday consumption (3.6 μg/kg bw per 24 hours). The HI and HR for average levels of Cadmium and lead were <1; on the other hand, the intake of great quantities of both poisonous metallic substances has the potential to be a public health hazard.

It indicates within the similar row of several litters are expressively different at (P < 0.01).

The reduction in the content of Hb in cows around the closed lead zinc smelter is attributable to the secondary shortage of copper, which can have a negative impact on iron metabolism. These outcomes have been facilitated by inferior levels of conc. of copper in cows who have exposure to atmospheric lead pollution as shown in Table 1. The same results are indicated for dairy cows following lead exposure and for goats following Mo poisoning[8].

A reduction much alike in the value of PCV has been identified by [9] in lead exposed dairy cows and [10] identified in goats after great levels of administration of molybdenum. Furthermore [11] also identified reduced...
levels of hematocrit in house mice that were exposed to atmospheric contamination from a coal-fired power plant. The past research on rats and also detected reduced values of hematocrit after the exposure to lead or cadmium.

**Conclusion**

Our study concluded that, cattle bred and managed near the industrial areas in Egypt can expose to the cadmium and lead toxicity through pollution of its food and water that results in alterations in the quantities of Cd and Pb in the muscle, liver and kidney in addition to variations in the profile of plasma hormones and function of liver in cows with natural exposure to Pb and Cd around various manufacturing locations.

Celiac and Thyroid Diseases in Some of Iraqi Patients with Juvenile Rheumatoid Arthritis

Wisal Salman Abd¹, Najah Salman Abd²

¹College of Science/Biotechnology Dept./University of Baghdad,
²Medical City / Ghazi Alhariry Hospital/ Ministry of Health

Abstract

The present study was accomplished on 76 patients with different autoimmune diseases, all patients were with juvenile rheumatoid arthritis (JRA). Thyroid function (TF), thyroglobuline antibodies (TGA) and antitissuetransglutaminase antibodies (AGA) were estimated by enzyme linked immunosorbant assay (ELISA). Twenty nine patients (38.2%) were with hypothyroidism, 16 (21.1%) were with autoimmune thyroiditis and 31 (40.7%) were with celiac disease. It could be concluded that the above immunological and biochemical markers are of importance for early diagnosis to some autoimmune diseases.

Keywords: Juvenile rheumatoid arthritis, autoimmune thyroiditis, thyroid disease and celiac disease.

Introduction

One of the most common chronic rheumatic diseases worldwide is the JRA ¹, ², ³, ⁴ which is enclosed to several disorders before sixteen years old, it is accompanied by a heterogeneous group of conditions characterized by inflammation of the connective tissues (example; joints)⁵ and it is also defined as the fifth most common chronic disorder in the children who come who arthritis without known cause for the first six weeks and persist for 6 months³,⁵. In France one in five thousands children are affected with the most frequent clinical forms, is oligoarthritis JRA, which is characterized by four joints involvement in the first six months especially in female ²,⁶. JRA have bad prognosis if it comes with uritis associated with dangerous advances. In some cases like Still’s disease which is systemic JRA and polyarticular disease, inflammation could continue till adulthood ⁴. A poor functional prognosis is associated with the involvement of severe hip and severe polyarticular forms. Celiac disease and autoimmune thyroiditis in adolescence have been described ⁴-¹⁰. Few information at hand for large of JRA ¹¹-¹⁶ in the present study thyroid function, antithyroid antibodies and celiac disease screen were evaluated children with JRA.

Patients and Method: Seventy six of patients and 12 control healthy individuals, all patients included in this study fulfilling diagnosis criteria for JRA ⁹. Fifty five (72.4 %) females and 21(27.6 %) males, ages ranges (4-17) yrs. All patients were admitted to Alfanar clinical Lab. since 2015. All patients have family history of autoimmune thyroiditis, RA, psoriasis, type 1 diabetes and celiac disease, 12 control healthy individuals were included in this study 6 girls and 6 boys (4-17) yrs. mean age was 8.

Sample collection: “Three milliliters of blood were withdrawn from patients and control by vein puncture. Sera were separated by centrifuge at 3000 rpm for 15 minutes. Samples were kept in the freezer at -4°C until ELISA assay performance.” Sera of patients were tested for AGA-IgA, thyroid function and antithyroglobulin antibody by ELISA. Thyroid function was accomplished by (ELISA kit-Biocheck), while AGA-IgA and TGA were accomplished by (BioHit,ELISA).

Results and Discussion

Diagnosis of celiac disease was confirmed by jejuna biopsy. Table(1) below showed in hypothyroidism 4 patients with autoimmune thyroiditis , 13 with celiac and 3 with autoimmune thyroiditis and celiac together,
in patients with autoimmune thyroiditis 4 patients were with hypothyroidism and 7 with celiac disease while in patients with celiac disease 15 patients were with autoimmune thyroiditis and 13 with hypothyroidism.

Only 17 (22.4%) patients came without other diseases hypothyroidism, autoimmune thyroiditis and celiac disease. Although the mystery of coincidence of abnormal thyroid function in CD, these diseases shared the same HLA haplotype and the same cytotoxic T lymphocyte associated Ag-4 gene. Ch’ng stated in his review percents of prevalence of celiac disease in autoimmune thyroiditis 2%-7.8%.

In comparison to control the prevalence of hypothyroidism, autoimmune thyroiditis and celiac disease was elevated in JRA patients p value < 0.001, Some researchers demonstrated a similar p value and far from others to that of Cassidy the percentage was 14%

The present data recommends regularly checking of thyroid tests, thyroid Abs, and Abs of celiac disease in children with JRA.

Stagi and his colleagues stated 6.6% of JRA patients had celiac disease, the results of the present work goes with that of Stagi. There is a genetic correlation between JRA and other autoimmune disorders. There are multi different determinants have a role in initiation of RA in adults and in children such as social, genetic, economic, and environmental. The above results go with the fact that thyroid function in JRA may be defected in any case if patient comes with or without ano+ther autoimmune association and, while others were in comparison with this opinion. Many other studies stated adversarial opinions about the association between celiac disease and RA. The present study showed significant differences between patients and control regarding celiac disease this result goes with that of p value ≤0.07, while another researcher showed a different results. The present work showed a considerable percentage of RA (25%), psoriasis (50%) and autoimmune thyroiditis, among the relatives of patients included in this study of 1st and 2nd family history, previous works describe family history some of them in agreement with ours while the others were disagree.

It could be concluded a higher prevalence of familial autoimmunity among patients with JRA, this may be due to a close genetic relation between celiac disease, autoimmune thyroiditis and JRA. This work serves as an early diagnosis to autoimmune diseases comes with JRA in order to decrease the risk of these diseases.

Sequence Analysis of Telomerase RNA Component (TERC) in Iraqi Patients with Breast Cancer Using Bioinformatics Method

Wissam Lateef Abdullah¹, Abbas Abdullah Mohammed¹
¹Department of Applied Sciences, University of Technology, Baghdad, Iraq

Abstract

Objective: Analyze sequence of telomerase RNA component (TERC) in Iraqi patient’s with breast cancer

Method: 17 Iraqi patients with breast cancer included in the current study, their age ranged (17-60 years). The DNA was extracted and TERC gene was amplified by polymerase chain reaction (PCR) using one primer then gel electrophoresis was used to detect the gene, then BLAST software used to analyze the sequence of TERC gene as compared with the reference sequence of this gene in the GenBank.

Results: Eighty mutations found in the sequence of TERC gene. An insertion mutation between the sites 135 and 136 appeared in all patients as compared with the sequence of TERC gene in the GenBank at NCBI database. This mutation was found to be related with breast cancer.

Conclusions: The insertion mutation between the sites 135 and 136 associated with breast cancer

Keywords: Bioinformatics Method, breast cancer, mutation, telomerase RNA component gene.

Introduction

Bioinformatics is an interdisciplinary approach between biological and computer sciences⁴. Human telomerase RNA component (hTERC) encoded by the hTERC gene mapping on the chromosomal region (3q26), it is a components of the telomerase⁵. Telomerase is a ribonucleoprotein, this enzyme adds a repeat sequence to the 3’ end of telomeres. A telomere is a region of sequences found at each end of chromosomes, it keep the end of the chromosome from DNA fusion or from damage with neighboring chromosomes⁶. Telomerase consists of two important elements, a telomerase RNA component (TERC) that contains the template for telomere DNA addition and a catalytic reverse transcriptase (TERT). The studies suggests an essential role for the regulation of TERC in maintenance of telomere and perhaps other functions in human cancer⁷.

Cancer consider one of the important health problems of the present era as well as the one of the important cause of death among population. Cancer defined as a malignant neoplasm, it includes a set of diseases that involve abnormal growth of the cell with the possibility to invasion or spread to other parts of the body⁸. Breast cancer is the most common type of cancer among female worldwide and its occurrence has raised in recent years, it with an evaluated (1.67 million) new cases, additionally 521,900 deaths represented for (25%) of all cases of cancer and (15%) of all deaths by cancer women in 2012⁹. The pathogenesis of breast cancer is not yet completely clear, in general researchers believe that a diversity of genetic factors and environmental factors together lead to the incidence of breast cancer⁰. The aim of the present study is to analyze sequence of TERC gene for patients with breast cancer by bioinformatics Method.
Method

The study included 17 female Iraqi patients with breast cancer, aged ranged (17-60 years), the patients selected from “Al-Amal National Hospital for Cancer Treatment” in Baghdad/Iraq during November 2018. The samples of blood were collected from patients and stored at (−20°C) to be later analysis.

The DNA was extracted from blood samples using Quick-gDNA™ Blood Mini Prep DNA extraction kit (Cat.No.: D3072 & D3073) Zymo/USA according to the manufacturer’s protocol, and agarose gel electrophoresis used to confirm the presence of extracted DNA.

The TERC gene sequences were taken from the (GenBank) database at “national center for biotechnology information” NCBI, where the NCBI reference sequence: NR_001566.1. The primer was designed for one exon of TERC gene using primer 3 plus, and provided by Integrated DNA Technologies company, Canada. The name and sequence of forward and reverse primers are shown in Table (1).

The gel electrophoresis was performed using 2% agarose gel, and the gel was visualized using UV-light after staining with red safe and the amplicons were checked and photographed. The amplicons were estimated by (100) bp DNA ladder Kapa/USA.

Amplified PCR products of TERC gene for 17 patients with breast cancer were sent to Macrogen Company/Korea for sequencing the one exon of TERC gene and compared with the reference sequence of TERC gene in the GenBank by “Basic Local Alignment Search Tool” (BLAST) software to detect variations in the sequence of gene.

Result

Detection of TERC Gene by PCR Technique:
The results were showed using the primer (TERC primer F and TERC primer R) to amplify of TERC gene in patients with breast cancer by PCR technique showed the amplicons had size (420 bp) and it gave a clear bands using gel electrophoresis on 2% of agarose gel for 90 min at 75 volt as shown in Figure (1 and 2).

![Figure 1: Products of PCR electrophoresed on 2% agarose gel, showing a clear bands had size 420 bp for one exon of TERC gene. Lane M: 100 bp DNA Ladder. Lane (1-15): Bands for breast cancer patients.](image-url)
Figure (2): Products of PCR electrophoresed on 2% agarose gel, showing a clear bands had size 420 bp for one exon of TERC gene. Lane M: 100 bp DNA Ladder. Lane (16, 17): Bands for breast cancer patients.

Sequence Alignment of TERC Gene: The results of TERC gene sequences for 17 patients with breast cancer were received from Macrogen Company/Korea, then analyzed using BLAST software, where the results showed 80 mutations in the sequence of gene for all patients as compared to the sequence of gene in the GenBank.

In the first patient, four mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Also between the sites 135 and 136 adenine (A) was inserted in the sequence. In the site 442 thymine (T) was substituted with cytosine (C). Also between the sites 443 and 444 cytosine (C) was inserted in the sequence.

In the second patient, eight mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Also between the sites 115 and 116 adenine (A) was inserted in the sequence. Also between the sites 132 and 133 adenine (A) was inserted in the sequence. Also between the sites 135 and 136 adenine (A) was inserted in the sequence. Also between the sites 434 and 435 guanine (G) was inserted in the sequence.

In the third patient, five mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Also between the sites 115 and 116 adenine (A) was inserted in the sequence. Also between the sites 132 and 133 adenine (A) was inserted in the sequence. Also between the sites 135 and 136 adenine (A) was inserted in the sequence. Also between the sites 434 and 435 guanine (G) was inserted in the sequence.

In the fourth patient, six mutations appeared which were: In the site 88 cytosine (C) was substituted with thymine (T). In the site 90 cytosine (C) was substituted with thymine (T). Also between the sites 115 and 116 adenine (A) was inserted in the sequence. Also between the sites 135 and 136 adenine (A) was inserted in the sequence. Also between the sites 441 cytosine (C) was substituted with adenine (A). In the site 442 thymine (T) was deleted from the sequence.

In the fifth patient, three mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Also between the sites 135 and 136 adenine (A) was inserted in the sequence. Also between the sites 135 and 136 adenine (A) was inserted in the sequence.

In the sixth patient, six mutations appeared which were: Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 132 and 133 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence. In the site 442 thymine (T) was deleted from the sequence. In the site 444 adenine (A) was substituted with guanine (G). Between the sites 446 and 447 adenine (A) was inserted in the sequence.

In the seventh patient, five mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the site 135 and site 136 adenine (A) was inserted in the sequence. In the site 440 guanine (G) was deleted from the sequence. Between the sites 444 and 445 adenine (A) was inserted in the sequence.

In the eighth patient, six mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence. In the site 440 guanine (G) was substituted with cytosine (C). In the site 442 thymine (T) was substituted with guanine (G). In the site 444 adenine (A) was deleted from the sequence.
In the ninth patient, four mutations appeared which were: In the sites 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 132 and 133 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence.

In the tenth patient, five mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 132 and 136 adenine (A) was inserted in the sequence. In the site 441 cytosine (C) was substituted with adenine (A). In the site 442 thymine (T) was substituted with cytosine (C).

In the eleventh patient, seven mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 132 and 133 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence. In the site 441 cytosine (C) was substituted with adenine (A). In the site 442 thymine (T) was substituted with adenine (A). In the site 443 cytosine (C) was substituted with guanine (G).

In the twelfth patient, four mutations appeared which were: Between the sites 135 and 136 adenine (A) was inserted in the sequence. In the site 441 cytosine (C) was substituted with adenine (A). In the site 442 thymine (T) was substituted with adenine (A). In the site 443 cytosine (C) was substituted with guanine (G).

In the thirteenth patient, three mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence.

In the fourteenth patient, four mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 132 and 133 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence.

In the fifteenth patient, one mutations appeared which were: Between the sites 135 and 136 adenine (A) was inserted in the sequence.

In the sixteenth patient, five mutations appeared which were: Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence. In the site 442 thymine (T) was substituted with cytosine (C). In the site 443 cytosine (C) was substituted with guanine (G). In the site 445 cytosine (C) was deleted from the sequence.

In the seventeenth patient, four mutations appeared which were: In the site 101 thymine (T) was substituted with adenine (A). Between the sites 115 and 116 adenine (A) was inserted in the sequence. Between the sites 132 and 133 adenine (A) was inserted in the sequence. Between the sites 135 and 136 adenine (A) was inserted in the sequence.

In all patients with breast cancer, an insertion mutation has been appeared in the sequence of TERC gene when the adenine (A) was inserted between the sites 135 and 136 as shown in Figure (3) showing the insertion of adenine (A) between the sites 135 and 136 in the sequence of TERC gene for a patient out of all patients with breast cancer as compared with the sequence of TERC gene in the GenBank at NCBI as a part of the results by BLAST software.

Figure (3): The results of alignment between the sequence of TERC gene for patient No.1 (query) and sequence of TERC gene in the GenBank (subject) by BLAST program, where the insertion mutation appeared between the sites 135 and 136 (indicated by the red arrow) by insertion of adenine (A) in the sequence of TERC gene of the patient.
Discussion

The presence of insertion mutations between the sites 135 and 136 in the sequence of TERC gene for all patients with breast cancer indicates a relationship between this mutations in the sequence of gene for patient’s and breast cancer, this indicate that this insertion mutation as one of the causes of breast cancer. These results were in agreement with other studies\textsuperscript{12, 13} which showed that the mutations in the neurofibromin 1 gene caused neurofibromatosis. Also the results were in agreement with another study\textsuperscript{14} demonstrating that a "mutation" in the CFTR gene caused cystic fibrosis. Also the results were agreement with another study\textsuperscript{15} which demonstrated that the mutation in the PAH gene caused phenylketonuria.

Conclusions

The insertion mutation between the sites 135 and 136 associated with breast cancer

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by the Department of Applied Sciences University of Technology.

Source of Funding: The study supported by authors only.

Validity and Reliability of the Indonesia Version of HIV Treatment Adherence Self-Efficacy Scale (HIV-ASES) in Men who have Sex with Men in West Sumatra

Yafi Sabila Rosyad¹, Hema Malini², Rika Sarfika³

¹Nursing lecturer, STIKes Yogyakarta, Daerah Istimewa Yogyakarta, ²Assoc. Professor, Faculty of Nursing, University of Andalas, ³Lecturer, Faculty of Nursing, University of Andalas

Abstract

The aim of this study was to translate the HIV Treatment Adherence Self-Efficacy Scale (HIV-ASES) and evaluate its validity and reliability in Men Who Have Sex With Men Seropositive HIV in West Sumatera Indonesia. The original HIV-ASES was translated from English into Indonesian. Validity and reliability testing is done by reliability scale analysis technique. The question item validity is seen from the magnitude of r-table value with r-count and reliability seen through Cronbach’s alpha coefficient. The results of this study show the HIV_ASES in the context of Indonesian all items of valid and reliable.

Keyword: Indonesian, adherence, self-efficacy, HIV/AIDS, MSM, Seropositive HIV.

Introductions

HIV is a chronic infections disease affecting people worldwide. There were approximately 36.7 million people living with HIV at the middle 2017 with 20.9 million people living with HIV (PLWHIV) currently receiving antiretroviral therapy (ART)⁴. Indonesia reported the currently receiving antiretroviral therapy (ART) increased from 63,066 in 2015 to 77,780 in 2017 in Indonesia⁵.

The use of antiretroviral (ARV) is an attempt to improve the quality of life and reduce the incidence associated morbidity and mortality⁶. ARVs serve to suppress the proliferation of HIV in the human body to increase CD4 cell counts. The lifetime use ART in people living with HIV make them vulnerable to non-adherence that can lead to resistant virus⁷. The use of ART requires a high adherence rate 90-95% in order to achieve treatment success and may lead to the onset of drug resistance⁸. Therefore, high treatment adherence has important in treatment of HIV/AIDS.

High level of adherence to antiretroviral therapy (ART) was influenced by internal motivation factor of self-efficacy about ARV. Self-efficacy is the determination of whether a person has ability to complete a certain behavior⁹. The self-efficacy of treatment beliefs has an effect on adherence to ART⁹,¹⁰. Non-adherence to ART may be affected by low level of education⁹. The meaning there is a good treatment success is directly proportional to the high expectation and inversely proportional to the level of depression.

The HIV Treatment Adherence Self-Efficacy Scale (HIV-ASES) ¹¹, have 12-item measurements using Likert scale with range 0-10 “cannot do at all” to “completely certain can do” with total score 120, where someone have good self-efficacy when have score 50 ¹⁰. The purpose of this study was to perform the validity and reliability in Indonesian version of HIV-ASES of Men Who Have Sex With Men (MSM) seropositive population by comparing the r-tab values with r-count and looking at the crobanch’s alpha value.

Method And Material

The analyses presented in this study are based on a total of 20 HIV+ at NGOs SaiyoSakato Bukit Tinggi West Sumatra. Eligible participants the following criteria: be at least 18 years old, have provided written informed consent, and have not side effect HIV treatment.
Questionnaires were completed by participants themselves. The research protocol was approved by the ethical committee of the Faculty of Medicine, Andalas University in Padang. Random sampling used to recruit participant receiving at the NGOs SaiyoSakato Bukit Tinggi in September 2017. Conducted research to examine self-efficacy about ARV using the English version of HIV-ASES. Researcher translate it into bahasa Indonesia. After a process of evaluation of the results of the translation, the researcher tested the validity and reliability of bahasa Indonesia HIV-ASES version.

Test validity is the extent to which a test accurately measures what it is supposed to measure. Reliability is the degree to which an assessment tool produces stable and consistent result in this case is a questionnaire can be used more than once, at least by the same respondent who will produce consistent data (12–14). Validity test was done by doing the correlation between scores of each variable with total score. Correlation technique used Pearson Product Moment correlation. The test decision compared the r value of each item statement with r table. The r value of the result was seen in the Corrected Item-Total Correlation column and the r table value was seen at the 5% significance level. If r results ≥ r table then the question item is valid and otherwise if r result < r table then the question is invalid. Invalid question items were omitted. Test reliability was done by comparing Alpha Cronbach’s (0.6) with r table. If Alpha Cronbach’s ≥ r table then the instrument is reliable, and otherwise if Alpha Cronbach’s < r table then the instrument is not reliable (12–14). HIV-ASES version in Bahasa Indonesia which amounted to 12 items questions obtained r-count value ranged from 0.729-0.929. With the number of respondents 20 then got the value of r-table 0.468, due to the value of r-table seen from the number of respondents minus 2 equals the value of r-table used is at number 48.

The first question item has r-count 0.907 which means greater than 0.468 it can be concluded that question number 1 is valid. The second question item has a value of r-count 0.929 which means greater than 0.468 it can be concluded that question number 2 is valid. The third question item has a value of r-count 0.792 which means greater than 0.468 it can be concluded that question number 3 is valid. The fourth question item has a value of r-count 0.879 which means greater than 0.468 it can be concluded that question number 4 valid. The fifth question item has a value of r-count 0.903 which means greater than 0.468 it can be concluded that question number 5 is valid. The sixth question item has a value of r-count 0.869 which means greater than 0.468 it can be concluded that question number 6 is valid. The seventh question item has a value of r-count 0.870 which means greater than 0.468 it can be concluded that question number 7 is valid. Item eighth question has a value of r-count 0.886 which means greater than 0.468 it can be concluded that question number 8 is valid. The ninth question item has a value of r-count 0.809 which means greater than 0.468 it can be concluded that question number 9 is valid. The tenth question item has a value of r-count 0.856 which means greater than 0.468 it can be concluded that question number 10 valid. The eleven Item tenth question has a value of r-count 0.729 which means greater than 0.468 it can be concluded that question number 11 valid. And the last Item tenth question has a value of r-count 0.842 which means greater than 0.468 it can be concluded that question number 12 valid (table 1). Thus, it can be concluded that the HIV-ASES version in Bahasa Indonesia of all items of question is valid.

Validity test was done by doing the correlation between scores of each variable with total score. Correlation technique used Pearson Product Moment correlation. The test decision compared the r value of each item statement with r table. The r value of the result was seen in the Corrected Item-Total Correlation column and the r table value was seen at the 5% significance level. If r results ≥ r table then the question item is valid and otherwise if r result < r table then the question is invalid. Invalid question items were omitted. Test reliability was done by comparing Alpha Cronbach’s (0.6) with r table. If Alpha Cronbach’s ≥ r table then the instrument is reliable, and otherwise if Alpha Cronbach’s < r table then the instrument is not reliable (12–14).

Results And Discussion

This study focused on the translations and assessment of the reliability and validity of the HIV-ASES Indonesian version among Men Who Have Sex With Men Living With HIV, providing strong support for the evaluation of this translated scale and confirming that it can be applied in assessing the adherence self-efficacy of MSM HIV+ in Indonesia. Target interventions for low-scoring items can be implemented to improve medication adherence.

Validity test was done by doing the correlation between scores of each variable with total score. Correlation technique used Pearson Product Moment correlation. The test decision compared the r value of each item statement with r table. The r value of the result was seen in the Corrected Item-Total Correlation column and the r table value was seen at the 5% significance level. If r results ≥ r table then the question item is valid and otherwise if r result < r table then the question is invalid. Invalid question items were omitted. Test reliability was done by comparing Alpha Cronbach’s (0.6) with r table. If Alpha Cronbach’s ≥ r table then the instrument is reliable, and otherwise if Alpha Cronbach’s < r table then the instrument is not reliable (12–14).
The questionnaire is reliable. This validity and reliability test were supported by several general researches that perform validity and reliability\(^{(11)}\), which is the creator of the questionnaire.

At the first test it was found that the seventh question there was a mistake in writing so that the researchers revised again and redistributed. From the results of the validity and reliability test it can be concluded that all items are valid questions and the HIV-ASES version in Bahasa Indonesia was reliable or feasible to be used in seropositive Men Who Have Love Sex With Men population.

### Conclusion

The HIV-ASES Indonesian Version is a valid and reliable instrument for measuring medication adherence rate of MSM. The Present finding providing HIV-ASES Indonesian Version can use in all community PLWHIV. Prospective studies can be conducted to investigate items and MSM with low adherence rate and efficiency of HIV follow-up studies.

The Association between Meaning in Life and Adherence to Antiretroviral Therapy (ART) of HIV-Seropositive within Men who have Sex with Men (MSM); Mixed Method

Yafi Sabila Rosyad1, Hema Malini2, Rika Sarfika2

1STIKes Yogyakarta Nursing lecturer, Daerah Istimewa Yogyakarta, 2Andalas University Nursing lecturer, Padang West Sumatera, Indonesia

Abstract

Purpose: To identify the distribution of meaning in life frequency and adherence to antiretroviral therapy (ART) as well as to perceive and explore the association between meaning in life and adherence to antiretroviral therapy (ART) of HIV-seropositive within MSM in Padang City, West Sumatra, Indonesia.

Method: This research used a mixed method with an approach of exploratory sequence design, which was in quantitative stage through a cross-sectional design approach that intended to know the relationship between variables. 102 sample size. In the qualitative stage, the researchers used the conceptual content cognitive map (3CM) method as a data retrieval technique and then continued with the interview.

Results: Characteristics of MSM in West Sumatra more than half were gay with early adulthood who were mostly on ART treatment less than one year. Almost all MSM were middle and upper educated, and they worked in sixteen sectors of employment in which the private sector was the largest. Most MSM had a meaningful life. More than half of MSM were discipline to go through ART treatment. There was a significant correlation between the meaning in life and the adherence of ART p (0,000) with the identification of several aspects that related to the meaning in life and ART adherence. They were spiritualism, lifestyle, psychological, life purpose, life achievement, knowledge, and motivation.

Conclusion: The importance of meaning in life within HIV-seropositive MSM that might influence the ART adherence. Therefore, the researchers recommend to conduct a compliance monitoring activity and provide logotherapy for MSM whose life is not meaningful.

Keywords: MSM, Meaning in life, ART adherence, HIV/AIDS, 3CM.

Introduction

The use of ARV requires a high adherence rate of 90-95% in order to achieve therapy success and can prevent the emergence of drug resistance(1,2). WHO has a target that 90% of People Living with HIV/AIDS (PLWHA) already underwent ART by 2016, but the target realization is only 53%. PLWHA who undergo antiretroviral therapy is increasing. In 2016, there are 19.5 million or about 53% of the total number of PLWHA, and in mid-June 2017 the number has progressed to 20.9 million or about 56.9% of the total number of PLWHA (3). Meanwhile, PLWHA in Indonesia who have undergone ART based on Ministry of Health report (2016), in 2015 there were 63,066 people where 2,056 of them experienced ART on the second line, and by 2017, PLWHA who had accessed antiretroviral therapy were 77,780 people where 2,374 people were on ART on the second line. From the data above, we can conclude that there are still many PLWHA who have not accessed ART, while the number of PLWHA in the second line shows improvement from year to year(4).

According to research by Audet, Wagner, & Wallston (2015), meaningfulness of life by PLWHA associated with the psychological welfare of patients(5). There has been no research on the relation of meaning in life toward ART, but based on research conducted by Corless et al.,(2006), about the relation of meaning in life to TB treatment adherence, it can conclude that
there is a relationship between the meaning in life and the level of TB treatment adherence\(^6\). The meaning of life is a daily experience in life that is real\(^7\) in both pleasant and unpleasant situations\(^8\) and if someone can live every event to meet then his life will be happy\(^9\). The feeling of happiness can be achieved if someone who can achieve his life goals\(^{10}\).

Researchers in preliminary study at NGOs Taratak Jiwa Hati with interview six participant find that all PLWHA are still difficult to remember to consume medicine and sometimes late to consume it and there are still MSM who feel their lives are meaningless. This study is important to undertake because it can give a description of ART adherence and the meaning in life of HIV-seropositive MSM. This study aims to identify the characteristics of HIV-seropositive Men who have sex with men (MSM), the distribution of meaning in life frequency and adherence to antiretroviral therapy (ART) as well as to perceive and explore the association between meaning in life and adherence to antiretroviral therapy (ART) of HIV-seropositive within MSM in Padang City, West Sumatra, Indonesia.

**Material and Method**

This research was mixed method through explanatory sequel design approach, where the qualitative data that was obtained in the research will help the explanation of the quantitative data result\(^13\). In quantitative phase, researchers used a cross-sectional design\(^13\). Total sampling use in this research with 102 Sample size MSM with HIV at NGOs Taratak Jiwa Hati West Sumatra Indonesia. Before conducting the research, the researchers tested the validity and reliability of the Meaning in Life Questionnaire (MLQ) in Indonesian version\(^14\) and Morisky-8 Scale\(^15\) also in Indonesian version, and all question items of both questionnaires were valid and reliable\(^16,17\). In the qualitative phase, the researchers used The Conceptual Content Cognitive Map (3CM) method as a data retrieval technique. This method was a method developed by Kearny & Kaplan\(^18\) by using open-ended questions that were used to deeply understand the important concepts of informants’ perceptions concerning the relationships between the meaning in life and ART adherence.

**Results and Discussion**

**Research Sample:** The characteristics of respondents including sexual orientation, age, education level, duration of ART, and occupation. More than half of the MSM were gay with early adulthood, a majority of them were on ART for less than one-year treatment, almost all MSM were middle and upper educated, and they worked in sixteen sectors of employment in which the private sector was the largest\(^19\). Based on research that the respondents who have sexual orientation as gay was 56 people and as bisexual men were 46 people. The age range of respondents was in the adulthood age between 25-45 years old, where this age range was for both early and late adulthood\(^4\). The education level of respondents, most of them, was in the middle and upper education with a percentage of 81.4%. Various researches indicated that the level of education was one of the factors that will interact in health status. Where, if a person had a higher educational status, it could reduce mortality and increase the income, even reduce twice as much mortality either directly or indirectly\(^20,21\). In terms of time span on undergoing antiretroviral treatment, more than half or 54% of respondents were categorized as a newbie because it was still under one year time.

**Meaning in life of HIV-seropositive MSM:** The majority of respondents(64.71%) had a meaningful life and about 35.29% felt a meaningless life of the 102 respondents, 72.5% felt that there was no distinct purpose in life, and almost all respondents(91.2%) were looking for something that made their life meaningful. Meaning in life had a different function for each individual, but according to Mackenzie & Baumeister (2014), the function of meaning in life could be divided into three function themes\(^22\). The meaning in life according to Starck(2014), was said to be the phase where a person reached his life goal\(^10\). According to Audet et al., (2015), the low meaning in life indicated non-adherence ART and provided a stimulus of management for handling the suffered disease\(^5\). We were able to analyze that most respondents had been able to find the meaning of their lives although the meaning in life that was found was from an unpleasant experience. The need for counseling to improve the meaningfulness of life of seropositive MSM (35.9%). By doing so, MSM population especially seropositive one will get more external support or motivation and can improve their meaningfulness in life.

**ART treatment adherence of HIV-seropositive MSM:** From the research results obtained that 57.8% respondents were adherence to antiretroviral therapy and the rest did not comply as much as 43 respondents or 42.2%. This level of adherence was seen from the accuracy of the dosage and the frequency of time-consuming ARV. According to Bangsberg, Kroetz, &
Deeks, (2007), ART adherence should be observed to discern the compliance level of the treatment, as some studies indicate that with treatment adherence of (95%) or more indicates the effectiveness of antiretroviral therapy\(^{(23)}\), but on adherence (75%) shows a rise of viruses with retention against drugs\(^{(24)}\). Some patients fail to maintain ART adherence\(^{(25)}\). Treatment and handling management of HIV are part of the management of chronic diseases, which have principles of medication adherence, prevention of drug retention, and morbidity prevention management\(^{(25)}\). This condition becomes a challenge for health workers. Nurses can maximize counseling services particularly for HIV counselor and psychiatric nurses that can provide special therapies to turn negative behaviors into the positive. Apart from health workers, peer advocates also need to improve their role to remind the companions to take the drugs in a timely and appropriate dose given.

Table 1 showed that there was a relationship between meaning in life and ART adherence. When a person whose life was meaningless will have 27.90 times risk to be non-adherence in undergoing antiretroviral therapy than a person whose life was meaningful. The exploration results obtained 23 statements which consisted of 7 categories. The category are the purpose of life, the achievement of life, knowledge, motivation, spiritualism, lifestyle, and psychological.

Farber et al (2003), the meaning of the success of good treatment is directly proportional to the high expectation and inversely proportional to the level of depression\(^{(26)}\). There has been no research on the relation of the meaning in life to the level of ART adherence, but based on a research that conducted by Corless et al (2006), about the relation of meaning in life to TB treatment adherence, it can conclude that there is a relationship between the meaning in life and the level of TB treatment adherence\(^{(6)}\).

The exploration of the relationship between the meaning in life and ART adherence can occur due to the fulfillment of the basic components of the formation of meaning. According to Mackenzie & Baumeister (2014), there are four basic components that form the meaning in life. First is the necessity for a purpose of life which can be categorized into results attainment and fulfillment of more abstract desire\(^{(22)}\). The exploration result from this life purpose component was that the participant had a life purpose to get married “...Although I am an LGBT, I have a plan to have a wife (P2)”.

The life accomplishing of each participant was unique and different in interpreting the achievement of their life. “...Can overcome all by thinking positively...experiencing the life...just like before HIV...(P1)”.

The other achievement of the meaning in life was always being motivated to experience the life “...Always keep the spirit, always optimistic and not pessimistic... (P3)” In addition, the participants also live his life by becoming a better person “...experiencing the life...by becoming a better person...(P4)”.

The next necessity is trust and faith. Participant’s spirituality indicated the existence of belief or faith by placing his trust in God “...Pray regularly...ask God by tahajud prayer (Moslem’s prayer near midnight), what is the crux of this problem so that it can be solved well (P3)”. Participants believed that by counseling their life purpose can be achieved, following the participant’s statement;

“...According to the hospital, as a person with HIV, I can have a wife and have offspring without spreading the disease by doing the program (P2)”

The last necessity is that one must have positive self-esteem. The meaning in life according to Starck (2014), by having a sensitive feeling with the experience of how to love his life\(^{(10)}\).
“...meet other people living with HIV... feeling no burden of thinking and ... should be motivated in undergoing this antiretroviral therapy... there is a desire to behave better again ... optimist to maintain health... be firm in facing this life and keep struggling do not get desperate (P3)”.

The freedom to choose what the participants did was to live a healthier life“...enough exercise, a good diet and have a deeper understanding of what HIV is (P2)”. Human suffering is the third concept of the meaningful theory.

“...with despairing by not taking ARV (P3) and why doing a healthy life while I’ve HIV and no one willing to befriend me, to approach me...(P2) “.

The uniqueness of a person’s meaningful life that is stimulated by various things ultimately can make someone adherence to undergoing antiretroviral therapy. However, to gain meaningfulness of life, one must be able to accept who they are and where their position now. The meaningfulness of life can be obtained not only in a pleasurable event but also be found from unpleasant events. HIV-seropositive is an unpleasant experience for everyone especially the respondents. Thus, health workers need to assist respondents in order to rediscover the purpose of their life so that they have the meaning in life as before HIV-seropositive.

Conclusion

PLWHA adherence to consume ART was influenced by the meaning in life, where, when PLWHA had a clear purpose that he wanted to accomplish in life, then that PLWHA will adherence to consuming ART. Meanwhile, PLWHA adherence was also influenced by peers, information attainment, and self-motivation. This research provides important suggestions for health workers to be actively involved in enhancing the motivation of PLWHA, especially MSM to behave openly so that the quality of life monitoring can be done.

Prevalence of Lower Back Pain among Health Care Providers Working in Operation Rooms in Mosul City Hospitals

Rami Ramadan Allo¹, Tameem Thamir Mayouf¹, Mohammed Tariq Ali¹

¹Mosul University, College of Nursing, Mosul, Iraq

Abstract

Background: The pain in the lower back is one of the most common health problems in the operating rooms in our hospitals due to the specificity of these places due to the limitation of movement and length period of standing on the feet and increase the number of operations per day and not taking enough rest or lack of breaks for rest with presence of risk factors may lead to exacerbate the problem of health workers.

Aim: this study aimed to determine the prevalence and risk factors for lower back pain amongst health care providers who are working in operation rooms at Mosul city hospitals including nurses, surgeon, and anesthetist.

Material and method: Descriptive study design was carried out in order to achieve the objectives of the present study. Constructed questionnaire was dependent for this study includes demographical data, nature of pain and some attributes of pain. Data were collected during two months from the 30th of December 2017 to 1st of March 2018. The study subjects consist of (157) persons who were working inside operation rooms in four hospitals Al-Salam, AL-Jumhory, Alkansa, and Ibn-Sena Teaching Hospitals.

Results: Most respondents (80.9%) had experienced lower back pain, and there was significant relationship between age and lower back pain, also there was significant relationship between tenure and lower back pain.

Conclusion: Lower back pain is a terrible problem inside operation rooms, and suffering from occurrence of lower back pain was increased with advanced age and with long period of years working inside operation rooms.

Recommendation: Some steps should be following to reduce lower back pain such as scheduling rest periods, and development of educational programs which enhance the ideal or proper use of body mechanics when lifting and transferring of patients and heavy objects.

Keywords: Lower Back Pain, Health Care Providers, Operation Rooms.

Introduction

International association for the study of pain defined pain as an unpleasant sensory and emotional experience associated with actual or potential tissue damage. It is a main symptom in many medical personnel inside operation rooms, and can interfere with a person’s quality of life and general health and functioning(1). The incidence of reported low back pain among hospital staff varies between different countries(2). Health care providers team inside the operation rooms are frequently have to lift and transfer patients who may move suddenly and implement repetitive procedures with incorrect or poor body posture, which lead to cause low back pain(3). Low back pain has been described as one of the major occupational problems among health care workers, the nurses have the highest incidence (4).

Aim: This study aimed to determine the prevalence and risk factors for lower back pain amongst health care providers who are working in operation rooms at Mosul city hospitals, including nurses, surgeon, and anesthetist.
Objectives of the study:

1. To determine the prevalence of lower back pain among health care providers who are working in operation rooms.
2. To identify the factors that leading to increase of lower back pain.
3. To identify the natural and quality of this problem.

Methodology: Descriptive design (cross-sectional study) was conducted among (157) medical personnel (surgeons, nurses, anesthetists) were obtained from the operation rooms from four general hospitals at Mosul city (Al-Salam, AL-Jumhory, Alkansa, and Ibn-Sena Teaching Hospitals). Constructed questionnaire was dependent for this study, and validated by 7 experts, where as their opinions, suggestions and recommendations were depended to adopt and direct the questionnaire. Data collections were collected throughout two months, from the 30th of December 2017 to 1st of March 2018. This study was conducted on male and female persons who working in operation rooms. The questionnaires were redistributed by giving it to our subjects then we explain the aims of study for him and explain the questionnaires questions for him too, then leave questionnaires for three days at hospitals or more if it needed more time and collect it by hand when they finish. Also the researchers were used body mass index (BMI) measure in this study which consist of five categories (decrease weight less than 20, normal weight 20-25, increased weight 26-30, obesity 31-40, and risk obesity more than 40.

Discussion

Lower back pain is a real problem that hinders the smooth running of the medical team in the operating rooms in any health care agency (5). Uncomfortable working positions because restriction of movement and privacy of space inside operation rooms and theatre (6).

The percent of lower back pain in our study was (80.9%), as in table 2. This percent come nearest to the study carried out by (1), which that show (78%) of respondents had experienced lower back pain among health care providers who are working inside theatre, also who demonstrate that (82.7%) of respondents had experienced lower back pain (7).

In our study there is increasing in percentage of incidence of lower back pain with advanced age, as in table 3. This fact come in agreement with a study conducted by which showed that more than 40% of operation theatre workers who suffered from lower back pain between age ranges of (35-55) years.

Increase body mass index (BMI) leading to increase the probability of incidence of lower back pain among health care workers (8), but our study didn’t indicate any significant relationship between BMI and LBP because 79% of the study sample were around normal BMI (51.6% for normal weight and 27.4% for increased weight as in table 1.

The chronic diseases such as diabetes mellitus, arthritis and other musculoskeletal and joints problems consider risk factors or contributing factors to lower back pain, in our study not found significant relationship between chronic diseases and lower back pain because (87.9%) from the sample not suffering from chronic diseases. Return to table 1.
Increase the period or years of work inside intensive care units and operation theatre lead to increase chance of occurrence of lower back pain (9). Demonstrate in their study the workers experience more than 5 years recorded feeling low back pain; this fact comes in agreement with our study where there is significant relationship between duration of work and lower back pain. As in table 4.

**Conclusion**

Lower back pain is a terrible problem inside operation rooms; in addition the occurrence of lower back pain was increased with advanced age and with long period of years working inside operation rooms.

**Recommendations:** Some steps should be following to reduce lower back pain such as scheduling rest periods, and development of educational programs which enhance the ideal or proper use of body mechanics when lifting and transferring of patients and heavy objects.

**Ethical Clearance:** People identified as potential research participants because of their status as relatives or carers of patient’s research participants by virtue of their professional role in the university and departments.

**Source of Funding:** Self-Funding

**Conflict of Interests:** The authors declare there is no conflict interests.

Positive Deviance Against Malaria Events in Majene District

Arsunan, A. A.¹, Indra Dwinata¹, Januar Ariyanto¹, Muhammad Akbar Nurdin¹, Aisyah²

¹Department of Epidemiology, Faculty of Public Health, Hasanuddin University, Makassar
²Department of Agribusiness at the State Agricultural Polytechnic of Pangkajene Kepulauan, Pangkep

Abstract

Essentially behavioral factors are actions or activities of human beings themselves which results in an imbalance between agent, host and environment that affects human health status, including the incidence of malaria caused by one of the factors which is good human activity that can be observed directly or indirectly. So this study aims to determine the effect of positive deviance on malaria incidence in Majene District. This research was conducted in Manyamba Village, Majene Regency, West Sulawesi Province, July - September 2018. This study used a mixed-method research design. Quantitative data is used to explain the relationship between the variables of the study and the incidence of malaria and qualitative data is used to determine positive deviance behavior using the focus group discussion method. The data obtained will be processed using SPSS V. 24. Based on the data obtained in the field there are several variables related to the incidence of malaria, namely positive deviance (p = 0.039), knowledge (p = 0.018) and work (p = 0.035). Multivariate analysis to see the effect on malaria, obtained results that the job variable has the strongest relationship to the incidence of malaria, with a value of p = 0.001. The results of the data obtained from the FGD obtained that there were 4 positive deviance behaviors in the community of Manyamba Village, Tamerodo District, Majene District; plant the toga, keep the lead head fish, burn the egg rack and bring it to the paranormal. Positive deviance behavior in the community can be used to prevent the occurrence of malaria through the active role of health cadres by forming healthy communities in the community.

Keywords: malaria, positive deviance, work, knowledge

Introduction

Malaria is one of the diseases that causes the most suffering and death to date. Disease caused by the Protozoa of the Genus Plasmodium, which is transmitted through mosquito bites, attacks almost all regions or regions on the surface of the earth. This disease has also been detected since ancient times. Various efforts that have not been done by humans to overcome this disease both through Preventive and Curative actions¹. Behavior is the biggest factor that leads to a person’s health. Health behavior is formed from individual characteristics such as knowledge, experience, attitudes and actions to interact with the environment. Another work factor that causes malaria transmission is the division of work shifts². Malaria transmission can be associated with the most activity carried out by someone by considering where the person is doing daily activities. This is the basis for seeing the relationship between one’s work and the incidence of malaria. Of all respondents in all provinces in Indonesia who work in agriculture and fishermen by 18.5%. As many as 41% of respondents affected by malaria were people with jobs as fishermen and farmers³.

Knowledge factors are often associated with increased malaria incidence in several places. As was the case in Uganda, only 68% of people took their children to health facilities when they had a fever. Lack of knowledge about the behavior of clean and healthy people living by choosing an open source of water rather than a closed one⁴. Increased knowledge of malaria manifestations and controls is an important role in controlling malaria incidence⁵. Based on the background above, the researcher is interested in studying positive
deviance in Manyamba Village, Tamerodo District, Majene District, West Sulawesi.

**Materials and Method**

This study uses a mixed-method research design. Quantitative data is used to explain the relationship between the variables of the study and the incidence of malaria and qualitative data is used to determine positive deviance behavior using the focus group discussion method. The population in this study were the people of Bussu Hamlet, Manyamba Village, Tammerodo District, Majene District, West Sulawesi. The sampling method for quantitative data uses Total Sampling with a total of 143 respondents. While the FGD participants were carried out by community leaders, religious leaders, health cadres and people in Bussu Hamlet. Data were analyzed using bivariate test with Chi-Square Test. Furthermore, multivariate test using Logistic Regression.

**Research Result**

Based on table 1, it shows that the highest frequency is Positive Deviance as many as 114 Respondents (79.7%) and Positive Deviance is 29 respondents (20.3%) of the total respondents as many as 143 respondents (100%).

Furthermore, the highest age variable is the early adolescent age group as many as 32 Respondents (22.4%) then continued with the lowest age frequency, namely the elderly age group as many as 4 respondents (2.8%). Then the highest frequency based on sex was female gender as many as 74 respondents (51.7%) and the lowest was male gender as many as 69 respondents (48.3%) of a total of 143 respondents (100%).

The level of education in table1.1 is known that the highest level of education is never schooling as many as 44 respondents (30.8%) while based on the lowest level of education level is high school equivalent to 5 respondents (3.5%). For the highest respondent frequency job variable based on risky work as many as 53 respondents (37.1%) and the lowest frequency based on non-risky work as many as 90 respondents (62.9%). And the frequency of malaria occurrence based on the highest history of malaria incidence is that of non-malaria as many as 102 respondents (71.3%) while the lowest frequency of malaria incidence is positive malaria as many as 41 respondents (28.7%).

Based on the results of the FGD, 3 (three) out of 8 (eight) informants informed that burning an egg rack can repel mosquitoes to prevent mosquito bites. As quoted in the following FGD:

“Ma ‘baka I know, e tellu (burning egg racks)” (RS, 33 years) Meanwhile 1 (one) of 8 (eight) informants informed that planting lemongrass leaves can repel mosquitoes so that they avoid mosquito bites. As quoted in the following FGD: “If I plant Sarre leaves near my house”
There were 3 (three) out of 8 (eight) informants using mosquito nets to avoid mosquito bites during sleep. As quoted in the following FGD: “Installing mosquito nets with the usual burn is an egg rack” (JA, 27 years old). In addition, 1 (one) of 8 (eight) informants requested help from a seaman in the form of a spell so as not to contract Malaria.

Table 2. shows the results of cross tabulation between dependent variables and independent variables. Which is known that the positive deviation variable has a significant relationship with $p = 0.039$. Then other variables related to the incidence of malaria in Manyamba Village, Tammerodo Subdistrict, Majene Regency are knowledge and jobs with $p$ value of 0.018 and 0.035 respectively.

Which means that the job variable has the strongest relationship with malaria incidence in Manyamba Village, Tammerodo District, Majene District, South Sulawesi.

Discussion

Positive Deviance with Malaria

The location of the area in the mountains and the absence of a permanent road. Makes the area isolated and certainly makes it difficult for people to access daily needs, including mosquito repellent. To avoid mosquito bites, people use insect repellent. But when insect repellent was no longer available, the informant tried to find other alternatives, such as egg shelves. One end of the egg rack was burned to smoke. This smoke is then used by residents to repel mosquitoes. Although the smoke produced is quite thick and makes people around shortness of breath. Egg shelves are still chosen as an alternative mosquito repellent because they are easy to find and also practical. In addition, there were informants who planted lemongrass. This lemongrass plant is seen on residents’ yard. Lemongrass planting is not preceded by the motive of preventing mosquito bites. But it is just a fulfillment of kitchen needs. Lemongrass leaves contain essential oils can repel mosquitoes. Lemongrass essential oil consists of cytral compounds, cytronella, geraniol, mirsena, nerol, farnesol methyl heptenol and dipetana. Cytronella compounds have dehydration (desiscant) toxicity. The toxin is a contact poison that can cause death due to continuous fluid loss. Insects exposed to this poison will die from lack of fluids. This is what makes informants free from mosquitoes.

Informant beds are equipped with mosquito nets. This mosquito net is rarely released from the bed. So that every time you sleep, this mosquito net stays installed. The use of mosquito nets is an effective and safe way to avoid mosquito bites. When one family member suffers from malaria. The informant first took him to the shaman. This is because the distance from the place of residence to the health facility is quite far and the cost of transportation is high compared to the treatment in the seaman. The treatment of the shaman comes from supernatural powers. Shamans use white water as an intermediary medium. Water will be given a mantra or recitation of the Holy Qur’an according to the illness. The informant does not only ask for spells for healing. But also to prevent malaria transmission. The role of positive deviance behavior in the community of Manyamba Village, Tamerodo Subdistrict, Mejene Regency, West Sulawesi has a statistically significant relationship with the incidence of malaria, in line with research conducted in rural areas in the country of Senegal by Ndiaye et al reported that positive deviance increases found in the community can improve health in general. Positive deviance is a new strategy in an effort to improve health promotion and approach to the community. Support for positive deviance was also found in research conducted in Cambodia, that positive deviance is one tool that can be used to control the incidence of malaria in an area by strengthening the community. Knowledge with Malaria Events

Knowledge of the community has an important role in malaria transmission in an area. The level of knowledge of the community in the Manyamba Village is dominant in the category of sufficient malaria knowledge, although education in the community of manyamba is dominant in the category of low education. The results of this study
indicate that there is a significant relationship between people’s knowledge and the incidence of malaria.

Individual knowledge is one of the important factors to cut the chain of malaria transmission in each family, especially the knowledge possessed by women as a mother. Although the community’s knowledge of malaria is sufficient, there is still a need for a kind of community formation consisting of cadre cadres to provide more knowledge related to malaria in the community. In addition, knowledge about how to transmit malaria, people need to be educated about preventing mosquito bites that can cause malaria by using insecticide-treated mosquito nets.

Work with Malaria

The geographical condition found in the research location in the form of mountains is one of the places of vector breeding. In villages affected by extraordinary events there are rivers near residential areas that are breeding places for mosquitoes. With such geographical conditions, the livelihoods of the majority of the population are gardening and farming. This is also one of the causes of malaria because when they do the work of the plantation area, unconsciously mosquitoes carrying malaria attack. Suharmasto states there is a significant relationship between work with malaria incidence and people whose occupations are at risk of 2.82 times risk of developing malaria compared to people whose jobs are not at risk. Meanwhile, according to research by Aisy stated that there was no significant relationship between work and the incidence of malaria. Various activities or human work often result in changes in environment that benefit malaria transmission.

Conclusion

Positive deviancy, work and knowledge are variables that have a significant relationship with the incidence of malaria. Work is a variable that has the strongest relationship with the incidence of malaria in Manyamba Village, Tammerodo District, Majene District, West Sulawesi. Positive deviancy behavior in the community can be used to prevent community events through active role of health cadres by forming healthy communities in the community.

Abstract

Aplocheilus panchax domesticated as candidates of broodstock is genetically identified in order to be cultivated and restocked. This research is aimed at identifying the gene of Aplocheilus panchax from the waters of West Papua. Samples were collected from several locations. In Sorong only seven samples were obtained due to the decrease of population of A. panchax, because increase population of predator. The length of the total genomes of A. panchax which were isolated ranged 20 and 30 kb. Their amplicon length was approximately 400 bp. The quality of DNA was excellent with high level of brightness, brighter than the DNA bands in the DNA marker. Cyt b sequences from the samples of KT_MKW_01 with forward and reverse primers were aligned and manually proof read to ensure that DNA sequences corresponded to the peak of electropherogram. The results of BLAST sequence obtained from real sequences from Cyt b gene of A. panchax had 99% similarity with GenBank and alignment indicated that point of polymorphism was not found. All the sequences had exactly similar nucleotide sequences, that the amplified Cyt b gene was a greatly conserved gene and 34 samples were grouped into the same haplotype based on fragment of Cyt b gene.

Key words: Cyt b gene, Kepala timah (Aplocheilus panchax), malaria, molecular genetics and waters of West Papua.

Introduction

Papuagovernment encounters difficulties in protecting its natural wealth and most importantly human beings that inhabit the area. The inhabitants of Papua cannot be separated from a terrible bogeyman, i.e. malaria. Furthermore, malaria is the number one killer in Papua with the incidence of cases in 2012 that about 231 thousand people suffered from malaria with an incidence rate of 96 cases per 1000 births. In addition, Papua according to news daily Republika ROL Online¹ has the highest Parasitical Annual Index (API) in Indonesia by more than 20 per 1000 population, which is far from the MDGs target of about one or less than one. This is also supported by high disparity value of API between regions, especially in eastern Indonesia by more than 10 per 1000 population. There are several challenges in controlling malaria including: limited access to health care, continuity of coverage, quality of (microscopic) diagnosis and case management, cross program and cross sector synergies and increased potential risk factors for malaria. This makes malaria control very difficult due to disease-transmitting vector, i.e. mosquitoes existing in nature and is not easy to deal with. In addition, environmental aspects facilitate the reproduction of mosquitoes and drugs lead to resistance².

Understanding the geographical distribution of molecular within a species is paramount to any attempts to conserve major genetic lineages, if such variance exists in the wild⁴. Kepala timah Aplocheilus panchax Hamilton inhabits the waters of Papua in both freshwater
and brackish waters that can be used as a bio-indicator of pollution of any water body. *Aplocheilus panchax* has a habit of eating mosquito larvae in nature. This makes Kepala timah serving as a natural pest controller (biopesticide), that it has the ability to eat malaria mosquito larvae, a terrible bogeyman for most of the people who live in Papua.

A well-maintained and unique nature that is different from other Indonesian regions. This is not only due to the number of species, but also its genetic diversity. It is associated with the complex formation of the islands (biogeography) and the isolation of certain places, which lead to high speciation. In regard to the aforementioned problems and potential, this research attempts to identify the genetics of Kepala timah from West Papua waters which can be domesticated as a candidate superior parents to be cultivated and restocked to nature in order to assist the local government program in the form of policy to prevent malaria transmission in West Papua.

This research aims to identify molecular genetics of Kepala timah from West Papua waters (Manokwari, Sorong and Oransbari) that in the next research will be domesticated to support the restocking efforts to nature, in order to assist the local government in controlling malaria in West Papua. Meanwhile, this research is beneficial to obtain a genetic data of Kepala timah from West Papua waters, which has the advantage of feeding on mosquito larvae in controlling malaria transmission in West Papua.

**Materials and Method**

**Place and Time**

The research was conducted for eight months from January to August 2016. It attempted to obtain genetic data of Kepala timah (*Aplocheilus panchax*) from West Papua waters that feed on mosquito larvae and is resistant to adverse environmental conditions so that it is able prevent malaria transmission in Papua.

The research was conducted in the sub-laboratory of Genetics and Molecular, Faculty of Fisheries and Marine Sciences, University of Papua. It included sample collection, sample extraction, samples in PCR and data analysis of sequence results that previously the samples had been sent to obtain the data of the sequence results.

**Tools and Materials**

Tools used in the research were aquarium equipment complete with aeration sets to temporarily raise fish samples taken from several locations or districts in West Papua. The tools for taking samples in locations included battery aerator, scoop or net and five liter jerry cans as temporary containers from the locations and plastic bags equipped with dissolved oxygen were used for transporting live fish from the locations to Manokwari. Meanwhile, the tools used collecting genetic samples were: analytical balance, micro pipettes, tube PCR, PCR machine (Thermal Cycler Type 1148), hot block, UV transluminator, microcentrifuge eppendorf, sample bottles, PCR tube rack, a set of electrophoresis equipment, erlenmeyer flask, freezer, measuring cups, goblets, bunsen lamp, magnetic stirrer, vortex machine, stationery, polaroid digital camera, MEGA 5.0 software. The materials used in this research were: oxygen given when packaging living samples for the purpose of transporting the samples. Materials for preparing DNA samples were DNA extraction kits, proteinase K, isopropanol, ethanol 70%. Materials used when running at PCR were Cyt b primer, primers, dream Taq, dNTP mix, DMSO, nuclease-free water, tissue, hand glove, microtube and tips. Materials used for electrophoresis were: agarose, TAE buffer, blue/orange loading dye, ladder, deion/molecular grade water and aluminum foil.

**Research Methodology**

In regard to genetic aspects of *Aplocheilus panchax*, research methods consisted of the following stages: sample collection, DNA extraction, amplification, electrophoresis, Exo/Sap, cycle sequencing, precipitation and data analysis (Figure 1).

**DNA extraction**

Samples of *Aplocheilus panchax* were collected from three districts/locations in West Papua (Manokwari, Sorong and Oransbari). Samples were taken randomly numbering ten individuals from each location. Afterwards, they were stored in 70% ethanol until they were used. DNA extraction employed a standard protocol of Geneaid kit (Geneaid, 2013).

**Mitochondrial DNA Analysis**

Mitochondrial DNA Analysis of Cytochrome b gene aimed to identify nucleotide diversity, haplotype and kinship between populations. Mitochondrial DNA used
was Cytochrome b gene. Amplification aimed to copy genes existing in mtDNA. The amplification process was performed using PCR, namely Gold program (Saiki et al. 1988) in accordance with a modified protocol of standard gold (Lourie 2005). The amplification firstly made a mixture between 1 mL of sample extraction and 24 mL of master mix (MM) consisting of ddH2O, 10X PCR buffer (Gold), dNTPs, MgCl₂, primers and Taq enzyme. The amplification process was performed in the (PCR) Thermal Cycler machine and using Taq Gold DNA polymerase as an enzyme in denaturing conditions of 94°C for 10 minutes, annealing of 50°C for 30 seconds and chain elongation of 72°C for 10 minutes, as many as 38 cycles. Primers were designed using Geneious Software (Biomatter) with PCR product ≥400 base pairs (bp). Sequences were downloaded from GenBank (http://www.ncbi.nlm.nih.gov). Phylogeny tree was constructed using Neighbor Joining method (NJ) (MEGA 5.2) with 1000 replication.

Results and Discussion

Genetic analysis of Aplocheilus panchax

Genetic analysis of Aplocheilus panchax in this research aimed to identify genetic diversity of some populations of Aplocheilus panchax from of waters Manokwari District, South Manokwari District and Sorong Municipality in West Papua Province. Information of genetic diversity is very important in determining the origin of parents to be used. The higher the genetic diversity of a population is, the better the resilience of the population from the disease will be. The genetic analysis in this research was carried out through several stages, namely: a. Collection of tissue samples, b. Isolation of total genome, c. amplification CYT B gene, and d. sequencing of Cyt B Gene.

Collection of tissue samples

Samples of Aplocheilus panchax used in this research were collected from several locations in the province of West Papua as shown in Table 1. Ten samples were taken from each location to represent the population in the location. In Sorong, only seven samples were obtained because the population of Aplocheilus panchax was decreasing. The researcher believes that the population of Channa striata, Trichogaster pectoralis and Oreochromis niloticus in Sorong area was presumably the cause of the small number of Aplocheilus panchax obtained. All samples were preserved in 96% ethanol and stored in the collection of sub-Laboratory of Genetics and Molecular, Faculty of Fisheries and Marine Sciences, University of Papua. Photos of some of the collected samples were presented in Figure 1.

Total Genomic DNA Isolation

Total genomes of Aplocheilus panchax samples in this research were isolated with a length of between 20-30 kb (Geneaid, 2013). The success of the genome isolation of was characterized by the appearance of DNA bands on agarose gel stained with ethidium bromide. The electrophoresis results of agarose gel from all samples are shown in Figure 1.

Genom of A. panchax from Manokwari (Amban Pantai) Genom of A. panchax from Manokwari (Oransbari)

Genom of A. panchax from Manokwari (Masni) Genom of A. panchax from Sorong
In general, the quality of the genome obtained was very good, which could be seen from the presence of a thick band at the upper part of the gel and a thin smear band elongated at the lower part. This elongated smear band could be due to DNA which was cut during the process of genome isolation, or the result of the remains of short RNA molecules. The less good quality of the genome could be seen at samples from Manokwari (id: KT_Mkw_15 and KT_Mkw_17). In this sample, the DNA band that appeared was only a smear band from the middle to the lower part of the gel. However, this condition was still good enough to be used as a template in PCR to amplify Cyt B gene. This was because the target genes of Cyt B to be amplified using primers L14841 and H15149 (Kocher et al. 1989) only had a length of approximately 300 - 400 base pairs.

Cytochrome b (Cyt B) Gene Amplicon

Cytochrome b gene amplification was performed in vitro using polymerase chain reaction (PCR). The 1 kb DNA marker was used as a marker. The length of amplicon obtained had a size of approximately 400 bp. The quality of DNA was very good with high levels of brightness, brighter than the DNA bands in DNA marker which had a concentration of 70 ng/µL for the brightest band of DNA marker (Thermoscientific 2012). This means that the concentration of DNA amplicon was higher than 70 ng/µL. This concentration was sufficient to be used in the sequencing stage. The electrophoresis results of PCR products are shown in Figure 2.

**Cytochrome b (Cyt B) Gene Sequence**

Sequencing reaction (nucleotide sequencing) in vitro with Sanger’s dideoxy termination method using labeled nucleotide (Dideoxynucleotide triphosphates). Sequencing reactions was conducted by 1st Base of Singapore, through PT. Genetikas Sains. The sequencing results were electropherogram in AB1 file format that was sent via email. This file could be read using MEGA5 software\(^1\). Each sample was sequenced using two primers, namely forward and reverse primers.

Cyt B sequences of KT_Mkw_01 samples with forward and reverse primers were aligned to be manually proof read in order to ensure that the DNA sequences and its peak of electropherogram had matched. Sequencing this sample has a very good quality. The proof reading process of these sequences was performed using MEGA5 software. Forward and reverse primers were aligned with the sequences and cut on the limit. The result of combination of the two sequences. The total length of nucleotides obtained was 358 bp.

In order to ensure that Cyt B sequences obtained were correct Cyt B sequences of *Aplocheilus panchax*, a comparison was performed with GenBank database (http://www.ncbi.nlm.nih.gov) by using BLAST (basic local alignment search tools). The results of BLAST. The results of BLAST by Satiamarga\(^1\) indicated that the sequences obtained were correct sequences of cyt B genes from *Aplocheilus panchax* with 99% similarity to sequences from GenBank with the access code AB373005.1.

Until September 2016, sequencing had been carried out for 37 samples from Manokwari Amban Pantai (10 samples) and Masni (10 samples); Oransbari (10 samples); and Sorong (7 samples). All samples had a very good quality of electropherogram, except 3 samples from Masni with the ID numbers (KT_Msi_12, KT_Msi_15, KT_Msi_18). The alignment to 34 samples was carried using clustalW contained in MEGA 5 software (Appendix 1). The results of the alignment did not indicate any point of polymorphism. All the sequences had the exact similarity of nucleotide sequences. This suggests that the amplified Cyt B gene was a very conserve gene (having a very low mutation rate). Therefore, the 34 samples could be grouped into the same haplotype based on Cyt B gene fragment in this research.
Conclusions

The results of the alignment do not show any point of polymorphism. All the sequences have the exact similarity of nucleotide sequences. This suggests that the amplified Cyt B gene is a very conserve gene (having a very low mutation rate).

34 samples can be grouped into the same haplotype based on Cyt B gene fragment.

This research suggests that genetic diversity analysis should be performed using RAPD (Random Amplification of Polymorphic DNA).

Abstract

Social Security Organizing Agency (BPJS) is organized through a social insurance mechanism and the BPJS membership is all Indonesian citizens without exception. Objective: To determine the effect of nasuonal health care and motivation of mothers giving birth in health care facilities in the work area of Bantilang Health Center East Luwu District in 2018 Method: This study used a cross sectional method. The population in this study were all obstetric patients at the time of the study. The sample in this study were some obstetric patients both from Maternity Mothers Care (KIA) and Family Planning (KB) Polyclinics and the delivery room (Inpatient) at the time of the ongoing study who were willing to become respondents using purposive sampling technique. Data collection using questionnaire research instruments and processed using SPSS program and distribution with distribution tables and bivariate analysis tables. Results: Univariate analysis looked for frequency distribution while bivariate analysis looked for the influence of each variable where National Health Insurance (JKN) variable (p = 0.000) and motivation (p = 0.003). Conclusion: There is an effect of nasuonal health care and motivation of mothers to give birth at health care facilities in the work area of Bantilang Health Center East Luwu District in 2018

Keywords: Maternity Mothers, Health Care Facilities, National Health Insurance and Motivation

Introduction

Health is the basic right of every person, all citizens have the right to receive health services, including the poor¹. In 2014, the government implemented a National Health Insurance (JKN) program organized by the Social Security Organizing Agency (BPJS)²⁻³. This BPJS is expected to meet the needs of citizens for health services. Based on data from the East Luwu Health Service, the number of JKN participation in the District. In 2016, East Luwu was 1,722,111 people, while in 2017 there were 2,597.53 people. KIA annual report, namely coverage of assistance by health workers as many as 5,671 maternity mothers from the target target of 6,234 mothers giving birth.

Based on the PWS KIA report on the Bantilang Health Center in East Luwu Regency, the number of maternity mothers at home or non health facilities in 2015 was targeted for 119 maternity mothers where there were 108 maternity facilities at 11 maternity facilities and a target in 2016 as many as 131 women giving birth in health facilities as many as 115 mothers giving birth while non-health facilities as many as 16 people and in 2017 the target of maternity mothers is 148 women giving birth in health facilities as many as 130 women giving birth while non-health facilities are 18 person. In a previous study conducted by Melina⁴ that the results of analysis with the chi square test obtained a significance value of 0.000, because the significance value (p-value) was obtained at 000 smaller than, 05 (p <, 05), the statistics show that there is a relationship between the use of national health insurance and the achievement of coverage of target services for pregnant women at Banguntapan II Health Center, Bantul Regency in 2016. From the results of Zahruddin’s⁵ study, it was shown that half of the respondents in Jrangoan Community Health
Center considered that subjective norms were very instrumental in supporting the delivery community to health facilities. There are three aspects assessed in this regard, namely community support, husband support and parental support. Based on the description above, the researchers are interested in conducting research with the title “The Effect of National Health Insurance and Motivation of Maternity at Health Service Facilities in the Bantilang Community Health Center Working Area in East Luwu Regency in 2018”.

Materials and Method

Research design

This research is a quantitative research with analytical survey method using crossectional research design where the independent variable and dependent variable data are taken at the same time to identify factors related to JKN role on maternal motivation in health care facilities in Bantilang Health Center, East Luwu Regency in 2018.

Location and Time of Research 1. Research Sites  
Research locations in Bantilang Health Center, East Luwu Regency 2. Research Time  
Time of study from March to September 2018

Population and Samples

The population in this study were all women giving birth at the time of the study that took place with a population of 98 people. The sample in this study was that some women gave birth at the time of the study that were willing to be respondents with a total sample of 49 people. By using yairu purposive sampling technique. The results of this study are presented in the form of frequency distribution tables as follow.

Table shows the highest percentage with good motivation to choose maternity in health facilities as many as 44 people (100%) while the lowest percentage with less motivation by choosing labor in non-health care as much as 5 people (100%) of the total respondents as many as 49 people. The chi-square statistical test obtained are 0.000 which means <value of α, 0.05 which means Ha is accepted which means there is an influence of motivation with maternity at health care facilities in the working area of Bantilang Community Health Center, East Luwu Regency in 2018.

Discussion

National Health Insurance

The results of this study indicate that JKN is a community need for national health insurance which is a necessity for basic and high levels. Basic level needs are needs that can be satisfied from the outside, for example physiological needs and the need for security. While high level needs are needs that can only be satisfied in the person concerned, for example the need for appreciation and self-actualization8,9. To certify the JKN program the role of all cross-sectors is needed to provide understanding and information to the public about the benefits of JKN so that the community can be motivated and can increase the coverage of universal and universal health services. The results of the above research indicate that the National Health Insurance (JKN) is part of the National Social Security System (SJSN). The National Social Security System is organized through a mandatory social health insurance mechanism based on Law No. 40 of 2004 concerning the National Social Security System. The aim is that all Indonesian citizens be protected in the insurance system, so that they can meet the basic needs of proper public health10-12. The results of the study are in line with the research conducted by Melina (2016. The results showed that pregnant women who used JKN whose achievement of coverage coverage for pregnant women reached 38 people (73.1%) and achieved the
target coverage of services for pregnant women as many as 14 people (26.9%).

Contingency coefficient values are $C = 0.502$ Thus it can be concluded that the closeness of the relationship of the contingency coefficient is moderate (0.40-0.599). The maintenance guarantee factor is one of the important factors for the community today where having a health care guarantee the community feels more protected if one day they are stricken with an illness because having health insurance they can be freed from medical expenses. Mothers who have not become BPJS members have reasons that different. The results showed that pregnant women were not yet members of the BPJS because they did not know how to take care of it, were in the process of being managed. Even though the Minister of Health of the Republic of Indonesia announced in 2019 the entire Indonesian community has been included as a member of the BPJS. One guarantee of maternity is the guarantee of childbirth. Collateral guarantee is a guarantee of funding for delivery services which includes prenatal care, delivery assistance, postpartum care, including postpartum family planning services and newborn services. In the process of implementing the National Health Insurance Program (JKN) to provide health protection in the form of health care benefits in order to meet basic health needs given to everyone who has paid contributions or fees paid by the government.

Motivation

Based on the results of statistical tests using SPSS version 20 with the chi-square statistical test it can be seen that the chi-square values obtained are 000 which means $>\alpha, 05$ which means $H_A$ is accepted which means there is an influence of motivation with maternity at health care facilities in the working area of the Bantilang Community Health Center in East Luwu Regency in 2018. The research above shows that motivation is an internal drive that causes the person to carry out certain activities in order to achieve a goal. Expectations for Health facilities are health service facilities used for carry out individual health care efforts, both promotive, preventive, curative and rehabilitative organized by the Government, Regional Government, and or Community. First Level Health Facilities, hereinafter abbreviated as FKTP, are health facilities that carry out non-specialist personal health services for the purposes of observation, promotion, prevention, diagnosis, care, treatment, and/or other health services (BPJS, 2016). People as users of health services will provide an assessment that quality health services as a form that can meet the needs because it is organized by: 1) Courteous and polite, timely, responsive, 2) Able to cure illnesses, 3) Able to prevent the development or the spread of the disease suffered to other people or the disease gets worse. For health care providers linking quality health services with: 1) Equipment independence, 2) Work producer or protocol, 3) Professional freedom in carrying out every health service in accordance with the latest health technology and, 4) How is the outcome or outcome of health services implemented, 5) For funders of health services To be able to improve public health, there are many things that need attention. One of them which is considered to have a quite important role is to provide health services. What is meant by health
services is every effort that is held alone or jointly in an organization to maintain and improve health, prevent and cure diseases and restore the health of individuals, families, groups and / or communities. Requirements for good health services can at least be distinguished from 13 types, namely available, comprehensive (comprehensive, integrated), continuous, equitable, sustainable, appropriate, acceptable (acceptable), accessible (affordable), affordable (effective), effective (efficient), and quality 18

**Conclusion**

1. There is an influence of national health insurance with maternity at health service facilities in the working area of Bantilang Community Health Center, East Luwu Regency in 2018. Statistical test results using SPSS version 20 with chi-square statistical test can be seen that the chi-square value is obtained, 000, which means < value of α, 0.05 which means Ha is accepted. 2. There is an influence of motivation with maternity at health care facilities in the working area of Bantilang Community Health Center, East Luwu Regency in 2018. The results of statistical tests using SPSS version 20 with the chi-square statistical test can be seen that the chi-square value is obtained which is 0,000 which means < value α, 0.05 which means Ha is accepted.

The Effect of Granisetron and Ondansetron on Hemodynamic During Cesarean Section Under Spinal Anesthesia

Syafri Kamsul Arif1, Ahmad Nur Islam 2, Alamsyah A.A.1, Muh. Ramli Ahmad1, Syafruddin Gaus1, Hisbullah1

1Staff, 2Resident, Department of Anesthesiology, Intensive Care and Pain Management Hasanuddin University, Faculty of Medicine, Makassar, Indonesia

Abstract

Spinal anesthesia is the most popular technique of anesthesia for Caesarean section (Cs) which is frequently associated with hypotension and bradycardia. Hypotension is harmful for maternal and fetal outcome. The Bezold–Jarisch reflex (BJR) is one of the mechanisms which explain the occurrence of hypotension after spinal anesthesia through serotonin-mediated vasodilatation. These receptors located peripherally as cardiac chemoreceptors on the cardiac vagal afferent and centrally in the chemoreceptor trigger zone. The aim of our study was to evaluate the effect 5-hydroxytryptamine 3 (5-HT3) receptor antagonists between Granisetron and Ondansetron on hemodynamic in parturients undergoing Cs with spinal anesthesia. Forty patients underwent Cs under spinal anesthesia randomly divided into two groups (20 parturients in each group). Group G received intravenous 0.03 mg/kg Granisetron 30 min before spinal anesthesia, group O received intravenous 0.1 mg/kg Ondansetron. Mean Arterial Blood Pressure (MABP), Heart Rate (HR), and vasopressor used were assessed. MABP changes was higher in group O compared to group G (p<0.05), although this result was not statistically significant (p>0.05). However, incidence of nausea and vomiting was significantly decreased in group G (p<0.05). Granisetron and Ondansetron have similar effect in prevent hemodynamic changes during Cs under spinal anesthesia.

Keywords: Granisetron, Ondansetron, hemodynamic, Caesarean section, spinal anesthesia.

Introduction

Spinal anesthesia is the most popular technique of anesthesia for Cs, which is frequently associated with hypotension and bradycardia. Hypotension is harmful for maternal and fetal outcome. Hypotension resulted from the decrease in systemic vascular resistance and central venous pressure due to sympathetic block. Sudden bradycardia may occur from shift in cardiac autonomic balance toward the parasympathetic system.1,2

Ondansetron and Granisetron are selective 5-HT3 receptor antagonists. These receptors located peripherally as cardiac chemoreceptors on the cardiac vagal afferent and centrally in the chemoreceptor trigger zone. On the other hand, the BJR is one of the mechanisms which explain the development of hypotension after spinal anesthesia through serotonin-mediated vasodilatation. Stimulation of cardiac chemoreceptors in the heart due to decreased in venous return increases parasympathetic activity, while decreases the sympathetic activity resulting in hypotension and bradycardia.2,3 From systematic review and meta-analysis, Heesen et al. in 2016 suggested 5-HT3 receptor antagonist were effective in reducing the incidence of hypotension and bradycardia.1 The effect are only significant in patients undergoing Cs, therefore in this study, we evaluated the effect of Granisetron and Ondansetron on the hemodynamic and side effects following spinal anesthesia in women undergoing elective Cs.

Materials and Method

This study was conducted at Mother and Child Hospital in Makassar, Indonesia between February and March 2018. Institutional ethical committee approval
and informed written consent were obtained from all patients. Participants were evaluated one day before surgery by an anaesthesiologist. Obstetric patients with ASA Physical Status (PS) II, between 20 and 45 years old, and undergoing an elective CS were included. Patients who refused to participate, had any contraindications to spinal anesthesia, history of hypersensitivity to local anesthetic agent, bleeding disorder, hypertensive and cardiovascular disorders in pregnancy were excluded. For eligible patients, demographic information was collected and a physical examination was performed. Age, BMI, and ASA PS class were recorded and analyzed.

In the pre-anesthesia room, baseline value recorded, non-Invasive blood pressure (NIBP) and HR were recorded and a peripheral 18-Gauge i.v. cannula was inserted. Patients were randomly assigned to receive 0.1 mg/kg Ondansetron (group O) or 0.03 mg/kg Granisetron (group G) 30 min before spinal anesthesia, where each group consists of 20 parturients. All patients received i.v 50 mg Ranitidine and preloading with 10 mL/kg Ringer’s lactated solution given over 15 min. The spinal technique was performed at L3-4 or L4-5 with the patient in the left lateral decubitus position. The 10 mg 0.5% hyperbaric bupivacaine with adjuvant 25 mcg fentanyl was administered after confirmation of cerebrospinal fluid through a 25- or 26-Gauge Quincke spinal needle. Patients were immediately placed in the supine position with 15º left tilt. The second anesthesiologist was blinded to the study solution, measured hemodynamic parameters and recorded the presence of nausea and vomiting.

HR and MABP were recorded before spinal anesthesia and at 2-min intervals up to 15 min, followed by 30-min intervals until the end of surgery. Rescue i.v. bolus doses of 10 mg ephedrine were given if the parturient had hypotension (hypotension was defined as a decrease in SBP <90 mmHg or in MABP more than 20% from the baseline). Decrease in HR to less than 50 beat/min was treated with 0.5 mg atropine sulphate intravenous.

The Statistical Program SPSS (SPSS Inc., Chicago, Illinois, USA) for Windows, version 25, was used for data entry and analysis. Data were expressed as number and mean ± SD for quantitative variables. Categorical variables were analyzed using Chi-squared test or Fisher’s exact test. Numerical variables normally distributed were compared between groups by Student’s independent samples t-test with p<0.05 was statistically significant.

Results

Forty patients were recruited: 20 parturients in each group. No significant differences were observed in patients demographic (age, BMI, and ASA PS) between the two groups (p>0.05). The incidence of nausea and vomiting significantly reduced in group G (see Table 1).

MABP and HR were observed in the two groups. The difference in time of measurement in each group was observed. MABP changes was higher in group O compared to group G (p<0.05), although this result was not statistically significant (p>0.05) (see Figure 1). There was no difference of HR changes between the two groups (p>0.05) (see Figure 2).

Discussion

Sympathetic blockade from spinal anesthesia decreases systemic vascular resistance and induces peripheral pooling of blood leading to hypotension. In response to hypovolaemia, stimulation of cardiac sensory receptors in the left ventricle induces the BJR and results in reflex bradycardia, vasodilation and hypotension. Chemoreceptors are activated in response to decreased blood volume by serotonin. Activation of 5-HT3 receptors, which are G protein coupled, ligand-gated fast-ion channels, results in increased efferent vagal nerve activity which frequently producing bradycardia. However, bradycardia occurs less frequently than hypotension following spinal anaesthesia.6,7,8

Ondansetron and Granisetron, although both of them from the same category and have same mechanism of action, may be due to the action of Ondansetron on mixed receptors and the high selectivity of Granisetron on 5-HT3 receptors, but it has minimal affinity for other 5-HT receptors, adrenergic, histaminic, dopaminergic, or opioid receptors.10,11

In the present study, two 5-HT3 antagonists, Ondansetron and Granisetron, as they block the BJR and may successfully treat postspinal hypotension, were used prophylactically and given 30 min before spinal anesthesia. The important finding in this study is that, despite the reduction in MABP changes in Ondansetron group higher than Granisetron group, there were no statistically difference in MABP changes in the two groups.

Our findings is consistent with study by Mahmoud and Shaaban in 2017 showed that prophylactic intravenous 4 mg Ondansetron or 1 mg Granisetron compared to saline as placebo were significantly reduced the severity of hypotension induced by spinal anesthesia.6 In our study, we gave prophylactictic 0.03 mg/kg Granisetron and 0.1 mg/kg Ondansetron 30 min before spinal anesthesia. It showed there were no difference in hemodynamic changes and there was no incidence vasopressor use in each group.

This study showed that Granisetron and Ondansetron have protective effect on hemodynamic response during Cs. Our results indicated that Ondansetron and Granisetron prevented the serotonin-induced BJR, suppressed venodilatation, augmented venous return to the heart and resu lted in lesser reductions in MABP.10

Limitations of this study were small sample size, used one dose of each drugs only, and amount of blood loss was not recorded in this study, which may influence the hemodynamic profile of parturients. We recommend further studies with larger sample size and large doses of Granisetron and Ondansetron to evaluate the effect on hemodynamic.

Conclusion

Granisetron and Ondansetron has similar effect on preventing hemodynamic changes during Cs under spinal anesthesia.

The Accessibility of Health Services for Multiethnics Community Towards Universal Health Coverage in Samarinda City: A Qualitative Study

Ratno Adrianto¹, Amran Razak², M. Alimin Maidin³, Darmawansyah⁴

¹Department of Administration and Health Policy, Faculty of Public Health, Mulawarman University; ²Department of Administration and Health Policy, Faculty of Public Health, Hasanuddin University; Department of Hospital Management, Faculty of Public Health, Hasanuddin University, ³Department of Administration and Health Policy, Faculty of Public Health, Hasanuddin University

Introduction

Since January 1, 2019, Indonesia has entered the era of Universal Health Coverage (UHC) that is sustainable. This success is considered an innovation in the coverage of almost all communities to be able to access available health services. In some districts / cities, the membership of the National Health Insurance System (NHIS) does not cover 100 percent, such as Samarinda. This has an impact on the low universal coverage of NHIS, so that citizens experience obstacles to accessing the health services they need.

Methods: There are four focus group discussions (FGD), which are made according to large ethnic groups in Samarinda, namely the Banjar, Javanese, Bugis and Dayak ethnic groups. The discussion participants were almost all housewives, they were considered to have a high level of concern for their household health problems, and eight main informant interviews. Content analysis was used to explore the phenomena that emerged in this study.

Results: Findings show that approachability dimensions (distance traveled, travel time, and transportation costs), including health insurance coverage, are a problem for some multi-ethnic communities. Although there was no discrimination in vulnerable groups such as the elderly and pregnant women, it was revealed that other patients felt different treatment when receiving services. Available health facilities are considered adequate. However, the number of health workers (doctors and paramedics), is considered lacking. The low level of government attention and lack of socialization from the Social Security Agency of Health (SSAH) are considered as obstacles to achieving UHC in Samarinda City.

Conclusion: There are still obstacles to access for ethnic groups who are located far from the city center. Revealed the existence of ‘discrimination’ patients when using health care facilities.

Keywords: accessibility, multiethnic community, universal coverage, samarinda city.
diversity with flexible and adaptive implementation features and quick evidence-driven decisions based on changing needs. UHC is one way to reduce disparity in access to health services.\(^4\)

Since January 1, 2019, Indonesia has entered an ongoing era of UHC. This success is assessed as an innovation in the coverage of almost all communities to be able to access available health services.\(^3\) Some districts/cities in Indonesia, SSAH membership coverage has not reached 100 percent including Kota Samarinda.\(^5\) This has caused people experiencing difficulties in accessing health services that they need.

This study employed qualitative research on the accessibility of health services to multi-ethnic communities, in Samarinda City supporting UHC. This study aims to explore dimensions that affect the accessibility of multi-ethnic communities to support UHC and the achievement of Sustainable Development Goals (SDGs) 2030.\(^6\)

**Theoretical framework**

The theoretical concept of the five accessibility dimensions of Levesque, et. al.\(^7\) was modified as a conceptual framework for this study. Access is defined as an opportunity to achieve and obtain appropriate health services in situations that are deemed necessary for care.\(^8\) Access is seen as a result of interactions between the characteristics of people, households, physical and social environment and characteristics of health systems, organizations and providers.\(^9\)

The concept of five dimensions of service accessibility includes Approachability; 2) Acceptability; 3) Availability and accommodation (Availability and accommodation); 4) Affordability; 5) Appropriateness.\(^9\)

**Conceptual definition used**

In this study, the concept of five dimensions of health service accessibility was modified to explore the dimensions of accessibility of health services to multi-ethnic communities in the city of Samarinda to utilize health facilities.

1) Approachability is the distance to get health services in the form of mileage, travel time, and travel costs (geographical access), including health insurance coverage.

2) Acceptability is that services provided do not conflict with customs, needs, beliefs, public trust, there is no discrimination in providing services, especially for vulnerable groups (not capable) and how people perceive service quality.

3) Availability and accommodation is that all types of health services needed by the community are not difficult, as well as their presence in the community at any time needed (availability of infrastructure, adequate health equipment, pharmaceuticals (medicines) and health human resources (doctors, midwives and nurses).

4) Affordability is the financial capacity of the community to utilize health services (description of community work, socio-economic status and income picture).

5) Appropriateness is the need for health services with services provided in accordance with community demand; and community perceptions in accordance with services provided by providers (health care providers).

This dimension of accessibility allows individuals or households to plan, choose, utilize and feel satisfaction with the health services they obtain.

**Materials and Method**

**Selection of participants**

The selection of Focus Group Discussion (FGD) participants was purposive sampling with the following criteria; they have or are currently using health facilities; always be alert and responsive to maintaining the health of his family; influential in making decisions on the utilization of health facilities; and willing as a participant. Key informants are selected purposively based on their relevance to health service policies; community leaders, and traditional leaders.

The target population for this study was 4 ethnic communities (Banjar, Javanese, Bugis, and Dayak ethnic groups). The number of discussion participants was 8 people each group (n=32). Key informants were 4 people from service providers, and 4 people from community leaders and traditional leaders (n=8).

**Data collection and analysis**

Accessibility of Health Services in the Multi-Ethnic Community Towards UHC in Samarinda City was explored through 4 Focus Group Discussion
(FGD) groups and 8 key informant interviews. FGDs are conducted in open spaces and halls where communities usually gather. In-depth interviews were conducted at the office or at the key informant’s home. FGDs and in-depth interviews were conducted after obtaining informed consent from participants and key informants. Interviews and discussions focused on the 5 dimensions of accessibility of health services including: approachability, acceptability, availability and accommodation, affordability and appropriateness.7 Data analysis used content analysis10 to analyze the phenomena found in the study.

Results

Focus group discussions of 32 participants (n=32), as many as 30 people (93.75%) were women. Therefore, almost all participants were housewives. There were 8 key informants of which 4 key informants were heads of the community health center and 4 other key informants were community leaders and traditional leaders (n=8).

This study uses the accessibility model of Levesque et.al. which has been developed according to the context of local communities and the policies of the Indonesian government. There are 5 dimensions of accessibility including approachability, acceptability, availability and accommodation, affordability, and appropriateness.

Approachability

Accessibility of proximity includes distance, travel time, transportation costs and ownership status of health insurance.

Mileage to health care facilities, especially hospitals, each ethnicity is different depending on its geographical location, but can be accessed by public transportation or private vehicles, and motorbikes. For ethnic communities that are close to urban areas (Javanese, Banjar and Bugis), they are relatively not constrained by the distance. Unlike the Dayak ethnic group, having difficulty accessing health center and hospitals, it takes around 30 kilometers.

Travel time to health service facilities for ethnic communities domiciled around Samarinda city (Javanese, Banjar and Bugis ethnic group) between 6-18 minutes using a motorcycle or car. Whereas with the Dayak ethnic group, it took almost 1 hour to get to the hospital.

In focus discussions, participants argued that travel costs were perceived as an economic obstacle due to extra expenses, although these costs varied according to the distance traveled and transport facilities used. For the Banjar, Javanese and Bugis ethnic group, because they live around the center of Samarinda, the average cost is Rp. 10,000, up to Rp. 20,000, - one way. Unlike the Dayak ethnic group who have to spend around Rp. 50,000, one way.

Regarding the ownership status of NHIS, in 4 discussion groups it turned out the participants were very diverse. Those who have been included as NHIS participants, most feel happy to have used their cards to meet their medical needs. Unlike the participants who have not been included in NHIS membership, they feel the cost constraints if they want to use health services.

Regarding the ownership status of NHIS, in 4 discussion groups it turned out the participants were very diverse. Those who have been included as NHIS participants, most feel happy to have used their cards to meet their medical needs. Unlike the participants who have not been included in NHIS membership, they feel the cost constraints if they want to use health services.

On the other hand, the population of Samarinda City itself, the coverage of NHIS participation has not yet reached the Universal Health Coverage (UHC) target, still 81 percent.5

Acceptability

Acceptance accessibility includes perceptions of service quality and discrimination in health services.

Public acceptance of the presence of modern health services is quite good. There are no significant obstacles to enjoying the medical needs of all ethnic group, both indigenous and immigrant ethnic group. Dayak ethnic group who still take good care of their culture and customs, have apparently relied on modern health services.

In the discussion it was revealed that participants were almost totally not familiar with the treatment system and care of their ancestors. Knowledge and traditional medicine systems are no longer an option, except occasionally using herbs such as betel leaves for the efficacy of reducing certain diseases. Even so, several cases of childbirth were handled by TBAs. Actions carried out by TBAs such as umbilical cord are
given powder, umbilical cord given coffee which finally festering.

**Availability and accommodation**

Some key informants from the service providers, stated that the condition of the infrastructure, the completeness of health equipment, the availability of medicines and the number of health workers (doctors and paramedics), were adequate. However, they admit that they still need an increase in the quantity and capacity of the availability of health facilities to be able to provide quality services.

**Affordability**

Accessibility of the users ability can be observed from the description of the work and income of the family head.

Job descriptions for the Javanese ethnic group are generally building coolies, Bugis ethnic group as fishermen and farmers, Dayak ethnic group as a farmers and Banjar ethnic group as farmers and traders.

The income picture of the multi-ethnic community is closely related to the type of work, so it is very varied, daily workers such as construction workers are around Rp. 75,000 / day or Rp. 180,000 per month. Fishermen can reach Rp. 100,000, - per day or Rp. 3,000,000, - while farmers are around Rp. 5,000,000 / month. Farmer’s income is around Rp. 3,000,000 per month. Those who work as traders earn an average of Rp. 4,000,000 per month.

**Appropriateness**

Accessibility in the form of suitability of demand with health services; and perceptions of services provided in accordance with health service providers.

The comments of several discussion participants stated that the service provided was good enough, hopefully this will continue. They do not doubt the professionalism of health workers who provide services. Meanwhile, several key informants said that they were in line with the operational standards of the minister of health regulations

**Discussion**

Affordability of health care facilities for multi-ethnic communities in Samarinda City is closely related to the problems of distance, travel time, and transportation. This will effect the economic burden of the household, due to the costs that must be spent from their pockets to access the health services. The transportation costs comes from their daily expenses. This obstacle has an effect on the delay in achieving UHC. Potentially, health service needs are influenced by distribution, distance, and means of transportation.\(^{12-13}\)

This study revealed the complexity of managing and utilizing NHIS, among participants who were not the member of NHIS, they chose to pay for themselves because they did not want to be involved in the complexity due to uncertainty waiting for NHIS cards to arrive, and other administrative problems.

The emergence of ‘discriminatory’ treatment when receiving health services. This will cause patient discomfort. Participants for this study argued that every health problem should be treated equally. Experience in Cape Coast, Ghana showed that the main obstacles to subscribing to health insurance include; long queues and waiting times, and negative attitudes of service providers.\(^{14}\)

In East Kalimantan province alone, there have been 5 districts/cities won UHC awards.\(^{15}\) This is different from Samarinda city which has not yet reached the UHC target.\(^{6}\) Whereas the city government of Samarinda has improved the SSAH management counter facilities in each sub-district and sub-district, socialization of SSAH to all levels of society and every citizen who comes to the location must be informed, as well as door to door socialization. The ineffectiveness of SSAH outreach was also revealed in discussions that participants were still not covered by NHIS, there were also dropouts. The multi-ethnic approach model as carried out in this study can be used to help in socializing UHC achievements in Samarinda City.

One sensitive issue that emerged among discussion participants, i.e. the health service users still had to pay from their pocket when receiving the services, this would be an economic burden.\(^{16}\) Many patients purchased drugs in the private pharmacy because they were not available at the health facilities, especially for those who are not easy to have cash. The same case occurred in Addis Ababa when the beginning of the Economic Basic Health Insurance (EBHI) implemented.\(^{17}\) This condition shows that there are still obstacles to the use of health services.

This study emphasizes the need for intensive
socialization to foster positive perceptions of SSAH management. This is expected to increase the participation of NHIS, thus supporting the achievement of UHC in Samarinda City. Health center as the leading gate-keeper of health services is expected to optimize the Mobile Health Center as an effort to glue the imbalance of health services due to obstacles to geographical access especially to ethnic Dayak communities.

**Conclusion**

The accessibility of health services to multi-ethnic communities in Samarinda City was adequate. Although there was no discrimination in health services for vulnerable groups, other patients felt different treatments when receiving health services. The overall coverage of NHIS participation had not yet become a barrier to achieving UHC in Samarinda City.

The Role of Estrogen and Progesterone Hormons Imbalance in Premenstrual Syndrome of Female Adolescent

Suriani Bahrun, Yunita Suriani Suardi, Yanti Mustarin, Kusumawardani Bakri

Abstract

Background: Teenagers with menstrual cycle still experience one or more symptoms of Premenstrual Syndrome (PMS). High estrogen levels and imbalance of estrogen and progesterone cause PMS symptoms.

Research objective: Identifying the role of estrogen and progesterone hormone imbalance on PMS in female adolescent.

Research method: using a non-experimental design, using a cross sectional approach with 40 samples.

Conclusion: The imbalance of the estrogen and progesterone hormones plays a role in the degree of premenstrual syndrome. The high imbalance of the hormones estrogen and progesterone will cause a low degree of premenstrual syndrome.

Keywords: estrogen, progesterone, premenstrual syndrome, female adolescent

Introduction

Menstruation is one sign of puberty in women. At present the average age of menstruation is getting earlier. The youngest age for menstruation is 8 years while the oldest age is 17 years. The better nutritional conditions accelerate the body's readiness to start menstruation in girls. In addition, information about sex that is more easily obtained from various media today can also trigger the brain to immediately activate sexual hormones. So that when it reaches the age of 17 years old, a woman has not yet experienced menstruation, she must immediately see a doctor because it indicates a disruption in reproductive function.

The symptoms that arise before the menstrual period are expected to be a disruption to daily activities in adolescent girls during menstruation. According to Dickerson et al (2005), about 85% of young women who still get the menstrual cycle experience one or more symptoms of Premenstrual Syndrome (PMS).

PMS or pre-menstrual syndrome is a condition where a number of symptoms occur just before menstruation, symptoms usually occur 7-10 days before menstruation and disappear when menstruation begins. These symptoms are physical and psychological disorders, physical complaints such as breast pain or swelling, flatulence or pain, headache, joint pain, back pain, nausea, vomiting, diarrhea or constipation, and the appearance of skin problems such as acne. Psychological problems include depression, sensitivity, irritability, sleep disorders, fatigue, weakness, and sometimes very rapid mood swings.

The prevalence of PMS is quite high, which occurs in around 70-90% of women of childbearing age and is more often found in women aged 20-40 years. Women who have given birth will be at higher risk of suffering from PMS. The exact cause of PMS is unknown.

It is estimated that 13-19% of reproductive-age women experience PMS, 3-8% even experience premenstrual dysphoric disorder (PMDD). Ashraf (2014) even stated that the prevalence of STDs reached 48% and the highest prevalence was in Asia and the lowest in Europe.

The results of a study conducted in Iran found that 98.2% of students aged 18-27 years experienced at least 1 mild or moderate degree of premenstrual syndrome. The overall evidence suggests that premenstrual syndrome is
a form of disorder commonly experienced by teenagers in Asia\textsuperscript{6}. Another study conducted by Locklear, 2010 found results that Justicia pectoralis Jacq. which has estrogenic, progestagenic and anti-inflammatory effects can be beneficial in menopausal women and PMS\textsuperscript{7}. Frank in Rimma stated that high estrogen levels and balance disorders of estrogen and progesterone cause PMS symptoms\textsuperscript{8}.

To get in-depth information about the role of estrogen and progesterone hormone imbalance with PMS, an assessment of estradiol, progesterone, and PMS degrees was carried out.

**Research purposes**

To identify the role of imbalance of estrogen and progesterone hormones with PMS in female adolescent.

**Research Method**

The design of this study uses a non-experimental design, with a cross sectional approach that is the observations are only conducted once according to the time determined by the researcher by looking at the relationship between the dependent and independent variables\textsuperscript{9}.

This research was conducted at STIK GIA Makassar and the Laboratory of Molecular Biology and Immunology at the Faculty of Medicine, Hasanuddin University.

The population in this study were female adolescent who experienced PMS (STIK GIA MAKASSAR students).

Sampling in this study using nonprobability sampling with purposive sampling technique that is sampling with certain considerations.

The sample size in the study was obtained based on the sample formula for correlative analytical research, as follows:

Based on the calculations above, the sample size taken was 40 samples that were in accordance with the inclusion criteria\textsuperscript{10}.

**Inclusion criteria and exclusion criteria**

**Inclusion criteria, namely:**

1. Women of childbearing age who are in the luteal phase
2. Menstrual cycle 28-35 days

**Exclusion Criteria, that are :**

1. Using hormonal therapy
2. Alcoholic history
3. History of reproductive system disorders
4. Do not sign informed consent
5. Not cooperative
6. Not obese

**Research Materials and Tools**

1. Form of Food Frequency Questionnaire
2. Stationery
3. Spoit 10 cc
4. Blood sample
5. Commercial kit: DIAsource E2-EASIA
6. CYP17 gene primer, PCR System 7300 (Applied Biosystems, USA) with SYBR Green

Table 1 shows that majority of respondents are in the age of 18-21 years old (26 respondents or 65%), and 22-24 years old (14 respondents or 35%). According to the menstrual cycle, respondents mostly have the 28-30 days cycle (21 respondents or 52.5%) and some have 31-35 (47.5%).

Based on the menstrual period, respondents mostly have 3-5 days (24 respondents or 60%) and some have 6-7 days (16 respondents or 40%). Based on the Body Mass Index, they mostly have moderate depletion (22, respondents or 55%), and minority of them have severe depletion (3 respondents or 7.5%).

Based on the characteristics of estrogen level, most of the respondents are on the higher category (30 people or 75%) and 10 of them are on lower category (25%). Based on the progesterone level, mostly they are on higher category (30 people or 75%) and 10 of them are on lower category (25%). Based on the estrogen-progesterone combination, mostly they have high level of estrogen and progesterone (20 people or 50%), 10 people have high estrogen and low progesterone (25%), the other 10 people have low estrogen and high progesterone, and no respondents has low estrogen and progesterone.

</table>

Based on table 2, the combination of high estrogen, low progesterone, the majority experienced moderate grade PMS (7 people or 70%). For the combination of low estrogen and high progesterone, the majority had moderate degrees of PMS (8 respondents (80%). The combination of high estrogen and progesterone, the majority experienced moderate degree of PMS (13 respondents or 65%). There were no respondents who had a combination of low estrogen and progesterone levels. The table also shows that there is a role for imbalance of estrogen and progesterone hormones with PMS degrees. The direction is negative and weak.

Discussion

The results of the research showed that there was the role of the imbalance of estrogen and progesterone hormones towards the degree of premenstrual syndrome. The higher the imbalance of estrogen and progesterone hormones, the lower the degree of PMS. Respondent who had high estrogen and progesterone levels was only one, with severe degree of PMS. This is due to the imbalance of the estrogen and progesterone hormones is not a single factor in PMS. Low calcium intake is one of the causes of PMS. From the data obtained, the respondents never consumed milk and spinach which are sources of calcium.

Meanwhile, respondents who had an imbalance of estrogen and progesterone (both high estrogen, low progesterone as well as low estrogen, high progesterone) have 2 respondents with severe PMS. This is partly due to low food intake (banana, papaya) which contains vitamin A which is a predisposition factor for PMS.

Conclusion

The imbalance of the estrogen and progesterone hormones plays a role in the degree of premenstrual syndrome. The high imbalance of the hormones estrogen and progesterone will cause a low degree of premenstrual syndrome.

Suggestion

Further research is needed regarding to the role of calcium, bananas, and papaya towards PMS.

Factors that Influenced the Use of Family Planning (KB) in Padang Hulu District of Tebing Tinggi 2018

Namora Lumongga Lubis¹, Hasnida²
¹Department of Public Health, University of North Sumatera, Jalan Universitas No. 21 Medan, Indonesia, ²Department of Psychology, University of North Sumatera, Jalan Dr. Mansyur No. 7 Medan, Indonesia

Abstract

As developing country, Indonesia still has to struggle with various problem. One of the main problem faced by Indonesia today is the growing number of population. The purpose of this research is to analyse the factors that influence the male use of family planning in Padang Hulu sub-district, Tebing Tinggi 2018. This research is using analytical observational with case control study design. The sample of this study consisted of 60 cases group and 60 control group. The case group sample was the male family planning acceptor and the control group sample including the male non family planning. Based on multivariate results that age and support of wives are predicators of male family planning. It is suggested for health workers to improve the promotion of vasectomy services, through the provision of education, knowledge and the use of family planning vasectomy in the form of counselling and family approach concerning the importance of family planning vasectomy and for men family acceptor is expected to be role model to his peers so that the other men would participate in family planning, especially vasectomy.

Keywords: Use of Male Family Planning, Possible Factors, Strengthening Factors.

Introduction

Male participation rates in contraceptive use in Indonesia are still very low at only 2.1% family planning and they generally use condoms. The percentage is lower compared to other countries, such as Iran 12%, Tunisia 16%, Malaysia 9-11%, even the percentage in the United Stated reached up to 32%. Based on BKKBN 2012 the participation of male using contraception is only 1.3% consist of condom user (0.9%) and vasectomy (0.4%). Therefore the socialization of family planning programs among men should be improved¹².

The ease and availability of service family planning facilities has a positive impact on the use of contraception. Men became less motivated to use contraception due to the low accessibility of information about family planning¹. According to ⁴ the cause of husband’s less participation in family planning is the limitation of knowledge about reproductive health and paradigm associated with patriarchy in which the role of husband is greater than women. Based on the research showed that wife support associated with husband’s involvement in family planning (condom and vasectomy) in Bantul Regency. Male participation in the practice of modern family planning methods in Indonesia is influenced by socio-demography that includes knowledge, wife’s age, husband’s education, number of surviving children and attitudes toward family planning programs⁵-⁸.

Tebing Tinggi, is one of the city in North Sumatera which inhabited by 147,771 people with a total of 23,550 couples with reproductive age. Active family planning participants in 2013 reached up to 17,450 people which consist of 200 males using vasectomy (1.15%) and 610 males using condom (3.50%) at the group age of 30-45 years old. The largest coverage of family planning acceptors was found in Rambutan sub-district consist of 52 people (1.23%) from the total 5,578 reproductive couples. In Bajenis sub-district there were 49 people (1.23%) from the total of 5,081 reproductive couples, Tebing Tinggi Kota 48 people (1.85%) from the total of 3,539 couples, Padang Hilir sub-district is 33 people (0.97%) from 4,697 couples, and Padang Hulu sub-district is 18 people (0.51%) from 4,655 couples (BKKBN 2013)⁹.
Material and Method

This study is an analytic observational study with case control method. Analytical observational case control study is a design to determine the relationship between variables by comparing case group and control group based on their status\textsuperscript{10}. The sample were consisted of 60 control groups and 60 case groups. Data were analyzed using simple logistic regression and multiple logistic regression test.

Univariate Analysis

Description of the respondents in the study showed that the most of respondents in the case group had entrepreneurial jobs it consist of cases of 38 people (63.3%). Based on the research, the Muslim respondents in the case group consist of 55 respondents (85%). And there were 58 Muslims (96.77%) in control group. The majority of respondent were Javanese consist of 28 people (46.7%) from case group and 35 people (53.8%) from control group. 47 people (78.3%) from case group had 1-2 children and in control group there were 52 respondents (86.7%) had (>3) more 3 children’s. 48 respondents (80%) respondents in case group an 55 respondents (91.7%) in control group had income 1-2 million. 27 respondents (61.7%) wife in the case group were within in control group above 35 years. 43 respondents (71.7%) in control group were within the age group above 35 years (>35). 32 of respondent (53.3%) from the case group and 40 respondents (66.7%) from control group had more than 12 years the length of marriage.

Bivariate Analysis

Simple Logistic Regression Test Results

The analysis results of simple logistic showed that there is a significant influence between age to male KB use. The results of analysis using simple logistic regression test showed that there is no significant influence between education on the use of family planning in men. The results of analysis using simple logistic regression test showed that there is no significant influence between knowledge on the use of family planning in men. The results of analysis using simple logistic regression test showed that there is no significant influence between the availability on the use of family planning in men.

The results of analysis using simple logistic regression test showed that there is no significant influence between the support of wife to the use of family planning. The results of analysis using simple logistic test showed that there is no significant influence between culture on male family usage.

Thus, based on bivariate analysis using simple logistic regression test, age variable and wife support have p value <0.25 so it can be include in multivariate analysis model and conducted by multiple logistic regression test with “enter” method.

Multivariate Analysis Results

Based on the results of multiple logistic regression test showed that risk factors influencing the use of contraceptive in men in Padang Hulu sub-district of Tebing Tinggi after being adjusted with other variables were p = 0.034, OR = 2.384 95% CI (1.068-5.320), wife support p = 0.042; OR = 2.428 95% CI (1.033-5.708).

Results and Discussion

The Relationship Between Age and Contraceptive Use in Men

The result bivariate analysis shows that there is significant influence between age with the use of family planning in men with p value = 0.014. The result of multivariate analysis also showed that age had significant effect on male KB use p = 0.034; OR = 2.384 95% CI 1.068-5.320. This means that men > 40 years old are 2.3 times more likely than men to use vasectomy contraception compared with men aged ≤ 40 years. Age can affects the one’s psychic, young age often cause tension, confusion, anxiety and fear that can affect one’s behavior\textsuperscript{11}. The results of this study is in line with the previous research that there is a specific relationship between age and men’s participant in family planning\textsuperscript{12}. The results is also accordance with the research conducted by\textsuperscript{13} showing the significant relationship between respondent’s age and their participants in family planning.

The Relationship Between Education with The Contraceptive Use in Men

Based on the results of simple logistic regression, that there is no influence between education on contraceptive use in men. This is evidenced from the calculation of simple logistic regression test can be seen
that the value \( p = 0.999 \) which means greater than \( \alpha = 0.05 \), then \( H_o \) accepted.

Conforming to Nurliana & Subiyatun\(^4\) states that there is no relationship between husband education with the use of contraceptives in the hamlet Tekik Bangunharjo Bangunkerto Turi Sleman, which proved the value with the value \( p = 0.185 \) (\( p > 0.05 \)). In contrast to research indicating that of 291 husbands in Sumber Agung Jetis Bantul, most husbands were educated at junior high school 150 (51.5%), and the least husband who had high education was 14 (0.5%). From the results of analysis it can be said most of the husband educated junior high. The results of this study revealed there is an influence between educational factors on the use of male contraceptive methods\(^5\).

Less educated people will be more likely to respond new ideas with emotion. Because the new things might be shock the people or change what they have done in the past. The level of education not only affects the willingness to use family planning, but also the selection of a method.

The Relationship Between Knowledge with The Contraceptive Use in Men

Based on the results of simple logistic regression test, that there is no influence between knowledge on contraceptive use in men. This is evidenced from the calculation of simple logistic regression test can be seen that the value \( p = 1.000 \) which means greater than \( \alpha = 0.05 \), then \( H_o \) accepted.

Knowledge and attitude associated with husband’s participation in family planning, husbands’ knowledge about family planning can be influenced by geography location, the respondents live closer to the city has the better knowledge about family planning than that of respondents who live in the village, because the geography location close to the city can facilitate more information about family planning to society\(^6\).

The Relationship Between Knowledge with The Contraceptive Use in Men

Based on the results of simple logistic regression analysis, there is no influence between the availability of male family planning services to the use of contraception in men. This is revealed from the calculation of simple logistic regression test can be seen that the value \( p = 0.650 \) which means greater than \( \alpha = 0.05 \), then \( H_o \) accepted.

This results of this study is contradict with previous research states, that factors that cause male family planning participation in various areas tend to be low are: First, information access is very limited. Men’s knowledge of contraception, such as type, side effects, effectiveness, mode of use, where to get contraceptives, benefits and others is still very low. Second, access to services is still limited\(^7\).

In accordance with the situation in the District of Padang Hulu Kota Tebing Tinggi, it was found that there was no relationship between the availability of male contraceptive services with the use of contraception in men. Although this study was not statistically significant but in terms of OR values, the availability of male family planning services has a tendency of 1.526 times to affect men in using contraception.

The Relationship Between Wife Support with Contraceptive Use in Men

Based on the results of simple logistic regression, there is a relationship between the wife support with the use of contraception in men. It is revealed from the result of simple logistic regression test with the value \( p = 0.017 \) which means smaller than \( \alpha = 0.05 \), then \( H_a \) is accepted. The result of multivariate analysis was dominant influential factor which showed that wife support had significant effect on contraception use in men \( p = 0.042; \) OR = 2.428 95% CI 1.033-5.709 This means that men who get wife support 2.4 times more the estimate of men willing to use vasectomy contraception in men than men who do not have the support of the wife.

This is conforming to previous research stated, that the support of wife to the contraception use is a positive attribute of the wife to family planning, if couples have a positive attitude toward family planning then they tend to use contraception. Other research also stated that there is a relationship between the support of the wife and the participation of the husband in the family planning program\(^8\).

The Relationship Between Culture with Contraceptive Use in Men

Based on the results of simple logistic regression test, there is no influence between the culture on the use of contraception in men. This is revealed from the simple logistic regression test showed that the value \( p = 0.855 \)
which means greater than $\alpha = 0.05$, then $H_0$ is accepted.

A study states that, there is no socio-cultural relation on family planning men’s acceptor with men’s participation in family planning\(^{14}\). In some studies, cultural standards are identified as barriers to male involvement in participating family planning programs. All respondents believe that the reasons for involving men in family planning programs include that men play a dominant role in family decision-making. Another reason expressed by the majority of participants is that men are the head of the family and give much influence to women’s decisions\(^{20-22}\). Men often assume that family planning services are designed and provided for women, so men are embarrassed to join the family planning program.

In contrast to other research, which states that respondents who are positive social culture as much as 86% participate actively in the vasectomy program\(^{21}\). This is different from the situation in Padang Hulu Subdistrict, Tebing Tinggi in 2018, found that there is no connection between culture and contraceptive use in men. Although this study was not statistically significant but in terms of OR values, cultures had a tendency of 0.935 times to influence men in using contraception.

**Conclusion**

Based on the results of research on the use of factors that affect the use of male Family Planning in Padang Hulu District Tebing Tinggi in 2018, the conclusions are stated as follows:

There is an effect between age, education, knowledge, cultural, on the use of family planning, then the availability of male contraceptive service on male family planning use as well. However, There is an effect of wife support on the use of family planning Based on multivariate test results, the dominant variable affecting the use of male KB is the support of the wife

Efficacy of Topical Cream of Garlic Extract (Allium Sativum) on Wound Healing in Experimental Mice using Aa Acute Wound Modeling: Determination of Expresión of Tumor Necrotic Factor (TNF-α)

Zaenal1, Rini Mustamin2, Rusli Taher3, Anwar Mallongi4

1Islam Makassar University, Makassar, South Sulawesi Province, Indonesia, 2Nusantara Jaya School of Health Sciences, Makassar, South Sulawesi Province, Indonesia, 3Graha Edukasi School of Health Sciences, Makassar, South Sulawesi Province, Indonesia, 4Department of Environmental Health, Faculty of Public Health, Hasanuddin University, South Sulawesi Province, Indonesia

Abstract

Garlic (Allium sativum) is one of the ethnomedicinal plants used by people in the tropical region. Its bulb is commonly utilized as traditional medicine for wound healing, particularly in the developing world. This study analyzed the efficacy of topical cream of garlic extract (Allium sativum) on the expression of tumor necrotic factor (TNF-α) and wound closure as the parameters of wound healing in the experimental mice using an acute wound modeling. The research design was a randomized post test control group design. The study was conducted at 4 laboratories, i.e., Biofarmaka Laboratory at the Center for Health Education Research at the Hasanuddin University for the preparation of topical cream of garlic bulb extract, Animal Laboratory of the Medicine Faculty of the Hasanuddin University for the care and treatment of the experimental mice, Histopathology Laboratory of the Research Center for Veterinary Sciences in Maros for the preparation of histopatological slides. A total of mice were 54 mice (Rattus novergicus) of wistar strain by making circular excision wound on dorsal with the diameter of 8 mm using punct biopsy. The experimental mice were divided into 3 groups that include the negative control group by treating 0.9 % NaCl, the positive control group by treating 3 % oxytetracycline and the treatment group by treating 10% topical cream of garlic extract. Wound tissues of mice were microscopically observed on day 3, day 7 and day 14 respectively. Results of the study proved that wound healing by using topical cream of garlic extract (Allium sativum) showed the highest effect in reducing the expression of tumor necrotic factor (TNF-α) and the lowest diameter of wound in the experimental mice compared to the control groups.

Keywords: Garlic, TNF-α, wound healing.

Introduction

In view of the modern concept, wound healing involves dynamic reciprocity between cytokines, cells, and the extracellular matrix during four overlapping phases. In cellular phase, wound healing process involves several types of cells working together to mount an inflammatory response, synthesize granulation tissue, and restore the epithelial layer. The second phase, the inflammatory phase, is characterized by the infiltration of inflammatory cells that secrete cytokines and growth factors, while assisting in the removal of apoptotic cells and debris. The third phase, the proliferative phase, involves the stage of tissue regeneration that is initiated in response to stimulatory factors initially produced during the inflammatory phase. Angiogenesis is central to wound healing and involves the growth of new capillary blood vessels. Finally, the remodeling phase encompasses the regression of capillaries, the reorganization of the extracellular matrix, and further
maturation of the tissue that ensures the structural and mechanical stability of the dermoepidermal junction\textsuperscript{3}.

Until 21st century, the prevalence and impact of wounds are likely to increase due to the growing epidemic of noncommunicable diseases and longer life expectancy. As indicated in a survey of the MedMarket Diligence in 2013, the estimated prevalence rates based on the wound categories worldwide in ascending order were surgical wounds (114,271 cases), traumatic wounds (1,627 cases), laceration wounds (20,645 cases), burn wounds (10,221 cases), chronic wounds (40,400 cases), carcinoma wounds (618 cases), melanoma wounds (103 cases), and skin cancer wounds (103 cases) consecutively.

In view of the national level in the developing world, the survey data derived from the National Basic Health Research\textsuperscript{4} reported that the proportions of types of wounds in Indonesia were dominated by bruised/chafed wounds (70.9\%), and it was followed by sprained wounds (27.5\%) and tear wounds (23.2\%). Viewed in terms of gender, 70.6\% wounds were observed in male and 71.2\% wounds were found in female, whereas, 26.6\% tear wounds were found in male and 17.8\% were observed for female respectively.

Based on the problem background as stated above, this study aims to inquire about the efficacy of garlic extract (\textit{Allium sativum}) on wound healing in experimental mice using an acute wound modeling for developing this ethnomedicinal plant.

Materials and Method

Location of the study

This study was conducted at 4 laboratories, i.e., Biofarmaka Laboratory at the Research Health Center of the Hasanuddin University for the preparation of topical cream of garlic extract, Animal Laboratory of the Medicine Faculty of the Hasanuddin University for the care and treatment of the experimental mice, Histopathology Laboratory of the Center for Veterinary Sciences in Maros for the preparation of histopathological slides.

Samples and animal care

The mice were caged in groups with free access to laboratory pellets and tap water and maintained under standard conditions (12/12 h light-dark cycle, and ambient temperature 22 ± 1 °C). All animals used in this study were cared for and treated humanely according to the Principles of Laboratory Animal Care\textsuperscript{5}. Ethical clearance for the treatment of the experimental animals were reviewed and approved by the Medicine Research Ethics Committee of the Medicine Faculty of the Hasanuddin University as stated in the Recommendation Letter of Research Ethics issued in the registration number: 2264/H4.8.4.5.31/PP36-KOMETIK/2015.

Preparation of garlic extraction

10\% garlic extract was prepared in this study. Samples of garlic bulbs were chopped into small pieces, and then they were let stand for a while until dry. Afterward, dried bulbs were crushed by using a blender until formed refined garlic bulbs and they were then added with 70\% ethanol solvent. Sonification was done to the mixture for 1 hour and it was then filtered. After the evaporation of the solvent, the extracted remaining materials were freeze-dried until formed the extract powder of garlic\textsuperscript{6}.

Preparation of topical cream

Procedure for the preparation of topical cream referred to the study of Bergtorm & Strobotter\textsuperscript{7}. The steps of topical cream procedure are described below.

Weighing the following materials

<table>
<thead>
<tr>
<th>Materials</th>
<th>Weight (g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stearic acid</td>
<td>1.5</td>
</tr>
<tr>
<td>Cetyl alcohol</td>
<td>2</td>

</tr>
</tbody>
</table>

Preparation of cream base

The materials used to prepare cream base including stearic acid, cetyl alcohol, and stearyl alcohol as well as propyl paraben. These materials were weighted and then they were mixed and heated up to 70°C (oil phase). Glycerin, propylene glycol, MP, and water were heated up to 70°C (liquid phase).
Oil phase and liquid phase were mixed together and heated up to 70°C while stirring the mixture by using the homogenizer until the mixture achieved reduction of heat up to 40°C. The mixture was then added with the novomer and α-tokoferol until formed cream base.

**Determination of tumor necrotic factor-α (TNF-α)**

Determination of tumor necrotic factor-α (TNF-α) was conducted at the Center for Health Education Research at the Hasanuddin University.

**Materials and Instruments for the determination of tumor necrotic factor (TNF-α)**

Materials and laboratory instruments used in this study including laboratory cloths, goggles, protective mask, gloves, micro pipette, Eppendorf, multichannel pipette, Bio-Rad, microplate reader 680, Bio-Rad, Maxi mix II, Thermolyne, Incubator, Memmert, Elisa Kit, human TNF-α (tumor necrosis factor alpha) ELISA kit, Elabscience, Pipet tip 10 µL, 100 µL, 1000 µL, distilled water (ddH₂O), reagent reservoir, test tubes of 1.5 mL, 15 mL and 50 mL.

**Procedure of acute excision wound model**

Each mouse was put into the anesthetizing box and it was anesthetized with ether solution with a dose of 0.5-1.0 cc by inhalation. After then, the dorsal area of each mouse was aseptically cleaned with hair removal cream (Veet). Subsequently, disinfection was done with 0.5% chlorhexidine in 70% alcohol. Acute injury was made with wound diameter of 0.8 cm (8 mm) by excision at the left and right bilateral areas of the dorsal.

**Measurement of wound area**

The wound area was measured by immediately placing a sheet of transparent paper over the wound and tracing its perimeter; the area of this impression was calculated using graph paper and a ruler in mm dimension. Observation of experimental mice after incision was conducted on day 4, 7 and 14 respectively.

**Design of the study**

This study was a purely experimental design by using randomized post test control group using mice of Wistar strain as the study samples. A total of samples were 54 mice divided into 3 experimental groups that include the negative control group, the positive control group and the treatment group. The negative control group was treated with 10% NaCl (placebo).

**Statistical analysis**

The experimental results were expressed as mean ± standard error, and analysis was done using SPSS version 20. Statistical correlations among three groups of mice were analyzed with Spearman’s correlation test. Statistically significant test was carried out by means of one-way analysis of variance (ANOVA) in which p < 0.05 was statistically considered significant.

**Results**

1. **Expression of tumor necrotic factor (TNF-α)**

Results of one-way Anova test in the negative control group showed that the expression of TNF-α showed statistically significant correlations on day 3 until day 14 (p: 0.058), whereas, the positive control group did not show statistically significant correlations in the 10% garlic topical cream group on day 3 until day 14 (p: 0.001) and day 7 until day 14 (p: 0.007). Results of Spearman’s correlation test showed that the expression of TNF-α was statistically significant correlations among all the mice groups, the negative control group (p: 0.048 and r: -0.682), the positive control group (p: 0.007 and r: -0.876) and the 10% garlic topical cream group (p: 0.002 and r: -0.779) respectively. Based on a two-way correlation, all experimental groups showed negative orientation of correlation. This means that the expression of TNF-α gradually reduced along with longer day in the process of wound healing. Spearman’s correlation test was highest in the positive group and the treatment group of garlic extract, whereas it was lowest in the negative control group.
2. Wound diameter

Results of one-way Anova test indicated that wound diameter in the negative control group showed statistically significant difference on day 3 until day 14 (p: 0.028) and day 3 until day 7 (p: 0.045). The positive control group showed statistically significant difference on day 3 until day 14 (p: 0.000) and day 7 until day 14 (p: 0.005) and day 3 until day 7 (p: 0.003) as well as in the 10% garlic topical cream group on day 3 until day 14 (p: 0.001) and day 7 until day 14 (p: 0.009). Results of Spearman’s correlation test in wound diameter showed statistically significant difference among the three groups that include the negative control group (p: 0.032 dan r: -0.506), the positive control group (p: 0.000 and r: -0.876) and the 10% garlic topical cream group (p: 0.000 and r: -0.779) based on the analysis of values of Spearman’s correlation test in which the highest value was observed in the positive control group and the lowest value was in the negative control group.
Table 1. Correlation between the expression of TNF-α and wound diameter.

<table>
<thead>
<tr>
<th>Groups</th>
<th>Day 3, 7 and 14</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>p</td>

</tr>
</tbody>
</table>

As shown in Table 1, results of correlation between the expression of TNF-α and fibroblast showed statistically significant correlation in the 10 % garlic topical cream group (TNF-α with wound diameter at p: 0.004).

Discussion

The effect of garlic topical cream on the expression of tumor necrotic factor (TNF-α)

Mean value of the expression of TNF-α for all the three groups showed the same pattern in which its expression decreased along with longer days on day 3, day 7 and day 14. This is in line with previous studies concerning the application of garlic ethanol topical cream that could accelerate wound healing process as antibacterial and anti-inflammatory reaction.

Inflammation is an initial reaction when the body is injured. This phase immediately occurs after injury and it may last up to 4-6 days. TNF-α is a sign of inflammation in the process of tissue restoration. Previous studies showed significant association between TNF-α and wound healing process. The decrease of TNF-α level indicates the inflammatory control and adequate process in wound healing. TNF-α stimulates synthesis of MMPs. High level of proteases in wounded areas lead to degradation of protein matrices and growth factor as the significant factors in wound healing process. In addition, TNF-α suppress tissue growth factor-β (TGF-β) in which TGF-β induces proliferation of myofibroblast to form essential proteins in reorganization of extracellular matrices such as α-smooth muscle actin (α-SMA), collagen type 1A, and fibronectin.

As reported in the study of Nagori et al., wound infection is the barrier of wound healing. The most important organisms including Staphylococcus aureus, Streptococcus pyogenes, Corynebacterium sp, Escherichia coli and Pseudomonas aeruginosa. Garlic bulb is an anti-mikrobial agent. It has capability in inhibiting growth of microbes, including viruses, bacteria, protozoa, and fungi.

In a study conducted by Nidadavolu, garlic ointment inhibits biofilm formation by bacterial pathogens from burn wounds. When thermal injury damages the skin, the physical barrier protecting underlying tissues from invading microorganisms is compromised and the host’s immune system becomes suppressed, facilitating colonization and infection of burn wounds with microorganisms. At a wounded area, bacteria often develop biofilms, which protect the bacteria from the immune response and enhance their resistance to antibiotics. Their study utilized the in-vitro wound biofilm model to examine the antibiofilm activity of garlic (Allium sativum).

The effect of garlic extract topical cream on the reduction of wound diameter

Mean value of wound diameter among the three groups showed similar pattern in which its expression decreased along with longer days on day 3, day 7 and day 14. Wound diameter was lowest on day 3 in the negative control group (3.8333 ± 1.16905) and was highest in the positive control group (5.3333 ± 1.03280), whereas, the highest diameter of wound was observed in the 10% garlic ethanol topical cream on day 7 (3.6667 ± 1.50555) and was lowest on day 14 (3.0 ± 0.63) in the 10% garlic ethanol topical cream (1.1667 ± 0.75277).

All previous studies as stated above are consistent with our study results concerning the efficacy of garlic extract (Allium sativum) on wound healing in experimental mice using an acute wound modeling for developing this ethnomedicinal plant.

Conclusions

Garlic (Allium sativum) extract topical cream with 10% concentration has better effect in wound healing compared to the control groups and showed the lowest level of tumor necrotic factor (TNF-α) and the lowest wound diameter compared to the control groups.

Structural Intervention Problematic of Condom Usage in Makassar City, Sulawesi Selatan Indonesia

Hairuddin K
Universitas of Megarezky, Makassar Indonesia

Abstract

The issue of the larger risk of sexually transmitted infections (STIs) requires all stakeholders of health development to work together to reduce the risk of STIs. This research focuses on regulation problematic of condoms usage in Makassar city. It used qualitative research method. This research found that the problem of regulation was in determinants of lack of community leaders’ knowledge that have strong political influence so that there was hesitation among decision makers. As the result, the effectiveness of community protection programs against the high risk of unhealthy sex did not run as it should be. Practical condom usage programs should be backed up by strong regulations, They finally were only personal alertness both the level of sexually transmitted workers and their customers.

Keywords: Advocacy, STIs, Commercial Sex Workers

Introduction

The spread of sexually transmitted diseases (STIs) is a consequence of sexual behavior problem Sharma and Nam1, Lack of awareness and knowledge of healthy sex2-4, sexual intercourse before marriage, Muula5, Patriarchal system by Cain D. et al6, and social stigma of condom usage7. Various Determinants show that the awareness of healthy sex is very complex. However, some researchers have not yet explained the influence of the determinants of political consequences for making regulation which can basically make healthy sex programs with condom usage in effective prostitution areas. Regulation that support the effectiveness of condom usage can protect society from the risk of transmission of sexually transmitted infections (STIs)

The Directorate General of P2P Ministry of Health of the Republic of Indonesia 2018 (2018: 139) stated that: There has been an increase of the new numbers of HIV cases in 2015 to 2017. There were 30,935 people infected with HIV in 2015 and there was an increase of 33,660 people in 2017. While there were 700 people in 2015 to 1,089 people in 2017 in South Sulawesi as sufferers. In 2017 AIDS cases amounted to 4,555 cases in Indonesia which can be specified as follows: causing of injection as many as 109 cases. AIDS cases amounted to 220 people and syringe cases were only 6 cases in South Sulawesi. This fact shows that the etiology of AIDS due to unhealthy sex is 4,445 for the national scale and 214 for South Sulawesi region. Etiology of unhealthy sex is awareness in using condoms8-13.

This fact shows that etiology is due to a lack of awareness of condoms usage. Therefore, it is needed a preventive action to change the people’s mindset about healthy sex through the use of condoms, especially they work as commercial sex workers.

Materials and Method

The type of research used qualitative research to obtain information about government advocacy on condom usage in CSWs in preventing STIs cases in Makassar City. This research described the commercial sex workers’ level of understanding and behavior with other related parties. Data sources were not only from female sex workers (WPS) but also from government parties. Data were collected by conducting in-depth interviews.

Results and Discussion

The result of this research elaborated data from informants who were in the field of STIs prevention, several figures from agencies engaged in health sector and supported by government institutions as policy
makers both of executive and legislative. Whereas the commercial sex workers (CSWs) themselves are workers who serve a lot and have profession as sex workers.

The fact in the field indicated that the problem of condom usage was not only due to lack of knowledge and weak supervision from government but there were problems with policy interventions so that program accentuation was not running optimally. As a result, the quantity of cases of sexually transmitted infections was still worrying. As the results of the following interview:

**It is true what was said by the health office, that the report provided was a fact, and even the latest data showed that it had risen to 214 sufferers in addition to injecting drug cases or IDUs that were also incomplete using the right condom "**(AIA’s statement)**

The AIA’s statement showed that the similarity of the etiology of STIs with data from the Directorate General of the P2P Ministry of Health in 2018 which confirmed these two determinants. Where from 214 cases, the etiology due to injecting drug cases was only the remaining 6 cases due to the problem of condom usage.

The facts above are strengthened by the testimony of informants who were engaged in community empowerment, especially public health. Informant Ail explained his activities to find solution to the problem of condom usage so that the risk of the spread of STIs did not increase.:

**“If the system that we apply here, there was a program that carried out in the field with outrising systems or outreach in the immediate field, then outreach in some locations where we conduct monthly discussion activities” (to do interview with Ail)**

The activities of non-government organizations (NGOs) showed that they fill in the actual space if it was implemented by government through regulations, so the problem of condom usage could be solved. They provided continuous assistance. Based on the results of the research we conducted that all provide assistance for HIV cases, because the program was done every day. Most of them worked with government institutions that directly deal with public health problems. dSw, as an informant, explained:

**“Usually we are together with NGOs specifically for CSWs; we do have NGOs friends to collaborate with Community Health Centre ‘Puskesmas’ (dSw as informant).**

The fact in the field indicated that health and medical interventions were the most commonly found with the aim of getting an overview of the incidence and prevalence of STIs and HIV / AIDS among certain communities while also observing patterns of trends and factors affecting the AIDS epidemic. In sex workers who are at risk for the program carried out by offering, if workers want to be tested it will be linked to a VCT clinic for testing. In particular the counselling process can be done after or post test to see if he is positively affected or not, counselling is still done. If it is found to be positive, the counselling is how he lives with PLWHA. This is as expressed by one NGO informant who has long worked as a companion for PLHIV in Kra AIDS South Sulawesi, Zla, that:

**“If it was stated positive by the laboratory, he was said to have positive false and he was negative said negative, so he was directed to use condoms (Zla’s statement).**

Based on the research conducted that has been carried out planning by partnering with the government by creating Pokja, with the aim of being based on the segmentation of potential areas of transmission. This segmentation is based on targets that were carried out previously even though there were new ones. The target of the working group (Pokja) is nightclubs, even though there is no prostitution, but there are behaviors that result in HIV / AIDS, as revealed by one of the informants from an NGO in the city of Makassar, that...... so we partnered with the government by creating a working group, our target is THM even though they did not say there was prostitution but there was risky behavior ...... (Zla’s statement).

But the structural intervention problematic is actually an additional obstacle to intervention that will make the condom usage program much more effective. There are problems of religious and anthropological conceptions found in the following information from informants:

**We did it, it was secretly not to be loose in public places, to avoid friction with cultural figures and religious leaders, so that if it is used only to get condoms,**
but if it really required, then there was a silent program (just silent). .......... (Zia’s Statement)

So there are religious and anthropological problems especially in social construction of condoms which causes entrusted politicians to make policies not to complete their duty. Fear of religious risk for condoms usage policy interventions is expressed by a legislator as follows:

“Actually, I really disagree with giving condoms, it’s called a solution to encourage people to commit adultery ...” (AdS’s Statement).

These non-technical issues cause structural intervention of policy making to solve the problem of condom usage un running optimally. The result is felt directly by them that actively promoting sexual health. There is no feeling of government support such as our interview with policy informants stated that ...... there is no regional regulations... “(AHi’s Statement).

Regarding condom usage, the government of Makassar city has not dared to provide a guarantee for the implementation of the policy. The reason cannot be, it is still constrained by the problem of the unpreparedness of the religious parties and people who still do not fully understand the condoms. As the result of our interview that:

“I didn’t want to talk about condoms, later NGOs. Did You know that what troubled condoms are”(AHi’s Statement)

The variety of obstacles cause of disparity between the appeal of the decision maker (government) and its implementation at the grassroots level (commercial sex workers). Based on the result of our interview with one of the CSWs that:

“As long as I became a sex worker, I had never heard of it. The government came to tell us. We usually used it to avoid illness”(Era’s Statement).

Personally, sex workers had already known about unprotected sex or sexual intercourse without condoms usage. Regulations that are expected to provide legal guarantees for the provision of ‘ATM’ Condoms or Condom Vending Machine in nightclubs are not prepared. This means that awareness programs on condom usage are more emphasized in personal awareness. Warner L, Newman DR, Kamb ML, et al in The Society for Adolescent Health and Medicine\textsuperscript{17} stated

: “The effectiveness of condoms for prevention of non viral STIs, especially gonorrhea and Chlamydia, is well-documented. A multisite prospective study found no incident infections with consistent and correct condom use”.

In a personal perspective, awareness of sex workers has been formed. But there are problems structurally. The effort to eliminate misunderstanding about healthy sex programs, especially condom usage, it is still being carried out by the aim of community leaders. Dsw, that:

“But we have worked together with AIDS Prevention Commission #KPA of City to provide understanding to the MUI, that condoms are not to justify protection, but it suppresses HIV/AIDS, there has been clear for that now” (Dsw’s statement)

The phenomenon above can be described in the flowchart of awareness of condom usage, according to Coombes et. Al (2017: 10)\textsuperscript{18} can be described as follows:

Looking at the fact of the research, the main problem of structural intervention was in absence of policies that are considered to accelerate the collective awareness of widespread condom usage. Policy makers still awkwardly maximize the program by intervening in a legal basis for the procurement of Condom Vending Machine or condoms ‘ATM’. The lack of maximum effort to make regulations has resulted in not being able to maximize funding to support every program both government and private sector or NGOs. In the end, market development condoms and market management condoms are not integrated.

Conclusion

The structural intervention problematic in this research is the reluctance or fear of policy makers to make regulations that are considered to maximize the effectiveness of condom usage and to cause widespread collective awareness of the importance of condoms. The determinant is misunderstanding of some community leaders both religiously and anthropologically.

Antenatal Care Documentation Information System Integrated with Web-based Government Employed Midwife Performance Index (Seindah Lutra)

Elviana Datulinggi¹, Ansar Suyuti², Mardiana Ahmad³, Syarifuddin Syarif⁴, Samrichard⁵, Azniah Syam⁶
¹Midwifery Study Program, Post Graduate School Hasanuddin, University Makassar, ²Faculty of Electrical Engineering Hasanuddin University Makassar, ³Midwifery Study Program, Post Graduate School Hasanuddin University Makassar, ⁴Faculty of Electrical Engineering Hasanuddin Engineering Makassar, ⁵Pelamonia Hospital Makassar, ⁶Nani Hasanuddin Health College

Abstract

Introduction: One of the reasons behind the difficulty to analyze Antenatal Care is the weakness of its documentation. To address this drawback, one of the methods is by designing an adopted antenatal documentation information system with web-based credit assessment for the midwives.

Method: Antenatal care documentation information system integrated with web-based government employed midwife performance index (Seindah Lutra) Design with System Development Life Cycle (SDLC) method. The prototype of Seindah Lutra is designed by using Php MyAdmin, MySQL data base and Apache web server.

The output is in the form antenatal patients database, midwives’ work shift recap, electronic antenatal documentation (subjective data, objective data, case analysis, management cases : physiologic, problematic physiology, pathology, pathology with accompanying illness, urgency )of with the recap of midwives’ credit point for performance index, valid and ready-to-use antenatal performance report and monthly antenatal report which is directly linked with the superior. The system validation of this research involves some experts in midwifery documentation, midwife’s credit rate for performance index, obstetritian and gineocologist, and information technology system. The system reliability test was conducted in a Community Health centers in Masamba sub-district, North Luwu district for a month using measuring test method. The system reliability test used the alpha cronbach with the score $r_{ii} = 0.776$, the strong reliability of the coefficient.

Conclusion: Seindah Lutra created antenatal database which is complete and continuous, with prompt access and clear performance assessment for the midwives, precise and measured value for the policy maker to analyze in order to improve the quality of antenatal care to reduce the risk of stillbirths and pregnancy complications and give women a positive pregnancy experience

Keywords: Information System, Antenatal Documentation, Midwife performance index

Introduction

The documentation of antenatal assessment is still deemed as too weak that it is difficult to analyze for the improvement of antenatal care (1). The Antenatal Documentation at public clinics is still carried out manually (paper-based), resulting in data redundancy,
low data completion, reading difficulties, weak accessability and inconsistency in the accuracy of the data information, time consuming risk screening, and inaccurate data analysis which caused slow pregnancy management \(^2,3\).

Due to post-workshift exhaustion, lack of energy, unstandardized documentation, lack of format, the midwives’ demeanor and overlapping job caused the midwives’ inability to carry out the documentation well \(^4,5\). Despite this shortcoming, midwives had sufficient knowledge on midwifery documentation. However, implementing punishment to the midwives who failed to do the documentation process is suggested \(^6\) to address said process’ poor practice because the accuracy of the documentation determines the service quality in assessing and evaluating the medical condition of the pregnancy and the next childbirth \(^7,8,9\). Antenatal care documentation is also used to assess the performance of the midwifes with the status of civil servant \(^10\). It is still currently difficult for midwives to prove their credit point and the process could take a lot of time and may result in inaccurate value for performance index \(^11,12\), thus the necessity to design an information system which is efficient in term of time, budget and energy to solve the documentation issues \(^2,3,13-16\).

By integrating midwifery documentation with credit point in an information system for **government employed midwife performance index**, a complete, comprehensive, and well-measured data base with quick and continuous access among the medical practitioners throughout the villages, local public clinics and policy makers will be created through monitoring and evaluation in order to improve the quality antenatal care.

**Resources and Method**

The antenatal care documentation information system integrated with web-based government employed midwife performance index (Seindah Lutra) design uses System Development Life Cycle (SDLC) method with the stages of problem identification, opportunity and direction analysis, determining the necessity analysis, designing recommended system, one-month system trial at the a Community Health centers in Masamba sub- district, district North Luwu. The system includes hardwares such as laptops with internet connection, as well as softwares such as browser, Apache web server, data base with MySQL, PhP MyAdmin as Graphic User Interface.

**Result**

**Designing information system**

SEINDAH LUTRA is a web-based information system designed as antenatal electronic documentation which usage includes assessing the performance of the midwifes in the line of antenatal care.

1. **Initial Menu Interface**

![Figure 1. Star Page design (Seindah Lutra’s Home)](image)

The initial menu interface (Figure 2) shows the system logo which is the web address (www.bidannetd.unhas.ac.id), log-in with username and password, and menu option.
3. Antenatal Patients Data Base and Documentation
The patient data base shows the medical record number of the patients who have done the antenatal check-up. This menu shows the Antenatal documentation which includes input questions for subjective data; objective data which includes the physical (head-to-toe) and laboratory check-up and will detect the check-up result if there are any abnormalities. Documentation analysis: this system provides assistance in analyzing 10 items of diagnosis enforcement. In the next check-up, midwives will choose the case in which the result is included (physiologic, problematic physiology, pathology, pathology with accompanying illness, urgency). Management: The menu shows the management based on the case chosen by the midwives, completed with informed consent menu dan referral letter. This electronic documentation is based on the flow of antenatal care and the authority of the midwife. (1, 10, 17-26).

Antenatal Care Monthly Check-up and Performance Recap Daily and monthly per-patient credit point Report
The antenatal monthly report as shown in Figure 4 shows the recapitulation of antenatal check-up in Community Health centers of Masamba sub-district, Luwu Utara district. The items of the report includes the number of Antenatal visits with the type of physiologic case, problematic physiology, pathology, pathology with accompanying illness, urgency, contacts with a health provider access, Remidal contact on the second and third trimesters, body mass index (BMI) with classification, mean arteri pressure (MAP), Roll Over Test (ROT), number of patients with HIV/AIDS, malaria, anemia, sexually transmitted infections case, hepatitis, protein and sugar (+), Grievances information, education, communication, Informed Consent, medical delivery letter. This recap will be checked at the end of the month to show the result of antenatal check-up.

The system points out the details of the credit rate per patient which is showing the details of the credit rate per patient, perday, and per month based on cases rate and the position owned by the midwife. Each treatment and nurture given to the patients are counted by the system. At the end of the month, the midwife will print the recap of the credit rate as the proof of the working performance of antenatal care. This system proves that the midwife performance is tangible, clear, and measurable. (10,20).

The system validation

The system validation of this research involves some experts in midwifery documentation, midwife’s credit rate for performance index, obstetrician and ginecologist, and information technology system.

The system reliability

The system reliability test was conducted in a Community Health centers in Masamba sub-district, North Luwu district for a month using measuring test method. The system reliability test used the alpha cronbach with the score $r_{ii} = 0.776$, the strong reliability of the coefficient ($\pm 0.60 - \pm 0.799$)

Conclusion and Suggestion

Antenatal care documentation information system integrated with web-based government employed midwife performance index (Seindah Lutra) is designed to: 1) produce the source of information about the complete health record data of the pregnant women quickly and continuously 2). Be used by the midwives and the policy makers to analyze the problems and make the decision in order to improve the quality of antenatal care to reduce the risk of stillbirths and pregnancy complications and give women a positive pregnancy experience 3). Evaluate and monitor antenatal care and the government employed midwife performance index.
which is tangible, clear, and measurable.

It is highly suggested that antenatal care documentation information system integrated with web-based government employed midwife performance index (Seindah Lutra) should be tried in a broader area.

Correlation of HbsAg, HBeAg and HBV DNA Viral Load in Chronic Hepatitis B Patients

Asvin Nurulita¹, Uleng Bahrun¹, Umi Intansari², Budi Mulyono²
¹Department of Clinical Pathology, Medical Faculty, Hasanuddin University, Wahidin Sudirohusodo Hospital, Makassar; ²Department of Clinical Pathology, Medical Faculty, Gadjah Mada University, Sardjito Hospital, Yogyakarta

Abstract

Introduction: The high incidence of Hepatitis B infection worldwide causes this to be a universal problem. Diagnosis and monitoring of HBV infection therapy currently uses HBsAg, HBeAg, anti HBe, anti HBc and HBV Viral Load tests. Limitations of the tools and costs of HBV DNA Viral load test causes monitoring of patients with chronic HBV infection is difficult. This study aims to look at the correlation between HBsAg, HBeAg and HBV DNA Viral Load in patients with Chronic Hepatitis B.

Method: Chronic Hepatitis B patients who meet the criteria consisted of 232 samples. HBsAg, HBeAg, anti HBe, and HBV DNA Viral Load data were analyzed using the Spearman's Correlation Test and Chi Square Test. There is a significant correlation and relationship if the test p value is <0.05.

Results and Discussion: Correlation test results showed a significant positive correlation between HBsAg and HBeAg against HBV DNA, with a role of 28.8% and 60% respectively. There is a significant relationship between HBsAg and HBeAg with HBV DNA. The percentage of subjects with high HBV DNA was found to be higher in subjects with HBsAg and HBeAg who were also higher than in subjects with low HBsAg, HBeAg and anti HBe.

Conclusion and Suggestion: In this study, it is concluded that there is a significant positive correlation between HbsAg and HBeAg with HBV Viral Load. HBeAg has the greatest role in HBV DNA.

Keywords: Chronic Hepatitis B, HBsAg, HBeAg, HBV Viral Load.

Introduction

The Hepatitis B virus (HBV) is a universal health problem, estimated at 240 million people have been infected worldwide. The highest endemicity rates in countries with HBV carriers (East Asia, sub-Saharan Africa and the Amazon basin) are around 8%, then East European countries 2 to 8% and West European and North American countries < 2%.¹²

Basic Health Research Results in 2007 showed that clinical hepatitis was detected in all provinces in Indonesia with a prevalence of 0.6% (range: 0.2% - 1.9%). The prevalence of hepatitis in 2013 (1.2%) was twice as high as in 2007. Five provinces with the highest prevalence of hepatitis were East Nusa Tenggara, Papua, South Sulawesi, Central Sulawesi, and Maluku. The highest percentage of hepatitis B in the age group 45-49 years (11.92%), age >60 years (10.57%) and age 10-14 years (10.02%), then HBsAg positive in the male and female groups almost same (9.7% and 9.3%). This shows that 1 in 10 of Indonesia’s population has been infected with the Hepatitis B virus.³

Diagnosis of HBV infection now uses serological marker examination and HBV DNA Viral Load. Detection of Hepatitis B surface antigen (HBsAg), Hepatitis B envelope antigen (HBeAg) and anti Hepatitis B core (anti HBe) is the initial foundation of diagnosis of chronic HBV infection, followed by HBV DNA Viral load examination for diagnosis and monitoring of therapy.⁴ HBV DNA Viral Load test is a very important marker for observing viral activity.⁴⁵
Various studies show that the high number of viruses plays an important role in the emergence of complications of chronic hepatitis B. Low virus counts are associated with a lower risk of hepatocellular carcinoma when compared with a high number of viruses. The number of HBV DNA viruses varies depending on various factors, so repeated checks are needed for monitoring disease course and treatment. Limitations of the tools and costs of HBV DNA Viral load test causes monitoring of patients with chronic HBV infection is difficult. Clinicians need other tests / markers to estimate the number of HBV DNA viruses with a faster, easier and cheaper method than HBV DNA Viral Load testing. 

HBV serology markers are currently growing rapidly. The HBsAg level test is the basis for diagnosing HBV infection. The HBsAg level test correlates with the amount of cccDNA HBV in the liver so that it is considered a marker of infected cells. HBeAg level test is an active viral replication indicator; the high number of HBV DNA viruses in pregnant women has a significant correlation with HBeAg levels. Anti HBe is an antibody formed in HBeAg. The formation of anti-HBe is a marker of seroconversion and is associated with inactive HBV. 

An easier and cheaper test to predict the number of HBV DNA viruses is very important for monitoring Chronic Hepatitis B. Research on HBsAg, HBeAg and anti HBe tests against HBV DNA Viral Load tests is still very lacking, especially in Makassar. This study was conducted to see the correlation between HBsAg, HBeAg, anti HBe and HBV DNA viral load levels in patients with Chronic Hepatitis B. This study aims to look at the correlation of HbsAg and BHeAg level against HBV DNA Viral Load in patients with chronic hepatitis in dr. Wahidin Sudirohusodo Hospital, Makassar.

**Materials and Method**

This study was a cross sectional study conducted at the Clinical Pathology Installation of dr. Wahidin Sudirohusodo Hospital Makassar and the Makassar Center for Health Laboratory. The study was conducted from January 2016 until the number of samples was sufficient.

The study sample was all adult patients with hepatitis B more than 6 months who were diagnosed as Chronic Hepatitis B Patients based on history, physical examination and laboratory results that showed HBsAg and anti-HBe reactive and normal SGPT levels (<45 IU / mL). Levels of HBsAg and HBeAg were examined using the Chemiluminescence Immunoassay (CLIA) method. HBV DNA Viral Load is examined using the realtime PCR method.

**Statistical Analysis**

Test data for HBsAg, HBeAg and anti HBe levels against HBV DNA Viral Load levels were tested using the Kolmogorov-Smirnov test for the normality of numerical data. Data distribution is not normal if the test p value is <0.05. The Spearman Correlation test was used to assess the correlation of HBsAg, HBeAg and Anti HBe levels with HBV DNA Viral Load. There is a significant correlation if the test p value is <0.05. The role of each test on HBV DNA Viral load is obtained from the rank correlation coefficient multiplied by 100%. Chi Square Test, to assess the relationship of HBsAg, HBeAg and Anti HBe levels in the category of HBV DNA Viral Load. There is a significant relationship if the test p value is <0.05.

**Results and Discussion**

The study involved 273 patients, of whom 41 were excluded due to hemolysis samples or insufficient sample volume. A total of 232 chronic hepatitis B patients were analyzed, consisting of 123 patients (53%) and 195 patients (84%) in the age group of young adults (19-44 years), as seen in Table 1.

Source : Primary Data

The results of the Ministry of Health’s Basic Health Research show that the incidence of positive HBsAg in men and women is almost the same, this was also found in this study, where men were 52% and women were 48%. This difference could be due to men’s lifestyles such as smoking, which can inhibit the response to the hepatitis B vaccine. The highest incidence is found in
In the age group 19-44 years, this is probably due to the number of patients involved in this study were less than 40 years old. Chathuranga (2013) found that there was no significant difference between age and immune response to hepatitis B.8

Table 2. Correlation of Mean HBsAg, HBeAg, and Anti HBe against HBV Viral Load

</tbody>
</table>

Source: Primary Data

There was a positive correlation between HBsAg, HBeAg and anti HBe levels against HBV DNA Viral Load with p < 0.00, wherein higher HBV Viral Load, the higher HBsAg, HBeAg and anti HBe levels. The correlation between HBV DNA and HBsAg is a strong correlation (r = 0.54) but with HBsAg role in HBV DNA Viral Load only 28.8% (Figure 1).

Figure 1. Correlation of HBsAg level and HBV DNA Viral Load

Gupta (2012) concludes that HBsAg correlates with HBV DNA in Chronic hepatitis B patients and can be used to predict the number of viruses in HBV DNA.9 Belopolskaya M in 2015 also found a correlation between HBsAg and HBV DNA levels in pregnant women, but HBsAg levels height does not always correlate with the high number of HBV DNA viruses.4 Zhu found that patients with high HBsAg levels also had high HBV DNA viral load.10

The role of HBeAg levels on HBV Viral Load DNA is greater than the role of HBsAg and anti HBe levels, which is 60.0% (Figure 2), while the role of anti HBe is only 47.7% (Figure 3). In this study also found a very strong correlation between HBeAg levels (r = 0.77) against HBV DNA Viral Load versus anti HBe which correlated strongly (r = 0.69)

Figure 2. Correlation of HBeAg and HBV DNA

Da Silva (2009) found a very strong correlation of HBeAg levels with HBV DNA Viral Load, a simultaneous decrease in HBV DNA Viral load and HBeAg levels after Lamivudin therapy, so that HBeAg levels in the initial week of therapy can be used as predictors of antiviral responses.11 HBeAg occurrence coincided with the production of DNA polymerase virus, therefore HBeAg showed more replication of the virus.4 Previous studies found a positive correlation between HBeAg and HBV DNA, 84.6% of patients with positive HBeAg had high HBV DNA viral load.12,13

Conclusion and Suggestion

This study concludes that there is a positive correlation between HbsAg and BHeAg level against HBV DNA Viral Load in patients with chronic hepatitis B. HBeAg level has the greatest role and strongest correlation to HBV DNA Viral load.

This study suggests the use of HBeAg level test to predict the number of HBV DNA either for diagnosis or monitoring the treatment of patients with chronic hepatitis B.

Women Participation in Fast Food Control in Kendari City, Indonesia

Tasnim Tasnim1, Maria Inge Lusida2, Anwar Mallongi3

1Public Health Department, STIKES Mandala Waluya, Kendari, Sulawesi Tenggara, Indonesia, 2Institute of Tropical Disease, Airlangga University, Surabaya, Jawa Timur, Indonesia, 3Department of Environmental Health, Faculty of Public Health, Hasanuddin University. Makassar

Abstract

Background: Kendari City Health Government faced fast food trader issue which affected to public health status. The prevalence of diseases which were caused by food continued to increase. Community participation in fast food control was needed because of limited health workers in health centres. Therefore, this study aimed to indentify affectivity of women participation in fast food control to food traders in Kendari city, Southeast Sulawesi, Indonesia.

Materials and Method: This study applied Quacy Experiment with the one group pretest-posttest design. The study was conducted in 3 villages in Kendari City because they have many temporary food traders. The sample of temporary food traders ware 39 traders and 17 women. The hypothesis of this study is that community involving in control to the temporary food traders will be effective to improving the fast food processing which will affect to the quality of sold food. Data analysis used Linier Regression.

Results: women could control the fast food traders to increase food hygiene and sanitation. The distance of the cadre’s home to the fast food trader significantly influenced to the fast food processing which eventually affected to the quality of the sold food.

Conclusions: women can a representation of a civil society to control food for traders in Kendari effectively because they are closed with food traders.

Keywords: Women, Participation, Food, Disease

Introduction

Kendari city health government in Southeast Sulawesi Indonesia faced the unsanitary huge fast food sellers. This has contributed to increasing the number of communicable and non communicable diseases such as diarrhoea and hypertension in Kendari city. In 2015, there were about 63.28% of diarrhoea and about 14.83% of hypertension. Those were higher than other district such as in North Konawe (6.64%) and Wakatobi (15.87%) of the prevalence of diarrhoea. While the prevalence of hypertension were also higher compared to 7.15% of Bau-Bau city. The Health Department in Kendari City implement several strategies. The strategies include collaborated programs between the producers, governments, non-government organization and communities. However, community involvement was still unclear. While the number of unsecure fast food sellers continued to rise. Health department has involved cadres or community volunteers involve in the village comprehensive health services. However, cadre’s involvement in the fast food controller has never been done until now. Therefore, this study aimed to identify the model of cadres’ involvement in controlling to the fast food traders to reduce the foodborne diseases in Kendari city of Southeast Sulawesi Province.

Figure-1. The Quasy-Experiment method with The One-Group Pretest-posttest Design

b. The Study Site and Time

This study was conducted in three villages in Kendari city of Southeast Sulawesi province Indonesia namely Andonohu, Rahandauna and Wundumbatu villages. This study was conducted from March to July 2018.

c. The Population and Samples

Population

All fast food traders were population in this study namely about 119 traders.

Sample and sampling technique

The samples of this study were 39 fast food traders who were selected with using the purposive sampling. The inclusive criteria of sample were active cadre available in the village and there many fast food traders.

d. Data collection

Data was collected through interview and observation. The interview was purposed to the fast food sellers and cadres in three villages. This study recruited 17 women a controller to the fast food traders.

e. Data analysis

Data was analysed into two ways, namely descriptive and inferential analysis. Descriptive analysis was to understanding percentage and distribution of each variable such as communities’ characteristic who involved in, the form, the mechanism of the fast food controlling. The inferential analysis was to analyse the relationship between the distance of cadre’s house to the fast food traders and the quality of the food hygiene and sanitation. The statistical analysis used linear Regression.

Results

a. Characteristic of women who involve in the fast food control

Women who were involved in this study were 17 people. All women aged 41.5 on the average and 7.3 of standard deviation. The majority of the age of cadres was between 40-44 years old (41.2%). There were only 5.9 % of cadres who aged more than 50 years. 29.4% of them aged 35-39 years old and 11.8% of them aged 30-34 years old and 45-49 years old. Some of them passed from senior high school (52.9%), while they who passed from diploma/Bachelor/Post Graduate were 23.5%. Other cadres passed from Junior High School (17.6%) and 5.9% of Primary School. There were about 70.6% of cadres who did not have job. Another cadres work as traders (17.6%), teachers (5.9%) and civil servant (5.9%). 94.1% of cadres were married, while 1 cadre was widow. The majority of cadres have two children (41.2%), 23.5% have three and five children. 5.9% of cadres have one and four children. They have been a cadre more than 1 years. They have had many experiences to do social activities and trainings. Detail of the cadres who involved in controlling the fast food traders was presented in this table below.

Table-1. Women’s experiences in the social activities

b. The Relationship between the distance of women’s house to the fast food traders and the quality of food hygiene and sanitation

Women have various type when they controlled the food traders. Some of them used motor cycles (82.4%), while others were on foot (17.6%). The duration of reaching the food traders were also verity as presented in the below table.

Discussion

This study found out that women or community health volunteers could control fast food traders because of many reasons. They have gotten training from Health Department and form Primary health care services, as showed about 9.2 times. They have become a volunteer more than 6 years. Therefore, they have had huge experiences, particularly in community engagement and Mobilization. They have also gotten their family’s support such as husband or parents. Family support is one of important factors of the individual behaviour besides the individual knowledge, belief and infrastructures. As presented above, the cadres passed from Senior High School (52.9%). Thus, they could synthesize health information which they got. Cadres with more higher educational level tends to have awareness about science and information. The several previous studies also found that cadres’ knowledge influenced to success in their social responsibility. Moreover, motivation is also the essential factor of successful for cadres. Motivation has significant relationship with
The human basic needs include physiological, safety, love, esteem and self-actualization needs. This is true that cadre’s involvement in the fast food control in this study because they want to get new experiences and self-actualization. This is based on Depth interview with cadres. Another thing, they hope to get an incentive from Primary Health Care Centre or from their village leader. Some of cadres (70.6%) do not have job. They are wives who do domestic chores only. If they got incentive such as a few money, there will be increasing their family income. Additional household income will give significantly impact for their children nutrition because they will increase their purchasing power for food. Increasing in the household income also can improve their household facilities such as water and latrine facilities. The housing condition also influence significantly to their under-five children’s nutrition status. Some of cadres have under-five years old children. Also, they can buy gasoline for their motor cycle because there are about 82.4% of them used motor cycle when they supervise the fast food sellers. This means that incentive includes in intrinsic factor which motivate the human to involve in the activity like involving in the fast food control. Other previous study also argued that cadre’s motivation was important factor for them to be active in the social activities in their village.

Other important factor why cadre were effective to involve in the fast food control is they have lots of free time. As above mentioned that there were about 70.6% of cadres were no job. Thus, they had lots of time to involve in the fast food control. This activity took about 6.7 minutes only. Even some of cadres (29.4%) who had a job, they still could use their free time to involve in this activity. The distance between the cadre’s home and the fast food seller is about 766 meters in average. Cadres have 3 children in the average. Therefore, they do not have heavy burden between their responsibility in their home and in this fast food control. As we known, the wives in this culture have responsibility to child rearing including the domestic chores.

Furthermore, cadre’s experiences in the previous activity could do the best approach and communication with the fast food traders. Thus, they could also give health promotion to the sellers during supervision. The cadres were about 41.5 years old in the average. They included in the adult people who changed their interest and responsibility towards socialist people. With the simple instrument of control the fast food quality, the cadres could show their ability to involve in the fast food control. The form includes several aspects such as about environment, the trader’s behaviour towards the food hygiene and sanitation. Thus, they could give health education for the food sellers during supervision. The number of assessment (0-10) of the quality of the food hygiene and sanitation is easier for the cadres. The number of 5 becomes the basic to determine the good or poor because this number was agreed as a middle number.

Conclusions

Women volunteer in the village who can help health worker to control the fast food traders because they have gotten lots of trainings and had huge experiences in the health promotion program. Therefore, they can influence the fast food traders to improve their food management. The process of controlling is simple and needs short time only.

Acknowledgement: I would like to thank to Ministry of Research, Technologi and Higher Education of Republic of Indonesia in financial support of this study. I am grateful to College of Mandala Waluya Health Sciences who give permission to take this study. My sincere goes to women volunteer and food traders in Kendari city for your participation.

Abstract

This study aims to determine total coliform present in water and to determine the health risk to the people who consume water contaminated by bacteria. The research was a cross observational study with microbe risk analysis conducted in Puty Village of Bua District, Luwu Regency. The sample consisted of 15 drilling wells and 34 respondents who owned drilling wells selected using purposive sampling method. The data was analyzed using MRA method and Excel programs. The results of the research indicate that the average concentration of total coliform in drilling water among 15 samples is 130-160.000000 MPN / 100 ml water. Meanwhile, for E. coli the average concentration in water exceeds the standard of drinking water quality, i.e 23-24000.000 cells/100 ml while the standard drinking water quality should be 0/100 ml water. The amount of risk for public who consume water contaminated by bacteria is in a high risk on average. The results of risk analysis indicate that the highest Probability of infection (P_inf/day) of Escherichia coli bacteria contamination in water among 15 samples is sample 5, i.e 2.40E⁻⁰⁴. Probability of infection/year (P_inf/year) is 874E⁻², while probability of illness (P_ill) is 1.28E⁺². Therefore, this is in a high risk category which means that it is risky of a disease.

Keywords: Microbial Risk Analysis, Escherichia coli, total coliform.

Introduction

Average water needs by Indonesia people is 60 liters per capita, include: 30 liters for bathing purposes, 15 liters for drinking purposes and the rest for other purposes¹. The presence of this group of bacteria used as an indicator of a product has been contaminated by fecal matter, namely bacteria residing with feces or feces. This is due to the natural habitat of these bacteria group is in the feces of humans and other warm-blooded animals.

Data by Riskesdas², the use of clean water that is most widely used for domestic purposes is protected dug wells amounted to 27.9% and boreholes or pump by 22.2%. Whereas, for the purposes of drinking water is the most widely used is protected dug wells amounted to 24.7% and boreholes or pump by 14%. These wells, if not addressed properly, has the potential to be contaminated with Escherichia coli.

Many risk factors are thought to cause diarrhea in Indonesia. One risk factor is often studied environmental factors including microbiological quality of water, the presence of pathogenic bacteria in the water, such as the bacterium Escherichia coli the most dominant risk. Factors contribute to diarrheal diseases are water, hygiene and sanitation (availability and ownership of
latrines, trash), the transmission through food, waste water and air.

A study of risk factors for the incidence of diarrhea by Natsir et al., found that poor sanitation relationship with the incidence of diarrhea which gained frequency distribution of clean water a bad category of 199 (90.5%) of 220 respondents; Poor handling of waste by 171 (77.7%); bad excreta disposal facilities by 124 (56.4%). While the frequency distribution of bacteriological water quality examination showed that of 218 (99.1%) positive water samples E. coli. The World Health Organization (WHO) reported the disease caused by the bacterium Escherichia coli that hit Germany and 11 other countries in Europe up to now has reached 2,260 cases and resulted in the death of 22 people. Until June 5, 2011, Germany has reported the incidence of 1,536 cases of EHEC (Escherichia coli enterohemoragik) which is an increase of 108 cases from the previous day and resulted in the deaths of six people.

Assessment approach associated with the procedure MRA can assist the risk assessment to characterize the source of exposure, the causative agent associated with symptoms, and other factors that contribute to the emergence of disease MRA has become a method is growing rapidly that systematically combines available information on exposure and dose-response to produce estimates the burden of disease associated with exposure to pathogens. MRA expressed great risk in the value P infection (P inf) or P illness (P ill). This study aims to determine the risk of contamination of Escherichia coli and total coliform in wells water to public health.

Materials and Method

Research Methods

This study used an observational study design with the approach of microbial risk analysis (MRA) to determine the health risk that would occur if infected by bacteria in the water.

Research Sites

This research was conducted in the village of Bua Puty districts during 2 months from May to June.

Population and Sample

The human population in this study are all people who consume water from well. For human sample in this study were 34 people who have dug well water samples was 15 samples. Sample is determined by purposive taken one time. Bacteria that become research object were Total coliform and Escherichia coli bacteria that present in water wells in the test laboratory. Sample Environmental health techniques for determining the amount of the concentration of bacteria in the water wells. Concentration results in analysis with Quantitative Approach Microbial Risk Assessment (QMRA) to determine how much the probability of Escherichia coli bacteria can cause infection (P infection) or disease (P illness) in the community.

Data Collection

Primary data obtained from the test results laboratories ie the number of E. coli and total coliforms in secondary Makassar. Data BTKL-PP obtained from recording data related to the community of Bua district office, health office and health center Luwu Bua about 10 highest diseases and the number of facilities 2014 clean water.

Data analysis

Data were analyzed using Analysis of Quantitative Microbial Risk Assessment (QMRA) which cover of Hazard Identification, Exposure Assessment, the analysis of dose response Risk characterization), and Risk Management. Presentation of data in tabular form accompanied by narration.

Research Results

Results showed that the number of E. coli and total coliform bacteria in wells water in the village Puty that used as sources of drinking water are not eligible for direct consumed. It present concentration of bacterium of Escherichia coli and total coliform. The result of temperature, and pH of the water wells test and analysis were also not meet requirement at all. The concentration of total coliform bacteria in water (Table 1) shows that water samples from 15 wells tested were not safe for consumption without treatment, the highest sample Total coliform at sample 5 with 160 million cells / 100 miles of water, and the lowest total coliform samples was at 130 cells / 100 miles of water at well number 15. In the sample (Table 2) shows the concentration of bacteria E.coli from 15 well water were tested all the samples showed no feasible and highest sample Escherichia coli bacteria.
was on 5 sample that is 24 million cells / 100 miles of water and a sample of the bacteria Escherichia coli lowest 20 cells / 100 miles of water.

**Figure 1.** Graph of State Temperature and pH of well water dug as a source of drinking water.

Figure I shows temperature and pH in the wells as a source of drinking water with an average of pH between 6.9 -9.2 while the normal limit of the pH is 6-8, meaning the highest pH value there is in the sample 14 are in RW 7 marks that it is on the water because the acid levels over the limit. Whereas highest pH in the sample 14 is 9.2 with the sampling time at 15:40 on the exposure limits with low pH 6.5 and the highest 9.0. pH or acidity pH ranges of drinking water 5-8. While the value of water quality standards 31.6 where temperature ever on the samples 2 to 15 and 30.9 on the sample 6, and 3 on the sample 5 is the maximum allowed 30.1 (BMA) water quality standards (26-29 °C).

**Quantitative Microbial Risk Assessment on wells as a source of drinking water.**

Quantitative calculation results in microbial risk analysis aims to determine the dose response of the
probability of infection and the risk characteristics of the population of the village society Puty. Table 3 shows the probability of infection per day based on \( P_{inf. \, d} = 1 - \left(1 + \frac{E}{\beta}\right)^{-\alpha} \) that people who consume water every day / liter contaminated with bacteria E.coli then he will be infected with about 23954E\(^4\) bacteria then categorized as high risk, while the probability of infection per year or infection due to consumption of water contaminated with bacteria during the year by the formula \( P_{inf. \, d \, y} = 365 \times \left(1 - \left(1 + \frac{E}{\beta}\right)^{-\alpha}\right) \) was = 8.74327E\(^2\) can be categorized high. And the risk for probability of gastrointestinal disease or \( P_{ill} = P_{inf. \, y} \times S \times I \) = 13.3771209E\(^{-1}\) if the resulting percentage is the risk of clinical disease 50% the risk of disease is a high risk. Of the 15 samples of the lowest concentrations of the bacterium Escherichia coli is a sample 9 as 20/100 miles. For \( P_{inf. \, d} = 1 - \left(1 + \frac{E}{\beta}\right)^{-\alpha} \) = 2.00E\(^{-10}\). For \( P_{inf. \, d \, y} = 365 \times \left(1 - \left(1 + \frac{E}{\beta}\right)^{-\alpha}\right) \) was 7,29E\(^{-10}\) while for \( P_{ill} = P_{inf. \, y} \times S \times I = 1.12E^{-5}\). Bahwa \( P_{ill} < 10^{-6} \) the greatest risk is 12,82016452E\(^{-1}\) with a concentration of 23 million cells of E. coli / 100 ml of water. This is a relatively high risk even as the highest mortality burden in the future. The high concentration of bacteria in the water as probable with the results of measurements of water temperature past the normal limit water quality standard yaitu31,6 ie on the samples 2 to 15 and 30.9 on the sample 6, and to 3 on the sample 5 is the maximum allowed 30.1 (BMA) water quality standards (26-29°C) but total coliforms are found under the maximum limit. It shows that the temperature conditions conducive to the growth of total coliforms. It is possible there are other factors such as levels of waste, as well as other things that cause could grow maximum of coliforms in the water\(^7\).

Risk characteristics that \( P_{ill} \) ketch more than 10-6 is an example of the highest concentrations of bacteria are \( P_{ill} = P_{inf. \, y} \times S \times I = 13.3771209E^{-1} \) is a high risk. Of the 15 water samples with assay results of analysis \( P_{ill} \) all smaller than 10-6 then all risks are categorized high. A study previously done by Kroli\(^8\), shows that the level of risk is lower (1.36E\(^{-07}\) for fig. 1 and 1.45E\(^{-07}\) showed that cater to the health-based targets. Taking the average contamination in the distribution, the risk is much higher (5.26E\(^{-04}\) for 1998 and 2.92 E\(^{-04}\) for 1999). Gastrointestinal infections arising as a result of this attack Escherichia coli bacteria to the intestinal wall causing movement of the solution in large quantities and damage the membrane electrolyte balance in mucus. It can cause water absorption in the intestinal wall decreases and causes diarrhea\(^9\)\(^-\)\(^13\).

Discussion

Results of the analysis of the content of total coliform bacteria in water samples dug research region ranged 130-160000000 MPN / 100 ml indicates that the water has been contaminated by human or animal feces that can cause gastrointestinal diseases. All samples were above the threshold of water quality standards are allowed to water intended for drinking water which should not be any bacteria that is 0/100 ml of water and for its designation as clean water \( \leq 50 \) MPN / 100 ml. This study shows that the number concentration of E. Coly between 23-24.000.000 ranges coli cells / 100 ml water. In 100 ml drinking water should not be on the content of the bacterium Escherichia coli. The presence of E. coli in drinking water indicates poor water quality. Bacteria indicator bacteria E. coli are sanitation and also be pathogen that frequently causes various diseases\(^6\).

In this study the results of the risk analysis of the sample greatest risk is 12,82016452E\(^{-4}\) with a concentration of 23 million cells of E. coli / 100 ml of water is on the sample 4 and sample 5 is 13,3771209E\(^{-1}\) with concentration E. coli bacteria in the water 23 million cells / 100 ml of water. This is a relatively high risk even as the highest mortality burden in the future. The high

Conclusions

Probability Risks of infection \( (P_{inf/d}) \) from Escherichia coli bacteria contamination in drinking water of 15 samples were highest in samples 5 was 2.40 E\(^{-4}\). Then, probability of infection / year \( (P_{inf/ \, y}) \) 1.34E\(^{-1}\) or the probability of illness \( (P_{ill}) \) is the category in the high risks 1.34E\(^{-1}\).

Abstract

Background/Objective: Contrast induced nephroptathy is potential side effect of contrast administration. A good marker is required in order to synergize with the creatinine marker so that CIN can be handled more quickly. This study aimed to compare the levels of interleukin 18 as a marker of inflammation and interleukin 37 as an anti-inflammatory marker in patients with CIN after administration of contrast media.

Material and Method: It was as cross-sectional study, subject of study were were all affordable populations who underwent Percutaneus Coronary Intervention (PCI) at the Cardiac Installation Center of Wahidin Sudirohusodo Makassar (as many as 30 patients). Healthy people used as control of study (10 people) and also AKI patients (10 people).

Results: Data indicated that both Non CIN and CIN groups had statistically significant IL-18 increases but decrease IL-37 even unsignificantly Data after media contrast administration showed that IL-18 of the control group differed significantly with CIN and AKI groups and did not differ significantly with non-CIN groups. After media contrast administration also showed that the IL-37 of control group differed significantly with AKI groups only and did not differ significantly with non-CIN and CIN groups.

Conclusion: Proinflammation activity, marked by IL-18 increased significantly after contrast administration but anti-inflammatory, marked by IL-37 decrease even unsignificatnly.

Keywords: Contrast, Contrast Induced Nephroptathy, IL-18, IL-37

Introduction

Contrast Induced nephroptathy (CIN) is side effect of giving contrast media that has become one of the main causes of kidney failure and causes a critical condition in patients. It has been a major determinant of Acute Kidney injury (AKI) and its incident has varied time after contrast media delivery, there are fast only 2 days and there are up to 30 days. Although a recent a meta-analysis study found that no significant difference between renal of patients given and those not given contrast many studies has indicated different result.

Marker of CIN traditionally still used increasing of creatinine serum within 24-48 hours after exposure but some studies have tried used inflammatory reponse as biomarker because delayed response of creatinine serum could reach 30 days and it was too late for patients to treat and prognostic will deteriorate. A good marker is required in order to synergize with the creatinine marker so that CIN can be handled more quickly even if the serum creatinine condition is still under normal conditions.

Pathophysiology of CIN-AKI is still being studied to gain a good understanding and consensus on prevention is not present yet. Inflammatory processes are involved in the CIN mechanism that occurs after the administration of contrast media, some studies use C-reactive protein (CRP) levels as an inflammatory marker and predictor. Proinflammation cytokine, interleukin 18 (IL-18) has been one of the early detection of AKI events, it can be detected at 24 hours and 48 hours after exposure. It
suppose as strong biomarker and moderate diagnostic IL-18 also has potential as a biomarker for CIN events.

12-14

Before being used as a biomarker in CIN events, it must first be ascertained whether there is indeed a difference in IL-18 levels in CIN and non-CIN patients and should also be comparable to patients with AKI. Response to inflammation by antiinflammation cytokine should be considered to be biomarker together with proinflammation cytokine. One of the most infrequently studied but important anti-inflammatory cytokines is interleukin 37 (IL-37). Clinicians need an early biomarker of CIN diagnostic and also an appropriate decision regards inflammation.

Interleukin-18 stimulates infiltration and activation of T lymphocytes and Natural killer (NK) and interferon-production. Interleukin-18 is released into the urine 6 hours after the onset of a kidney injury 15. Interleukin 37 (IL-37) is a family of IL-1 that has a close relationship as well as a natural inhibitor for Interleukin 18 (IL-18), this cytokine is also a suppressor for TNF-α that induces neutrophil activation 16.

This study aimed to compare the levels of interleukin 18 as a marker of inflammation and interleukin 37 as an anti-inflammatory marker in patients with CIN after administration of contrast media. This study will also compare between IL-18 and IL-37 in patients with CIN and AKI patients.

**Materials and Method**

**Design and Subject**

It was as cross sectional study, subject of study were all affordable populations who underwent Percutaneus Coronary Intervention (PCI) at the Cardiac Installation Center of Dr. Wahidin Sudirohusodo Makassar and meet the inclusion criteria.

Inclusion criteria were serum creatinine levels were normal before contrast administration, adults aged 30 and above and willing to participate in research by signing Informed consent. Criteria of control were healthy young adults 20-40 years old who are not getting contrast and have no history of kidney disease and other illnesses based on serum history and serum creatinine. Subject was drop out when the patient’s condition worsened, patients refuse blood collection after 24-48 hours after contrast medium delivery. Patient categorized as CIN when a patient who after contrast has a serum creatinine increase of ≥ 0.5 mg / dl or an increase of 25% from baseline within 24-48 hours.

The contrast agent in this study was a type of iodine contrast, nonionic with Low-Osmolar Contrast Media (LOCM) or Iso-Osmolar Contrast Media (IOCM) and injected into the patient’s body either through an artery or vein.

**Ethic**

Each action was conducted by the consent and knowledge of the patient who was sampled by the informed consent sheet and stated to fulfill the ethical requirements to be implemented from the Medical Research Ethics Committee of Hasanuddin University Medical Faculty. Ethical clearance has been accepted before study from Medical Research Ethics Committee of Hasanuddin University Medical Faculty (UH16080614).

**Procedures**

Procedure conducted was:

1. Record the identity of patients who meet the inclusion criteria and provide a full explanation of what will be done to them and if agreed they will fill out and sign the informed consent.

2. The subjects who met the inclusion criteria were taken venous blood sampling before and after contrast administration as many as 3 ml. The serum was obtained after the tube containing the blood was allowed to freeze for 30 minutes at room temperature and centrifuged for 20 minutes at a rate of 3000 rpm. Samples are stored at -80 ° C until sufficient samples, at most 12 months, when the sample will be diluted at 25 ° C before analysis.

3. Serum level of IL-18 and IL-37 examination was performed at the Biomolecular Laboratory and Immunology of the Faculty of Medicine, Hasanuddin University based on Human ELISA KIT Instruction.

**Statistics Analysis**

Data presented with table using mean, deviation standard (SD), mean difference and probability value
(p-value). Analysis of pre and post administration of contrast data used paired T test and comparison of group used independent T-test for normal distribution data and Mann Whitney U for data have not normal distribution. Level of significance was 0.05.

**Results**

**Interleukin 18**

Data indicated that both Non CIN and CIN groups had statistically significant IL-18 increases (p-value=0.000), although the increase in the CIN group was much higher than in the non-CIN group (86.11 pg/ml versus 127.15 pg/ml) (Table 1).

**Discussion**

An increase in inflammatory activity characterized by elevated pro-inflammation cytokine interleukin 18 appears to suggest that inflammatory activity may be a predictor and at the same time as a diagnostic for CIN incidence for patients who get contrast administration. Although this still needs to be continued with further research because this study only provides basic data of significant differences.

The pathogenesis of CIN is very complex. Several previous studies have shown that inflammation is important in the prevention of renal impairment. Immune cells of both the natural immune system and the immune system include Dendritic Cells (DC), Natural Killer T
cells, T lymphocytes, B lymphocytes, neutrophils, and macrophages are known to participate in the early stages of injury. Thus, control of inflammation can reduce kidney damage significantly.\textsuperscript{17,18}

Inflammation is mediated by the adhesion of leukocytes to injured endothelial cells. There is increased escalation of leukocyte adhesion molecules such as ICAM-1, P-Selectin and E-Selectin in endothelial cells in response to injury. Increased chemoattractant factors such as fractalkine (CX3CL1) can be expressed when kidney injury occurs and promote macrophage infiltration. This leads to the activation of leukocytes, capillary obstruction and increased production of proinflammatory cytokines.\textsuperscript{19,20}

Data also showed that IL-37 level did not increase but decrease even not significantly. It is shown that contrast administration has high risk to develop be acute kidney injury. Immune response should increase IL-37 to prevent severe inflammation but it did not happen\textsuperscript{21,22}.

Study related IL-37 are still very rare, especially those associated with CIN, this study provide a basic data to develop. Increased proinflammatory cytokines, IL-18 and decreased anti-inflammatory cytokines, IL-37 have the potential to be predictors and diagnostics with further study.

**Conclusion**

Proinflammation activity, marked by IL-18 increased significantly after contrast administration but anti-inflammatory, marked by IL-37 decrease even unsignificantly.

Influence of Teeth Brushing Behavior, Saliva Flow Rate, Salivary Hydration, Saliva Viscosity and Saliva PH on Risk of Caries Occurrence in Adolescents in Gianyar, Bali, Indonesia

(Research conducted at SMAN 1 Ubud-Gianyar District Bali)

Anak Agung Gede Agung1, Regina Tedjasulaksana1, Maria Martina Nahak1
1Dental Hygienist Department-Polytechnic of Health-Ministry of Health - Denpasar-Indonesia

Abstract

Background: Objective: The purpose of this study was to determine the effect of brushing behavior, salivary flow rate, salivary hydration, salivary viscosity and saliva pH on the risk of caries occurrence in adolescents at SMAN 1Ubud Gianyar. Method: This research is cross sectional study, with 235 samples selected by purposive random sampling. All samples were measured DMF-T, salivary flow rate and salivary hydration, followed by saliva collection 2 hours after eating last meal during the day for analysis of viscosity and salivary pH, followed by an assessment of toothbrushing skill with the guidance of toothbrushing rubric. The collected data were analyzed by chi-square statistic test. Result: there was a significant correlation between toothbrushing behavior with caries incidence rate with p = 0.00 (P≤0.05), whereas flow rate, hydration, viscosity and salivary pH did not significantly affect caries incidence rate with p≥0.05. Conclusion: Toothbrushing behavior significantly affects caries incidence rate when compared with physical and chemical properties of saliva.

keywords: tooth brushing behavior, saliva, caries, adolescent

Introduction

Dental caries occurs due to the interaction of the four factors of the host (teeth and saliva), microorganisms, substrate and time duration, which is the length of the interaction process between these factors. The process of caries occurrence begins with the fermentation of substrates containing carbohydrates by bacteria in plaque on tooth surfaces that can lower plaque pH below 5 within 1-3 minutes. The decrease in plaque pH of plaque will lead to demineralization on the surface of the enamel. The process of neutralization by saliva can increase salivary pH, and the process of remineralization takes place. Caries results from a larger demineralization process than remineralization.

According to Rosenberg (2010), caries ranks second after the common cold. The caries experience varies considerably between countries, depending on behavioral factors, age, socio-economic circumstances and the pattern of life and diet of the community. Caries prevalence in developing countries tends to increase with increasing consumption of foods that contain lots of sticky processed sugar and inadequate coverage of dental services. Basic Health Research Results of (RISKESDAS) 2013 showed that there was an increase in dental caries prevalence from 2007 to 2013, and the highest increase at age 12 years was 13.7%. The prevalence of active caries in children aged 12 years reaches 43.4%.

Adolescence is a period of transition from childhood to adulthood and in the process, there is development of physical, psychological and social maturity. According to Hurlock (2001), in general, adolescence is divided into three parts: the beginning of adolescence lasts from the age of 12-15 years, middle adolescence lasts from the age of 15-18 years and the end of adolescence begins from 18-21 years which is legal mature age. Adolescence is characterized by biological, cognitive and socio-emotional changes that influence self-care behaviors including keeping the teeth and mouth clean.
According to Notoatmodjo (2012), behavior is an activity or activity of a highly complex organism, among others: behavior in speaking, dressing, walking, perception, thought and emotion. Brushing behavior is one of the important and effective health behaviors for the maintenance of oral and dental health and prevents plaque buildup in teeth. According to Sihite (2011), tooth brushing behavior is influenced by several factors: brushing, brushing, brushing time and tools and ingredients to brush teeth. Notomatodjo in Sihite (2011), explains that the risk of caries and periodontal disease in society, one of which is the behavioral factor that is the attitude of neglecting tooth and mouth hygiene.

Saliva is also one of the factors that contribute to caries risk. Saliva is a secretory secretion of various glands in the oral cavity and plays an important role in maintaining balance in the oral cavity. Adequate salivary function, important in defense against caries attacks. Saliva contains certain organic and inorganic materials which, if excessive or decreased, can cause salivary imbalances. Saliva function is as a lubricant, buffer, cleanser, anti-solvent and anti-bacterial. Chemical composition, flow rate, viscosity, salivary hydration, acid-base properties (pH) and antibacterial properties of saliva are associated with the risk of caries occurrence in a person.

Caries risk is a person’s chances of having a carious lesion over a period of time. The risk of caries differs from person to person, and may even vary in the same individual, depending on how to maintain oral hygiene and the salivary buffer function. Assessment of caries risk in a person is necessary because caries can affect anyone regardless of age, gender, race or socioeconomic level. Caries can affect children, adolescents, adults and geriatrics. Information on caries risk assessment can be used as a strategy in planning the precautions.

High school students belong to adolescence which is in late adolescence, susceptible to dental caries because at this time biological, cognitive and socio-emotional changes that affect self-care behaviors include maintaining oral hygiene. The average age of high school students ranging from 15-19 years is the right age to measure the salivary flow rate.

Materials and Method

This research is cross sectional with survey design. The sample size is 235 students, selected by purposive random sampling. Intraoral examination was conducted first to measure DMF-T respondents and observed salivary flow rate and salivary hydration. The salivary collection was performed 2 hours after the last meal and conducted on the afternoon, conducting a salivary analysis including: salivary viscosity and salivary pH concluded with an assessment of tooth brushing skill with guidelines for tooth brushing rubric.

The collected data were then analyzed using bivariate analysis to find out the correlation between caries risk factor and caries incidence with chi-square statistic test.

Results

The results of analysis of tooth brushing time with caries experience score (DMF-T) can be seen in table 1 below:

<table>
<thead>
<tr>
<th>Tooth brushing time</th>
<th>Caries experience / DMF-T</th>
<th>total</th>
<th>%</th>

<td>35.5</td>
<td>61</td>
</tr>
<tr>
<td>Total</td>
<td>52</td>
<td>22.1</td>
<td>67</td>
</tr>
</tbody>
</table>
The table above shows that 91.5% of respondents who brushed their teeth at the correct time has a low DMF-T score. While 35.5% of respondents who brush their teeth at the wrong time have high DMF-T numbers. The result of analysis with chi-square obtained value $P = 0.00 (<0.05)$ or there is significant correlation between tooth brushing time with caries experience.

The results of the relationship analysis of tooth brushing techniques with caries experience (DMF-T) are seen in Table 2 below:

### Table 2: The Relationship between Tooth Brushing Technique with Experience of Caries (DMF-T) at Student of SMAN 1 Ubud Gianyar Regency 2017

</tbody>
</table>

Table 2 above shows that of 235 respondents were examined, 33 people (14.04%) brushed their teeth with the correct technique and out of these, 81.8% had low caries category. Other 202 people (95.96%), brushing teeth with the wrong technique and from that amount, 49 people (24.3%) experienced caries with high category. The result of analysis with chi-square obtained value $P = 0.00 (<0.05)$ or there is significant relation between tooth brushing technique with caries experience.

The effect of salivary flow rate on DMF-T is shown in table 3 below:

### Table 3: Effect of Saliva Flow Rate on Caries Experience (DMF-T) at Student of SMAN 1 Ubud, Gianyar Regency 2017

<td>22.1</td>
<td>67</td>
</tr>
</tbody>
</table>

Table 3 above shows that 219 samples (93.19%) have high salivary flow rates but have a high caries experience rate as well, compared with those with low salivary flow rates. The result of analysis with chi-square obtained p-value $= 0.602 (p> 0.05)$, which means there is no significant relationship between salivary flow rate with DMF-T number.

The effect of salivary hydration on DMF-T is shown in table 4 below:
Table 4: Effect of Saliva Hydration on Caries Experience (DMF-T) at students of SMAN 1 Ubud Gianyar Regency 2017

<table>
<thead>
<tr>

<tr>
<td>Total</td>
<td>52</td>
<td>22.1</td>
<td>67</td>
</tr>
</tbody>
</table>

Table 4 shows that most respondents had high salivary hydration. From 127 respondents who have high hydration there are 27 respondents or 21.3% who have high caries. The chi-square test showed no significant relationship with \( p = 0.757 \) (\( p > 0.05 \)) or no significant effect of salivary hydration with caries experience.

The result of saliva viscosity analysis on dental caries / DMF-T incidence is seen in table 5 below:

Table 5: Effect of Saliva Viscosity on Caries Experience (DMF-T) in students of SMAN 1 Ubud Gianyar Regency 2017

<table>
<thead>
<tr>
<th>Saliva viscosity</th>
<th>Caries experience / DMF-T</th>
<th>total</th>

<td>3</td>
<td>11.5</td>
<td>8</td>
</tr>
<tr>
<td>Total</td>
<td>52</td>
<td>22.1</td>
<td>67</td>
</tr>
</tbody>
</table>

Table 5 above shows that most of the respondents (74.04%) had viscosity saliva with thick category, but 47.7% of these had low caries experience. Results of chi-square analysis showed no significant relationship between salivary viscosity with caries experience with \( p = 0.757 \) (\( p > 0.05 \)).

Saliva pH analysis result on dental caries incidence (DMF-T) is seen in table 6 below:

Table 6: Effect of Saliva pH on Caries Experience (DMF-T) at SMAN 1 Ubud Students Gianyar Regency 2017

<table>

Table 6 above shows that most respondents had normal and alkaline pH saliva. Of the 51 respondents (21.70%) who had an acidic pH of only 11 people (21.6%) and had high caries. The result of statistical analysis with chi-square showed that there was no significant relationship between salivary pH and caries experience with \( p = 0.839 \) (\( p > 0.05 \)).

**Discussion**

The results showed that there is a significant correlation between tooth brushing behavior and DMF-T number in adolescent at SMA Negeri 1 Ubud with \( p = 0.00 \) (\( p < 0.05 \)), so tooth brushing behavior was a risk factor for caries occurrence. Brushing behavior is one of the most effective health behaviors for the maintenance of oral health because it prevents plaque buildup in teeth. Brushing teeth skillfully at the right time can prevent caries (Sihite, 2011). According to Princess, et al. (2010), tooth brushing is the act of cleaning the teeth and mouth of food scraps and debris that aims to prevent the occurrence of disease in the network hard and soft on the mouth.

The results also showed that salivary flow rate, salivary hydration, salivary viscosity and salivary pH did not significantly affect the risk of caries occurrence in adolescents. Most students have a high salivary flow rate but have a high DMF-T number as well. Salivary hydration in most students is high but has a high DMF-T number as well. The saliva viscosity of most students is relatively thick, but has a low DMF-T. The saliva pH of most students is normal and has a low DMF-T number as well.

Saliva flow rate shows how much saliva is continuously secreted to protect and coat the oral cavity. Salivary flow rate at rest is 0.3 ml / min1. Zunt (2010), wrote that the average saliva flow of a normal person is 0.5-1.5 liters/day. When salivary flow is stimulated below 0.7ml / min, it can increase a person’s caries risk, but it also depends on other interacting factors. Salivary viscosity is the viscous viscosity that is closely related to the glycoprotein composition. If salivary viscosity is increased, it indicates that saliva in the saliva decreases, so saliva becomes thick, and the individual is at high risk for periodontal tissue disease. A person is said to be at high caries risk if it has a low salivary flow. Salivary deficiency can cause dry mouth, thus increasing the risk of caries occurrence. Multiple salivary secretions, dilute viscosity and normal salivary pH will facilitate control of dental and mouth disease.

Saliva is not the only factor that contributes to the caries incidence rate, as other factors contribute to the risk of caries. The risk of caries is a person’s chances of having multiple carious lesions over a period in the future. The risk of caries in each person is different, not even permanent for life in the same person. Caries risk may change if the patient performs a caries prevention action either by himself or the dentist.

**Conclusion**

Tooth Brushing behavior is significantly associated with caries experience in adolescents at SMA Negeri 1 Ubud, but Saliva flow rate, salivary hydration, salivary viscosity and salivary pH are not significantly related to caries experience in students, so it can be concluded that behaving correctly in tooth brushing will prevent caries.

**Conflict of Interest**: None

Video Effect for the Prevention of Knowledge Increasing Stunting in State High School 1 Children in Topoyo Central Mamuju

Ismail Kamba1, Amran Razak2, Sirajuddin Saefuddin3, Sukri Palutturi4
1Department of Community Nutrition Mulawarman University, 2Department of Health Policy Administration Hasanuddin University, 3Department of Community Nutrition, University of Hasanuddin, 4Administration Department of Health Policy, University of Hasanuddin

Abstract
The purpose of this study was to find the influence of video compared to videos plus and increase knowledge for the prevention of stunting in the State high school students in Topoyo Central Mamuju. The research was conducted on February 1, 2018 until February 1, 2019. The research in State High School Topoyo Central Mamuju regency of West Sulawesi province. The population of this study were all male and female students at State High School Topoyo totaling 710 people. While the control sample by using a ratio of 1 : 1 the number of control samples as much as 171 respondents. So the total sample of 171 + 171 = 342 respondents. Knowledge changes from pre-test to post test after intervention by watching videos and video learning material plus 1000 HPK and prevention of stunting among children under five had an influence (the measurement result p = 0.000); then tested in the control group did nothing to influence the control group (p = 0.713 measurement results); and the use of video plus in learning there is no difference between the video and the video plus (the measurement result p = 0.640). It is recommended that pWhat Knowledge society about the golden period of life known as the first 1,000 days of life needs to be established early to the students so that Central Mamuju Regency Health Office, needs to create a joint program with the school so that the students’ understanding as the nation becomes more qualified generation.

Keywords: Knowledge, Stunting, HPK. Pregnant woman

Introduction
Based on data from the Global Nutrition Report, Indonesia is on ranking top 15 from behind1-3. So that Indonesia is considered as the 15th worst in the world after Madagascar stunting2-4. Sequence worst stunting in the world the following are: Timor Leste amounted to 57.7 percent, Madagascar amounted to 49.2 percent, Guatemala amounted to 48.0 percent, Pakistan amounted to 45.0 percent, Lao People’s Democratic amounted to 43.8 percent, Republic Mozambique amounted to 43.1 percent, Nigeria amounted to 43.0 percent, Malawi amounting 42.4 percent, the Central African Republic by 40.7 percent, amounting to 40.4 percent of Ethiopia, Chad amounted to 38.7 percent, India by 38.7 percent, amounting to 38.5 percent of Mali and Indonesia is rated fifteen world with stands at 36.4 percent6.

One third of children stunted in the world is India, and children in rural areas worst affected6-8. The determinants of stunting among children in rural indigenous and odisha jharkhand, India, requires intervention and treatment6,10. The World Health Organization (WHO) reported that a total of 49.2% of children were chronically malnourished in Madagascar11, Placing the country suffered the highest prevalence of stunting in the world. Short children as a result of chronic malnutrition, causing adverse consequences of short-term and long-term if not addressed at an early age6, Short-term risks are susceptible to various infectious diseases such as diarrhea and pneumonia due to a weakened immune system12. Toddlers with nothing short category stood at 52.0 percent. This means that there are approximately 48.0 percent of children under five in West Sulawesi who suffered stunting. It shows much higher than the national average there is difference in numbers about
10.2 percent compared to 37.2 pesen national stunting.

Learning media is the messenger technology that can be used for learning purposes. So learning media is a tool that can be used for learning. The types of instructional media according to taxonomy Leshin, et al (in Arsyad, 2002: 79-101) are as follows: (a) human-based media is the medium used to transmit and communicate the role or information; (B) print-based media is most commonly known are textbooks, handbooks, workbooks or exercises, journals, magazines and loose sheets; (D) visual-based media (image) in this case plays a very important in the learning process in schools; (D) based audiovisual media combines the use of sound require additional work to produce it; (E) a computer-based media choose different functions in the field of education and training, the computer acts as a manager in the learning process, known as the Computer Managed Instruction (CMI). This research “The Effects of Increasing Knowledge Against the video for the prevention of stunting among children under five in State High School Topoyo in Central Mamuju.” This study used a quasi-experimental or quasi-experimental.

**Materials and Method**

The research design uses “Quasy-Experiment”, namely pre-test and post-test with control group design. The research was conducted at the date of February 1, 2018 until the date of April 1, 2019. The research in State High School Topoyo Central Mamuju regency of West Sulawesi province. The population of this study were all male and female students at State High School Topoyo Central Mamuju Regency, which amounted to 710 people. By using proportional random sampling. Total sample of 171 respondents totaled treatment and control sample as many as 171 respondents.

The table above shows that respondents aged 17 years more than other respondents as many as 113 respondents (66.1%). More female respondents than male respondents as many as 118 respondents (69.0%). Parental education more respondents completed primary school (primary school) other than as many as 89 respondents (52.0%). Respondents’ parents work more farmers than other jobs as many as 125 respondents (73.1%).

To determine the student’s absorption associated with this video presentation, first pre-test on two groups. The first group is called the group of cases and the second group is called a control group. The case group targeting State High School 1 Topoyo. The number of students as many as 710 people. By using the formula Slovin obtained a sample of 171 people. In applying these samples using the technique of proportional sampling conducted in 18 classes. Each member of a representative sample in each class taken at random, but still consider the representation of the sexes. At the time of randomization to enroll students who are elected to the sample in each class. Members of the sample is what will be the target of experimentation as follows: (a) first, follow the pre-test by answering a questionnaire distributed to each class in accordance with a list of predetermined sample; (B) second, watch video learning material 1000 HPK on the first day and watch the instructional video with 1000 HPK material accompanied by explanations of the teacher / instructor (in this experiment researchers who act as teachers / instructors) on the second day. Intervention / treatment on the first day done in four classes with each set schedule so as not to interfere with the learning process. Intervening on the second day was also performed on four classes to organize their own schedule; (C) third, following the post-test twice. Post the first test done after the intervention / treatment on the first day (watch the video) and the first post-test is also done post-intervention / treatment on the second day (watch video plus explanations of teachers / instructors). Post second test carried out on the fifth day post-intervention / treatment performed on each class based on the target that the research samples.

Table 3. shows that knowledge of respondents viewing through video with good category were 84 respondents (49.1%) and less category total of 87 (50.9%); knowledge of respondents viewing through video plus good category as many as 128 respondents (74.9%) and less category as many as 43 respondents (25.1%); whereas the results of the analysis of differences in the level of knowledge after watching the video and video plus is $p = 0.640$, which means there is no difference in the level of knowledge after watching the video and video plus or in other words.

**Discussion**

The first results, namely that there is a significant effect of pre-test to post-test in the treatment group. It is clear that knowledge is formed when there is the stimulus provided by the sources of knowledge. Stimulus will respond strongly in case of the sensory impression. Received knowledge will be stored in memory until the specified time will be released back into the raw knowledge to someone. The stronger the person’s knowledge of something, it is determined that a deep impression received by the human brain. Impression is also influenced by the experience of a person against such knowledge. So that a person’s level of knowledge to be better if it has a better experience on such knowledge. The experience in question is never gain the same knowledge repeatedly. For example, the provision of material on nutrition only incidentally do it, it will be different results if done systematically. In addition to the influence of the frequency of administration of knowledge, it is also influenced by the intensity or the power of knowledge. For example, knowledge of which is given sporadically, would be different if knowledge is only given spontaneously. By him, knowledge is not only determined at the time of its formation, but how to maintain the required knowledge, including elevation. also influenced by the intensity or the power of knowledge. For example, knowledge of which is given sporadically, would be different if knowledge is only given spontaneously. By him, knowledge is not only determined at the time of its formation, but how to maintain the required knowledge, including elevation. also influenced by the intensity or the power of knowledge. For example, knowledge of which is given sporadically, would be different if knowledge is only given spontaneously. By him, knowledge is not only determined at the time of its formation, but how to maintain the required knowledge, including elevation.

The second result, that there was no significant effect of pre-test to post test in the control group, it is clear that knowledge of a person does not have restrictions on the sources from which it came. When the students of Vocational High School 1 Topoyo, not given the intervention or treatment that does not mean knowledge of the 1000 HPK is not owned, because the sources of knowledge can come from anywhere. Sources of knowledge at this time are manifold, ranging from the conventional sources of knowledge such as interpersonal communication, also with the involvement of the simplest medium to modern. Ranging from personal media to social media, such as media phones, mobile messaging to facebook, whatsapp (wa), and others. It’s just that being able to explore knowledge specifically requires a focus on specific learning. In addition, Vocational High School students do not really discuss matters relating to certain subjects (such as biology and the like).

The third result, it is known that there is no difference between the two methods use video and video plus, it is explained that the video plus does not mean there has a better ability for a process of confirmation given by the teacher or instructor. Only the confirmation process does not occur because students are more passive after watching the video. Supposedly after watching a process of confirmation or interactive porses. This confirmation
process in accordance with the theory of communication that requires a transformation in communication feedback or feedback so that doubts on the received knowledge, could confirmed back to the communicator or on a media source. In the communication process tersebesar doubt an obstacle to acceptance or adoption of a message in the form of knowledge.

The significant difference in the forms of such treatment. New knowledge is essentially formed from the existing knowledge is then used in a particular context. The process of formation of knowledge through shared experiences while interacting directly. For example one can know the knowledge about child care because he had been taking care of children. Formation of knowledge by transforming knowledge into explicit form. For example, concepts, drawings and written documents. An effective way to externalization is through dialogue. Formation of knowledge to manage existing knowledge from both inside and outside in the form of more complex and systematic.

Conclusions

Knowledge changes from pre-test to post test after intervention by watching videos and video learning material plus 1000 HPK and prevention of stunting among children under five had an influence (the measurement result p = 0.000);

Then tested in the control group did nothing to influence the control group (p = 0.713 measurement results);

Plus the use of video in learning there is no difference between the video and the video plus (the measurement result p = 0.640).

Religious Character in Improving Primary Health Services Quality in South Sulawesi

Muhammad Tahir¹, Ridwan Amiruddin², Sukri Palutturi³, Fridawaty Rivai⁴, Lalu Muhammad Saleh⁵.

¹) Doctoral Students of Public Health at Hasanuddin University and Stikes Muhammadiyah Sidrap, 2) Department of Epidemiology Faculty of Public Health Hasanuddin University, 3) Department of Health Policy and Administrative Faculty of Public Health Hasanuddin University 4) Department of Hospital Management and Administration Faculty of Public Health Hasanuddin University 5) Department of Occupational Health and Safety.

Abstract

Measurement of service quality with accreditation method is one of the tools to ensure the quality of service for community health centre, but from several models of quality improvement it is considered to have weaknesses because no one pays attention to religion, so that the model is not properly used in Indonesia. The aims of this study was to analyze the effect of religious character on the continuous improvement of the quality of primary health services in South Sulawesi. This research is a qualitative study with a case study approach. The data collection technique was carried out by Focus Group Discussion (FGD). The informants in this study were 10 people consisting of surveyors, religious leaders, community health centre heads, non-governmental organizations, lecturer and academics. Data analysis was done by content analysis method. The results of the study state that there were 10 religious characters that should be owned by health center officers, namely discipline, fair, honest, clean, trustworthy, good at communicating, patient, friendly, committed and wise. It is recommended to community health centre officers to apply this religious character so that service quality can be improved and sustainable.

Keywords: service quality, religious character, community health centre officers.

Introduction

The World Health Organization¹ expects all people in the world to get quality health services. For this reason, Indonesia has made efforts to provide quality and affordable health services. One of the quality recognition is the result of accreditation. Accreditation is a form of evaluation of the quality and feasibility of an institution carried out by an organization or accreditation body. Improving service quality as a concept according to Baldrige has dimensions, including: leadership, strategic planning, focus on patients served, measurement, analysis and knowledge of management, focus on human resources, management programs, and results obtained.² ³ The Model for Understanding Success in Quality (MUSIQ) which was developed to improve the quality of health services has also yet conducted a study of consumer focus, implementation focus, access, patient safety, religious character, and innovation. Though this aspect is also very important influence on improving service quality.

Even though building religious character on each employee will certainly have a positive impact on the ability to act in providing services to patients. This has been proven through research that the quality of Islamic services has a positive and significant impact on customer satisfaction. In line with the CARTER Theory which was suggested by Othman and Owen (2001) that there is a strong relationship between compliance with Islamic law and consumer satisfaction.⁴ ⁶

Research conducted at 25 German hospitals to assess the relationship between accreditation status and patient satisfaction involving 3,000 patients using the
Picker questionnaire to assess the seven dimensions of patient satisfaction, found that there was no significant relationship between patient satisfaction and hospital accreditation status.7

Number of community health centre in Indonesia is 9,913 and there are 7,508 accredited community health centre. Based on data from 13 provinces in Indonesia for 3 years (2016-2018) that 45 community health centers had been evaluated for 3 days per health center using accreditation instruments that had been prepared and determined by the Indonesian Ministry of Health consisting of 9 chapters, 42 standards, 168 criteria and 776 rating elements. The results showed that there were 2.2% not accredited and 97.8% accredited. Basic accreditation status was 45.5%, middle accreditation status was 40.9%, primary accreditation status was 13.6% and there was no community health centre with plenary accreditation. This showed that the quality of health services in health centers is still very low.8

Unsustainable quality improvement will have an impact on low patient satisfaction, lack of trust in health services, increased morbidity and mortality, increased maternal mortality, infant mortality, under-five mortality, decreased life expectancy, and low degree of public health. From these various problems, it is expected that there will be a concept for developing a model for the continuous improvement of primary health services that can be applied in health centers.

Materials and Method

This research is a qualitative study with a case study approach. The data collection technique carried out was by Focus Group Discussion (FGD). This research was conducted at the Grand Puri Perintis Hotel on April 9, 2019. Informants in this study were 10 people consisting of surveyors, religious leaders, community health centre heads, non-governmental organizations (NGOs), lecturer and academics. Data analysis was done by content analysis method.

Results

Informants involved in this study were ten informants consisting of two surveyors, 1 religious leader, 1 accreditation assistant, 1 head of community health centre, 2 people from NGOs, 1 lecturer and 2 academics. Specifically, characters based on religious values refer to the basic values contained in religion (Islam). From the results of the Focus Group Discussion (FGD), all informants agreed that religious character is important to be applied in the community health centre. The informant’s answer about the religious character that must be possessed by a community health centre officer has revealed several characters. The informant who stated that discipline was one of the religious characters that must be attached to the officers of the center, the quotations from the FGD were as follows:

“........ Well, I think between religious characters and disciplines characters is very similar, so how to develop a firm discipline based on the basics of religion so it will grows the sense of awareness...“

(Surveyor, 63 years)

“Well alluding to religious character, if we were in Makassar the religious character was actually what you mentioned, almost the same meaning as the disciplinary character that was said earlier ............ .. “

(Accreditation companion, 42 years)

In addition, some informants stated that taking fair action during the service process is also a reflection of religious character, as the following quote:

“ ...... ... So on, then each officer must provide safe services and also do not discriminate ethnic groups, religions, so health services are universal, so they cannot discriminate. Therefore an officer must be fair, regardless of the patient’s background “

(NGO, 40 years old)

“ so on the fifth, everything is for the patient, so whatever happens to the patient, moreover service must provide justice, all layers of society come to the community health centre “

(Surveyor, 63 years old)

There are also informants who specifically argue that religious character refers to the basic values contained in the Islamic religion, namely the value that comes from the example of the Prophet in behaving daily, namely shiddiq (honest), amanah (trusted), tabligh (communicative) and fathanah (intelligent/wise), and all behavior always remembers Allah SWT. The following is the quote for the interview:
"... a quality is influenced by the leader, well, this leader, as mentioned by Mr. Adam, that the character is attached to the actor, but to the leader and besides the actor in its attached to the structure, this must be based on the prophetic character, the trust, siddiq and tabliq this, this is what should be a legalization when someone wants to be a leader, for this researcher I will give advice when the leader wants to be appointed as decision maker he should have this trait “

(Surveyor, 41 years)

"... Well this maybe, my advice also might be that religious characters could be brought to the nature of the prophet, trusteeship, siddiq and so forth “

(Lecturer, 52 years)

"... So that with his ears he heard there was Allah, with his eyes there there was Allah, with his hands Allah”

(Religious figure, 55 years)

Results of the FGD with several informants, there are those who say that maintaining cleanliness is also a religious because cleanliness is a part of faith, moreover hygiene has also been regulated in the accreditation of community health centre. The following are the results of the FGD with the informant:

“So hand washing is part of what is called, well-dressed, and it is regulated in the accreditation of the community health center that binding in a commitment, there is a culture of shame, also a part of faith, it is associated with religious it is already approached “

(surveyor, 41 years)

Patience in working especially in service is also included as one of the religious characters that should be owned by the officer. As quoted by the following FGD interview:

“after I thought about it, it seems like mmm... community health centre had two key words, namely patience and trust”

(Surveyor, 63 years old)

“This religious character is also inseparable from patience, this must be translated as patience, can the workload be handled by complaining, meaning not complaining, not giving up, high fighting spirit, now it must be measurable “

(Academician, 52 years old)

Other religious characters that should be owned by service officers in the community health centre discussed in the FGD are commitment and friendly attitude.

“The religious character of the officer must have a high commitment, there is a strong sense of empathy, that is the religious character that if there are sick people to be well served, this religious character must also be an example”

(Academician, 47 years old)

“... then the behavior approach, that is what we might know at this community health centre smile, greetings and regards”

(Lecturer, 52 years)

Discussion

Understanding character according to Maxwell is how far better than just words. According to Shihab, character is a set of experiences about education and history which then encourage abilities that exist within a person to be able to be a measuring tool or a human side to make it happen. The character of a person can be concluded that something found in individuals who personalities that are different from others in the form of attitudes, thoughts, and actions.

The results of the discussion of informants about religious characters agreed upon the indicators consisting of discipline, presenting God in his activities, fairness, patience, friendliness, commitment, tabligh (transparent/ communicative), fathanah (intelligent), amanah, and shiddiq (honest).

Discipline is the operative function of human resource management that is very important, because the better the level of discipline of the community health centre officers, the higher the work performance that can be achieved. Without good discipline it is difficult for the head of the community health centre to realize quality and optimal work results. The issue of work discipline continues to be sought for its upgrading and improvement. This is based on the assumption that with a high culture of discipline, it will improve the quality of work. Disruption of service to patients or the community will be a complaint so that people are not satisfied with
the services they receive, the dissatisfaction of patients or the community means the inability of community health centers to improve their quality continuously.

Presenting God in its activities means that every action of a health worker in providing health services to the community believes that God is witnessed everything done so that it can give service sincerely, work on the basis of worship, without any pressure / force in giving tasks. With the principle of presenting God in their activities, health workers at the health center will be able to provide health services as much as possible so that they can improve the quality of ongoing services.

According to informants, fair is a part of religious character, being fair in providing health services is an act that does not discriminate patients/society, does not discriminate men and women, does not discriminate services based on religion, ethnicity, race, and socio-economic status. Health services in the community health center do not apply to the queue system but apply to a triage system (prioritizing patients who are more serious and emergency) and priority patient systems (disability patients, the elderly, pregnant women and infants). The principle of fairness in providing health services will certainly be able to provide continuous upgrading and quality improvement.

Informants agreed that patience and friendliness is a must for health workers in providing health services to the community, although taking care patients/communities who are emotionally unstable and do not understand service procedures need extra patient in dealing with it. Facing these conditions, health workers should not be carried away with emotion on the behavior of patients / communities, instead they must remain calm and friendly to give explanation to patients / society.

Commitment to improve the quality of community health centre is an important factor in the delivery of services. Commitments in improving the quality of health services for community health centre must start from the head of the community health centre to all staff, because the commitment is actually an agreement to improve the quality of services to the community. Weak commitment in service will have an impact on not providing maximum service to the community. Not optimal community health centre services will be a public complaint.

Rasulullah’s exemplary values according to the informant must become the attitude and behavior of the community health centre staff, such as shiddiq (honest), trust (trustworthy), tabligh (communicative / transparent), fathanah (intelligent) must be the value of health services, community health centre officers must be honest in providing health services, being able to convey the health condition of the community properly, there are no corruption, collusion and nepotism officers in providing services, being honest with fellow community health centre officers, including not using community health centre facilities for personal gain.

Community health center officers must be trustworthy to do the work according to their main tasks, authority and responsibilities, carry out activities in accordance with the schedule, targets and places that have been determined, be responsible for all actions / services provided to the community, and if there is an error, dare to bear the risks. The nature of tabligh (transparent/communicative) is very important for a community health centre officer to provide services because they must be able to convey information accurately and clearly to the community and be able to motivate the community in achieving performance.

The nature of Fathanah (smart) is one of the characteristics that can be applied by community health centre officers in providing services such as being able to understand the needs and expectations of the community towards community health centre services, acting very carefully and in accordance with policies, guidelines / guidelines, terms of reference for activities and procedures, and being able to carry out analysis on the issue of continuous quality improvement.

**Conclusions and Recommendations**

Based on the results of the FGD conducted with ten informants, all informants agreed that important religious character was applied in the community health centre. The religious characters that should be owned by officers in the community health centre according to the informants are quite varied. The informant stated that religious character cannot be separated from the character of discipline, being honest is one of the religious characters that should be possessed by community health centre officers.

Patience in carrying out the workload according to the informant is very important to be included as
a religious character. Apart from being patient, high commitment, clean and friendly nature also become a character that cannot be separated from religion. According to the informant, being friendly in services at the community health centre is considered an important point in efforts to improve the quality of the community health centre.

Informants agreed that religious characters cannot be separated from values derived from the example of the Prophet in behaving in daily life, namely shiddiq (honest), trust (trustworthy), tabligh (communicative) and fathanah (intelligent / wise).

It is recommended that each officer in the community health centre be able to apply religious character in providing services, so that the quality of service can be sustainable in accordance with what is expected, not limited to just accreditation assessment. In addition, the results of this study suggest that these characters are not only shown when in a service building, but can be applied in daily life including outside service time.

Analysis of the Expression Toll-Like Receptor 4 (TLR4) in Chronic Suppurative Otitis Media with and without Cholesteatoma

Riskiana Djamin¹, Restu Isnayah Handayani¹, Abdul Kadir¹, Muhammad Fadjar Perkasa¹
¹Department of Otolaryngology Head and Neck Surgery, Medical Faculty, Hasanuddin University, Makassar, Indonesia

Abstract

In recent years, the increasing incidence of chronic suppurative otitis media (CSOM) diseases worldwide is often associated with the role of TLR4 as a component of innate immunity. This study aimed to analyze the TLR4 levels in patients with chronic suppurative otitis media with and without cholesteatoma. This study was conducted using the cross-sectional technique on 30 patients divided into two groups. The first group is CSOM with cholesteatoma that consisted of 10 patients and the second group is CSOM without cholesteatoma that consisted of 20 patients. Each sample was examined for TLR4 levels and bacterial identification cultures in secretions and several samples were also examined for TLR4 levels in the middle ear mucosa. TLR4 levels were examined by the ELISA method.

The results showed that TLR4 levels in middle ear secretions and mucosa of CSOM patients with cholesteatoma were higher than chronic suppurative otitis media without cholesteatoma but there were no significant differences. TLR4 levels in mucosal samples are higher than secret samples but there are no significant differences. There were no significant differences in TLR4 levels in both secret and mucosal samples between groups of CSOM with cholesteatoma and CSOM without cholesteatoma. There were no significant differences in TLR4 levels between the secret and mucosal sample in both CSOM with and without cholesteatoma.

Key Words: Chronic Suppurative Otitis Media, Cholesteatoma, TLR4, Innate Immunity

Introduction

Otitis media (OM) is a middle ear infection associated with inflammation. This disease frequently afflicts humans and is the major cause of hearing loss worldwide. Substantial morbidity associated with OM is further exacerbated by the high frequency of recurrent infections leading to chronic suppurative otitis media (CSOM).¹ Chronic suppurative otitis media (CSOM) is a serious health care concern worldwide due to its substantial financial and non-financial burden.² Otitis media is the most common disease in children in the United States, with about 5 billion spent each year in direct and indirect costs.³ The World Health Organization (WHO) estimates that about 65-330 million people suffer from CSOM and that as many as 50% of these have some form of significant associated hearing loss and this disease results in reduced quality of life for patients.¹,⁴

Chronic suppurative otitis media is divided into chronic suppurative otitis media without cholesteatoma and with cholesteatoma. Both are distinguished by looking at the inflammatory process, the presence or absence of cholesteatoma and the location of the tympanic membrane perforation, and different management.⁵ The pathogenesis of otitis media is considered multifactorial, however, a bacterial infection is a major cause of acute and chronic otitis media.⁶,⁷ In a study conducted by Pancawati in 2016 in Makassar, it was found that the
overall pattern of the pathogen that caused CSOM was gram-negative aerobic bacteria. The body’s immune response to microorganisms, including bacteria, consists of innate immunity and adaptive immunity. The innate immunity response acts as a non-specific first-line barrier to defense.

Toll-like receptor (TLR) is a homologous protein in the cell membrane Antigen Presenting Cell (APC) that functions as a functional receptor that activates leukocytes to trigger innate immune responses or inflammatory responses to fight pathogens. TLR is an important mediator and the best innate immune receptor of the innate immune response. There are 11 types of TLRs have been identified from mammals and each response to a different class of pathogenic infections and is named TLR1-11. TLR4 mainly recognizes a large number of pathogens associated with PAMP that are specific to LPS (lipopolysaccharide) in gram-negative bacteria.

Studies in humans have been carried out regarding the role of TLR in CSOM. Studies in animals have added in vivo evidence regarding the importance of TLR as innate immunity in OM resistance. The involvement of the innate immune system and TLRs in OM, as well on their relevance for new vaccination strategies and immunotherapies.

Materials And Method

Patient selection

The research subjects were selected from two patient groups of CSOM: Group I consist of 10 patients CSOM with cholesteatoma and Group II consist of 20 patients CSOM without cholesteatoma. Each sample was examined for TLR4 levels and bacterial identification cultures in secretions. 5 of 10 patients from Group I and 10 of 20 patients from Group II was examined for TLR4 levels in middle ear mucosa. All patients were diagnosed based on history, physical examination and CT-Scan of temporal bone examination. Patients with acute suppurative otitis media, inactive chronic suppurative otitis media, congenital and primary acquired cholesteatoma, and patients with a history of other acute and chronic infectious diseases were not included as subjects in this study.

Middle ear secretion swab culture

Middle-ear swab culture was performed for both sample groups. The external auditory canal was cleaned, and the middle ear discharge was collected using sterile cotton swabs than placed in a sterile tube and subjected to bacteriological examination.

Middle ear secretion collection

The external auditory canal was cleaned, and the middle ear discharge was collected using sterile cotton swabs than placed in an Eppendorf tube contains 1 ml phosphate buffer saline (PBS). The samples were stored in a freezer with a temperature of -20°C for further use in ELISA.

Middle ear mucosa collection

During each operation, the middle ear mucosa was exposed via tympanostomy anterior or posterior. The mucosae were collected using a microcurette and forceps than placed in an Eppendorf tube contains 1 ml phosphate buffer saline (PBS) than stored in a freezer with a temperature of -20°C for further use in ELISA.

ELISA

TLR4 protein levels were selectively tested by ELISA kits. The standard curve range of the ELISA kit is 0.05 ng/ml – 15 ng/ml and sensitivity are 0.027 ng/ml. Middle ear secretion and mucosae from the two groups were recollected. Middle ear secretion and mucosae homogenized in 0.5 ml of PBS. All samples were centrifuged for 5min at 13,000 g and the supernatant was tested in duplicate for TLR4 according to the manufacturer’s instruction.

Statistical Analysis

Data were analyzed using SPSS (Statistical Package for Social Sciences) version 24.0 for Windows. Samples were analyzed using independent T-test.

Results

Types and proportions of cultured pathogens

All of the samples were positive for bacteria. The most pathogen in CSOM without cholesteatoma are gram-negative bacteria, species Pseudomonas aeruginosa with 8 samples (40%), followed by gram-positive species Staphylococcus haemolyticus with 3
samples (15%). The most pathogen in CSOM with cholesteatoma are gram-negative bacteria, species *Pseudomonas aeruginosa* (Table 1).

**Discussion**

In this study, the most pathogen in CSOM with and without cholesteatoma are gram-negative bacteria, species *Pseudomonas aeruginosa*. Pancawati in Makassar also received the most pathogen in CSOM without cholesteatoma are gram-negative bacteria but species *Proteus mirabilis* in CSOM with cholesteatoma. Harshika in India also obtained the dominant microbiological pathogen in CSOM is *Pseudomonas aeruginosa*.

*P. aeruginosa* is the main cause of CSOM disease in the tropics. *Pseudomonas* is more able to survive than other pathogens because it only requires minimal food and produces pyocyanin and bacteriocin which is its ability to carry out local infections in the form of necrotic activity by extracellular enzymes, which have characteristics such as epithelium damage, circulatory breakdown, and loss of tissue protection devitalizing organisms from normal defense mechanisms.

Toll-like Receptors (TLR) 1-10 plays a very crucial role in inducing and activating the natural immune system during an infection. Recent data have shown an important role for TLR in the inflammatory response to bacteria in the ear, and these receptors are particularly important during recovery from otitis media in mice.

Si (2014) on examining TLR4 levels using Real-Time - PCR and Western blot found low TLR4 mRNA levels and TLR4 protein levels in the middle ear mucosa of CSOM compared to normal middle ear mucosa. This is one proof of the involvement of TLR4 in the pathogenesis and recovery of CSOM.

Usually, TLR is expressed in immune cells, epithelial cells, and endothelium. The ligand is called Pathogen Associated Molecular Patterns (PAMP). The TLR bond and its ligand will cause signal transduction to release proinflammatory cytokines such as IL-1 and TNF-α. The most important histopathological features of cholesteatoma are the cholesteatoma matrix, immune cells, and stroma (stroma). The pathogenesis of cholesteatoma is still controversial. Excessive production of several cytokines such as IL-1α and IL-1β is found in the cholesteatoma epithelium and stroma. IL-6 is found in the stroma and intestines of cholesteatoma. These cytokines affect epithelial proliferation and bone resorption that occur in cholesteatoma. The discovery of these inflammatory mediators and the intercellular connecting molecule explain the immunologic aspects of the growth of cholesteatoma.

The results of this study generally obtained levels of TLR4 secret samples and mucosal samples in the CSOM group with cholesteatoma higher than TLR4 levels in CSOM without cholesteatoma but did not show a significant difference. Jesic et al. also found no significant difference in TLR4 expression between the granulation tissue of CSOM with cholesteatoma and CSOM patients without cholesteatoma on
TLR4 examination with histopathological and immunohistochemical examination techniques. Whereas Hirai et al.\textsuperscript{26} found higher TLR4 expression in middle ear mucosa CSOM with cholesteatoma than middle ear mucosa CSOM without cholesteatoma by immunohistochemical examination.

Higher TLR4 levels in CSOM with cholesteatoma caused by an infection process that occurs in CSOM with cholesteatoma is more severe than in CSOM without cholesteatoma. Cholesteatoma is a good medium for bacterial growth so that infection occurs. Infection can trigger a local immune response which results in the production of various inflammatory mediators and various cytokines. Inflammatory mediators and cytokines can stimulate keratinocytes of the cholesteatoma matrix to be hyperproliferative, destructive.\textsuperscript{27} In this study, TLR4 levels did not show a significant difference probably due to the lack of samples in this study.

The results of this study generally obtained levels of TLR4 in mucosal samples higher than TLR4 levels in meddling ear secret samples both on group CSOM with cholesteatoma and CSOM without cholesteatoma but did not show a significant difference. TLR4 levels in the secretions and mucosa which are almost the same and statistically do not show a significant difference in each sample group show that TLR4 levels can be measured using secret samples and mucosal samples.

Bacterial infections are the dominant factor in most cases of otitis media. The natural immune system of the mucosa (epithelial cells and other mucous cells) functions as a barrier and anti-infection. The natural immune system of the mucosa plays an anti-infectious role by recognizing Pathogen Associated Molecular Patterns (PAMP) through Pattern Recognition Receptors (PRR), such as Toll-like receptors (TLR). TLR activation mobilizes the innate immune response, including infiltration of inflammatory cells, production of inflammatory cytokines, and defense against bacterial infections.\textsuperscript{25}

**Conclusion**

TLR4 levels in secret and mucosal samples are higher in CSOM with cholesteatoma than in CSOM without cholesteatoma but there were no significant differences. TLR4 levels in mucosal samples are higher than secret samples but there were no significant differences in both group CSOM with and without cholesteatoma.

Intranatal Care Documentation Information System Integrated With Web-Based Government Employed Midwife Performance Index (Seindah Paniai)

Novita D.Ch.Kana, Ansar Suyuti, Mardiana Ahmad, Syafruddin Syarif, Samrichard, Azniah Syam,

Midwifery Study Program, Post-Graduate School, Hasanuddin University, Faculty of Electrical Engineering, University of Hasanuddin Makassar, Midwifery Study Program, Post-Graduate School, Hasanuddin University, Faculty of Electrical Engineering, University of Hasanuddin Makassar, Pelamonia Hospital Makassar, Nani Hasanuddin Makassar School of Health

Abstract

Introduction. Midwifery care documentation which is written in the forms of Subjective, Objective, Analysis, and Management development (SOAP) is not committed maximally which is caused by the double responsibility, unavailable format, tiredness, limited time, and repeatedly written data in the registering conventional book and it complicates the collecting of midwife’s credit numbers to increase their functional level.

This study aims to design an integrated information system of childbirth care documentation for the credit numbers of civil servant midwives (Seindah Paniai).

Method. The design of Seindah Paniai uses the System Development Life Cycle (SDLC) method. The Prototype of Seindah Paniai system is designed by using MySQL database and Apache web server.

Results. The design of Seindah Paniai system includes: login use, midwife care assignments, patient data, delivery (subjective data, objective data, case analysis, management of I-IV first-time delivery care, informed consent, latent phase observation sheets, partographs, internal reference forms), performance midwife and recapitulation of delivery data in one month. The constructive validity or the content of information system involves experts and intrinsic validity is done with black box testing, all test items are accepted. Reliability of information system uses a questionnaire (Likert) with retesting test and Alpha Chornbach methods (p = 0.832> 0.05).

Conclusion. Seindah Paniai system documented Kala I-IV’s delivery care. Seindah Paniai displays the value of the midwife’s credit number according to the functional level. Seindah Paniai is valid and reliable to use.

Seindah Paniai system needs to be completed with the interesting wall displays and the trials of service system to see the accepting.

Keywords: Information system, Delivery documentation, Midwife performance index.

Introduction

Midwifery documentation is the legal proof of recording and reporting the frame of thought which is used in the process of taking decision in accordance with their competence (1)
Midwifery documentation as a reflection of care models illustrates the problem solving methods which is carried out at each stage of midwifery care in systematic, precise, clear, accurate, concise, and clear manner (2). Documentation is carried out immediately and write it in the note forms on the progress of SOAP (Subjective, Objective, Analysis, Management) that can be a legal evidence for implementation of midwifery care (3).

Dike’s 2015 study on childbirth documentation obtained results: 80 (87%) respondents knew about documentation; 92 (100%) for continuity of care; 89.1% for law; 87% for quality care. But 71 (77.2%) respondents did not do documentation (4).

The role of technology in documenting midwifery in the form of recording and reporting to the Information system has been widely developed, such as SIK 5NG (5). Development of Information Systems for Maternal and Infant Health Services (6), PrasavGraf Android (7), e-Partograf (8) and PartoPen (9).

Information systems with digital partographs have been used as a means of detecting and clinical decision making in childbirth (10,11). But in its implementation, even though midwives have good knowledge about partographs, its use is still lack (12,13).

This case is caused by the lack of midwife motivation, physical and emotional fatigue. Therefore, the support and appreciation from supervisor are needed so that, the care can be well documented (14–16).

One of the appreciation terms for work performances and midwife services is promoting them for being Civil Servants (17). There has been the determination for the number of credit assignments for functional health officials (18) but the application of maternity care with SOAP documentation that refers to normal delivery care does not yet exist.

Preliminary studies about hospitalization in five Public Health Centers in Makassar City and two others in North Luwu Regency found that, the data of delivery was recorded in more than one register manually. The data and recording reports were stored in the form of ‘paper base’ which make it difficult for searching when the data is needed. On the other hand, it also requires much time for finding it which is caused by the buildup of data files. And when the recording data is incomplete, the data or archives cannot be shown. Documentation of giving birth in several places is only a delivery report without any care of providing documents. The unavailable of care documenting format is the reason of the incomplete data to the daily activities of the midwife. When completing the list of proposed credit numbers for an increase in the functional level, the midwife must reopen the stack of delivery care documenting files and manually calculate the credit score acquisition one by one.

MATERIALS AND METHODS

Materials and Methods

The design of Seindah Paniai uses the System Development Life Cycle (SDLC) method, which includes problem identification, need analysis, system design, implementation, and evaluation (19,20). The Prototype of Seindah Paniai system is designed by using MySQL database and Apache web server. The prototype simulation test was carried out for 1 month.

Data analysis

Information systems are validated constructively (involving experts), intrinsic with (black box testing) (21,22) and reliability with the retesting test by using Alpha Cronbach. And the process of collecting data use the SPSS version 24.

Results

Designing Information system

Software for building systems includes: MySQL with programming languages: html, java script, php, css for display; graphic User Interface / GUI for MySQL: phpMyadmin; application for text editor: Sublime Text Editor; File Treanser Protocol (FTP) application: FileZilla.

The results of Seindah Paniai Information designing system

a. Login and start page

Seindah Paniai system can be accessed by logging in the user name using the midwife employee’s number and personal password for each user.
The initial page with the slogan «Save and Health”. Before conducting documentation input, the midwife must input a guard assignment that is tailored to her condition, whether the duty is to keep the shift in place, on call, or to work in the affected area.

The data on registered patients is the biodata of spouse using the citizenship registered number and the patient’s medical record number as the identity key.

b. Delivery

Seindah Paniai system provides subjective data, objective data, analysis and management from the period of giving birth I-IV. The options are checked according to the patient’s condition. Subjective data includes patient complaints, menstrual history, the history of past and postpartum pregnancy, current pregnancy history, family disease, and psychosocial conditions. Objective data includes the whole body such obstetric examinations, internal examinations and investigations. Case analysis consists of physiological cases without problems, physiological problems, pathology, pathology with co-morbidities, and emergencies. Management is adjusted to analyze cases chosen by midwives.

Before the management is done, informed consent is inputted first. In the first stage of childbirth, there is a latent and partograph phase observation sheet to assess the progress of giving birth. In every delivering babies, the care is given by choosing and giving a check mark. If not available in the choice, the midwife can input the care in the column provided. The midwife cared for her according to authority, so that the output of the internal referral form was provided. At the step of IV, midwives completed their documentation in partograph and supervision two hours postpartum. Seindah Paniai system keeps all childbirth documentation in the patient’s medical record file. If data is needed, the medical record
c. Performance (performance index of civil servants midwives)

Government employed midwife performance index are obtained in accordance with midwives’ functional levels and analysis of cases handled, referring to Minister of Health Regulation number 551/2009 (17) and PerMenPAN 001/2008 (23). Seindah Paniai system displays the credit score obtained from each patient at each period of birth and the outgoing credit score in one month. Recapitulation of delivery service coverage data in one month is displayed at the end of the system.

The system of validities and reliabilities.

The Validities of Seindah Paniai system involves the experts (Doctor Specialists Obstetri Ginecology, team members of midwife’s documenting evaluators, the specialists of technology information and the counting of midwife performance index of South Sulawesi province).

The testing of constructive validities and content.

The Items and content which are validated constructively is the format data assessment of subjective, objective, analysis, management (SOAP), and the integrated item with SOAP performance index.

The testing of intrinsic.

The intrinsic validities of Seindah Paniai system use the black box testing. Black box testing examine the special function from application and the test of input and output is for the function without concerning to the process. There are some errors that can be identified such as: the lost and error function, the error between face, the error of data structure (database access) the error of initialization and performance in the end of program (24).

Table 1 shows that the output Seindah Paniai is in accordance with what is expected or received and it can fulfill the needs of user which is free from errors.

c. Reliability Test

The reliability testing of Seindah Paniai system uses a Likert questionnaire with 13 items of questions which include information system logins, guard duty, patient data, SOAP I-IV delivery, performance (SOAP integration and credit score acquisition according to midwife’s functional level) and data recapitulation. Questionnaires with 4 items of answers were tested by retesting test by using Cronbach Alpha (p = 0.832 > 0.05).

Conclusions and Recommendations

Information systems document the period I-IV delivery care. The information system displays the midwife credit score according to the functional level. Valid and reliable information system to be used.

Seindah Paniai system needs to be completed with the interesting wall displays and the trials of service system to see the accepting.

Abstract

Otitis media effusion (OME) is presence of fluids in the middle ear without any sign and acute inflammation symptoms with complete of tympanic membrane. This study aimed to analyse the cotinine level in urine as a risk factor of otitis media in children.

This study is using the analyse observational with case control design. Involving 52 childrens devided into 2 groups. First group consists of 22 patients with otitis media effusion. Second group consists of 30 childrens as controls. The diagnosis of otitis media effusion are determined by tympanometry examination and we found B type for the result. All subjects was checked the cotinine level in urine.

The result of this study show that mostly the cotinine levels in Otitis Media effusion (2.55) a little lower than controls (2.63), but the statistic not significant. This shows there’s not significant relation between cotinine level and otitis media effusion.

Keywords: otitis media effusion, cotinine level in urine, tympanometry.

Introduction

Otitis media effusion (OME) is presence of fluids in the middle ear without any sign and acute inflammation symptoms with complete of tympanic membrane. The presence of fluids in the middle ear can cause decrease function of tympanic membrane that make hearing loss¹ ².

OME generally occurs as a short term disorder accompanying with respiratory infection in children, or as a chronic process. About 80% of children can have one episode of OME before 10 years old with mostly case occurring the range of 6 months until 4 years old and about 50% children sustain bilateral OME ¹ ³.

In 2007, WHO reported all prevalence 3.8% of non suppurative chronic of otitis media ⁴. A cross sectional study in Saudi Arabia showed data on prevalence of OME in 1488 children 6-12 years old) are 7.5% ⁵. Chen and friends in Taiwan reported the frequency of OME in 3013 children (3-6 years old) are 5.24% ⁶. Rizaldi in his study reported the prevalence of OME in the children 0-14 years old in East Jakarta are 1.3% ⁷.

The etiology and pathogenesis of OME are multifactorial. The Expose of cigarette’s smoke is one of the environment factors that cause OME that can cause irritation (toxic trauma) which is can damage the cilia, hyperplasia in the goblet cell, and hypersecretion in the mucus, and impaired function of mucociliary transport in Eustachian tube and middle ear⁸ ⁹.

The American Academy of Otolryngology Head and Neck Surgery (AAO-HNS) officially said that the exposure of cigarette’s smoke can increase the risk of otitis media in children. According to Talaat et al, the effect of harm cigarette’s smoke not only for the active smoker but also risks to peoples around them, especially infants and children¹⁰.

Materials and Method

Study design

This study is using the analyses observational with case control design.
Place and Time

This study took place in ORL-HNS clinic at Wahidin Sudirohusodo Hospital and Hasanuddin University (Unhas) Hospital, research laboratory Hasanuddin University Hospital. Study started from November 2018 until March 2019.

Population and Sample

The population target are children between 0-18 years old who got the ORL-NHS treatment in Wahidin Sudirohusodo hospital and Unhas hospital. The selection population using children between 0-18 years old because WHO announce children until 18 years old have a big risk to get OME and highest prevalence of passive smoker in Indonesia (1).

Data Process

Analyze data using SPSS 2.2 version. Statistic analyze with descriptive statistic calculation and distribution of frequency and also Independent t-test statistical test, if the test result show significant statically.

The test results are significant if the value is p <0.05

Results

Case control study have been conducted in children between 0-18 years old. Total sample 52 children, 22 with OME (Case group), and 30 children without OME (control group).

P can not count because all subjects not cross the cut off level (>100ng/ml).
The mean results of tybe B tympanometry found (2.55) slightly lower than in type A (2.63), but not statistically significant with a value of p> 0.05. This shows that there is no significant relation between cotinine levels and tympanometry results.

**Discussion**

The characteristics according gender in OME sample were obtained with ratio 59%:41% (table 2). Xenelis et al, 3:1. Rizaldi found that comparison between male and female in children range ages 0-14 years old is 1,5: 1.7,11. As Restuty said correlating this study with the volume of mastoid cells in female tend to have a greater volume of mastoid cells than male, so OME is less common in women.12

In this study children with OME were highest ages range of 2 to 16 years old with mean of 9.2 years old (table 1). This is not related with some literature as Casselbrant and Mandel (2014) stating that the prevalence of OME is highest at the age of 6 months to 4 years old and this number will decline at the age of 6. This cause by the anatomy of Eustachian tube in infants and children under 7 years old is shorter and more horizontal and also the unperfect of immune system causes a higher risk of OME in children.12

From samples in table 2, it can be concluded that all samples were passive smoker and there’s no positive of cotinine level were found. This happens because subjective judgments do not always get reliable information, so that’s why the level of exposure can be influenced by the type of cigarrete, the distance to the source of cigarrete smoke, the length of exposure and the condition of ventilation at that time. Its useful for epidemiological study and intervention to control subsequent of exposure to cigarette smoke.13

We found the result of the OR in sleep disorder and snoring that cause the adenoid hypertrofi is 3.8 times and 1.5 times increase the risk of OME. Whereas for common cold that cause by ISPA, increase the risk of OME 1.3 times. In children, OME is generally arises as a short term disorder, with accompanying an upper respiratory tract infection. Several studies have been proven it, Zhang et al in their study, collecting 4 studies of URTI, obtained results that URTI means increasing the risk of Otitis Media. (OR,6,59;95% CL,3,13-13,89;P <0.00001), Children who have a history of URTI in the last 1 month, have chances 7 times to suffer OME, compared to children who do not have a history of URTI.1,23

From table 4, the mean results of type B tympanometry were obtained (2.55) slightly lower than in type A (2.63), but not statistically significant with a value p >0.05. This shows there’s no relation between cotinine level and tympanometry results. In table 3 the mean cotinine level in OME (2.55) was slightly lower than controls (2.63), but not statistically significant. This shows that there is no relation between the cotinine level and OME.

Examination of cotinine level in urine, this study was carried out by the Enzym-linked immunosorbert Assay (ELISA) method, using a cut-off 100ng/ml referring to the Yeh et al study that was available in Indonesia. The result of this study, we found that there’s no positive cotinine level or exceeded the cut off limit in case group or group controls. The result of this study not correlated with the theory which state that exposure to cigarette smoke...
smoke acts as a risk factor of OME which is believed to occur through the mechanism of irritation in Eustachian tube and middle ear that cause hyperplasia of goblet cell and damage the cilia can cause disappearance function of mucociliary transport.15

Some study have different in setting the cut off rate of cotinine level in urine to assess a person’s smoking status between not being exposed to cigarette smoke (non smoker and being exposed (active/passive smoker). Moyer et al. conclude that the cut off 20 ng/ml for the boundary between non smoker and mild passive smoker used the HPLC tandem mass spectrometry method. Yeh and friends set a cut of 100 ng/ml to limit non smoking status and smokers (passive and active) using the lateral flow chromatographic immunoassay method.14,17,18

According to Danch, to get an estimate of cut off the cotinine level in urine, its necessary to have a statistical distribution of cotinine level in urine for the local population so that’s persons smoking status can be distinguished. Cut-off number can be different among population in various regions of the world because of many influencing factor. Kwon et al. stated that cotinine metabolism from nicotine is associated with genetic polymorphism of cytochrome P450 (CYP) 2A6.15-21

There have been no studies in Indonesia determined the cut-off of a person’s smoking status, so the authors refer to the study of Yeh et al, who used a cut-off 100ng/ml using the lateral flow chromatographic immunoassay method that available in Indonesia. The cut-off number has a sensitivity of 92% and specificity of 91 %14. But according to Jung and Danch’s opinion, that the cut-off number will different between population in various regions, of course the cut off selection in this study that refers to the study of Yeh et all has limitations because held in another populations. So that method of analysis and determination of the cut-off in this study needs to be adjusted to the characteristic of the Indonesian peoples.

Conclusion

That can not be proven significantly, the cotinine levels in urine as a risk factor of OME. Upper respiratory tract infection and adenoid hypertrophy increase the risk factor of OME. OME is more common in male than female. Need a further study with an objective method of analysis the cotinine levels in urine using other techniques and large of samples size to obtain more accurate data. We need to set the cut-off number of value as a reference for cotinine levels in urine.

Analysis of Plasma F2-Isoprostane Level After Administration of Vitamin C in Patients with Chronic Tonsillitis

Sutji Pratiwi Rahardjo¹, Abdul Qadar Punagi¹, Magdalena Octavia Sidabutar¹, Muh. Fadjar Perkasa¹
¹Department of Ear, Nose, Throat, Head-Neck Surgery, Medical Faculty, Hasanuddin University, Makassar, Indonesia

Abstract

Background: Chronic tonsillitis can cause oxidative stress in the body.

Objective: The study aims to analyse plasma F2-Isoprostane level in chronic tonsillitis patients with and without risk of Obstructive Sleep Apnea Syndrome (OSAS).

Materials and Method: The design of this study is a clinical trial with pre and posttest control group. Sampling was done in Wahidin Sudirohusodo Hospital and Kassi-kassi Health Center, Makassar. In this study, the sample size of each group was 20 samples, consisting of chronic tonsillitis patients with OSAS risk in the first group and chronic tonsillitis patients without the risk of OSAS in second group. Both groups were given 1x1000 mg tablet of vitamin C for 14 days.

Results: The results of this study showed that there was no significant decrease in plasma F2-Isoprostane level in patient with chronic tonsillitis with and without risk of OSAS after administration of vitamin C. There was no significant difference in decreased of plasma F2-Isoprostane level in patients with chronic tonsillitis at risk of OSAS after the administration of vitamin C especially in chronic tonsillitis patients without OSAS risk.

Conclusions: There was no significant decrease in plasma F2-Isoprostane level in patient with chronic tonsillitis with and without risk of OSAS after administration of vitamin C. There was no significant difference in decreased of plasma F2-Isoprostane level in patients with chronic tonsillitis at risk of OSAS after administration of vitamin C especially in chronic tonsillitis patients without OSAS risk.

Key Words: Chronic Tonsillitis, OSAS, F2-Isoprostane, Vitamin C

Introduction

Chronic tonsillitis is the most common disease of recurrent inflammation of the throat. Based on medical records of Laryngology and Pharyngology of ENT Head and Neck Department in 2010 at RSUP dr. M. Djamil Padang stated that there were 465 patients diagnosed with chronic tonsillitis from a total of 1110 patients visit at the sub-laryngeal polyclinic and 163 cases underwent tonsillectomy, meanwhile the number of the new patients diagnosed with chronic tonsillitis at Wahidin Sudirohusodo Hospital Makassar from January 2013 until July 2018 were 320 patients.

A study conducted by Khan et al at Khyber Hospital, Pakistan in 2011-2012 regarding the distribution of ENT disease and found 8980 people suffering from chronic tonsillitis as much as 27.37%. In this study chronic tonsillitis was at the top of the incidence of other ENT diseases. Another study conducted by Alfrida (2009) in Makassar found that chronic tonsillitis was also found in school age of 5-15 years (61.4%).

Corresponding author:

Chronic tonsillitis with or without adenoid hypertrophy is very common in childhood. Recurrent inflammation can cause sore throat, fever, dysphagia and malaise. Chronic tonsillitis is one of the most common causes of Obstructive Sleep Apnea Syndrome (OSAS) in children and lead to negative impact on sleep quality.  

OSAS is the forced cessation of breathing during sleep for at least 10 seconds, with a decrease of oxygen in the blood due to blockage of the upper respiratory tract. This is characterized by the occurrence of hypopnea, where respiration decreases by more than 50% at least 5 times per hour. This metabolic change triggers oxidative stress and systemic inflammation which then causes the release of reactive oxygen species, antioxidant enzymes and inflammatory indicators.  

The definitive diagnosis of OSAS is by polysomnography. In some countries, if polysomnography is not available, other parameters can be used such as Berlin questionnaire, Epworth Sleepiness Scale (ESS) as a parameter for OSA diagnosis.

In India a study was conducted to test the validity of Berlin questionnaire to identify patients at risk of developing OSA, this questionnaire was considered easier to use and more accurate. With this questionnaire people could be differ from high risk and low risk of OSA, and the internal reliability is acceptable because the answers of each questionnaire are assessed per category.

OSAS is characterized by the present of period of recurrent upper airway collapse which results in a hypoxic or reoxygenation cycle and causes an increase in oxygen species formation by oxidative stress. The oxygen free radicals formed will catalyze lipid peroxidation which will produce isoprostane. Carpagnano et al (2002) reported that isoprostane in peripheral blood and exhalation of condensate in OSAS patients has increased.

Free radicals are involved in various pathological conditions including chronic tonsillitis. Lipid peroxidation is the main indicator of free radicals related to the severity of cell membranes. Free radicals including Reactive Oxygen Species (ROS) and lipid peroxidation formed in chronic tonsillitis can increase, lead to cell damage and tissue injury. Plus, the free radicals can damage the leukocyte lipid membranes, hence permeability increases and reduces the function of leukocyte immunity. It can also damage DNA, thus reducing the synthesis and reproducibility of leukocytes. Human body will form antioxidants to prevent further cell damage. Low levels of antioxidants can cause frequent tonsillar infections.

The formation of free radicals will not cause damage or interfere the physiological processes of the body if the enzymatic protection system (the free radical scavenger) and non-enzymatic protection systems (antioxidants) are sufficient to inhibit the reaction of the free radical and can detoxify the formed free radicals. One of the non-enzymatic protection systems for free radicals is vitamin C. Vitamin C acts as an antioxidant by donating the hydrogen atoms to free radicals. A study conducted by Block et al. (2008) that dose of vitamin C was given 1000 mg per day for two months can reduce plasma F2-Isoprostane level in overweight smokers, passively exposed nonsmokers and healthy nonsmokers. Another study conducted by Moreno et al (2004), by giving the orange juice rich in vitamin C can reduce plasma F2-isoprostane level in healthy people on day 14th.

Materials and Method

Patient selection

The research subjects were selected from two groups of chronic tonsillitis: Group I consist of 20 patients chronic tonsillitis with OSAS risk and group II consist of 20 patients chronic tonsillitis without OSAS risk and both groups were given 1x1000mg of vitamin C for 14 days.

Sampling procedures

History taking and examination (otoscopy, anterior and posterior rhinoscopy, pharyngoscopy, indirect laryngoscopy) were conducted on the patients with the inclusion criteria as samples. The subject or patient’s family signed the informed consent form. The subjects filled out the Berlin questionnaire which evaluated the symptoms of OSA. Examination of plasma F2-Isoprostane level with the working principle:

Taking Blood Samples

Performed in the cubital median vein. Draw 3 cc of blood using a needle into a tube that already contains EDTA. Plasma separation and storage is carried out in the Molecular Biology Laboratory of Hasanuddin University Hospital Makassar.
Measurement of plasma F2-Isoprostane level was measured in the Molecular Biology laboratory of Hasanuddin University Hospital Makassar. Measurements were made according to the Enzyme-Linked Immunosorbent Assay (ELISA) method.

ELISA

F2-Isoprostane measurement were carried out according to the ELISA method.

Statistical analysis

All data is processed using SPSS version 22, then tested using the T-Test.

Results

From January 2\textsuperscript{nd} 2019 to April 4\textsuperscript{th} 2019, a study was conducted to analyze the plasma F2-Isoprostane level in patients with chronic tonsillitis after giving 1x1000 mg of vitamin C for 14 days. Chronic tonsillitis patients with inclusion criteria were given the Berlin questionnaire to assess the risks of OSAS, then their plasma F2-Isoprostane level were examined.

In this study there were 40 samples of chronic tonsillitis patients, 20 samples were chronic tonsillitis patients with risk of OSAS and 20 samples of patients with chronic tonsillitis without risk of OSAS and both groups were given 1x1000 mg vitamin C for 14 days.

Table 1 shows that most samples in this study were female which is 24 patients (60%). The most common age was <20 years which is 15 patients (37.5%). As for tonsil size category, 25 patients (62.5%) with T2-T2 and 15 patients (37.5%) with tonsil size T3-T3.

Table 4 shows a comparison of the decrease in F2-Isoprostane level between chronic tonsillitis patients with OSAS risk and without OSAS risk. The average decrease of F2-Isoprostane level in patients with chronic tonsillitis with OSAS risk is 21.54 with a standard deviation of 48.92, while the mean average of F2-Isoprostane decrease level in patients with chronic tonsillitis without OSAS risk was 8.81 with a standard deviation of 44.19. Based on the independent T-test statistical tests showed that there was no significant in comparison of the decrease in F2-Isoprostane levels between chronic tonsillitis patients with OSAS risk and without OSAS risk with a value of $\rho = 0.751$ ($\rho < 0.05$).

### Discussion

This study were conducted on 40 chronic tonsillitis patients who came to the ENT Head and Neck polyclinic of Dr. Wahidin Sudirohusodo Hospital and Kassi-Kassi Health Center from January 2nd to April 4th 2019. To assess the prevalence of Obstructive Sleep Apnea Syndrome (OSAS), patients and their families were given Berlin questionnaires that has been translated into Indonesian. This questionnaire consists of three parts. The first part is about do they snore, how hard and how often they snore and if it disturbs others. The second part is about do they experience fatigue after sleep, how often they feel tired and have they fall asleep while driving. The third part includes the history of high blood pressure. Someone is assumed at risk of OSAS if they have at least two of the above criteria.

From 40 samples, venous blood sampling was carried out in 20 chronic tonsillitis patients with OSAS risk and 20 chronic tonsillitis patients without OSAS risk. Then the blood samples were sent to the laboratory of University Hasanuddin Hospital Makassar to examine plasma F2-Isoprostane level.

The results of this study found that the proportion of women (60%) is higher than men (40%) whom were diagnosed with chronic tonsillitis. This is corresponded with the study reported by Shalihat, et al. (2015) as chronic tonsillitis were most commonly affects female which is 84 people (56.4%). Teenagers are more concerned with their body shape and appearance so many of them will delay their eating schedule and reduce the portion of food they consume as for a perfect body posture. But this behavior will lead to malnutrition and weaken the body immunity which then vulnerable to infections and other health problems.

Out of the total number of 40 patients, maximum number of patients belonged to the age group of less than 20 years (37.5%). This is corresponded with the study conducted by Alfrida in Makassar (2009) at which the percentage of chronic tonsillitis patients at school age of 5-15 years were 61.4%. These children often consume unhealthy foods which contain a lot of preservatives, sweeteners and also cold drinks. These foods and drinks can cause irritation to the throat, which can lead to infection of the throat or tonsil. Besides, children who often suffer from upper respiratory tract infection or acute tonsillitis usually are not adequately treated.

The most tonsil size found was T2-T2 in 25 samples (62.5%). This is different from the study reported by Shalihat, et al. (2015), as mostly tonsillar size in patients with chronic tonsillitis is T3-T3. In chronic tonsillitis there is a persistent or recurrent infection occur, causing the tonsils to work harder to fight germs so that the tonsil become enlarged. Consequently, hyperplasia and fibrosis formation from the parenchymal connective tissue and lymphoid tissue results in tonsillar hypertrophy.

In this study, there was a decrease in plasma F2-Isoprostane level in patients with chronic tonsillitis...
with OSAS risk after the administration of vitamin C for 14 days, which is from 106.92 to 85.38, but this is not statistically significant (\(\rho\) value = 0.064). While in patients with chronic tonsillitis without OSAS risk there was also a decrease in plasma F2-Isoprostane levels after administration of vitamin C for 14 days, which is from 80.19 to 71.37, but not statistically significant (\(\rho\) value = 0.383). Previous study by Alain (2011)\(^1\) has shown that isoprostane level was significantly higher in OSAS patients compared to healthy patients. Some mechanisms are responsible for increasing ROS and RNS production in OSAS, including recurrent hypoxia and reoxygenation cycle, increased of inflammatory response, sympathetic activity and ROS production.\(^1\)\(^8\) Recurrent hypoxia occurs in patients with OSAS. Hypoxia will decrease the oxygen supply to tissues and cells, thus disrupt the electron transport to the cell membrane. These result in electron leakage and lead to oxygen radicals formation that will trigger the occurrence of superoxide radicals (\(O_2^-\)). Superoxide radicals can damage cells and tissues.

Sleep apnea syndrome has been recognized as a very common public health problem (3-6% in adult population) with an increase of cardiovascular morbidity and mortality. The studies recognize the most common form in syndrome (80%), obstructive sleep apnea syndrome (OSAS), as 60-70% of patients are obese, about 68% is hypertensive patients, 63% of dyslipidemia, and 16% are diagnosed with type 2 diabetes or prediabetes.\(^1\)\(^9\)

OSAS consists of recurrent apnea episodes or hypopnea during sleep resulting in hypoxemia. The cycle change in arterial oxygen saturation can increase ROS production and disturb the balance between prooxidants and antioxidants. The recurrence episodes of apnea or hypopnea and the decreased of oxygen saturation in the blood can alter cell metabolism, such as ischemia or reperfusion. Thus, result in loss of cell compartment integrity. At this state, the iron released from lysosomes can cause or increase the production of free radicals. These abnormalities in cell then followed by mitochondrial damage, associated with a direct relationship of free radicals to the respiratory chain. Both of these situations result in the accumulation of ROS, namely superoxide radicals (\(O_2^-\)).

From this study there were differences in the decrease of F2-Isoprostane level between chronic tonsillitis patients with OSAS risk and without OSAS risk, but it is not statistically significant (\(\rho\) value=0.751).

The average decrease in F2-Isoprostane level in patients with chronic tonsillitis with OSAS risk is 21.54, whereas chronic tonsillitis patients without OSAS are 8.81. Based on the study reported by Soetjipto (2007)\(^2\), airway obstruction can cause OSAS, from 79 samples of adults there were 64.56% with multi-location obstruction. The location that caused obstruction in most adults was nasal turbinates (76.4%), followed by oropharynx due to enlargement of tonsils (65.91%) and velopharynx caused by palatal abnormalities (64.81%). Besides that, obstructive hypoventilation is caused by the partial obstruction of the air flow which causes hypoventilation and hypoxia.\(^2\)\(^1\)

Oxidative stress has been involved in various diseases including cancer, cardiovascular disease, ischemia or reperfusion, aging, and chronic tonsillitis. Reactive oxygen species (ROS) including hydroxyl radicals, superoxide radicals, and hydrogen peroxide, which are produced by activated granulocytes, play an important role in many biochemical processes such as intracellular messages in cell differentiation, apoptosis, immunity, and defense against microorganisms. In contrast, the overproduction of these ROS, which occurs in inflammation process, produces oxidative stress. The main target of ROS is polysaturated fatty acids in cell membranes that cause lipid peroxidation and isoprostane formation, which can cause damage to cell structure and function.

There are many evidences show that ROS during chronic inflammatory process mediates the regulation of tonsillar pathophysiological functions. The inflammatory response is the first protective barrier against upper respiratory tract infections. Several recent studies have shown that inflammatory reactions are often closely related to the generation of free radicals. It has been shown that oxidative metabolism of peripheral blood granulocytes is altered in 30% of patients with tonsillar hypertrophy and in 75-90% of patients with recurrent tonsillitis.\(^2\)\(^2\)

OSAS is characterized by a recurring period of upper airway collapse and a hypoxic or reoxygenation cycle that causes an increase in oxygen species formation by oxidative stress. Oxygen free radicals formed will catalyze lipid peroxidation which will produce isoprostanes. Research conducted by Carpagnano, et al (2002)\(^1\)\(^1\) showed that isoprostane in the peripheral blood and condensate breaths from patients with OSAS.
were increased. Hypoxia is a condition of low oxygen concentration in cells or tissues that can threaten the life of cell, and it can result in cell injury which will cause an increase in ROS by mitochondria. Cells have a defense against attack from ROS, in the form of antioxidant enzymes, they act as inhibitors that can inhibit oxidation by reacting with reactive free radicals that will form non-reactive free radicals. In the body, free radicals cause lipid peroxidation processes which can produce isoprostane compounds.

Isoprostane is a prostaglandin-like compound formed in vivo through lipid peroxidation through unsaturated fatty acids. Isoprostane has several advantages over other oxidative stress biomarkers. One of the advantages of isoprostane is that chemically stable. Isoprostane has a different ring structure and has strong biological activity.

Vitamin C is one of the antioxidants that dissolves in water, has an effect as free radical scavenging and inhibiting the process lipid peroxidation. The study conducted by Block et al. (2008) that dose of vitamin C was given 1000 mg per day for two months can reduce plasma F2-Isoprostane level in overweight smokers, passively exposed nonsmokers and healthy nonsmokers. This difference in results may be due to a short duration of intervention, a lack of patient compliance with vitamin C, patients exposed to cigarette smoke even though as a secondhand smoke and other extrinsic factors which can increase levels of free radicals.

Vitamin C is an effective antioxidant and is called the first defense system. When ascorbate runs out, F2-Isoprostane will form in plasma which is exposed to aqueous peroxyl radicals, so that vitamin C can be used as an antioxidant against lipid peroxidation.

**Conclusion**

There was an insignificant decrease in plasma F2-isoprostane level in patients with chronic tonsillitis with and without risk of OSAS after administration of vitamin C and there was no significant difference in decreased of plasma F2-isoprostane level in patients with chronic tonsillitis at risk for OSAS after administration of vitamin C especially in chronic tonsillitis patients without OSAS risk.

Comparison of Intraoperative Bleeding and Postoperative Pain of Tonsillectomy Using Method of Radiofrequency Dissection and Excision Dissection

Amsyar Akil¹, Eka Savitri¹, Heike Wilda Lokey¹
¹ Department of Ear, Nose, throat, head-neck surgery, Faculty of Medicine, Hasanuddin University, Makassar

Abstract

Background: The operation of tonsillectomy in addition to the technique of simple tonsillectomy can also be done by the technique of bipolar radiofrequency that in research in 2007 in German universities found postoperative pain and Intraoperative bleeding is significantly lower with the use of bipolar radiofrequency compared with simple tonsillectomy. To date, there has been no research on the comparison of radiofrequency techniques and excision dissection in Indonesia, especially in Makassar.

Purpose: Find the best tonsillectomy technique based on the volume of bleeding and postoperative pain.

Research materials and methods: This research is done by the cross sectional of fourteen patients. The tonsillectomy procedure done by using radiofrequency dissection of 6 patients and with excision dissection of 8 patients, then measured the number of intraoperative bleeding and postoperative pain.

Results: This study showed that there was a decrease in the volume of intraoperative bleeding and a lighter pain in radiofrequency dissection compared to the excision dissection that was evaluated during the 6-hour post-operative. The 24-hour postoperative evaluation does not exhibit significant pain differences in both dissection techniques.

Conclusion: The use of radiofrequency techniques in tonsillectomy procedure is better than the excision dissection technique because it can reduce the volume of intraoperative bleeding as well as the lighter postoperative pain complained.

Keywords: chronic tonsillitis, radiofrequency, excision dissection

Introduction

Tonsillectomy is the most commonly performed procedure in the history of surgery and one of the oldest procedures that is still done since 1000 BAD and the frequency decreases drastically since the emergence of antibiotics. In 1985 in the United States, the incidence of tonsillectomy was 350,000 to 400,000 per year and in 2006, more than 530,000 operating procedures of tonsillectomy in children were carried out. In the last decade, the tonsillectomy is not only performed for recurrent tonsillitis, but also for a wider range of conditions including dietary difficulties, weight gain failure, overbite, tounge thrust, halitosis, snoring, and also Speech disorder. The American Academy of Otolaryngology-Head and Neck Surgery has issued an official recommendation which is an agreement of experts on the indication of the action of Tonsillectomy.¹, 2, 3

Corresponding author:
Wilda Heike Lokey,

Tonsillectomy can cause pain, bleeding and edema in the injured part, sore throat, difficulty swallowing, eating and drinking disorders, nausea and vomiting until it falls on a state of dehydration. It can decrease patient
satisfaction against the operation of Tonsilectomy. The results of previous retrospective studies received a secondary incidence of post-tonsillectomy reaching 10.1%, this is largely due to the release of mediators during pain that resulting an increased treatment duration. 4

The use of radiofrequency is widely applied in the medical world. Previously researched use of radiofrequency in fat-attachment surgery on the palate, 5 on thoracic surgery and joint operations, 6 and also used for chemotherapy, 7 some researchers also connect the use of radiofrequency in surgery Adenootonsillectomy in patients with cochlear implant implants with results of no influence that worsens due to the use of radiofrequency. 8

The study of Pfaar et al for treatment using bipolar radiofrequency compared with simple tonsilectomy was conducted at German University in 2007 with results on radiofrequency groups, found that Postoperative pain, difficulty swallowing and speaking, and intra-operative blood loss is significantly lower, and the operating duration is significantly shorter (all p < 0.05). 9

Materials and Method

Patient Group Criteria

The study consisted of 14 patients suffering from chronic tonsillitis undergoing tonsilectomy and divided into two groups. The first group, 6 patients of chronic tonsillitis, used a radiofrequency dissection and a second group of 8 patients with chronic tonsillitis, using excision dissection technique. Patients conducted anamnesis, physical examination, as well as fill in the approval of the operation procedure and conducted laboratory examination and thorax x-ray for the preparation of surgery. The postoperative patients was given the same analgesic paracetamol that is adjusted for the patient’s weight. Patients with persistent adenoid hypertrophy, lower respiratory tract infection, tonsil tumor, anatomical disorder of the head and neck area, suffering from systemic or metabolic diseases such as diabetes mellitus, hypertension, stroke, pulmonary tuberculosis, and blood disorders patients, are included in the exclusion criteria.

Intra-operative bleeding measurement

The bleeding measured in this study is an intra-operative bleeding measured based on the volume of the gauze weight mixed with blood reduced by the initial kassa weight of 0.4 grams, then calculated based on the calculation of blood density overall is 0, 94x10^-9 in ml and added to the volume of blood in the suction tube that has been reduced by another fluid used to rinse.

Measurement of postoperative pain

Pain is calculated by using a visual analog scale (VAS) with the results obtained are the value of VAS more than 0 mm and less than 10 mm expressed no pain, mild pain is the value according to the VAS more than equal to 10 mm to 30 mm, moderate pain is values according to VAS 31 mm to 70 mm. Severe pain is the value according to VAS 71 mm to 90 mm, very severe pain is the value according to the VAS 91 mm to 100 mm. This pain measurement is measured during 6 hours post-operative and 24-hour post-operative.

Results

Sample characteristics

The gender of the sample is more male sex patients who are 8 people (57.14%) The most sample age is the age of <20 years, which is 6 people (42.86%), for the category of tonsils size 6 people (42.86%) has a tonsils size of T2-T2 and 8 persons (57.14%) has a T3-T3 tonsils size.

Comparison of the volume intraoperative bleeding between an excision dissection and radiofrequency surgery
The mean value of the volume of bleeding in the excision dissection of the surgery is 75.625 ml with a standard deviation of 49.3672, while the average volume of bleeding in radiofrequency surgery is 7.612 with a standard deviation of 4.4058. According to statistical T-test shows that there is a comparison of the volume of significant bleeding between the patient’s excision dissection and radiofrequency with a value of \( \rho \) value = 0.000 (\( \rho = < 0.05 \)) (table 2).

**Discussion**

In this study, it can be seen that most male gender samples were 8 people (57.14%), evidenced by the study results on the profile of tonsillitis patients in Sangla hospital, men are more often exposed to tonsillitis because men have lower immune system than women, where women Has an estrogen hormone that has functions as a reinforcement of humoral and cellular antibodies.
The most sample age is < 20 years, which is 6 people (42.86%), describing that children and adolescents have low body resistance so it is easy to get infected. Described also in some children followed by the enlargement of the adenoid gland. So that there can be an obstruction in respiratory system at bedtime is referred to as OSAS (Obstructive Sleep Apnea Syndrome). Obstruction of upper respiratory system that occurs at bedtime can cause hypoxia (lack of oxygen), this condition can decrease Immunological resistance that can lead to infection and frequency of pain can interfere with children’s growth and development, especially in childhood growth, so that the tonsillectomy needs to be done. Carneiro study in Brazil also reported improvement in quality of life in children who have had tonsillectomy. This occurs due to reduced sleep disorders caused by tonsil hypertrophy. The tonsillectomy also reduces the incidence of upper respiratory tract infections and reduce antibiotic use.

In this study there were 6 people with a tonsils size of T2-T2 (42.86%) and 8 people have a tonsils size of T3-T3 (57.14%), which means the largest tonsils size is found to be the size of T3 – T3. This result was in accordance with the cross sectional study in 812 patients who had tonsillectomy, there were 341 (42%) with a tonsils size of T3, as much as 308 (38%) T4 size, as much as 130 (16%) T2 size and as much as 33 (4%) ukuranT 1. Until now there is no data that can explain about the differences between some of these studies. One of the tonsils enlargement factors is the infection in tonsils. The size of the tonsils is enlarged due to a parenchyma hyperplasia or fibrinoid degeneration with a crypts tonsils obstruction. Recurrent infections and blockages of the tonsils resulting in increased stasis of debris or antigen in the crypts, also occurring reduced integrity of the crypts epithelium so as to facilitate bacteria into tonsil parenchyma.

This study showed a comparison of the bleeding volume between excision dissection and radiofrequency surgery. The average volume of bleeding in an excision dissection is 75.625 ml with a standard deviation of 49.3672, while the average volume of bleeding in radiofrequency surgery is 7.612 with a standard deviation of 4.4058. Based on statistical T-test shows that there is a significant comparison of the bleeding volume between the patient’s excision dissection and radiofrequency with a value of Pvalue = 0.000 (p = < 0.05). The Volume of bleeding during surgery depends on the condition of the patient and its own operatoric factor. Bleeding may be more when there is excessive scarring or acute infections such as acute tonsillitis or peritoncil abscesses. Bleeding that occurs due to capillary or small veins, ripped veins generally stop spontaneously or with tampons. If it still fails, the external carotid artery ligation can be performed. From reports of various libraries, the surgical techniques known as “hot” techniques (Electrokauter, radiofrequency, Koblasi, etc.) can reduce morbidity and risk of postoperative bleeding.

Comparing the 6-hour postoperative pain between excision dissection and radiofrequency, the average pain in excision dissection is 6.13 with a standard deviation of 0.64, while the average pain in radiofrequency dissection is 5.50 with a standard deviation of 2.07. According to statistical T-test shows that there is a significant ratio of pain between the patient’s excision dissection and radiofrequency with a value of Pvalue = 0.000 (p = < 0.05). Whereas at 24 hours post operation, comparison of pain between dissection radiofrequency and excision dissection obtained the average pain in excision dissection is 3.38 with a standard deviation of 1.18, while the average pain in the dissection of radiofrequency is 4.17 with a standard deviation of 1.94. Based on statistical test T-test shows that there is no significant comparison of pain between the patient excision and dissection of radiofrequency with a value of Pvalue = 0.484 (p = < 0.05). Of these two different pain statements can be seen that each person’s pain threshold differs. For severe post-operative pain tonsilectomy depends on several factors, such as: patient’s health condition, operator skills, tonsilectomy technique, surgical complications and pain management.

Comparative postoperative pain reduction between excision dissection and radiofrequency dissection obtained an average decrease in pain in excision dissection is 2.75 with a standard deviation of 1.03, while the average reduction of pain in radiofrequency dissection is 1.33 with standard deviation 2.06. Based on T-test statistics, there is a significant comparison of the pain reduction between the patient’s excision dissection and the dissection of radiofrequency with a value of Pvalue = 0.010 (p = < 0.05). This suggests that in the excision dissection there is a noticeable change of pain reduction from the 6-hour post-operative to the 24-hour postoperative. The possibility of the use of the dissection dissection of many tissue damage occurs compared to the use of radiofrequency. This is in accordance with the literature says that pain caused by tissue damage as well
as increased release of the mediator that can generate pain impulses subsequent pain and finally causing muscle spasm \(^{(16,20)}\)

The frequent postoperative pain of tonsillectomy is difficult to prevent since the oropharyngeal region and fossa of the peri-tonsiller are pain-sensitive areas. Both are innervate by the trigeminal nerve (n. III) branches and the glossosfaringeus nerve (n. IX) which is highly sensitive to pain stimulation and connected to the somatic cortex in the cerebral. \(^{(18,19)}\)

Post-operative pain management of tonsillectomy is a special concern for both ENT-HN surgeon and anesthetic doctors. High incidence of pain or postoperative anxiety after tonsillectomy increase the risk of secondary bleeding of postoperative tonsillectomy. \(^{21}\)

To prevent these postoperative pain, it is necessary to know the mechanism for postoperative pain, the negative impact of pain, the effort to reduce postoperative pain and to choose rational analgetic to overcome the postoperative pain of tonsillectomy. \(^{412}\)

In research from Victor et al. 2018 the use of radiofrequency can reduce postoperative pain in comparison with other methods of operation. \(^{12}\)

**Conclusion**

The use of radiofrequency techniques in tonsillectomy is better than the excision dissection technique because it can reduce the volume of bleeding occurring as well as the pain complained more lighter.

Patients undergoing tonsillectomy using radiofrequency should be considered for analgesic use while those undergoing excision dissection should use analgesic for postoperative pain treatment.

Relationship between Inflammatory Response on Chronic Rhinosinusitis with Polyps and without Polyps Review for IL-8, Eosinophil and Neutrophil

Abdul Qadar Punagi¹, Sofiatun Nurhuda Putri¹, Husni Cangara², Sutji Pratiwi¹
¹ Department of Otorhinolaryngology, Head-Neck Surgery, ²Department of Pathology Anatomy, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia

Abstract

Background: This study aimed to ascertain the association between inflammatory response in chronic rhinosinusitis with polyp and without polyp based on IL-8, eosinophil, and neutrophil observation.

Method: the study was conducted on 20 chronic rhinosinusitis patients with polyp and 20 chronic rhinosinusitis patients without polyp. Examination of IL-8 level was done by using ELISA method, while eosinophil and neutrophil cell examination was done by using nasal cytology.

Results: Of the 20 patients with chronic rhinosinusitis with polyps and 20 patients without polyps, IL-8 levels were significantly increased in patients with chronic rhinosinusitis without polyps. Meanwhile, in nasal cytology examination, eosinophil cells increased dominantly in chronic rhinosinusitis patients with polyps, while neutrophil cells increased dominantly in chronic rhinosinusitis patients without polyp (p<0.05).

Conclusion: There were difference of IL-8 level and eosinophil, neutrophil cells between chronic rhinosinusitis with polyp and without polyp.

Keywords: IL-8, eosinophil, neutrophil

Introduction

According to the 2012 European Position Paper on Rhinosinusitis and Nasal Polyps (EPOS), chronic rhinosinusitis (RSK) is an inflammation of the nasal mucosa and paranasal sinus which symptoms’ last for than 12 weeks, characterized by two or more symptoms, such as nasal congestion, obstruction, congestion or nasal discharge. This condition can be accompanied by facial pain spontaneously or appear when suppressed, and reduced ability to smell. Meanwhile, in endoscopic examination could find polyps or mucopurulent secretions from mediated meatus and edema in the meatus. Besides, Computed Tomography (CT) scan results are obtained mucosal changes in the ostiomeatal complex or paranasal sinuses.¹

Rhinosinusitis is an inflammatory disease of the nasal mucosa and paranasal sinuses. According to consensus of 2004, rhinosinusitis is classified chronologically into several categories; acute (up to 4 weeks), sub-acute (4 to 12 weeks), and chronic (more than 12 weeks). When it occurs on several sinuses, it is called multisinusitis and called pansinusitis if it occurs on all sinuses.²

The prevalence of chronic rhinosinusitis has also been reported in several areas in Indonesia. A study in Cipto Mangunkusumo Hospital’s Department of ENT’s Rinology Division found 69% of 435 patients had rhinosinusitis, while a study in Makassar which taken from three hospitals had prevalence 41.5% of all cases treated in rhinology sub-division.³⁴

Chronic rhinosinusitis can be classified into two subtypes namely chronic rhinosinusitis without polyps and rhinosinusitis with polyps. The two groups are different in inflammatory profile and remodeling process. Those differences can affect prognosis, asthma comorbidity, appropriate surgical procedures, relapse rates, and pharmacological management.

The main cause of chronic rhinosinusitis is obstruction of sinus ostium. Various factors, either local or systemic can cause inflammation or conditions that lead to obstruction of the sinus ostium, such as recurrent upper respiratory tract infections, allergies, irritant material exposure, anatomic disorders, and immune deficiency. Although some studies mentioned the role of eosinophils in the pathogenesis of chronic rhinosinusitis, especially in patients with a history of allergies, other studies also mentioned the effect of neutrophil recruitment into mucosal surfaces, especially in patients without a history of allergies.

**Materials and Method**

This study was conducted in otorhinolaryngology division of Hasanuddin University Hospital and Wahidin Sudirohusodo hospital during December 2018-March 2019. This study aimed to identify the difference of inflammatory responses (IL-8 levels, eosinophils, neutrophils) in patients with chronic rhinosinusitis with polyps and without polyps, and also observed the pathomechanism of the occurrence of polyps in chronic rhinosinusitis.

The sample is affordable population who met the study criteria. Samples were taken by using consecutive sampling method, which is all patients with chronic rhinosinusitis with polyps and without polyps who met the inclusion and exclusion criteria based on the order of the patients’ register. Inclusion criteria, based on European Position Paper criteria on Rhinosinusitis and Nasal Polyps (EPOS) 2012, were ages 18-70 years old, consent to take part in the research study and sign the Informed Consent, while the exclusion criteria including; have a history of severe systemic disease (kidney disease, liver disease, malignancy, autoimmune disease, heart disease). Nasal / paranasal sinus tumor, Has a history of previous sinus / nose surgery (Functional Endoscopic Sinus Surgery), Anatomic variations such as severe septal deviation, septal perforation, and synechiae, Atrophic Rhinitis Patients.

Samples were taken from the right and left inferior nasal concha surfaces of patients diagnosed with chronic rhinosinusitis with polyps or without polyps, and examined for IL-8 levels by using ELISA method. Meanwhile, Eosinophil and neutrophil cells were analyzed by using nasal cytology method under a microscope with a 100x objective and examined throughout the field of view were grouped into 6 grades:

1. Grade 0, inflammatory cells <10 per field of view
2. Grade 1, inflammatory cells 10-49 per field of view
3. Grade 2, inflammatory cells 50-149 per field of view
4. Grade 3, inflammatory cells 150-299 per field of view
5. Grade 4, inflammatory cells> 300 per field of view

**Results**

Table 1 shows that eosinophils cells in the polyp group mostly categorized 1 and 2 (80% and 10%) compared to category 0 (10%), while in the group without polyps, there are more categories 0 and 1 (80% and 20%), while category 2 does not exist at all, the results of chi square statistical test show a significant difference with p = 0.000 (p <0.05).

The mean of eosinophils counts per10 field of view in chronic rhinosinusitis with polyps was 297.95, while without polyps was 236.25. There were significant differences between the two groups with p = 0.000 (p <0.05). (table 2)

Table 3 shows category 0 and 1 of neutrophils in the polyp group is the same (50% and 50%), while in the group without polyps, neutrophils category 1 (75%) is more than category 0 and 2 (15% and 10%). The results of statistical tests showed a significant difference between the two groups with p = 0.046 (p <0.05).

Mean of neutrophil level in polyw was 168.35 and without polyw was 245.45. there were significant differences between the groups with p = 0.041 (p <0.05). (table 4)

Based on the table 5, there are significant differences between IL-8 levels in chronic rhinosinusitis with polyps and without polyps with p = 0.004 (P <0.005)

**Discussion**

The result of this study showed a significant difference between eosinophil counts in chronic rhinosinusitis with polyps and without polyp. It means that the role of eosinophils is very dominant in chronic rhinosinusitis with polyps. This is similar with previous studies. EPOS 2012 showed that chronic rhinosinusitis with polyps is an inflammation triggered by Th2 which caused infiltration of eosinophils in the blood to nasal mucosal tissue. High eosinophil levels in chronic rhinosinusitis with polyps lead to more severe disease associated with olfactory nerve dysfunction, more nasal obstruction and nasal secretions. Inflammation due to Th2 and eosinophils affects polyp formation through stromal tissue and pseudocystic edema, and also increase fibrin production due to activation of factor XIII-A which causes the process of remodeling nasal mucous tissue.

This study found a significant difference between neutrophil counts in chronic rhinosinusitis with polyps and without polyp. It means that the role of neutrophil is very dominant in chronic rhinosinusitis without polyps. This result is similar with a study conducted in Korea which stated that chronic rhinosinusitis without polyps is dominated by inflammation due to neutrophil-associated mediators and chemokines such as CXCL-2 and IL-8, which are associated with the severity of the disease. The Korean study also proves that the pathogenesis of chronic rhinosinusitis without polyps have two forms of inflammation regulated by Th1 and Th2, although the role of neutrophils remains dominant and is associated with disease progression. Chronic rhinosinusitis without polyps is dominated by neutrophils because the inflammatory type is a combination of Th1 and Th17. A previous study was also stated that the Asian race had the characteristics of chronic rhinosinusitis with polyps dominated by neutrophils, while Caucasian (European) race dominated by eosinophils.

IL-8 expression in the sinus mucosa increases in chronic rhinosinusitis especially without polyps because it is associated with its main activity in neutrophils and through stimulation by Th1. The results of Interleukin 8 (IL-8) are a chemokine produced in large quantities by epithelial cells in response to various stimulus including proinflammatory cytokines, bacteria, fungi, and viruses, and tend to be a kind of protein that activate neutrophils with two invitro effects, chemotaxis and the release of enzyme granules. In allergic diseases, IL-8 is also chemoattractant in eosinophils, so it can be increased in rhinosinusitis with polyps du to Th2 effect that stimulates eosinophils. Normal values of IL-8 in adults based on a cohort study in Europe are 0.56 - 3.80 (18 - 39 years) and 0.56 - 7.52 (40 - 65 years), so in general, mean of IL-8 levels in the patients of this study was quite high from its normal range, which shows that IL-8 activity in chronic inflammatory processes such as CRS is very high.

**Conclusion**

This study concludes that eosinophil cells were higher in rhinosinusitis with polyps, while neutrophil cells were higher in rhinosinusitis without polyps. IL-8 level was significantly higher in rhinosinusitis without polyps.

The Women’s Pregnancy Intention in Makassar City, Indonesia

Apik Indarty Moedjiono1, Arifin Seweng1, Indra Fajarwati Ibnu1, Anwar Mallongi1

1Faculty of Public Health, Hasanuddin Universitas Hasanuddin, Makassar Indonesia

Abstract

Contraceptive use is one of the main ones, which suggests that serious efforts are needed to increase contraceptive use. Understanding comprehensively the issue of the intention of conceiving by referring to ecological theory, this study provides benefits in preventing unwanted pregnancies. This study aims to analyze determinant factors of pregnancy intention with a cross sectional study design. Subjects were 100 fertile women selected randomly in working area of Patingalgoang and Panambungan Community Health Center, Makassar City in 2018. Determination of study sample was based on results of the screening for pregnancy intention in last pregnancy, women who take part in screening are divided into intended and unintended pregnancies. Data obtained through interviews using a structured questionnaire and analysis by logistic regression. Results showed that side effects, availability of methods and number of living children were found to be significantly associated with the pregnancy intention.

Keywords: pregnancy intention, theory of ecology, maternal health

Introduction

The increase in unintended pregnancies is marked by high case of unmet need for contraceptive. An estimated 225 million women in developing countries have unmet needs for modern contraception, of this number, 71% million do not use any method and rest use traditional methods1. Unmet need for contraceptive in Indonesia in 2017 which is 10.5%, this percentage has decreased slightly compared to 2012 which was 11.4%, and around 29% of contraceptive users stopped their methods in first 12 months of use2,3.

Unmet needs for contraceptive are defined as married women of reproductive age who do not use any contraceptive method but want to delay or limit the next pregnancy4. In ideal situations, all women who want to delay or limit their pregnancy will use contraception. But some women do not use contraception and are at risk of having unintended pregnancy. An unintended pregnancy occurs if a woman does not intend to get pregnant later or at any time in future. Mistimed pregnancies occur if a woman does not intend to get pregnant when pregnancy occurs, but intends to get pregnant at some time in the future. Subsequent division, unintended pregnancies include unwanted and mistimed. Intended pregnancy is a pregnancy that is desired when it occurs or faster 5,6.

Based on the results of the PMA survey in Makassar, 2015, unmet need (25.4%) higher than the national level (14.4%)7. Based on the 2016 report, Patingalgoang and Panambungan Community Health Center are two health centers with work areas serving coastal communities with a high birth rate8, thus the study of pregnant intentions is feasible for studied at women who use that facilities at the working area. This research then uses Ecological Theory to analyze determinant factors of the intention of pregnant women. Choice of ecological theory in determining determinant factors is very important to look at these factors holistically9, so that the study of specific pregnancy intentions in coastal communities will provide comprehensive information, that there are certain systems that shape women’s life experiences in form of their intention to conceive.

Materials and Method

This study uses a quantitative method with a cross
sectional study design. This study looked at effects of side effects, susceptibility to pregnancy, role of the husband, value of the child, mechanism of promises, waiting times, availability of methods, provision of information, age of mother and number of children alive. This research was conducted in working area of Patingalloang and Panambungan Community Health Center. Study population was 100 fertile women. Determination of study sample based on results of screening the last pregnancy intention, women who were netted in the screening were divided into intended and unintended pregnancies. Samples will be selected from each group of pregnant intentions, with proportions equal to simple random sampling. Data will be obtained through interviews using a structured questionnaire. Data analysis will be carried out by logistic regression.

Table 1 shows that wife’s age category is the most aged 26-35 years (54%). The highest husband age is in the age group 26-35 years (61%). The highest wife education is at the level of high school graduation / equivalent (44%). Husband’s education is highest at senior high school level / equivalent (55%). Women who have used and are not currently using contraception (73%). The most widely used type of contraception is injection (74%). Place to get the most contraception is at the puskesmas (71%). The length of termination of contraception is 1-5 years (45%). Reason for the women to stop using the highest contraception was because they wanted to have children (46%). Respondents who want pregnancy (50%).

Table 2 shows the multi-variable factors associated with pregnancy intention among women in Makassar City, Indonesia.

Susceptibility to pregnancy, role of the husband, value of the child, mechanism of promises, waiting times, provision of information, age of the mother are found as a factor that are not significantly related to pregnancy intention, while side effects, availability of methods was found to be a significantly related factor with alpha 10% toward the pregnancy intention, and number of children living with alpha 5%.

**Discussion**

Injectable contraception and pills are contraceptives most often stopped because of side effects at 12 months of use in developing countries\(^\text{10}\), the same thing was found in this study that 74% of women used injection contraception followed by other hormonal contraceptives namely implants and pills, reasons for stopping contraception 20% due to side effects (Table 1). Statistical tests showed that side effects had a significant effect on pregnancy intention at 10% significance (Table 2). Termination of contraception for reasons of side effects without being followed by use of contraception immediately which causes women to experience an unintended pregnancy is very important to anticipate, including in women who perceive side effects\(^\text{11}\), information about contraception including about side effects obtained from fellow women not through health workers so that errors at occur in given and receipt of information \(^\text{12}\). Misinformation can lead to non-compliance. Including the contraceptive use in a typical way and increase cases of contraceptive failure ultimately increasing the incidence of unwanted pregnancies\(^\text{13}\).

The results of this study found that although the level of significance of method was alpha 10%, this variable needs to be an important concern (Table 2). The favorite method among women is the short-acting hormonal method but the continuity of the use of the method is hampered because it often runs out of stock\(^\text{14}\). One indicator of service quality and can prevent termination of contraception is to provide various types of contraception\(^\text{15}\), even preparing 1 additional method can anticipate discontinuation of contraception because the method preferred by women is not available \(^\text{16,17}\). Improving the recording and reporting system that is integrated with various other health institutions by adopting a technology system will provide quick information about contraceptive supplies. This will also support institutions in their efforts to map and analyze institutions to increase the availability of contraception.

In addition to addressing the depleted stock instead of letting women go home from service without contraceptive protection or making referrals to other facilities, because women cannot go directly to the referral service, this is related to opportunities or personal constraints for women to access services. Efforts to provide comprehensive counseling on the types of contraception will be able to help women use contraception that has never been used or tried, because women choose contraception not because they have been used before but it can also be because only that method

</table>
is women known. Counseling is an important component of service quality \textsuperscript{15} counseling can also be a solution in preventing cessation of contraception because of an error in perceiving contraception, therefore it can be said that termination of contraception is not caused by a woman’s fault but can occur because the information delivery system is not optimal, whether the service provider has given women’s rights to obtain contraceptive information. The thing that needs to be understood and anticipated is the possibility of counseling efforts that are not functioning properly, because the performance of officers in providing counseling is very dependent on the training and skills they have, so this can limit the methods they can offer\textsuperscript{18}. In addition, if the institution is only based on waiting time as an indicator of quality service, certainly giving counseling is considered contrary efforts to reduce patient waiting time\textsuperscript{19} including to set the mechanism for the next visit, can be anticipated with several solutions namely to encourage more women to come outside of rush hour, add staff and consultation rooms, to ask for the opinions of women the most preferred service hours\textsuperscript{20}. Set the provider break time in turn, preparing social media-based consulting services.

The results of this study indicate that vulnerability does not have a significant relationship toward the pregnancy intention. Similar research results have been reported\textsuperscript{21} that vulnerability does not motivate women to use contraception, even though women perceive themselves to be fertile but women report having sex without contraception. One strategic effort in encouraging contraceptive use is through the involvement of husbands in maternal health services\textsuperscript{22}. Indicator of the role of the husband in improving maternal health there are various kinds\textsuperscript{23, 24} husbands who are involved in the planning phase, discussing and reminding mothers to use contraception can prevent mothers from experiencing unwanted pregnancies through the use of contraception \textsuperscript{22}. The results of this study indicate that the role of the husband does not significantly influence at pregnancy intention. In addition, even though the husband’s education was quite good, 55% said that he had graduated from high school but this was not enough to encourage the husband’s role. Researchers previously reported that the role of husbands is constrained by factors of cultural and traditional beliefs. Maternal health services are considered the domain of women, only women can be involved in maternal services so that this is the reason husbands do not have a maximum role in maternal health \textsuperscript{24}.

These results indicate that value of child is not significant, but number of children born alive is significant (alpha 5%) toward pregnancy intention (Table 2). This shows that for some women control of fertility is needed after the target number of children has been reached. This shows that there are rational considerations for the number of children based on financial burdens and occasion to care for children. The consideration of the ideal number of children is also the result of social construction embedded in the traditional cultures and beliefs of some countries \textsuperscript{25}. The magnitude of the influence of norms of society can influence decisions about the number of ideal children ultimately affecting the decision to use contraception. The results of this study imply that contraceptive services need to target women whose are have the number of children and a certain reproductive age. Synergizing with various parties because changes in attitude require a local culture approach and culture-based approach.

**Conclusion**

There is a need to reduce the desire to increase the number of children by synergizing various parties. The ideal number of children is formed because of cultural structure of society, and dealing with it requires collective change in social norms and attitudes of the community. In addition, the importance of increasing women’s awareness and understanding in interpreting side effects and increasing staff capacity to motivate women to use contraception. Addressing the issue of availability of contraception requires a variety of policies and systems that are strong in providing services so as to prevent depleted stocks.

Abstract

In Indonesia, Typhoid must be taken seriously from various parties, because this disease is endemic and threatening public health. The vitamin D receptor gene (VDR) has been involved in modulation of susceptibility on inflammatory conditions including typhoid fever.

This study aimed at investigating VDR genes expression and its relationship with bacterial load in typhoid fever patients

This study used analytical survey design with cross-sectional approach, which focuses on Vitamin D Receptor (VDR) genes expression and its relationship with bacterial load in typhoid fever patients. The total sample was 55 sufferers. The statistical test used was Mann U Whitney with the confidence degree of 95% and value of α <0.05. All data were analyzed using the SPSS Version 21.0 program.

The results showed the weak VDR gene expression (47.3%) and the strong one (52.75%), bacterial load was in the average at 43,583,636.36 ± 75,649,400.29, and there was relationship between VDR gene expression with bacterial load (p <0.001), which is the bacterial load tendency is higher in patients with weak VDR gene expression than the strong one.

Strong VDR gene expression decreases bacterial load in cases of typhoid fever.

Keywords: VDR, bacterial load, typhoid fever

Introduction

Typhoid fever is a systemic infection caused by Salmonella typhi, usually through consumption of contaminated food or water. Acute illness is characterized by prolonged fever, headaches, nausea, loss of appetite, and constipation or sometimes diarrhea. Symptoms are often non-specific and clinically indistinguishable from other febrile illnesses. However, clinical severity varies and severe cases can cause serious complications or even death. The poor sanitation and lack of sterile drinking water make it worst1,2,3.

Typhoid fever is a concerning public health problem in the world, especially in poor populations from developing countries. Globally, this disease is estimated lead to 220,000 deaths and 22 million cases per year, especially in school-age children or younger. Typhoid fever is one of the most common sources of bacteriological etiology in many developing countries. In these countries, the burden of disease is often
In Indonesia, typhoid must be taken seriously from various parties, because this disease is endemic and threatening public health. The problem is increasing complex with increasing carrier cases or relapse and resistance to the drugs used, obstructing treatment and prevention efforts. In 2008, typhoid morbidity in Indonesia was reported at 81.7 per 100,000 population, with distribution by age group 0.0 / 100,000 population (0–1 years), 148.7 / 100,000 population (2–4 years-old), 180.3 / 100,000 (5–15 years-old), and 51.2 / 100,000 (≥16 years-old). This figure shows that the highest number of carriers is 2-15 years-old group. The study of cases in major hospitals in Indonesia, indicate a trend increase in typhoid cases year by year with an average pain 500 / 100,000 population and deaths estimated at around 0.6–5%.

Typhoid is caused by the bacterium Salmonella. Salmonella infection in humans can be categorized into two types, caused by the low virulence serotype of Salmonella enterica which causes food poisoning, and caused by high virulence serotype of Salmonella enterica typhi (S. typhi), which lead to typhoid, and a group of serovars, known as S Paratyphi A, B and C, which causes Paratyphoid.

Blood cultures are generally used in laboratory diagnoses, but little information about the number of bacteria circulating in the blood or the distribution between plasma and phagocytic cells. Previous research found that in the bone marrow of 78 patients had an average of 4 times more bacteria. There was a significant negative correlation (p < 0.05) between the number of bacteria and the age and length of fever before hospitalization. There was a significant positive correlation (p = 0.05) between bacterial count and temperature, period of decline fever after treatment, and multiple resistance from each bacterial isolate, even though there was a similar previous treatment history.

Previous research on 426 mild typhoid fever patients and 35 severe typhoid fever patients where all patients lived in geographically isolated villages in South Sulawesi, Central Sulawesi, Southeast Sulawesi, East Kalimantan and Papua islands which are endemic areas in Indonesia. It was found that there was no evidence for gene association of VDR polymorphisms with the severity of typhoid fever.

In this study, researchers will examine the gene expression of the Vitamin D Receptor (VDR) and its relationship with bacterial load in patients with typhoid fever.

**Material and Method**

**Design**

This study is an analytical survey study with a cross sectional study to look at the expression of the Vitamin D receptor gene (VDR) and its relationship with bacterial load in patients with typhoid fever.

**Sampling**

The population in this study was the blood of patients with typhoid fever who were admitted to hospitals in Makassar (Wahidin Sudirohusodo Hospital, Pelamonia Hospital, Bhayangkara Hospital), Salewangang Hospital, Maros Regency, and Pangkep Regional Hospital in South Sulawesi. This study used purposive sampling technique with total sample as many as 55.

Inclusion criteria: patients with typhoid fever with the length of fever > 3 days above 37.5°C consecutively, dirty tongue and positive (+) widal and willing to take part in the study and sign the informed consent.

Exclusion criteria: patients with fever caused by other types of bacteria and have already received antibiotic treatment.

**Examination of VDR and Bacteria load**

**Tools**

The tools used in this study were: micro pipette P2 (2-
Materials

Blood samples infected with *S. typhi*, label paper, BD Bactec, Real Time Reagent PCR mRNA Gene VDR, L6, L2 Buffer, Ethanol 70%, Aceton and Tris EDTA.

Examination of VDR gene expression

Peripheral venous blood specimens from the study subjects were taken as much as 10 ml, inserted in the blood tube containing EDTA, and then DNA extraction and purification were carried out. The measurement of VDR gene mRNA expression was measured using real-time reverse transcriptase polymerase chain reaction (RT-PCR) (Agergaard, et al., 2015). Strong: if the VDR value is $\geq$ the average value (10.24); Weak: if the VDR value <average value (10.24)

Bacterial load examination

Laboratory tests in the form of bacteria load by taking blood samples from veins aseptically and then performed blood sampling used Hemocytometry tool to determine the number of bacterial load to be reported per / mm³, then bacterial load is measured using colony count.

Data Analysis

The statistical test used was Mann U Whitney with a confidence degree of 95% and a value of $\alpha <0.05$. All data were analyzed using the SPSS Version 21.0 program (SPSS, Inc. Chicago, IL).

Result and Discussion

The average age of the respondents was 31.93 ± 10.075 years, more than half are male (50.9%), living in Pangkep (50.9%), high school / College (67.3%), and work as professionals (41.8%)

The expression of VDR gene was strong (52.73%) and the weak one (47.27%). The bacterial load was in average at 43,583,636.36 ± 75,649,400.29 (Table 1).

Discussion

VDR gene expression

The results of this study found the weak VDR gene expression (47.27%) and the strong one (52.73%). Vitamin D receptor (VDR) is the ligand activated transcription factor found almost in all cells and tissues in human body. The gene encoding the VDR is located on chromosome 12q13 (Figure 5), consisting of
11 axons, and more than 100 kilo base (kb) stretched genomic DNA.

**Bacterial Load**

The results of this study showed bacterial load average of 43,583,636.36 ± 75,649,400.29. Bacterial load is the number of bacteria measured in the compartments of objects and organisms. The bacterial amount of a material can be determined in various ways, depending on the material and type of microbes specified.

Germs can also replicate in macrophages. After the replication period, the bacteria are spread back into the circulatory system and cause secondary bacteremia while marking the end of the incubation period. Secondary bacteremia causes clinical symptoms such as fever, headache, and abdominal pain.

Relationship between VDR gene expression and bacterial load.

The statistical test results found that there was a relationship between VDR gene expression and bacterial load (p <0.001) with a higher bacterial load tendency in patients with weak VDR gene expression than the strong one.

VDR is very important in regulating intestinal homeostasis by preventing invasion of pathogenic bacteria, inhibiting inflammation, and maintaining cell integrity. Vitamin D directly modulates T cell receptors (TCR). The action of vitamin D, 1,25-dihydroxyvitamin D3 (1,25 (OH)2D3) hormone is mediated by the vitamin D receptor (VDR), the ligand activated transcription factor which control gene expression. After ligand is activated, VDR binds directly to the specific sequence located near the promoter and recruits a variety of co-regulation complexes that perform the additional functions needed to modify transcription output.

Vitamin D shown to reduce the expression of pro-inflammatory cytokines and have a regulating effect on autophagy and various immune cells including T cells, B cells, macrophages, dendritic cells, and epithelial cells. It has been reported that 1,25 (OH)2D3 suppresses the development of inflammatory bowel disease (IBD) in animal models. 1,25 (OH)2D3 deficiency has been reported in patients with IBD. Given the diverse immune function of vitamin D, the degree of deficiency may have important implications for the development and maintenance of intestinal homeostasis. Possible roles of vitamin D status and VDR signals in modulating the effects of intestinal microflora in other conditions such as asthma and obesity have been suggested.

Previous research showed that VDR - / - of the mice had increased bacterial clotting in the intestine. The microarray data found that VDR signals respond to Salmonella pathogens in intestinal colitis in vivo. Bacterial stimulation, both commensal and pathogenic, regulates VDR expression and location and negatively regulates bacterial-induced intestinal NF-κB activation. In general, probiotic-induced nuclear receptor signals are not well marked. The proliferation of VSL3 # is associated with nuclear receptor signals in the IL10 - / - colitis model. Nuclear receptors have been shown to negatively regulate NF-κB activity stimulated by bacteria in the intestinal epithelium. Probiotic treatments can increase VDR expression and activity of the host. Increased expression of VDR and increased mRNA cathelicidin in intestinal epithelial cell cultures when treated with Lactobacillus plantarum were seen. Monoassociated probiotic pig models for assessing probiotic effects on VDR expression in vivo and finding intestinal VDR increased significantly after probiotic colonization compared to germ-free pigs.

**Conclusion**

The strong VDR gene expression decreases bacterial load in cases of typhoid fever.

**Ethical Clearance:** Research permit is obtained from Ethics Commission FK UH Makassar (No. 609 / H4.8.4.5.31 / PP36-KOMETIK / 2018). After that, the researcher explained to the respondents about the objectives, benefits of the research, and procedures for collecting data. Researchers asked respondents to sign an informed consent as a form of consent to become respondents.

Stunting Status of New Children Enter Elementary School Between Urban and Rural Areas in Jayapura City, Papua

Wahida Y. Mapandin

Lecturer of Nutrition Department, Faculty of Public Health, Cenderawasih University

Abstract

Background: The optimal growth of school-age children depends on providing nutrition with good and correct quality and quantity. One way that can be done to determine the implementers of nutrition improvement is to determine or see the physical size, both in height and weight. A person’s physical size is closely related to nutritional status. Measurement of nutritional status in school children can be done by anthropometry. Based on WHO 2007 anthropometry standards for children aged 5-18 years, the nutritional status of children is determined based on the value of Z-score TB/U and BMI/U. Objective: The purpose of this study was to determine whether there were anthropometric differences in children entering primary school based on the index TB/U and BMI/U. Method: The type of research used is descriptive analytical research with cross sectional approach. The study population was 84 children who had just entered elementary school and this study used the Total Sampling Technique, where the number of samples was the same as the population of 84 school children. Results: The results of the study showed that there were no anthropometric differences in children entering primary school based on the TB/U and BMI/U index in urban and rural areas. Statistical analysis of TB/U using a non-parametric test shows the probability value (sig)> 0.05 (0.078> 0.05). While the BMI/U is known the probability value (sig)> 0.05 (0.140> 0.05). Energy and protein intake for urban and rural school children tends to be less. Nutritional deficiency is a factor associated with the nutritional status of school-age children. This is exacerbated by the high incidence of infections in children and most of the parents of disadvantaged people so that the purchasing power of food in households is low. Conclusion: There is no anthropometric difference in children enrolled in primary school based on the TB/U and BMI/U index in urban and rural areas.

Keywords: TB/U, BMI/U, School Children, City, Village.

Introduction

Protein is needed to build, maintain and repair body tissues. Protein also has an important role in growth. Children who have a high risk of stunting may have limited essential amino acids (such as tryptophan and lysine) in their food intake. Stunting in children, besides being caused by a deficiency of macro nutrients, is also associated with zinc (Zn) deficiency. Zinc (Zn) is an essential mineral that plays a role in the synthesis, secretion, and control of growth hormones (Growth Hormones). The low synthesis of growth hormones can inhibit linear growth and is thought to cause stunting conditions in infancy.

Zinc serum is one of the biomarkers that is often used to assess zinc status. The timing of serum zinc sampling, contamination of blood samples with other materials such as dust, and the use of non-metallic blood sample tubes is an issue of measuring serum zinc in the population. The relationship between serum zinc and growth is associated with zinc function increasing pituitary secretion as a raw material for growth hormone/GH. Studies in Thailand show that low serum zinc levels tend to occur in short boys. In studies in rural China, which geographically contained low zinc in the soil, the prevalence of zinc deficiency was <25%. The study in Ethiopia showed no difference in serum zinc levels based on the severity of stunting. The results of several studies on the comparison of serum zinc levels according to the status index of height according to age in children are still inconsistent and studies that reveal serum zinc levels in children in coastal areas have not been widely used in Indonesia.

The International Zinc Nutrition Consultative Group (IZiNCG) estimates that more than 25% of the population...
in developing countries is at risk for zinc deficiency. The prevalence of moderate zinc deficiency of 5-30% occurs in children and adolescents. Insufficient zinc intake is a major cause of zinc deficiency in developing countries including Indonesia. The zinc content in vegetable, vegetable and fruit foods depends on the zinc content in the soil. The coastal area is one area where the zinc content in the soil is low. Quantitative data on zinc intake in school-age children in coastal areas of Indonesia has not been widely documented.

In children in families with low income levels, inadequate zinc intake can occur because most of the intake comes from plant foods and consumes little animal food. The coastal area of Jayapura City, Papua is an area rich in fishery products. Fishery products are one of the foods that contain iron and zinc, however, consumption of food containing high and possibly higher because it is more affordable in terms of the economy. Another thing is evidenced by the still high rate of stunting of children under five in Jayapura City by 16.4%. It is suspected that school-age children on the coast are one group with a risk of insufficient zinc intake.

This study aims to describe the intake of protein, zinc and calcium and to know the differences in protein, zinc, and calcium intake with the incidence of stunting in elementary school children in the coastal area of Jayapura City.

Materials and Method

This research is an observational study with the research design used is case control. The research was carried out in selected elementary schools, namely Kotaraja Public Elementary School which is included in the administrative area of Jayapura City. Data collection is planned for June to August 2018. The population in this study were all elementary school children in the Jayapura City area. The sample inclusion criteria were elementary school students aged 9-12 years who were enrolled as students in Kotaraja Elementary School, while the subject exclusion criteria were school children suffering from mental disorders and physical disabilities. Calculation of sample size is calculated using the sample size formula for the control case study and the determination of the proportion of cases refers to the results of the Neldawati study, with α = 5%, β = 10%, p1 = 0.781, p2 = 0.5, the number of samples is 92 people, then the estimated lost of follow is 10% so the number of samples is 46 people. In this study using a case and control ratio of 1: 1 so that the number of samples was 46 cases and 46 controls or a total of 92 samples divided into schools with different areas of residence for students.

Primary data collected was height measured using microtoice with a precision level of 0.1 cm. Data on food consumption patterns including energy, protein, calcium, zinc and dietary intake were obtained by performing 1 x 24 hour food recall, food frequency data obtained through the Food Frequency Questionnaire. Data processing was carried out using the chi square test at a significance level of 95% (α = 0.05). Variables are bound to the incidence of stunting while the independent variables of this study are intake of protein, zinc and calcium.

Research Results

Effects of Protein Intake on Stunting Events: Protein intake was obtained from the results of filling food form 1 x 24 hours which was then processed using nutrisurvey. Based on the research that has been done, the results of protein intake can be seen in the following table:

<table>
<thead>
<tr>
<th>Protein Intake</th>
<th>Stunting incidence</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>n</td>
<td>%</td>
<td>n</td>
</tr>
<tr>
<td>Less</td>
<td>20</td>
<td>69</td>
<td>12</td>
</tr>
<tr>
<td>Enough</td>
<td>9</td>
<td>31</td>
<td>17</td>
</tr>
<tr>
<td>Total</td>
<td>29</td>
<td>100</td>
<td>29</td>
</tr>
</tbody>
</table>

p=0.035; OR = 3.148

Based on table 1 above, it can be seen that the proportion of stunting for low protein consumption habits is 20 children (69.0%) while only 9 children are high (31.0%). Normal children with low protein consumption habits as many as 12 children (41.4%), while the high as many as 17 children (58.6%). The results of statistical analysis using the chi-square test showed that, there was a significant relationship between protein consumption habits and the incidence of stunting (p = 0.035; OR = 3.148). Thus the protein consumption habits that have less risk are 3.148 times stunting compared to normal.

Effect of Zinc Intake on Stunting Events: Zinc intake was obtained from the results of filling 24-hour food recall forms for 1 day, the results of the recall were
processed using nutrisurvey which was then compared with the nutritional needs of school children. Based on the research that has been done, the results of zinc intake can be seen in the following table:

**Table 2. Effect of Zinc Intake on Stunting Children in SD InpresKotaraja Elementary School**

<table>
<thead>
<tr>
<th>Zinc Intake</th>
<th>Stunting incidence</th>
<th>Normal</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>n</td>
<td>%</td>
</tr>
<tr>
<td>Less</td>
<td>18</td>
<td>75.9</td>
</tr>
<tr>
<td>Enough</td>
<td>11</td>
<td>24.1</td>
</tr>
<tr>
<td>Total</td>
<td>29</td>
<td>100</td>
</tr>
</tbody>
</table>

p=0.036; OR = 3.109

Table 2 above shows that the proportion of stunting for low energy consumption habits is 18 children (62.1%), while the high is 11 children (37.9%). Normal children with low energy consumption habits are 10 children (34.5%), while the high children are 19 children (65.5%). The results of statistical analysis using the chi-square test showed that there was a significant relationship between zinc intake and the incidence of stunting (p = 0.036; OR = 3.109). Thus zinc intake which is less risky is 3,109 times stunting compared to normal.

**Effects of Calcium Intake on Stunting Events:**

Table 3. Effect of Calcium Intake on Stunting Children in SD Inpres Kotaraja Elementary School.

<table>
<thead>
<tr>
<th>Calcium Intake</th>
<th>Stunting incidence</th>
<th>Normal</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>n</td>
<td>%</td>
</tr>
<tr>
<td>Less</td>
<td>22</td>
<td>75.9</td>
</tr>
<tr>
<td>Enough</td>
<td>7</td>
<td>24.1</td>
</tr>
<tr>
<td>Total</td>
<td>29</td>
<td>100</td>
</tr>
</tbody>
</table>

p=0.002; OR = 5.971

Based on table 3 above it is known that the stunting proportion for low calcium consumption habits is 22 children (75.9%), while the high is only 7 children (24.1%). Normal children with low calcium intake as many as 10 children (34.5%), while the high as many as 19 children (65.5%). The results of statistical analysis using the chi-square test showed that, there was a significant relationship between calcium consumption habits and the incidence of stunting (p = 0.002; OR = 5.971). Thus calcium intake which has less risk of 5,971 times stunting compared with normal intake.

**Discussion**

Protein is needed to build, maintain, and repair body tissues. In addition, protein also plays an important role in growth. Protein is a nutrient needed by the body for growth, building body structures (muscles, skin and bones) and as a substitute for worn-out tissue. Based on the results of research by Sulistianingsih and Ari Madi Yanti in 2015 it was found that protein was associated with the incidence of p-value 0.002 stunting. This is in accordance with the study of the theory that the function of protein is as a builder substance. The entire cell layer consists of proteins that carry micronutrients. Protein functions in carrying out body regulation and the formation of new DNA for the body. Long-term protein deficiency will cause disruption of body regulation and growth hormone can be disrupted which can cause nutritional disorders such as stunting. The results of the chi square statistical test in Chastity research in 2017 also showed a positive relationship between protein intake and the incidence of stunting in adolescents with a value of p = 0.001 which means that there is a significant relationship between protein intake and the incidence of stunting.

The tight relationship between protein and growth causes a child who lacks protein intake to experience slower growth than children with sufficient protein intake (Bender, 2002) and in conditions that are worse in protein shortages over a long period of time can result in cessation of the growth process. Children’s protein needs include tissue maintenance, changes in body composition, and the formation of new tissues. Protein requirements for growth are estimated to range from 1-4 g/kg to additional body tissue.

The normal concentration of total calcium in plasma is 2.4-2.5 mM while the concentration of free calcium ions ranges from 1.25-1.3 mM. Effective calcium homeostasis is important in many biological processes, including bone metabolism, cell proliferation, blood coagulation, hormonal signaling transduction and neuromuscular function. Calcium balance is maintained by 3 main organs, namely: the gastrointestinal system, bones, and kidneys. Adequate calcium intake can help protect bones throughout our lives. In children and adolescents, adequate calcium intake can help produce higher bone mass. Partial loss of calcium daily through ekresi (urine and feces), sweat, and lungs when we breathe is normal, consuming enough calcium every day can restore lost calcium. Lack of calcium intake
in children will increase the risk of bone fracture in children, so that children cannot achieve optimal bone growth\textsuperscript{15-17}. During growth, demands for bone mineralization are very high, very low calcium intake can cause hypocalcemia, despite the secretion of the maximal parathyroid gland, which can result in low bone mineralization matrix and osteoblast dysfunction\textsuperscript{14}.

Calcium deficiency will affect linear growth if the calcium content in the bone is less than 50% of the normal content. In infants, lack of calcium in the bones can cause rickets, whereas in children, lack of deposits can cause growth retardation\textsuperscript{18-19}. During growth, demands for bone mineralization are very high, very low calcium intake can cause hypocalcemia, despite the secretion of maximal parathyroid glands, which can result in low matrix mineralization of new bone deposits and osteoblast dysfunction. Calcium deficiency will affect linear growth if the calcium content in bone is less than 50% of normal content. In infants, lack of calcium in the bones can cause rickets, whereas in children, lack of deposits can cause growth retardation\textsuperscript{19-21}.

**Source of Funding:** Self

**Conflict of Interest:** None

**Ethical Clearance:** Obtained from Faculty committee, Cendrawaih University.

**Conclusions**

Protein, zinc, and calcium intake was significantly lower in stunting children than in non-stunting children of primary school age in Jayapura City. Stunting is a chronic nutrition problem that can be addressed in an early warning by monitoring nutritional status, especially height, at the posyandu so that it can be detected and given immediate intervention.

Determinants of Exclusive Breastfeeding in 6 Months Old Infant in Jeneponto District

Nur Ulmy Mahmud, Tahir Abdullah, Arsunan A.A., Burhanuddin Bahar, Veni Hadju, Masyita Muis, Sri Sumarmi

1Postgraduate School Students Faculty of Public Health, Hasanuddin University of Indonesia, 1Faculty of Public Health, Muslim University of Indonesia, 2Faculty of Public Health, Hasanuddin University of Indonesia, 3Faculty of Public Health, Airlangga University, Indonesia

Abstract

Background: The coverage of exclusive breastfeeding in Indonesia is still very low, especially in Jeneponto district. The purpose of this study was to determine the determinants of exclusive breastfeeding. METHOD: This study is a continuation of the main research, the design used is an experiment followed by a study cohort involving pregnant women and their babies then analyzed at the age of 6 months. 340 samples were randomly divided into 3 groups (Moringa leaves powder (MLP), Iron Folic Acid (IFA), Moringa leaves extract (MLE)) given to pregnant women (2nd trimester) and 1 month after delivery. Data analysis using logistic regression. RESULTS: The results showed that of 340 samples intervened (MLP 32.6%; IFA 35.9%; MLE 31.5%), as many as 42.9% of infants were exclusively breastfed and 57.1% of infants were not exclusively breastfed. The logistic regression test results showed that babies who received colostrum at birth were 3.185 times more likely for exclusive breastfeeding than those who did not get colostrum (AOR 3.185, CI95% 1.324-7.659); mother’s work (AOR 1.923, CI95% 1,044-3,540); family income (AOR 2,050, CI95% 1.202-3,498); Mother’s education (AOR 2.512, CI95% 1.451-4.351), maternal knowledge (AOR 1.679, CI95% 1.020-2.764) and birth weight has the possibility of exclusive breastfeeding compared to the comparison. CONCLUSION: The results showed that the determinants of exclusive breastfeeding in 0-6 months infants in Jeneponto District were giving colostrum, mother’s work, family income, mother’s education, and mother’s knowledge about the benefits of exclusive breastfeeding.

Keywords: Exclusive breastfeeding, mother’s knowledge, mother’s education, family income.

Introduction

The neonatal period is an important period for survival in infancy. Nutrition and breastfeeding are the things that are most needed in this period for the physical and mental development of babies. Breast milk, colostrum and prelacteal feeding are strongly influenced by knowledge, mother’s beliefs and socio-culture. UNICEF recommends breastfeeding should begin within half an hour after giving birth. Delays in breastfeeding can affect the quantity of milk produced. In addition, late stimulation can cause hypoglycemia, hypothermia and acidosis, especially for those at high risk such as low birth weight (LBW). Breast milk contains antibodies from mothers that help fight disease, protect babies from diarrhea and acute respiratory infections. Breastfeeding also stimulates the baby’s immune system and responds to vaccination. Continuing breastfeeding for more than six months, accompanied by nutritious foods that are sufficient, safe and appropriate, soft, and also help ensure good nutritional status and protect against disease. It is estimated that optimal breastfeeding of children under the age of two has the potential to prevent 1.4 million deaths in toddlers in developing countries each year

Globally, only 43% of six-month-old infants receive breast milk exclusively (UNICEF 2016). In low and middle income countries, more than 68 million children born this year are not exclusively breastfed. Most non-breastfeeding children exclusively consume water, milk, formula milk, or complementary foods other than breast milk, often causing infections in unsafe environments, only 45% of breastfed children within one hour after birth and only 46% continuing to breastfeed up to the age of two (UNICEF 2016). Exclusive breastfeeding and continued up to two years can accelerate body weight
gain and body length in the first few months of life, based on globally reported data, 6.9 million children under five died in 2011, around 1 million could be saved simply as breastfeeding exclusive\textsuperscript{4,5,6}Galactagogues are herbs that increase volume and facilitate the flow of milk. Several studies confirm the efficacy of galactagogue in helping nursing mothers. However, it is usually promoted and given 3 days after giving birth to induce lactation. \textit{Moringa} leaves increase the effect of lactation as evidenced by a greater increase in maternal serum prolactin levels. Prolactin is the most important hormone in lactation initiation. \textit{Moringa} leaf powder is an effective galactagogues to increase volume and facilitate ASI\textsuperscript{7}

In Indonesia, the coverage of exclusive breastfeeding for infants aged 0-6 months is fluctuating. In 2007 only around 62.2\% and in 2008 it was 56.2\%. Meanwhile, based on the provincial health office report in Indonesia in 2018 for exclusive breastfeeding coverage of 37.7\%. The coverage of exclusive breastfeeding in South Sulawesi Province in 2009 to 2014 is still below the national standard. In 2014, the exclusive breastfeeding coverage was still 56.31\%. Jeneponto Regency in 2008-2012 showed exclusive breastfeeding coverage was far from the 80\% national standard. In fact, from the profile data of the South Sulawesi Provincial Health Office in 2012, Jeneponto district is the district with the lowest coverage of breastfeeding, which is around 20.57\%. Furthermore, in 2013 it showed an increase to 67.66\%\textsuperscript{8,9}

\section*{Method}

This research is a continuation of the main research. The research method used in this study was an experiment followed by a cohort involving pregnant women (second trimester) with their babies from birth to age 6 months. This study will be divided randomly into 3 groups, the first group is pregnant women who get \textit{Moringa oleifera} flour, the second group is pregnant women who get Fe tablets and the third group is pregnant women who get extracts. The intervention will be given in the second trimester (pregnancy to 4 to 6 months) and followed by intervention after giving birth until their baby is 1 month old.

The population in this study was the number of pregnant women in 6 sub-districts located in Jeneponto Regency, South Sulawesi. Sub-district elections will be carried out based on an agreement with the Jeneponto Health Office with consideration of the performance of health workers in the Puskesmas, especially midwives and nutrition workers who oversee the sub-district so that this research can be carried out properly.

Samples were all mothers who participated in the previous study of 600 pregnant women but with various reasons several mothers had dropped out, so the number of samples participating in this study were mothers who had given birth and had babies aged 0-6 months as many as 340 babies

Data that has been collected will be processed and analyzed using SPSS software. Before further statistical tests, all data processing variables will be presented in the form of averages, standard deviations, ranges and frequencies. Normality test is useful to determine whether the collected data is normally distributed or not, unpaired t test is used to compare differences between treatments in variables, logistic regression test is used to identify factors related to exclusive breastfeeding, bivariate analysis is used to select candidate variables that will included in multivariate regression

This research was carried out after obtaining approval from the Ethics Commission of the Faculty of Public Health, Hasanuddin University number UH16090723. Before the implementation of measurements and interviews will be given an explanation of the actions to be taken for each respondent (Mother and baby). After the explanation, the respondents were asked for approval to participate in this study by signing an informed consent

\section*{Results}

The results of this study were carried out in 6 Districts of Jeneponto District. This research was conducted by interviewing respondents in the area

\begin{table}[h]
\centering
\begin{tabular}{|l|c|c|}
\hline
Variable & Frequency (n) & Percent (%) \\
\hline
Mother Age (n=340) & & \\
<26 year & 134 & 39.4 \\
\geq 26 year & 206 & 60.6 \\
\hline
Gender of the child (n=340) & & \\
Man & 177 & 52.1 \\
Women & 163 & 47.9 \\
\hline
\end{tabular}
\caption{Socio-demographic characteristic of respondents}
\end{table}
Based on Table 1, Socio-demographic characteristic of respondents based on mother’s age, it is known that the highest number of respondents was at the age of ≥26 years as much as 60.6% and the least at age <26 years as many as 39.4%. Based on the sex of the child, it is known that the highest number of respondents is male sex as much as 52.1% and women as much as 47.9%. Most maternal education at the low education level is as much as 67.6% and the level of higher education is 32.1%. For the work of mothers, it is known that more mothers do not work, namely as much as 81.5% and those who work as much as 18.5%. Family income in monthly is at most <2 million, 74.4% and 2 million as much as 25.6%.

Based on Table 2, Distribution of characteristic related to breastfeeding in mother, it is known that the highest number of respondents gave birth to health facilities as much as 87.9% and those at home as many as 12.1%. Based on the birth process, it is known that the highest number of respondents gave birth normally as much as 93.8% and sectio as much as 6.2%. For normal birth weight as much as 96.5% and LBW as much as 3.5% For breastfeeding patterns, it is known that more babies are exclusively breastfed as much as 57.1% and those without exclusive breastfeeding are 42.9%. Prelacteal is 70.9% and not prelacteal as much as 29.1%. For giving colostrum as much as 92.4% and those who did not get colostrum 7.6%. The knowledge of mothers about the benefits of breastfeeding is the most that is not years of benefits, namely as much as 67.1% and those who know as much as 32.9%. Whereas the number of children at most mothers who have more than 1 child is 67.9% and those who have 1 child are 32.1%

*Each Factor adjusted for the others. Odds ratios from univariate and multiple generalized estimation equation logistic regression models, **Significant (CI 95% >1)

Identifying factors related to exclusive breastfeeding, bivariate analysis was performed to select candidate variables to be included in multivariate regression. The results of giving colostrum, work and mother’s education, family income, and mother’s knowledge of the benefits of breastfeeding for children associated with exclusive breastfeeding.

Multivariate logistic regression is used to identify predictor variables after controlling variable confounding. All variables <0.25 in bivariate analysis were included in the model namely Colostrum, Mother’s Work, Family income, Mother’s education, Mother’s knowledge, Birth weight.

The results can be seen in table 3. The mother who gave the child a collection, was 3.185 times more likely to give exclusive breastfeeding than those who did not give it (AOR 3.185, CI95% 1.324-7.659), as well as employment, income, education, knowledge of the benefits of ASI and birth weight, namely (AOR 1.923, CI95% 1.044-3.540); (AOR 2.050, CI95% 1.202-3.498); (AOR 2.512, CI95% 1.451-4.351); (AOR 1.679, CI95% 1.020-2.754); (AOR 3.205, CI95% 0.870-11.805) has the possibility of exclusive breastfeeding compared to the comparison.

Discussion

The results of the study on Aged 6 Months In Jeneponto District Determinants Of Exclusive Breastfeeding On Infants revealed that of 340 infants, about 57.1% of infants were exclusively breastfed and 42.9% were not exclusively breastfed. Based on the results of the logistic regression test, colostrum administration, mother’s work, family income, mother’s education level and mother’s level of knowledge about the benefits of breastfeeding.

In this study 92.4% of mothers gave colostrum and 7.6% who did not give colostrum. This is because when the baby is born, the mother does not directly have breast milk. About 67.1% of mothers who do not know the benefits of breastfeeding and only 32.9% of mothers who benefit from breastfeeding, even though mothers do not know the benefits of breastfeeding but mothers continue to give exclusive breastfeeding to their babies due to very low family income.
In line with the research conducted by Marhamah, A.A Arsunan, Wahiduddin (2012), the results of this study indicate that the results of this study indicate that breastfeeding is the most important factor in the study of breastfeeding until the baby is 6 months old. So, it is a continuous lactation education program from prenatal to postnatal to increase breastfeeding practices involving husband or the mother’s family. Breastfeeding is the best natural food a mother can give to a newborn child, besides its composition is suitable for the growth and development of a baby who changes according to the needs of the baby at all times. Breast milk also contains protective substances that can prevent various infectious diseases. Giving ASI also has an extraordinary emotional influence that affects the inner relationship of mother and child and the development of the child’s soul (Azwar, 2001). Research conducted by (Pujiati Abbas, 2011) that breast milk contains zinc minerals that have been proven effective for reducing pneumonia (pneumonia), diarrhea and other infectious diseases. Zinc can also reduce the duration and severity of ARI.

In line with research conducted by (Namangboling et al., 2017) that exclusive breastfeeding can prevent the occurrence of diarrhea caused by infection in infants and can maintain the nutritional status of infants, because breast milk is the best food with complete nutrition and is very good for baby’s needs in its growth and development. The provision of ASI carried out exclusively can reduce the prevalence of the incidence of malnutrition in children. Breastfeeding promotion is considered as an intervention that aims to maintain nutritional status, individual health status, and can reduce mortality by 8% globally.

ASI provides all the energy and nutrients needed by babies during the first six months of life. Giving breast milk to the baby in the first hour of birth can accelerate the removal of the placenta, reduce postpartum bleeding and also accelerate recovery from the trauma of childbirth and can help the mother’s uterus to return to size before pregnancy. A data from developing countries showed that babies who did not get ASI were six times more likely to die from infectious diseases in the first two months of life.

**Conclusion**

The results showed that the determinants of exclusive breastfeeding in 0-6 months infants in Jeneponto District were giving colostrum, mother’s work, family income, mother’s education, and mother’s knowledge about the benefits of exclusive breastfeeding.

Analysis of Microplastic Content in Baronang Fish (Siganus sp) and Kakap Fish (Lutjanus sp) in the Coastal Area of Bangkala Subdistrict, Jeneponto Regency

Yuliati¹,², Anwar Daud³, Anwar Mallongi³, Burhanuddin Bahar Bahar⁴

¹Postgraduate Student of Public Health Department, Hasanuddin University, Makassar City, South Sulawesi, ²Faculty of Public Health, Muslim University Indonesia Makassar City, South Sulawesi, ³Department of Environmental Health, Faculty of Public Health, Hasanuddin University Makassar City, South Sulawesi, ⁴Department of Nutrition, Faculty of Public Health, Hasanuddin University Makassar City, South Sulawesi, Indonesia

Abstract

Background: Micro plastic is a problem for the environment and public health measuring 0.3-5 mm.

Objective: To analyze the microplastic content of Baronang Fish and Snapper Fish in the Coastal of Bangkala Subdistrict.

Method: The method used is the analytical survey, laboratory approach with Minitab software 16. Fish samples were identified using FishBase. The obtained microscopy was calculated based on number and type, photographed with optilab, and measured by raster image software.

Results: The microplastic content of Snapper Fish is higher than that of Baronang Fish at each station. The microplastic content of Snapper Fish at Station 1 is 18 particles/fish while Baronang Fish is 14 particles/fish. The microplastic content of Snapper Fish at Station 2 is 18 particles/fish while Baronang Fish is 13 particles/fish. The microplastic content of Snapper at station 3 is ten particles/fish while Baronang Fish is six particles/fish. This happens because Snapper Fish has more prominent characteristics than Baronang Fish, including having faster growth, having excessive eating behavior, tolerant of turbidity and salinity and more actively moving. Based on these characteristics, the chances of microplastic entering the body of Snapper Fish through eating activities are greater than that of Baronang Fish. The largest type of microplastic fiber is found in the digestive tract of Snapper and Baronang Fish.

Conclusion: Baronang and Snapper Fish originated from Bangkala Subdistrict Beach, Jeneponto Regency containing microplastic. The microplastic content of Snapper Fish is greater than that of Baronang Fish.

Keywords: Microplastic, Baronang Fish, Snapper Fish.

Introduction

Waste is a problem for people throughout the world, both garbage originating from land and sea. Many years people do not care about marine pollution because of the large volume of seawater, and its ability to thin all types of foreign substances so that it almost not cause an impact at all. Therefore the sea is considered as waste dumps. However, this view began to gradually to change. This is due to, among other things, the waste is thrown into the sea increasingly the more time and in high concentration, so it happens environmental pollution on a local scale¹. If continuous disposal of waste into the sea, then feared there will be a global impact of marine pollution. One type the most common waste in the land and sea area is a plastic waste².

Marine litter (marine debris) can be defined as a solid, produced or processed by humans, directly or indirectly, accidentally or accidentally, thrown away or left in the environment sea³. Bellas J et al⁴ estimate that 10% of all newly produced plastics will be discharged through the river and end at sea.
Plastics are synthetic polymer materials made through the process polymerization. Everyday human life in this century is inseparable from plastic usage. Its nature is difficult to degrade in nature to make it the biggest waste contributor that causes damage to the balance nature. The continued use of plastic increasing worldwide causes plastic waste to become an issue that is often discussed. Disposal of plastic waste to the environment can cause various environmental problems.

Eriksen M, et al. estimate that at least there are 250,000 tons of plastic waste that floats in the ocean. Plastic waste buried in the sea has the potential impact of chemical waste tends to increase with decreasing plastic particle size (microplastic). Microplastic is less sized plastic particles from 5 mm. Microplastic has the potential to have an impact more serious than plastic that has a larger size because it can be ingested by fish and plankton so that it can disrupt the chain system food in the water.

One plastic waste that can affect the food cycle around coastal and marine areas are microplastic. Microplastic is wrong one part of marine waste which when piled up in the waters will cause disruption of the food chain to fish. Research conducted by on the coast of China, the results obtained from 263 fish examined were 26 commercial fish species. 32.7% were identified as swallowing more than one type of microplastic. Of all the types of fish examined, 63.5% were benthic fish and 36.5% were pelagic fish. A total of 73 types of microplastic were identified, 48 (65.8%) were fibers and 25 (34.2%) fragmented, the rest were polymers (polypropylene, polyethylene, alkyd resin, rayon, polyester, nylon, and acrylic). Potentially threatening more serious microplastic than with large plastic materials as organisms inhabit lower tropics, like the plankton, have particles susceptible to the microplastic digestion process as consequently it can affect high levels of tropical organisms through the process bioaccumulation. Laboratory test results show that microplastic can be digested by marine organisms when one particle from microplastic can resemble food.

Microplastic pollution also occurs in Indonesia. Research conducted by Masanti YDin Semarang, the results obtained by Belanak Fish and Snapper Fish (Lutjanus. sp) contain microplastic of 15 particles/fish. This is what inspires researchers to conduct microplastic research on Baronang (Siganus. Sp) and Snapper Fish (Lutjanus. sp) found around Bangkala Subdistrict, Jeneponto Regency because Jeneponto Regency is the largest fish producer in South Sulawesi. The purpose of this study was to determine the microplastic contents of Baronang (Siganus. Sp) and Snapper Fish (Lutjanus. Sp) in the vicinity of Bangkala Subdistrict Beach, Jeneponto Regency.

**Material and Method**

**Sampling:** The fish sample is put in a thermos of ice fish that has been filled with icestone. In addition, interviews were also conducted with local fishermen to find out the location of the arrest.

**Microplastic Identification in Fish:** All equipment is sterilized with acetone and distilled water. Sample fish identified using Fishbase. Fish is taken by the channel digestion from the base of the esophagus to the anus then the canal digestion soaked in 20% alcohol. Fish digestive tract crushed with a mixture of a solution of nitric acid (65%) and perchloric acid (68%) with a ratio of 4:1, so the channel comparison digestion and a mixture of solutions of nitric acid and perchloric acid are 1: 5. Soaking is carried out for 24 hours in an acidic room. Next, the suspension was boiled for 10 minutes and left for 30 minutes. The suspension is then diluted with distilled water 4 times dilution and filtered with a 0.5 mm filter. The pellet the filter is then transferred to a petri dish, pierced with a hot needle to ensure that the pellet is microplastic, and observed by type (fiber, film, fragment, pellet) and coloring a stereo microscope. Next is the microplastic obtained is calculated the number of each type, photographed with optilab, and then measured by raster image software. The process is done as much as two treatments in fish digestive tract samples and controls. Treatment of controls is carried out by following all procedures on fish but only use quads.

**Processing Data Analysis:** Data analysis used descriptive statistical analysis for knowing the number of microplastic between stations. Data analysis performed namely the laboratory approach using Minitab 16 software.

**Result and Discussion**

**Microplastic on the Fish Digestion:** Microplastic content found in the digestive tract of Baronang Fish (Siganus. Sp) and Snapper Fish (Lutjanus. Sp) found around the Beach Bangkala District, Jeneponto Regency.
Based on Picture 1. From the results of the study indicate that Snapper Fish (Lutjanus. Sp) contains more microplastic with an average of 18 particles/fish compared to Baronang (Siganus. sp) with average 14 particles/fish.

Based on Picture 2. From the results of the study indicate that Snapper Fish (Lutjanus. Sp) contains more microplastic with an average of 18 particles/fish compared to Baronang (Siganus. sp) with the average of 13 particles/fish.

Based on Picture 3. From the results of the study indicate that Snapper Fish (Lutjanus. Sp) contains more microplastic with an average of 10 particles/fish compared to Baronang (Siganus. sp) with average 6 particles/fish.

The results of research from all stations show that Snapper Fish (Lutjanus. Sp) contains the most microplastic. This happened because snapper (Lutjanus. sp) has several characteristics more prominent than Baronang fish (Siganus. sp), among others, have relative growth faster and tends to have greater eating behavior (greedy). In addition, Snapper Fish (Lutjanus sp) is very tolerant of turbidity and salinity. Based on these characteristics, the potential or microplastic opportunities enter the body of Snapper Fish (Lutjanussp) through eating activities higher than grouper. The results of this study are in line with research conducted at Ancol Beach, Port Queen, and Labuan. The results obtained showed that Snapper fish (Lutjanussp).

Small microplastic size (≤ 5 mm) allows microplastic has high potential to be digested by various marine organisms. Fiber (filamentous), filament, and films are also found in fish mesopelagic with an average length of 2.2 mm. A new study on microplastic proves that at each stage of ontogenic Catfish (Clariasbatrachussp) in estuary waters in the south-west part of Atlantis, all of them contain microplastic. The microplastic ingested by fish or marine organisms will have an impact on marine organisms both physically and chemically. If ingested, microplastic can be passing through the intestine or can be maintained in the digestive tract.

Fiber is the most common type of microplastic on the digestive tract of Snapper Fish (Lutjanussp) and Baronang Fish (Siganus. Sp). This is in accordance with the research carried out by Lusher et al. (2013) who reported that the highest type of microplastic being in the digestive tract of fish is fiber (68.3%). If plastic particles accumulate in amounts of large intestines in small animals, will have the same effect as garbage large plastic and clogging the digestive system. Accumulation of garbage in the digestive tract can cause taste full fake. This causes the fish to experience a decrease in appetite. There are also concerns that if swallowed by organisms, small objects from plastic waste may facilitate chemical contaminant transportation. Microplastic found in marine biota such as fish, of course, make an impact if consumed by humans. Health effects that can arise are intestinal disorders and stomach (irritation). Chemicals contained in plastic can increase cancer cells growth.
Constitution

Baronang fish (Siganus. Sp) and Snapper Fish (Lutjanus sp.) Originating at around Bangkala District Jeneponto Regency contains microplastic. Macroplastic in Snapper Fish (Lutjanus sp). More compared to Baronang Fish (Siganus. sp.) Microplastic content in Snapper Fish (Lutjanus sp.) at station 1 an average of 18 particles/fish, station 2 averages 18 particles/fish and station 3 averages 18 particles/fish.

Acknowledgment: The author would like to thank the government of Jeneponto Regency, especially the community of Bangkala Subdistrict, who have received and helped in this study so that researchers can attend the international conference APACPH-KL EARLY GLOBAL HEALTH CONFERENCE CAREER, Faculty of Medicine, Universitas Malaya, Kuala Lumpur.

Abstract

Background: Nutritional problems in infants aged 6-11 months are strongly influenced by complementary feeding. The inaccuracy of time in complementary feeding to infant.

Aims: To examine the factors associated with the appropriate time of complementary feeding to infant in Jeneponto districs.

Method: This was a cross-sectional study. The sample were mothers who had infants aged 8 and 10 months with total 125 infants. Bivariate analysis using chi-square and multivariate logistic regression were conducted.

Results: The results of the bivariate analysis showed that frequency of following ANC ($p = 0.045$), birth weight status ($p = 0.025$) and mother occupation ($p = 0.029$) were independently associated with the appropriate time of complementary feeding. Based on multivariate analysis indicated that mothers who visited to ANC [AOR: 4.14 (95% CI: 1,576-10,885)], mothers who had normal birth weight status of infants (95% CI: 2.142-88,628)] and mother who consumed iron capsules [AOR 5.27 (95% CI: 1.72-16.06)] were found key factors the appropriate time of complementary.

Conclusions: The appropriate time of complementary feeding was significantly associate with maternal occupation, frequency of visiting ANC and birth weight status. The variable that most influences the appropriate time of complementary feeding was birth weight status.

Keywords: Complementary feeding, infant, determinant.

Introduction

Complementary feeding is defined as a process that starts when breast milk alone is no longer enough to meet a baby’s nutritional needs, and therefore other foods and fluids are needed, along with breast milk (1). Infants (ages 0-11 months) are a golden period as well as a critical period because at this time there is rapid growth and development which reaches a peak at the age of 24 months where nutritional deficiencies and diseases contribute globally to higher levels of malnutrition among children children under the age of five$^1$.

The problem of malnutrition causes four out of one hundred babies born each year to not survive more than five years, which are generally victims of diseases and conditions exacerbated by these nutritional problems; one in three toddlers has a growth disorder and almost one fifth of toddlers experience less weight$^2$.

The problem of malnutrition still a major problem in Indonesia. This is evidenced by the still finding cases of malnutrition in children in various regions. One factor that can affect nutritional status is intake. A person’s nutritional status is a picture of what he consumes. Children aged 6-24 months get nutritional adequacy from breast feeding and complementary feeding$^3$.

Child development will be disrupted if complementary feeding are not introduced at the age of 6...
months, or given in an improper way. Because at the age of 6 months, the baby’s needs for energy and nutrition begin to exceed what is provided by breastfeeding, and complementary feeding is needed to meet those needs.

Nationally, based on 2013 basic health research, national stunting prevalence reached 37.2% consisting of 18.0% very short children and 19.2% short children, increased from 2010 (35.6%) and 2007 (36, 8%)4.

Babies are very vulnerable during the transition period when complementary feeding begins. Ensuring their nutritional needs are met thus requires that complementary food be on time-meaning it is introduced when energy and nutrients are needed beyond what can be provided through exclusive breastfeeding and often5.

Provision of prolonged exclusive breastfeeding has the potential to cause a lack of energy and nutrition when the introduction of complementary food is incorrect or delayed. Meeting the nutritional needs of infants aged 6-12 months based on the intake of advanced breastfeeding on Demand and complementary feeding. Age of infants 6-12 months is the age that is susceptible to malnutrition due to the provision of complementary feeding which is not appropriate both time and composition. Inappropriate time is <6 months or <7 months, while the improper composition is lack or excess nutrients. Some complementary feeding babies lack fat intake and some excess carbohydrates derived from simple carbohydrates, the introduction of food taste in infants 6-12 months will determine the eating habits of these children6.

Introducing complementary feeding at an earlier risk of obesity at a higher economic level and delaying complementary feeding causes the supply of energy and protein and other micronutrients to be inadequate for babies7.

Other studies have shown that early feeding can increase the risk of eczema. However, there are few data that support the relationship between early solid feeding and other allergic conditions8. In addition, the initial introduction of solid foods can cause malnutrition results such as low iron stores by displacing rich energy and iron which is highly bioavailable in breast milk, and continues to increase the risk of diarrheal disease. The aims of this study was to look at factors associated with the timing of complementary feeding in infants in Jeneponto Districs.

### Materials and Method

This type of research is observational analytic with crossectional study design. The location of the study was carried out in the district with a population of 482 babies The sample in this study were mothers who had babies aged 8 and 10 months as many as 125 children. The reason for choosing samples that were 8 and 10 months old was because that age was a transition of complementary feeding at texture and frequency. The sampling technique is accidental sampling. Data collection through interviews using a questionnaire. Data analysis using bivariate with chi-square and multivariate with logistic regression.

This research was carried out after obtaining approval from the Ethics Commission of the Faculty of Public Health, Hasanuddin University number UH16090723. Before the implementation of measurements and interviews will be given an explanation of the actions to be taken for each respondent (Mother and baby). After the explanation, the respondents were asked for approval to participate in this study by signing an informed consent.

Table 3. The results of multivariate analysis showed that the possibility of giving complementary feeding correctly to mothers who during pregnancy were ANC visits ≤4 times higher than ANC> 4 times [AOR: 4.14 (95% CI: 1.576-10.885)], possible complementary feeding in infants born with normal weight is higher than babies born with low body weight [AOR: 13.77 (95% CI: 2.142-88,628)] and the possibility of giving complementary feeding correctly to mothers given capsules iron is higher than those given Moringa flour [AOR 5.27 (95% CI: 1.72-16.06)].

**Discussion**

This study found that the frequency of participating in ANC was a determining factor in the time to introduce complementary feeding. Pregnant women who follow ANC> = 4 times may introduce complementary feeding correctly compared to pregnant women who participate in ANC <4 times this is because visits that are more frequent to health services make it possible to obtain information from health workers about the importance of providing complementary feeding properly time to baby. This study is consistent with studies conducted in Ethiopia that children whose mothers have antenatal care visits (ANC) are more likely to introduce complementary feeding on time than children whose mothers have never had antenatal care services when they are pregnant9-11.

BBL status is a determining factor in the time to introduce MP-ASI. Normal-born babies are more likely to introduce complementary feeding in a timely manner than babies born with a weight below normal (<2500). Babies born normally are faster growth and development because exclusive breastfeeding is not problematic compared to those below normal birth weight so it is possible to delay of complementary feeding earlier. Whereas babies born under normal have problems at birth due to having to be hospitalized so they part with their mothers. This causes low exclusive breastfeeding and is replaced by formula milk. This study is consistent with the results of a study in Brazil showing that the relationship between types of breastfeeding and difficulties in providing complementary food, especially in food rejection, as well as an increased chance of formula-fed infants having difficulty serving complementary meals compared to other types of breastfeeding. In addition, they also need prolonged hospitalization, contributing to low milk production or even disrupting mother-baby bonds that might reduce the possibility of forming a full breastfeeding pattern12,13.

Tablet Fe consumption during pregnancy is a determining factor in the time to introduce complementary feeding. Babies born to mothers who consume Fe tablets during pregnancy may introduce complementary feeding in a timely manner compared to babies born to mothers who consume Moringa flour capsules and Moringa extract. Supplements given to pregnant women in order to prevent anemia. Prevention of anemia during pregnancy will prevent low birth weight, this is consistent with other studies that say that the treatment of anemia in pregnant women must be done because it has an impact on fetal growth and development such as low birth weight (LBW) and this will have an impact on later growth and development14-16. If the baby is born normally, the growth and development is in accordance with his age so that the time of introduction of complementary feeding can be appropriate.

**Conclusion**

This study showed that the timing of the introduction of complementary feeding was significantly associated with ANC visits at the time of pregnancy, consumption of Fe tablets during pregnancy and birth weight. The
more pregnant women go to health services, the more exposed they are to information about the importance of introducing MP-ASI to babies. For the next researcher, it is expected to look deeply into the reasons for the mother not introducing MP-ASI on time by using a qualitative research design.

Abstract

The maternal mortality rate is the number of maternal deaths during pregnancy, labor and childbirth. Maternal mortality is an important problem because it causes the state to lose a number of productive forces, increasing child morbidity and mortality. This study aims to determine the risk factors for maternal mortality. The research used was analytic observational with a case control study design with a sample size of 120 people consisting of 30 case groups and 90 control groups with a ratio of 1: 3, Data analysis used bivariate analysis with Odds Ratio and multivariate analysis with multiple logistic regression. The results found there are three variables which are risk factors for maternal mortality, namely late referral (OR = 4.620, 95% CI = 1.513-14.113), history of maternal disease (OR = 3.028, 95% CI = 1.095-8.669), and obstetric complications (OR = 3.081, 95% CI = 1.161-7.896). While antenatal examination, family planning history, parity and distance of pregnancy are not risk factors for maternal mortality. Health workers are advised to strengthen the referral network system, conduct early detection of risk factors and manage obstetric complications.

Keywords: Maternal Mortality, Obstetric Complications, Maternal Disease History Antenatal Examination, Family Planning History.

Introduction

Globally in 2015 around 830 women died every day and in Indonesia 38 women were due to complications during pregnancy or childbirth. Based on the Intercesnal Population Survey (SUPAS 2015) the Maternal Mortality Rate (MMR) is 305 per 100,000 live births. Total maternal deaths were 14,640, reported 4,999 mothers and those not reported 9,641 maternal deaths. The agenda for reducing the MMR’s Sustainable Development Goals (SDGs) globally by 2030 is 70 per 100,000 live births and Indonesia targets MMR in 2024 to be 232 per 100,000 live births1.

Nearly 20% of maternal deaths occur before delivery, 82% occur after labor or abortion, 46% occur within 24 hours of delivery and 69% occur within seven days after delivery. Most reported maternal deaths occur in health facilities. The highest maternal mortality sites were 77% in hospitals, 15.6% at home, 4.1% occurred in trips to hospitals/health facilities, 2.5% in other health facilities and 0.8%2.

The World Health Organization (WHO) in developing countries in some countries have high AKI such as Sub-Saharan Africa 179,000, South Asia 69,000, and Southeast Asia 16,000. The maternal mortality rate in Southeast Asian countries is ranked first by Laos, namely 357 per 100.00 Births, Vietnam 49 per 100,000 live births, Thailand 26 per 100,000 live births, Brunei 27 per 100,000 live births, Malaysia 24 per 100,000 live births and Singapore have a maternal mortality rate of 7 per 100,000 births.

The Maternal Mortality Rate in Indonesia still reaches 305 per 100,000 live births, this figure places Indonesia as the country with the second highest mortality rate in Southeast Asia. It is still very far compared to neighboring Malaysia and Singapore. Based on data from the South Sulawesi Health Office in 2015 the number of maternal deaths was 149 cases, in 2016 there were 156 cases and the number of maternal deaths in 2017 reached 115 cases. South Sulawesi Province is included in the top 10 list of provinces contributing to maternal mortality in Indonesia in 2017. Sinjai District ranks the second highest in MMR in South Sulawesi province. Based on the health profile of Sinjai district, Maternal Mortality Rate in 2016 was 293 (12 cases) per 100,000 live births, decreased in 2017. Namely the
MMR reported 148 (6 cases) per 100,000 KH, the target of the 2017 Strategic Plan is 113 per 100.00 KH. In 2018 the MMR was 297 per 100,000 KH (12 cases), the target of the Strategic Plan 2018 was 113 cases per 100,000 Births³.

Cases of maternal deaths due to pregnancy, childbirth, and childbirth in Sinjai District are generally caused by bleeding, hypertension, pre-eclampsia, eclampsia, infection, abortion, anemia, nutritional status and others. Most deaths occur within seven days after saline or the puerperium. Some studies show maternal mortality is influenced by factors related to maternal factors, reproductive status factors, factors related to obstetric complications, factors related to health services, socio-economic factors and socio-cultural factors.

**Materials and Method**

**Location and Design of Research:** This research was conducted in the working area of the Sinjai District Health Office. This type of research is observational analytic with case control design.

**Population and Samples:** The population in this study were all pregnant women, maternal and postpartum mothers at 13 (thirteen) Puskesmas from 16 (Sixteen) Puskesmas located in the Sinjai District Health Office area for the period 2016 to 2018. Samples were 120 mothers in which groups cases are all maternal deaths (maternal mortality, maternal mortality and postpartum maternal mortality) and the control group are all pregnant women and mothers giving birth in the Puskesmas area where there are cases of maternal deaths, with a case sample ratio: control is 1: 3, so Minimum sample amount is 30:90. The withdrawal of case and control samples was done by selecting samples randomly from all mothers who gave birth in the area of the Sinjai District Health Office.

**Method of collecting data:** This study uses secondary data obtained from the Sinjai District Health Office. Data collected from 13 (thirteen) Puskesmas in Sinjai District for 2016 to 2018 are: Balangripa Health Center, Island IX Health Center, Bulupoddo Health Center, Samataring Health Center, Kampala Health Center, Samaenre Health Center, Aska Health Center, Mannanti Health Center, Lappadata Health Center, Manimpahoi Health Center, Manipi Community Health Center, Central Lembang and Puskesmas Biji Nangka.

**Data analysis:** Data on general characteristics of respondents, independent variables and dependent variables were processed using SPSS. To determine the risk factors for maternal mortality in pregnant, childbirth and postpartum mothers in Sinjai District, data analysis was used using univariate analysis, and multivariate analysis with multiple logistic regression.

**Results**

Table 1 shows the comparison of the proportion of age between cases and controls, the age category with the lowest presentation at age> 35 years where the case group and controls presented the same number (43.3%). Comparing the proportion of education levels between cases and controls, the education level with the lowest presentation was at the low education level where the control group was higher (60.0%) than the case group (50.0%). Comparison of the proportion of employment status between cases and controls, the lowest status of work with presentations was for mothers who worked where the case group was higher (16.7%) than the control group (15.6%).

Referral delay, with B value = 1,350, p = 0.007, with the risk being assessed through Exp (B) = 4,620, this value implies that late referrals have a significant influence (p = 0.007) on the incidence of maternal mortality with a 4,620 risk times greater than mothers who are not late to be referred.

Disease history, with a value of B = 1.108, p = 0.023, with the risk being assessed through Exp (B) = 3.028, this value implies that the history of the disease has a significant influence (p = 0.023) on the incidence of maternal mortality with a large risk 3,028 times greater than mothers who did not have a history of disease.

Obstetric complications, with a value of B = 1.125, p = 0.033, with the risk being assessed through Exp (B) = 3.081, this value implies that obstetric complications have a significant influence (p = 0.033) on the incidence of maternal deaths with a large risk 3,081 times greater than mothers who did not experience obstetric complications.

Discussion

In this study showed a significant result that the delay in referral, provided a risk of 4.620 greater for the occurrence of maternal deaths. The results of this study are in line with the research of Aeni (2013) that the delay in referral was proven to be significantly related to maternal mortality (OR = 10; p value = 0.013, 95% CI = 1.34-74.5). Factors of delay are especially late in making decisions to refer to and delay in reaching a referral place related to maternal death. This happens because the mother’s unwillingness to go to a health facility immediately and considers the signs of complications that are common in pregnancy, while other family members do not know the signs of emergency in obstetric complications. In general, this occurs in mothers with parity> 1 because they feel experienced in a previous pregnancy.

The results of the study were also in line with Atjo’s study, which was one of the causes of maternal deaths due to the delay in deciding to refer to a hospital, meaning that the delay from arriving to the hospital until medical treatment became one of the causes of maternal and childbirth deaths and numbers maternal mortality (Maternal Mortality Rate) is the ratio of the number of maternal deaths to 100,000 live births, this figure is an important indicator in efforts to achieve better quality of health services for pregnant and childbirth mothers in the city of Palu. When viewed from the Odds Ratio (OR), the delay in medical treatment also has the highest OR (30,447) compared to the others.

Other infectious diseases that are still the main problem of public health are Tuberculosis (TB). In pregnant women. In pregnant women TB can worsen maternal health and nutritional status, and affect fetal growth and development and the risk of contracting the baby3.

Research results in line with the research conducted by Jayanti, et al5 indicate that there is an influence between history of illness on maternal mortality. Mothers with a history of illness increased the risk of maternal death by about 9 times greater than those of women without a history of disease (OR = 8.9 95% CI; 2.76-28.71).

Godefay et al6 study of risk factors for maternal mortality in Tigray Ethiopia states that a history of maternal disease affects maternal mortality where mothers with a history of disease have a risk of 5.58 times compared to mothers with no history of disease.

In this study obtained the most existing history of disease data in the case group that is equal to 56.7%. The types of diseases found include chronic diseases such as cardiac hypertension asthma and infectious diseases such as TB, syphilis and nutritional problems, namely SEZ. Based on data on causes of maternal mortality, it was found that there were 2 (two) maternal deaths due to TB disease, 2 maternal deaths due to diagnosed heart disease and other maternal deaths due to eclampsia caused by hypertension in the mother before pregnancy.
A history of maternal disease is a disease that has been suffered by the mother before the last pregnancy based on the results of an antenatal examination and the results of laboratory tests. With a mother who has a history of chronic diseases that can interfere with the mother’s pregnancy journey or aggravate the problem of her pregnancy.

The results of this study indicate a significant risk of a history of maternal disease against maternal mortality. The history of maternal disease is a disease that has been suffered by the mother before the last pregnancy based on the results of an antenatal examination and the results of laboratory tests. With a mother who has a history of chronic diseases that can interfere with the mother’s pregnancy journey or aggravate the problem of her pregnancy.

The results of this study indicate a significant risk of a history of maternal disease against maternal mortality. The history of maternal disease is a disease that has been suffered by the mother before the last pregnancy based on the results of an antenatal examination and the results of laboratory tests. With a mother who has a history of chronic diseases that can interfere with the mother’s pregnancy journey or aggravate the problem of her pregnancy.

The results of this study are in line with Suriani’s research, in this study showed that there was a significant relationship between the history of the disease and the incidence of maternal mortality. The statistical test results show that mothers with a history of risky diseases have 15 times the chance to experience a maternal death event. This is because the history of the disease during pregnancy cannot be avoided by pregnant women because the history occurs before pregnancy and affects later in pregnancy.

Factors that contribute to maternal mortality are direct causes of maternal death, namely factors associated with complications of pregnancy, childbirth, and childbirth such as bleeding, infection, hypertension in pregnancy (HDK) preeclampsia/eclampsia, congestion and abortion. Maternal mortality caused by obstetric complications In 2017, hypertension was 33.07%, obstetric bleeding 27.03%, other obstetric complications 12.04%, infections in pregnancy 6.06% and 4.81% due to other causes.

Obstetric complications such as hypertension in pregnancy are a major trigger for the occurrence of preeclampsia and eclampsia in pregnant, maternity and postpartum mothers. As many as 10% of pregnancy problems in the world are caused by hypertensive disorders including pregnancies with hypertension and pre-eclampsia.

The results of this study indicate that obstetric complications are significant risk factors for maternal mortality. This research is in line with the risk factor research conducted in Gowa South Sulawesi by using a case control study design by looking at the effect of health status consisting of pregnancy complications stating that women with high risk health status were found with (OR = 9.750) having 10 times more risk large maternal mortality compared to mothers who have low risk health status.

The yego et al. study of risk factors for maternal mortality in tertiary hospitals in Kenya stated that a history of complications affected maternal mortality with a value (OR 9.0, 95% CI 4.2-19.3), in which mothers with complications such as eclampsia has a risk of dying as much as 9 times higher than women who do not have a history of obstetric complications.

Researches found that the main cause of obstetric bleeding complications was uterine atony, placental retention, mothers with a history of previous bleeding, Pre eclampsia, labor induction and macrosomia (large infants).

In this study 76.7% of obstetric complications occurred in the case group. The complications that occur are as a direct result of pregnancy, and the types of obstetric complications that occur are anemia, hypertension, congestion, bleeding Pre eclampsia/ eclampsia, infection, Early Rupture of the membranes (KPD) and Hyperemesis Gravidarum. Some cases of complications were detected when the mother performed an ANC examination but no collaboration was conducted for laboratory examinations and even some cases were not referred to for treatment. For example, mothers who have hypertension are detected by a midwife in the village but no further treatment is done. Likewise, the handling is done by referring to the Hospital, but when the mother goes home, no monitoring is carried out, even the mother is never visited, so the mother experiences severe complications.

Conclusions

Based on the results of research and discussion with reference to the formulation of the problem and the research hypothesis, conclusions can be drawn, namely the delay in referral, obstetric history and complications (Complications of Pregnancy, Childbirth and Postpartum) are significant risk factors for the incidence of maternal deaths in Sinjai District.

Abstract

Background: Until now, maternal mortality is very high. Every day, around 830 women die from preventable causes related to pregnancy and childbirth. Most occur in developing countries and related to the ability of low family resources. The research objective is to determine the effect of family factors on the use of childbirth facilities.

Method: The study design used a cross sectional study, starting September 2016 to February 2017. Samples were 730 baby mothers, spread in 22 health center areas in Muna Regency. Sampling in proportion to simple random sampling.

Results: Most respondents preferred to give birth at home 473 people (64.8%). The family component that is significantly related to the place of delivery is communication with husband OR = 2.23, family structure OR = 2.89, community support OR = 2.76. Husband’s occupation, marital status, access and wealth do not show a significant relationship with the place of delivery. Further analysis by multivariate, variables significantly related were husband communication (Adjusted Odds Ratio (AOR): 1.61 [1.02-2.53]), family structure (AOR: 2.56 [1.82-3.59]), and community support (AOR: 2.17 [1.09-4.32]).

Conclusion: Communication with the husband, family structure, and community support have a significant relationship with the choice of place of delivery while the husband’s work variables, marital status, access and wealth are not related.

Keywords: Family, facilities, childbirth.

Introduction

One factor in maternal and infant mortality is home delivery. Most maternal deaths arise from unpredictable complications. Therefore the role of trained health workers is important for the safety of mothers and babies during childbirth. Women do not get services in health facilities due to lack of trained health workers and family support factors. The role of the family context that influences reproductive health service decisions such as delivery in health facilities and trained delivery attendants has received serious attention especially in Asia and Africa. The family factor is a feature of social organization related to marital status, partner communication, access, community support, poverty, which is bound by a norm and trust in the community influences the decision to use health services. The state of maternal health in Indonesia is still far from expectations, marked by the high mortality rate, which is still showing 305/100,000 KH in 2015, while the MDGs target 102/100,000 KH and even the medium-term development plan for 2019, Indonesia targets 306 per 100,000 KH. Hard work must be done to achieve the targets set for sustainable health development (SDGs) of less than 70 per 100,000 KH in 2030. Southeast Sulawesi Province also has a high maternal mortality of 312/100,000 KH with an increasing number of maternal deaths. To support these efforts, the government of the Republic of Indonesia since 1989, began a safe motherhood movement with a village midwife program that succeeded in increasing the proportion of births.
Claims of delivery by the puskesmas for maternal conditions on delivery at a health care facility\(^8\). To enhance the role of the family, in 2010, an active alert village program was declared, where husbands, families and communities are expected to be active in order to better recognize danger signs and complications of pregnancy and increase births by trained personnel in health facilities\(^12,13\). The family factor is very important that determines the decision of the mother to choose the place of delivery as some previous studies in Asia and Africa\(^14\), but researchers want to see the other side that is different in the region of Indonesia, especially the eastern part., marital status, communication with husband, family structure, access to facilities, community support and wealth with decisions on where to deliver in Muna Regency.

### Materials and Method

The study design used a cross sectional study, starting September 2016 to February 2017. The sample was 730 infants from 2,222 populations spread across 22 health centers in Muna Regency. Sampling in proportion to simple random sampling. Data analysis consisted of univariate, bivariate by classifying variables into two categories of husband’s work; (not working; if you do not have a permanent job and work; have a permanent job), Marital status (Not married; if you do not have a marriage certificate or divorced and Married; have a marriage certificate) communication with husband (no; no discussion; There is if there is discussion with the husband), family structure (no; no influence and no; there is influence) access to facilitation (difficult; very difficult or difficult and not difficult; easy or very easy), community support (not support; not support or very unsupportive and supportive; supportive or very supportive), wealth based on total asset scores in Quintil (low; Q1 to Q2 and high; Q3 to Q5) and further analysis by multivariate.

### Results

#### Characteristics of Respondents:

The number who participated until the end of the study was 730 mothers who had children aged 0-1 years. The description of research results can be seen in the following table 1.

| Table 1. Characteristics of family components by place of delivery in Muna District in 2017 |
|---|---|---|---|
| Variabel | Delivery in Home (%) | Delivery in health facility (%) | Total N (%) |
| Delivery places | | | |
| 473 (64.8) | 257 (35.2) | 730 (100) |
| Husban job | | | |
| Not work | 66 (14) | 40 (15.6) | 106 (14.5) |
| Labor | 86 (18.2) | 29 (11.3) | 115 (15.8) |
| Farmer | 132 (27.9) | 26 (10.1) | 158 (21.6) |
| Fishery | 20 (4.2) | 8 (3.1) | 28 (3.8) |
| Business | 43 (9.1) | 18 (7.0) | 61 (8.4) |
| Private staff | 25 (5.3) | 34 (13.2) | 59 (8.1) |
| PNS/TNI/POLRI | 17 (3.6) | 35 (13.6) | 52 (7.1) |
| Other, Honorer | 84 (17.8) | 67 (26.1) | 151 (20.7) |
| Marital status | | | |
| Not marriage | 1 (2) | 1 (4) | 2 (3.0) |
| Marriage | 472 (99.8) | 256 (99.6) | 728 (99.7) |
| Husband communication | | | |
| None | 111 (23.5) | 31 (12.1) | 142 (19.5) |
| Yes | 362 (76.5) | 226 (87.9) | 558 (80.5) |
| Family Struktur | | | |
| Self willing | 241 (51) | 68 (26.5) | 309 (42.3) |
| Husband | 162 (34.2) | 107 (41.6) | 269 (36.8) |
| Parent | 55 (11.6) | 52 (20.2) | 107 (14.7) |
| Father in low | 50 (12.1) | 8 (31) | 18 (2.5) |
| Community leader | 1 (2) | 0 (0) | 1 (0.1) |
| Friend/neighbor | 1 (2) | 2 (8) | 3 (0.4) |
| Health staff | 3 (6) | 20 (7.8) | 23 (3.2) |
Based on marital status, generally the marital status is 728 people (99.7%). Based on the family structure, most decisions are determined by the mother’s own will of 309 people (42.3%). Access to childbirth facilities is generally easy namely 583 people (79.9%). Based on community support, generally it supports 527 people (72.2%). Wealth status, most are in the range of Q4 (rich) ie 332 people (45.5%)

**Family factors related to the place of delivery**: To see the relationship between family components related to the choice of place of delivery (Table 2), a bivariate and multivariate analysis was performed. The results of the bivariate analysis showed that the husband’s work, marital status, access to labor facilities and wealth did not have a significant relationship with the place of birth (p> 0.05). Communication with husband has a significant relationship (p <0.05) OR = 2.23. This shows that mothers who do not communicate with their husbands regarding planning helpers and delivery places have 2.23 times the chance to give birth at home compared with those who communicate. The family structure has a significant relationship (p <0.05) OR = 2.89. This shows that the absence of the role of family structure towards pregnant women has a potential 2.89 times that mothers will give birth at home compared to those who have a role. Community support also has a significant relationship (p <0.05) OR = 2.76. This shows that mothers who do not have the support of the community have 2.76 times the opportunity to give birth at home compared to those who have the support of the community. Next we conducted a multivariate analysis. The test results using logistic regression analysis with back ward elimination method. The results show that women who do not communicate with their husbands regarding birth planning (Adjusted Odds Ratio (AOR): 2.61 [1.02-2.53]) are more likely to give birth at home than those who communicate. In the absence of the role of family structure in pregnant women (AOR: 2.56 [1.82-3.59]), it is 2.56 times more likely to give birth at home compared to mothers whose families have influence. The lack of community support for pregnant women (AOR: 2.19 [1.57-3.06]) has the potential of 2.19 times mothers giving birth at home.

**Discussion**

Our study aims to look at the determinants of the influence of family factors on the use of health facilities as a place of delivery. WHO recommends that safe deliveries should be performed in a health facility, but in this study only 35% were found. This figure is still far below the coverage of Southeast Sulawesi 61.7% even nationally 83.7%. Most of the respondents’ husbands work as farmers and laborers. The husband’s work is very important in terms of improving the family’s economy which can determine the ability to give birth in a health facility. In this study it was found that mothers with farmer husbands, laborers or unemployed have limited abilities so that labor tends to be done at home. If they want to go to the puskesmas or hospital, they depend more on the cost of childbirth on the poor health insurance (Askeskin), assistance from parents or in-laws.

The importance of communication with the husband appears in this research. Planning a helper and place of delivery if done earlier will make the husband have the responsibility in preparing funding for delivery. A similar previous study, found the importance of communication with a partner during pregnancy to be able to prepare for labor by trained staff at a facility.

The influence of family structure largely determines labor in a home or health facility. In this study it was found that there were no strong interventions from families regarding the place of delivery, giving the opportunity for pregnant women to give birth 2.89 times at home. More worrying is the culture of giving birth at home by midwives and traditional healers may have the support of the family. Distance and economy are the reasons for not using facilities as in previous studies, but this study is different because access to facilities is quite easy and the level of wealth is quite high. This evidence of family support for giving birth at home is very strong.

As social beings we need the support of other people or the community around us in life, including support...
when giving birth. Support from the surrounding community comes from neighbors, relatives, or other relatives. In this study it was found that pregnant women who did not get community support had 2.7 times the chance of giving birth at home. Therefore community support is very important in encouraging pregnant women to use health facilities as a place of delivery. Such community support may be in the form of financial assistance, thoughts, health service information or moral support that encourages pregnant women to give birth in a health facility.

**Conclusion**

The results showed the husband’s communication factors, family structure, and community support had a significant relationship with the choice of place of delivery while the husband’s work, marital status, access to facilities and wealth were not related.

Abstract

In Indonesia, health services are still a problem both in terms of financing, quality, and public access. The purpose of this study is to analyze the availability of public health services in the Dayak tribes. Informants in this study are indigenous Dayaks Society, the Society who were and had experienced/illness, Dayak Customary Chief, Head of health center and health workers. Analysis of the data in this study using thematic analysis. The primary data obtained from direct observation and in-depth interviews and focus group discussion (FGD), while the secondary data obtained from the study documents. Based on this research, accessibility of public health services in the Dayak based on an interview to the informant still have limited Human Resources (HR), infrastructure, medical equipment and pharmaceuticals (drugs). Advice to the city administration should have to provide health care facilities that can be accessed 24 hours as “Homecare Health Center” mainly Dayak and other communities who live on the outskirts of the city of Samarinda. There needs to increase the number of health workers, especially doctors and surveillance personnel.

Keywords: Aksesibilitas, Layanan Kesehatan, Dayak.

Introduction

Health workers there were more concentrated in urban areas, it is possible urban health centers are economically better and very promising in very remote health centers appeal. Remote areas and rural disadvantage, not only because it has fewer health care facilities, but also the difficulty associated with health sector workers. Access is not only distance, but also the availability of resources, namely the means (Tumanggor 2010), infrastructure, and human resources and budgeting.

Households knowledge about the existence of a midwife or maternity hospitals nationwide was 66.3 percent, the highest in Bali (85.2%) and lowest in Papua (9.9%). Knowledge of the existence of integrated health service post as much as 65.2 percent, the highest in West Java (78.2%) and lowest in Bengkulu (26.0%). Proportion of Households using various modes of transportation motorcycle to the government hospital in 53.6 percent of urban and 46.5 percent rural. To use public transport in urban areas 28.0 percent and 35.5 percent rural. While using more than one mode of transport in urban areas while in rural areas 8.5 percent 11.4 percent.

Samarinda city is one of the most multi-ethnic settled because the number of immigrants from other regions and indigenous people who are looking for work in the city of Samarinda, thus requiring attention related to public access to health services remains low and is not covered, the number of health workers are still lacking, time and distance to health care is still a problem. Past research has studied some of the dimensions of accessibility, but research is mostly done using quantitative Method and yet many researchers who studied qualitatively. Among some of the existing research dimension, the dimension of accessibility proposed consists of the accessibility factor approachability, acceptability, availability and accommodation, affordability and appropriateness has not been widely used as a reference in the accessibility of health services research. Based on several research studies, theories about the accessibility of health services, the researchers were interested in examining the accessibility of the availability of health services for the Dayak people in the city of Samarinda.
Materials and Method

In this study, researchers used a qualitative research method with case study approach is a study that aims to describe and understand and explain how the accessibility of health services availability Dayak community in Samarinda. The research was conducted in the city of Samarinda which are urban areas wulayah Kalimantan Dayak tribal communities. The election procedure informants in this study is using purposive procedure. The informant in this research that indigenous Dayaks Society, the Society that are and have experienced/illness, Dayak Customary Chief, Head of health center and health professionals. Analysis of the data in this study using thematic analysis, The data collection was obtained by conducting interviews with informants.

Results

Factors Availability and Accomodation all kinds of health services needed by the people is not difficult, as well as its presence in the community at any time that it takes the form of infrastructure, equipment adequate health, pharmaceuticals (drugs) and health human resources (doctors, midwives and nurses).

Infrastructure: Infrastructure for health services provided in the city of Samarinda felt was sufficient. Health infrastructure as befits a provincial capital in other places, there are many choices for accessing and utilizing health facilities especially the government and private Hospitals.

One of the key informants, addressing conditions of health care infrastructure in the city of Samarinda, as follows.

“Infrastructure in general is sufficient, in the sense of being rich, the infrastructure of the ingredients may need additional kinds of things, such as parking and all kinds” (DK)

This is confirmed also by other informants:

“the building is good, sir” (DI2, 58 Th)

Medical tools: Medical equipment is something that people felt inadequate, because there are still some requirements with appropriate equipment for quality health care. It is revealed from the following disclosure of some key informants:

“Praise be to God, it is enough because we are not hospitalized, it is not treated like that” (DK)

“So thank God, if that at least we have fulfilled” (JM)

“Primary health care problem in Pampang is sometimes there is no blood check equipment, cholesterol check tools and other checks” (DI2, 58 Th)

Pharmacy: Procurement and availability of drugs, especially in the health center, was considered good enough as explained by key informant described below:

“Use it as possible. Alhamdulillah, right now the health center has already had a pharmacist, let alone want to accreditation, the goal must be that it must be complete”(DK)

“There was once, and it happened indeed in the pharmaceutical warehouse is empty. But whatsitname that there are drugs that his choice another term is no other choice he did the same, but could not really empty consumables same “(JM)

“Then there is the doctor or the spouse who is checking this pain, right, right, there is always no medicine, you just have to come back home who has a fever, sir, how come you come to the doctor, uh, to the health center again tomorrow is closed again. So what should I do, the puskesmas is 24 hours, sir. Now that drug is often not there sir. The area here is including the city area, near samarinda”(DI1, 60 Th)

“Only the medicine at the health center for the illness that was not so severe, the severe illness was immediately referred to, which I saw there was no blood and cholesterol check”

“So if I, I am my disease because I am old, I am 72, my prostate disease must go to a public hospital, so this month I went to the public hospital to take prostate medication, no medicine this month. So if at the puskesmas why should I go to the hospital to take medicine, why don’t the medicine go to the health center so that it is also close to mine, also the cost from Pampang is 50 Kepuskesmas can also be sent if they do, but it is also difficult every month I get there this month there is no medicine. So they told me to wait for the drug this month but I haven’t left. But thankfully because I have no problems with urinary problems, it’s a disorder if the prostate is a genuine parent. I also had surgery for stone kidney stones yesterday, if the service at that time is ok, the service is only because of the reason we postpone the long delay until 1 month wait, many women say
we suffer from us too long we wait, suffer the cost of suffering pain ha ha ha ha” (DI2, 58 Th).

**Human Resources:** Human Resources for Health is required to create an appropriate health services and qualified patient needs.

“Iyah Internship, every year right we can be an additional 5, 5 so so very helpful at both the field and what it later so. But his own doctor if power is actually also “(DK).

The existence of human resources for health in the city of Samarinda, especially PHC is recognized, a key informant had provided, as stated below.

“The doctors we are actually hospitalized we had 3, under 4 we have 7 but e just now just one doctor mutase to Jogja follows husband, one doctor again pulled out due to be Acting head of the health centers in lempake that here one doctor learning tasks in Unhas also, So under the 2 remaining above 2 to 4, dentist 1 “(JM)

“Because we hear complaints so even if we are not allowed stay where where but complaints that we need to hear this society procession. Moreover, they go for treatment was not often come for treatment to the clinic there was no doctor there is also no cure “(DI1, 60 Th).

“if I sir, if here we want to go to health services, there should be a midwife or a spouse. there is no midwife because we as housewives want complaints from women as well, we have to have the midwife only if we are ... if we consult the womb pain difference, the midwife knows we feel free we feel we want to “(DI7, 50 Th)

**Discussion**

Factors Accessibility all kinds of health services needed by the people is not difficult, as well as its presence in the community at any time that it takes the form of availability of facilities and infrastructure, equipment adequate health, pharmaceuticals (drugs) and the source human resources (HR) factors accessibility Availability (Availability and Accomodation) all kinds of health services needed by the people is not difficult, as well as its presence in the community at any time that it takes the form of infrastructure, equipment adequate health, pharmaceuticals (drugs) and the source health human resources (doctors, midwives and nurses).

**Infrastructure:** Infrastructure for health services provided in the city of Samarinda felt was sufficient. Health infrastructure as befits a provincial capital in other places, there are many choices for accessing and utilizing health facilities especially the government and private hospital. Currently, the city of Samarinda at least have had the health facilities (infrastructure), such as the hospital as much as 17 government and private hospitals, 24 health centers with various levels of stratification continues level to meet the standards and quality of health services measured.

Although health service infrastructure rated adequate, but the following few key informants suggested still the need to improve infrastructure in order to meet the standards of quality health.There is a desire to rehabilitate the building, especially at the primary care level to plan their special space to care for the elderly, their meeting place/meetings broader staff and meet the standards supported boardroom meeting facilities.

With the potential power of health service infrastructure, especially 24 health centers scattered throughout the districts, and villages, health centers in the city of Samarinda can initiate emergency services 24 hours, gradually based on the medical needs of emergency in the district area (based kominitas such ethnic Dayak tribes and rural communities Samarinda city). To support the 24-hour service for emergency conditions needed some cars faster health care (home care). This car is equipped with a small body supporting health facilities for those suffering from heart disease and more importantly equipped with telemedicine.

**Medical tools:** Medical equipment is perceived all health care-related partners (providers and users/patients) are still inadequate. This was revealed by some health care providers who say certain types of equipment not available, the patient is required in the examination.

For example, dental care unit facilities, can already kindling revocation of all kinds, the term in accordance with service standards. When referring to the Minister of Health, especially the basic examination (not hospitalization), the equipment available is deemed to have complied.

Based on the recognition of some participants in the discussion (FGD) from the Dayak tribe, they say if standard hospital equipment such as hospitals Abdel Wahab Syahranie (Hospital AWS) and RS Abdul Muis and other hospitals (private hospitals) in Samarinda city, judged complete and adequate.
**Pharmaceuticals (Drugs):** Pharmaceuticals (Drugs) are available both in auxiliary health center and health centers have never experienced problems in terms of both supply and availability. Drugs that are needed by the community can be obtained easily, especially in auxiliary health center. Demand for drugs from auxiliary health center conducted every month, adjusted for the needs of island communities. For drug distribution auxiliary health center parties should come to the clinic to take the demand for drugs by using the services in every single month which coincides with the monthly health center workshop.

**Human Resources (HR) Health:** Not only in Indonesia, the physical availability of health services begins with the service, but the distribution of services and medical personnel are not uniform across Australia. The concentration of medical practitioners, for example, the highest in large cities (392 medical practitioners equivalent full per 100,000 population), and significantly lower in the remoteness of the other, with outdoor areas that have the lowest rates (206 medical equivalent of a full time practitioners per 100,000 population).

The problem of inadequate staff and lack of health care services reverberate throughout the interview. “There is no chemist, no doctor, no other services, so everything is pretty limited at this stage”. Some reportedly in need of services including X-rays, a defibrillator, a local surgery, kidney dialysis services. Issues of health human resources is still a problem that needs to be resolved. Interesting facts discovered why health care workers who are in the area of the island is always deficient because when the life of a health worker has been prosperous, so they decided to leave the place where he works, and chose to live and serve in place better and have better access anyway.

**Ethical Clearance:** Taken from favultu of public health ethical committee

**Source of Funding:** Self

**Conflict of Interest:** Nil

**Conclusion**

Based on the description above, it can be concluded that the availability of Dayak community health services is inadequate, this is based on the availability of facilities and infrastructure in health facilities which are considered inadequate, such as infrastructure, medical equipment, pharmaceuticals and unmet health human resources. needs of health care facilities.

Role of Genetic Polymorphisms of Angiotensin Converting Enzyme to Cardiovascular Endurance in Men Ages 13-14 Years After Fartlek Training for 3 Months

Fatoni1,2, Haerani Rasyid1, Rosdiana Natsir1, Ilhamjaya Pattelongi1, Andi Ihsan², Adam Mappaompo², Sudirman²

Abstract

Physical ability is influenced by two factors, namely environmental and genetic factors. Environmental factors that influence are exercise intensity, nutritional intake, and age. Another factor that is not less important in influencing cardiovascular endurance is genetic factors. One of gene variation that is considered to determine the athlete’s potential is the variation in the ACE gene symbolized by I and D. The ACE gene insertion/deletion polymorphism (I/D) has an important relationship with cardiovascular fitness with genotype II which shows a lower level of cardiorespiratory fitness with VO2max than the Non II genotype (ID and DD). The purpose of this study was to assess how the role of the ACE gene in male cardiovascular endurance aged 13-14 years. This study provides a three-month fartlek training program and conducts cardiovascular endurance tests before and after taking a three-month fartlek training program. In group II genotype subjects showed the results of increased cardiovascular endurance compared to the Non II genotype subject group. Research can conclude a strong relationship between the variation of the angiotensin converting enzyme gene II genotype against male cardiovascular age 13-14 years.

Keywords: ACE gene, cardiovascular endurance, fartlek training.

Introduction

Efforts to improve sports performance cannot be separated from physical conditions, because the physical condition supports when practicing or competing to show the best performance by displaying techniques and tactics effectively and efficiently. Good physical condition is one of the absolute requirements to achieve optimal performance. Sports training strategies focus on athletes’ interests and achievements. Genetic potential of individuals must be considered to get high achieving athletes, because with the appropriate genetic variation there is a greater chance of producing accomplished athletes than athletes who have inappropriate genetic variations if they receive the same training intervention and motivation. This research concentrates on finding the right genetic profile to contribute to sports performance. One of the main objectives of this research is to help trainers to identify and guide individuals with genetic potential to become elite athletes.

ACE gene is an important factor that needs to be considered. The results of this study provesthat human physical performance is influenced by genetic profiles1. Allele I was found to have a beneficial effect on higher maximum oxygen uptake values. Characteristic distribution of genotypes was found, where allele II was more common in individuals doing aerobic exercise and DD alleles in individuals who were disciplined in anaerobic exercise2.

The role of ACE gene polymorphism with cardiovascular response with irregular resistance training in women. The subject of DD alleles is greater in post-exercise hypotension, While the allele I showed a greater increase in heart rate after endurance training3 the integration of several genes added to environmental factors, identification of talents and prescription of training programs that maximize the athlete’s individual potential based on genetic variable characteristic, will be able to make a revolution in sports science. polymorphism gene ACE II which states higher ACE activity has a correlation with the ability for sports that require endurance, while DD polymorphisms and higher ACE activity are related to sprint ability4. Variations
in the Angiotensin Converting Enzyme gene which were interacted with resistance showed differences in changes in endurance results, namely genotype II which was better than the variation of DD genotype, with an average increase of 11.57ml/kg/minute, while the DD genotype decreases by an average of -8ml/kg/minute.

There is an individual variability characterized in response to endurance training, and some research results suggest that this part of the variation is genetically regulated. In addition, the results show that genetic variation. The ACE gene can affect blood pressure response to exercise, although more research is needed to confirm this finding.

Research results of Myerson S, et al. His analysis showed a linear tendency to increase the frequency of allele I with running distance. The allele I ACE gene is associated with improved endurance performance. In addition, the insertion/deletion (I/D) type polymorphism of the ACE gene also influences the process of performance in the heart as the results of the study. Aziza, L., et al. which states that the insertion/deletion (I/D) type polymorphism of the ACE gene affects ACE concentration in the blood and affects blood pressure. Blood pressure changes are affected by changes in angiotensin II, aldosterone or active vaso substances.

This relatively new approach needs to be considered by sports institutions in determining the right strategies to foster the seeds of young athletes to improve sports performance. So, research can be utilized by considering the variation of the genotype II of the ACE gene in the search for potential talent for Indonesian endurance athletes. If the genetic information of prospective young athletes obtained earlier, is expected to have a significant influence on the effectiveness of sports training in general.

**Research Method**

This type of research is a retrospective cohort study using a cross-sectional design or approach to describe the correlation between factors and effects. Research in October 2018 January 2019 in South Sulawesi. The population in this study were SMP N 3 Sungguminasa students with a age range of 13-14 years, amounting to 78 people to be the number of samples in this study but those who completed until the end of the study were 59 samples. Data were analyzed using SPSS version 24. The results are displayed in the form of narratives and tables.

**Measurement Procedure:** The 12-minute run test designed by Cooper is a field test that is relatively easy and inexpensive, because it requires enough running track or can also use public roads and time measuring devices (watch or stopwatch). The cooper test (running 12 minute) is used to determine endurance. The implementation of the 12-minute run test requires a rather complicated procedure, in which participants are required to stop when the 12-minute time has been exceeded, then they need to give a sign where the stop is, to immediately measure the distance the result is taken. If there are many test participants, it needs carefulness to measure it. The distance reached is then confirmed in the physical fitness category table to determine the fitness status of the sample. The test categories are distinguished by sex and age group. In the implementation the 12-minute run test requires a running track even though it can be carried out on the streets.

**Test implementation**

1. Beginning attitude
2. Participants stand behind the start line
3. Movement:
   a. In the “READY” command, the participants took a stand, ready to run
   b. On the “YES” command the participants ran as much as possible until the time showed 12 minutes
   c. After reaching 12 minutes the stopwatch is turned off and the runners are told to stop at their respective places
   d. What is measured is how many meters can be taken while running for 12 minutes. If it stops it is considered a failure
   e. Record of results

The distance taken during a 12-minute run is recorded in meters, as a result of the test takers.

**Ways To Calculate Cooper’s VO₂ max test**

\[
\text{VO}_2\text{max (ml/kg/mnt)} = \frac{(\text{Distance (Meter)} - 504.9)}{44.73}
\]

Results obtained from the above calculations. After that, classify according to the fitness category table based on the Cooper test.
Result and Discussion

This study was conducted from October 2018 to January 2019. Selection of respondents by age category and sex at SMPN3 Sungguminasa Gowa Regency by ages 13 to 14 years old. In this study involved 59 male sex students. Characteristics of research subjects include age, weight, and height.

Based on Table 3 above it can be seen that the effect of fartlek training for 3 months showed an increase in cardiovascular endurance (VO2max) significantly p < 0.001 by (4.9 ± 0.7) ml/kg/min, from (27.6 ± 4.5) ml/kg/min to (32.5 ± 3.8) ml/kg/min in the genotype II group. Whereas the Non II genotype showed a significant increase in VO2max p <0.001 by (2.6 ± 0.1) ml/kg/min, from (29.2 ± 4.9) ml/kg/min to (31.8 ± 4.8) ml/kg/min. Furthermore, the fitness test category can be seen in table 4.

</tr>
</tbody>
</table>

The increase in VO2max due to the effect of fartlek training for 3 months on subjects in the II genotype and Non II genotype groups showed an increase in cardiovascular endurance (VO2max) significantly p <0.001, however the increase did not change the category of fitness level which was still in the “Bad” category, if adjusted to the table above categories.

Statistical test results obtained significance value of 0.000 (P <0.005), so it was concluded that there was a difference in Test cooper on the first measurement with the second measurement score.

To see a comparison of the increase in cardiovascular endurance (VO2max) in both groups of II genotypes and Non II genotypes ACE genes after taking 3 months of fartlek training.
Conclusion

In this study, the distribution of 59 participants who were students aged 13 to 14 years at SMP N 3 Sungguminasa, Gowa Regency obtained II genotype 57.6% and Non II genotype 42.6%.

Based on the results of the variation of the angiotensin converting enzyme gene that was interacted with changes in cardiovascular endurance showed male subjects aged 13-14 years who took fartlek training for 3 months with the ACE gene, that group II genotypes had a greater increase than the Non II genotype group either through approach to distance when running for 12 minutes or the ability of VO2max. However, the increase in cardiovascular endurance of subjects in both genotypes II and Non II subjects did not change in the fitness category.

Abstract

Background and Objective: Radiotherapy and chemotherapy are main therapy for tumor. Nasopharyngeal carcinoma (NPC) is a malignant tumor which come from nasopharyngeal epithelial cells (a squamous cell carcinoma). MicroRNAs (miRNAs) are non-coding RNAs, acting as post-transcription regulators in the target gene. MiRNAs have an important role in the pathogenesis of NPC, they may act as tumor suppressor genes or as oncogenes and their regulation is related to the prognosis of the disease and the outcome of therapy in the target gene. This study aims to determine the effects of chemoradiotherapy on miR-21 and miR-29c in blood plasma of nasopharyngeal carcinoma patient.

Materials and Method: Prospective cohort was used as a research design. The study was conducted in Wahidin Sudirohusodo Hospital Makassar in February-November 2017. Plasma of blood collected after chemoradiotherapy will be isolated, then synthesized into c-DNA and calculated the quantitative amount with qRT-PCR.

Result: There were 16 samples consisting of 9 NPC plasma post chemoradiotherapy and 7 plasma NPC post radiotherapy. From the plasma we detected miR-21 and miR-29c. The expression of miR-21 in post chemoradiotherapy decreased compared to pre-therapy, in contrast, the expression of miR-29c in postchemoradiotherapy increased compared with pre-therapy. The expression of miR-21 in post chemoradiotherapy decreased compared to post radiotherapy, in contrast, the expression of miR-29c in post chemoradiotherapy increased compared with post radiotherapy.

Conclusion: We found essential differentiation between mRNA-29c expression before and after radiotherapy at nasopharyngeal carcinoma patient, so it can consider as predictive factor for therapy responses.

Keywords: Nasopharyngeal carcinoma, miRNA, miR-21, miR-29c, chemoradiotherapy, radiotherapy, qRT-PCR.

Background

MicroRNA is an endogenous RNA non-protein-coding molecule with size of (18-25nt), its primary function is to decrease transcription and/or protein content in its target. MicroRNAs (miRNAs) have been shown to play a role in the clinical and biological behavior of human cancer cells, including NPC. In NPC, miRNA plays an important role in the pathogenesis of NPC as tumor and oncogene suppressor genes and its regulation is related to disease prognosis and therapy outcomes.

The first known miRNA characteristic in NPC is miR-29c (Sengupta et al). It was also found that miR-29c serves as tumor suppressive, enhances migration and invasion of NPC cells through regulation of extracellular dimetric components. While the study by Zhang et al showed that the decrease of miR-29c occurred in increased resistance to apy and platinum-based chemotherapy through regulation of antiapoptotic Mcl-1 and Bcl-2. Like other miRNAs, miR-29c can work through multiple ways to suppress proliferation, survival, and motility of NPC cells.
Among all types of miRNA, miR-21 is a key oncogene, since it was found in many cancers and contributes to multiple malignant processes such as increasing proliferation of NPC cells, suppressing apoptosis, tumor growth in MCF-7 cells and decreasing invasion and metastasis in MDA-MB-231.15

Nasopharyngeal carcinoma (NPC) is a malignant tumor which comes from nasopharyngeal epithelial cells (a squamous cell carcinoma (SCC), a multifactorial genetic disease with endemic characters. An estimation of 87,000 new cases of nasopharynx appear each year.1-2 of NPC is primarily found in men of reproductive age (the ratio of male and female patients is 2.18:1) and 60% of patients between the ages of 25 and 60. The highest incidence rate in the world is found in the province of Southeast China with 40 to 50 cases of nasopharyngeal cancer among 100,000 inhabitants.

In Indonesia, nasopharyngeal carcinoma is ranked 4th after breast cancer, cervical cancer, and lung cancer with an incidence of about 4.7 per 100,000 population (GLOBOCAN 2012). Most patients who come for treatment are already in an advanced stage, resulting in poor treatment outcome and prognosis. In Dadi hospital and Dr. Wahidin Sudirohusodo hospital during the 10-year period (1990-1999) found 274 cases (47.98%) of NPC from malignant head and neck tumors in the ratio between male and female of 2.6:1. From Nasopharyngeal carcinoma profile data at Dr. Wahidin Sudirohusodo hospital Makassar, South Sulawesi province from January 2004 to June 2007 NPC has constituted 33% of malignancy in the ears, nose, and throat, (2000-2009) found 362 cases (57.28%) of malignant head and neck tumors6,7

Despite improvements in chemoradiotherapy, the prognosis of NPC remains poor with a 5-year survival rate of less than 60%. The main cause of treatment failure and metastasis is the occurrence of resistance to radioactive substances and antitumor drugs.27

Based on these backgrounds, this research was conducted to determine the effects of chemoradiotherapy on the expression of miR-21 and miR-29c in blood plasma of patients with nasopharyngeal carcinoma.

This study has no conflict of interest. Source of Funding: are independent.

Materials and Method

Location and Time of the Research: The study was conducted at ENT Head & Neck Dr. Wahidin Sudirohusodo hospital the period of February-November 2017.

Design and Variable Research: This study is a prospective cohort study. Independent variables (chemoradiotherapy and radiotherapy), intermediate variables (nasopharyngeal carcinoma), dependent variables (miR-21 and miR-29c expression) and external variables (EBV infection, lifestyle, and genetic).

Population and Sample: Thetest population was NPC patients of stage I, II, III, IV who had not been treated, came to the Polyclinic of ENT Head & Neck Dr. Wahidin Sudirohusodo hospital, then monitored during therapy (chemoradiotherapy) during February-November 2017. The sample is the entire population that meets the research criteria.

Research Ethics: Any action is made on the consent of the patients/the parent(s) of the patients through the informed consent sheet and fulfilled the ethical requirements to be implemented from the Commission on Biomedical Research Ethics in Human Faculty of Medicine Hasanuddin University. Recomendation number: 921/H4.8.4.5.31/PP36-KOMETIK/2017

Method of collecting data: Sampling was done by consecutive sampling, all patients with nasopharyngeal carcinoma that has not been treated, either by chemotherapy / radiotherapy / chemoradiotherapy that meets the inclusion criteria.

The inclusion criteria were NPC patients (all stages) who had been diagnosed based on histopathologic examination, aged> 15 years, no malignancy found in other organs, no history of hemostatic disorders, NPC patients with chemotherapy regimens Cisplatin + Paclitaxel, and are willing to be research samples.

The exclusion criteria are NPC patients who had been diagnosed based on histopathologic examination, aged> 15 years, no malignancy found in other organs, no history of hemostatic disorders, NPC patients with chemotherapy regimens Cisplatin + Paclitaxel, and are willing to be research samples.

The dropout criteria were lysis blood samples, the patients who died before the chemoradiotherapy protocol was completed, the change the chemotherapy regimen (Carboplatin/Docetaxel).
Group 1: Blood plasma samples after treatment (neoadjuvant chemoradiotherapy), regimens of cisplatin and paclitaxel, followed by radiotherapy.

Group 2: Blood plasma samples after radiotherapy only.

The both groups received the same treatment process, as (± 2-5ml of blood plasma) is taken and inserted into the tube which has been given EDTA 10%. After that it is centrifuged at 3000 rpm for 10 minutes. Plasma is taken and stored in the-80°C refrigerator and labeled. Then the isolation of RNA is done with the plasma samples using miRCURY RNA Isolation Kit-BiofluidExiqon (Cat No.300112, Exiqon), then synthesized into cDNA using the Universal cDNA Synthesis Kit II (Cat No. 203301, Exiqon). Then the quantitative quantity is measured by qRT-PCR (Bio-radinc, C1000). The tool used is Exilent SYBR Green Master Mix 2.5mL (Exiqon, Denmark), Primer set miRCURY LNA has-miR-21-5p (Cat No. 204230) with primary sequence, has-miR-29c-3p (Cat No. 204729) with primary sequence and has-miR-16-5p as reference genes (Cat No. 2057020) with primary sequence.

Statistic analysis: The statistical analysis used CFX Manager 96 Software (version 3.0 for windows, Bio-Rad Laboratories Inc, California). The steps were data entry, select tools, Exiqon PCR wizard. Select CFX 96, enter data file containing panel layout. Entry fail data of each sample ct. Set the interpolate calibrator, internal control, sheet validation and normalization with gene reference. The data was stored in control panel software. The analysis was done by T-test, heat map and descriptive statistic.

Results

Results Analysis of miR-29c and 21 expression in patients with nasopharyngeal carcinoma

There are 3 graphs generated from PCR quantification performed using BIORAD and analyzed using CFX 96 Manager software: graph amplification, melt curve and melt peak. Each chart has been distinguished based on the three target colors red = miR-21, blue = miR-29c and green is the reference gene of miR-16.

Amplification Curve:

Figure 1 shows the amplification results of all samples in RFU (Relative Fluorescence Unit). The result of fluorescence captured in each quantification cycle is translated into curve form. The more left or the earlier fluorescence is captured, indicating a higher level of miRNA expression.
a. Melt Curve

Figure 2 shows a melt curve, where the higher the temperature, the sample will be denatured and the captured fluorescence will end. This curve shows the total reaction that occurs, so we can know that the sample preparation is good enough.

b. The melt curve peak

Figure 3 is a graph that can be used to view the sensitivity and specificity of amplification targets. In this study, total reaction of each reaction has peak.
The value of the cycle of quantification (cq) obtained is:

**Discussion**

This study collected 27 samples of venous blood of NPC patients. However, of all the samples collected there were only 16 plasma samples consisting of 9 samples of post chemoradiotherapy and 7 post radiotherapy samples which can be continued up to qPCR examination for technical reasons. Initially, DNA isolation and DNA synthesis were done at the hospital of Hasanuddin University Hospital. Samples in the form of cDNA were then sent to the molecular biology laboratory of Gajah Mada University for qPCR examination. We found increased of miR-21 expression from 5 NPC post chemoradiotherapy samples, this caused by unresponsive to therapy and biogenetical mutation. This study also found decreased of miR-29c expression in 1 sample of NPC post radiotherapy, this caused by unresponsive to therapy and biogenetical mutation, so we need further examination to see dedaiser mutation.

**Conclusions and Recommendations**

Based on our study we conclude that the expression of miR-21 in patients with nasopharyngeal carcinoma who have been treated with chemoradiotherapy is lower compared with patients who have not received therapy. In this study, it can also be concluded that the expression of miR-21 in patients with nasopharyngeal carcinoma who have been treated with radiotherapy is also lower compared with patients who have not been treated with therapy. Whereas the comparison between miR-21 expression in patients with post-therapy nasopharyngeal carcinoma with chemoradiotherapy was higher when compared with post-therapy with radiotherapy alone. But the expression of miR-29c post-chemoradiotherapy therapy obtained the opposite result to the expression miR-21.

Audiometric Profile of Fishermen Using Motor Boat in Barombong Village, Makassar

Muhammad Anwar¹, Eka Savitri¹, Trining Dyah¹

¹Department of Otorhinolaryngology Head and Neck Surgery, Medical Faculty, Hasanuddin University, Indonesia

Abstract

Objective: To analyze the audiometric profile of Indonesian fishermen in the village of Barombong as well as determine the prevalence and degree of hearing loss and its related factors.

Method: This was an observational, cross-sectional study of adult full-time fishermen recruited from the village of Barombong in the city of Makassar within the province of South Sulawesi who were part of a voluntary screening for hearing loss. All pure tone audiometry tests were conducted by a single, experienced audiologist using the same pre-calibrated Interacoustics AD226 Diagnostic Audiometer. Noise intensity of the participant’s working environment was sampled by a single audiologist using the same pre-calibrated Extech 407732 sound level meter for a duration of 30 minutes.

Results: The mean age of the study group was 43.93±8.10 years with 95% confidence interval of 26.65-34.04 years, the mean working period was 19.45±3.95 years with 95% confidence interval of 11.48-15.31 years. The mean noise intensity the participants were exposed to was 101.7±2.342dB with 95% confidence interval of 98.9-101.7dB. There was a statistically significant (P<0.05) positive relationship between the age of participants and degree of hearing loss with r-value of 0.6467. Degree of hearing loss was also significantly related (P<0.05) to the working period of participants with r-value of 0.6203. There was also a significant (P<0.05) positive correlation between degree of hearing loss and noise intensity the participants were exposed to with r-value of 0.2482.

Conclusion: Our study showed that a significant majority of fishermen working in the Barombong village experienced hearing loss. Significant decline in hearing threshold was observed and was significantly related to age, working period and noise intensity the participants were exposed to. Hence, there is a great need to raise awareness regarding the dangers of noise-induced hearing loss among fishermen and the need for preventive measures to be put in place to prevent hearing loss and therefore a declining quality of life for the fishermen.

Keywords: Noise-induced hearing loss, sensorineural hearing loss, occupational hearing loss.

Introduction

South Sulawesi has a strategic geographical position with a long coastline of 1,937 km² and large fishing grounds that extend beyond the Makassar Strait to the Flores Sea and Bone Bay, with as many as 199,216 fishermen. In the coastal city of Makassar, yearly catch produced up to 18,000 tons while marine fisheries production reached 12,731 tons per year. Earlier surveys of the fishing population places the number of fishermen to be around 11,497 with 4934 units of fishing gear¹³.

The village of Barombong in Makassar city is predominantly occupied by fishermen. Fishermen work almost every day with frequent sea trips using a motor boat as their means of water transport in order to fish. However, most fishermen are unaware that exposure to noise from the machine of their fishing boats is an insidious cause of hearing loss.

Most fishermen whom experience damage to their hearing is due to noise-induced hearing loss (NIHL). Noise-induced hearing loss (NIHL) is damage to hearing that is caused by prolonged exposure to loud noise, usually ten years or more. Noise is defined as the
mixture of various pure tone sounds with differing frequencies. Noise with intensity of 85 dB or more can cause damage to the Corti hearing receptors in the inner ear. The Corti’s organ sound receptors are often damaged at frequencies of 3000-6000 Hz frequency and most heavily affected at the 4000 Hz frequency. This is classified as sensorineural hearing loss that typically affects both ears to similar degrees.

Pure tone audiometry (PTA) is a tool commonly used to assess the type of hearing loss and hearing threshold to those who experience hearing problems. Furthermore, PTA can help evaluate the degree of hearing loss and is useful in screening for hearing problems. Pure tone sound means the sound produced only has one frequency, expressed in the number of vibrations per second. Audiometric examination requires a sound proof room, and audiologist and a cooperative patient.

Preliminary survey of fishermen in Barombong village in Makassar city revealed that fishermen are exposed to motorboats that generate noise of high intensity for long hours. This working condition has a great potential to cause hearing loss among fishermen that can significantly reduce their quality of life with time. Furthermore, most fishermen do not use protective equipment to minimize noise exposure and have been working for more than 10 years for more than 8 hours per day. Thus, our study aims to provide a closer look at the audiometric profile of Indonesian fishermen in Barombong, determine the prevalence and degree of hearing loss and its related factors as well as establish the need for preventive measures against noise-induced hearing loss.

**Materials and Method**

This study is an observational, cross-sectional analysis conducted between 21st December to 30th December 2018 performed according to the tenets of the Declaration of Helsinki and approved by the institutional review boards of Wahidin Sudirohusodo Hospital.

**Subjects:** Participants were full-time fishermen recruited from the village of Barombong in the city of Makassar within the province of South Sulawesi and consisted of adults over the age of 21 working in the village of Barombong who were part of a voluntary screening for hearing loss. Exclusion criteria included past history of ear infections, past history of trauma to the ear and past history of ear surgery.

**Sound Level Measurement:** Noise intensity of the participant’s working environment was sampled by a single audiologist using the same pre-calibrated Extech 407732 sound level meter for a duration of 30 minutes.

**Pure Tone Audiometry:** All pure tone audiometry tests were conducted by a single, experienced audiologist using the same pre-calibrated Interacoustics AD226 Diagnostic Audiometer. Participants were required to avoid exposure to noise for at least 12 hours prior to audiometry test. All tests were performed with participants in a soundproof booth that met ambient noise level standards at multiple frequencies.

**Classification of Noise-induced Hearing Loss:** Hearing loss was defined as the mean of hearing threshold at 1000, 2000, 3000 and 4000 Hz that is more than 25 db in either ear. The degree of hearing ability was classified as normal (≥25 dB), mild (26 to 40 dB), moderate (41 to 55 dB), moderately severe (56 to 70 dB), severe (71 to 90 dB) and profound (>90 dB) hearing loss.

**Statistical Analysis:** The acquired data was analyzed using a commercial analytical software program (GraphPad Prism 8.0, San Diego, CA, USA). Descriptive statistics were obtained based on survey results. Spearman correlation analyses were conducted to determine the correlation value (r) of age, length of working period, noise intensity of working environment and hearing threshold in regards to degree of hearing loss. Degree of hearing loss were represented numerically as 0 for normal, 1 for mild, 2 for moderate, 3 for moderately severe, 4 for severe and 5 for profound hearing loss. A P-value of <0.05 indicated that the variables considered was statistically significant.

**Results**

Pure tone audiometric of 40 fishermen were included for analysis in this study. All of the participants were male. As summarized in Table 1, 18 out of 40 (45%) participants were between the age of 30 to 40, 13 out of 40 (32.5%) participants were between the age of 41 to 50 and 9 out of 40 (22.5%) participants were over the age of 51. 4 out of 40 (10%) participants worked as fishermen for 5 to 10 years, 2 out of 40 (5%) participants worked for 11-15 years, 20 out of 40 (50%) worked for 16 to 20 years while 14 out of 40 (35%) of participants worked for more than 21 years as full-time fishermen.

The mean age of the study group was 43.93±8.10 years with 95% confidence interval of 26.65-34.04 years, the mean working period was 19.45±3.95 years with 95% confidence interval of 11.48-15.31 years. The mean noise intensity the participants were exposed to was 101.7±2.342dB with 95% confidence interval of 98.9-101.7dB.

Prevalence and degree of hearing loss were analyzed in 80 ears from 40 participants. Only 2 out of 80 (2.50%) ears showed normal hearing, while 78 out of 80 (97.50%) ears showed hearing loss. 42 out of 80 (52.50%) ears showed mild hearing loss, 35 out of 80 (43.75%) ears showed moderate hearing loss while 1 out of 80 (1.25%) ears showed moderately severe hearing loss. No severe or profound hearing loss was observed.

Spearman correlation analysis showed that there was a statistically significant (P<0.05) positive relationship between the age of participants and degree of hearing loss with r-value of 0.6467 as shown in Figure 1. Degree of hearing loss was also significantly related (P<0.05) to the working period of participants with r-value of 0.6203 as shown in Figure 2. There was also a significant (P<0.05) positive correlation between degree of hearing loss and noise intensity the participants were exposed to with r-value of 0.2482 as shown in Figure 3.
Discussion

Most participants in this study have been working for more than 15 years as full-time fishermen while being exposed to noise of loud intensity from motor boats with an average of 101.7 dB. Furthermore, the fishermen surveyed had little awareness about NIHL and its implications. None of the participants exercised any noise-proofing measures. Such long term exposure to high noise levels cause fishermen to be at high risk for occupational NIHL.

Our study revealed that a significant majority (97.50%) of fishermen experienced noise-induced hearing loss although they had no habits that exposed them to loud noise and had no previous medical condition of the ear. Hence it can be deduced that hearing impairment experienced by the fishermen was due to occupational NIHL. Most fishermen experienced mild to moderate HI, with percentages of 52.50% and 43.75% respectively, while 1.25% presented with moderately severe HI loss. No HI was found in 2.50% of that surveyed which could be explained by shorter working period (5-10 years) and younger age (30-40 years) of the participant.

Studies on occupational NIHL have generally shown that the higher the intensity of noise exposure received by the workers, the higher the risk of such workers have hearing loss. It has been proven that the fishermen in our study experienced hearing loss due to exposure to noise over threshold value, and the degree of hearing loss is has positive correlations with factors such as age, working period and therefore period of exposure to noise, as well as the level of noise intensity stemming from the motor boat. Anies et al found that the risk of HI was not significant although participants were exposed to noise level ≤ 75 dB for more than 8 hours per day. Even at the level of exposure to 80 dB, there could be no increase in the risk of HI, but when noise level is between 85-89 dB HI is significant after 5 years of work, with 1% showing significant HI, 3% after 10 years and 5% after 15 years. When exposed to noise level of 90-94 dB, 4% experienced HI after 5 years, 10% after 10 years and 14% after 15 years. When the noise level was above 95 dB HI increased to 7% after 5 years, 17% after 10 years and 24% after 15 years\(^6\-9\).

The difference in hearing threshold values in both ears of the participants are likely to be influenced by the position and type of activities carried out at the time on the boat. Working position of the participants that are closer to the machines that is the main source of noise in the boat affects the hearing threshold of participants. For example, participants who steer the boat adjacent to the diesel motor engine would have higher hearing threshold than those who work further away from the engine. Participants who steer from the left and those who steer from the right of the engine would also experience different hearing threshold between both ears. This is also supported by study of NIHL among Gulf Coast fishermen, whom showed different levels of hearing loss that is significantly influenced by their position on commercial fishing boats, with fishermen working at the engine rooms having greater severity of HI than those working out of the engine rooms.

There is a need to implement and provide easy access to hearing protection devices (HPDs) among fishermen to prevent progression of NIHL. Most resist wearing HPDs with a misconception that the use of HPDs will interfere with daily verbal communication and sensitivity to warning sound signals. However, studies have shown that HPDs in a noisy environment does not affect quality of communication or perception in those with normal hearing. However, when HI is significant, quality of hearing is reduced drastically and cause greater problems in communication and perception of sound.

Hearing loss prevention programs should also be put in place to assess noise levels in the working environment, regulation of noise levels and audiometric monitoring of hearing loss. Education and the implementation of prevention Method at primary healthcare institutions should become an important part of preventive healthcare especially among fishermen who make up a large part of the working population in Indonesia.

Limitations: There were several limitations to our study as it was performed in a single fishing village. Hence, findings of this study may not be representative of the larger Indonesian population. Furthermore, as a cross-sectional study, further longitudinal study is needed to better shed light to the process of chronic exposure that causes progression of noise-induced hearing loss in fishermen.

Conclusion

Our study showed that a significant majority of fishermen working in the Barombong village experienced hearing loss. Significant decline in hearing threshold was observed and was significantly related to age, working period and noise intensity from motor
boats the participants were exposed to. Hence, there is
a great need to raise awareness regarding the dangers
of noise-induced hearing loss among fishermen and
the need for preventive measures to be put in place to
prevent hearing loss and therefore a declining quality of
life among fishermen.

Implementation of Partnership between Midwives and Traditional Birth Attendants Inkotabaru District

Anggrita Sari1, Adriana Palimbo1,3, Angga Irawan1, Sukamto2, Isda Herlina4

1Lecturer of Sari Mulia University, Banjarmasin, Indonesia, 2South Kalimantan Provincial Health Office, Banjarmasin, 3Student Doctoral of Public Health, Hasanuddin University, Makassar, Indonesia, 4Public Health Center of Berangas, Kotabaru

Abstract

Background: Maternal and infant mortality ratio, in the Kota Baru high enough, one of them because of labor that much by the Traditional Birth Attendants (TBA). Midwives offer fewer deliveries and coverage has not reached the 95% target and fewer midwives than TBA.

Objectives: This study aims to know the implementation of the partnership program between midwives and traditional birth attendants in Kotabaru District.

Method: This study use da qualitative approach to the design of case studies, with purposive sampling technique. The number of the main informant as much as 3 people and informantriangulation 6 people. This research was conducted for 1 month consists of content analysis and data processing.

Results: The results show human resources are still lacking, inadequate facilities and funding partnership that is often paid late. Midwives and TBA is not made a written agreement, and over the role of the TBA will not be in accordance with the regulations. The support from the village head and community leader that there is no information and the number of TBA partnering is still less.

Conclusion: Our findings conclude the importance of cross-program coordination and involvement in the District Health Office and across sectors at the District Government level. This participation is urgently needed from local stakeholders playing a major role in the successful implementation of maternal and child health programs.

Keywords: Midwives; traditional birth attendants; implementation of partnerships.

Introduction

Traditional Birth Attendant’s (TBAs), "dukan beranak" in Indonesia, has been around for a long time, and are still practicing labor and childbirth, where most deliveries occur at home and are not assisted by skill birth attendant such as midwives. This situation increases the risk of death for the mother and her baby. TBA is a trusted employee in the family and community in all matters relating to women’s reproductive problems and their work is obtained from generation to generation. Indonesia, which has a variety of tribes, customs, and cultures in the community, they are considered capable of providing emotional comfort and security to mothers during pregnancy check-ups, assisting mothers and caring for their mothers and babies after birth for up to 40 days. TBA’s knowledge of pregnancy and birth is so lacking that if complications arise they are unable to overcome them even realize it. However, in addition to providing technical assistance, TBA also practices unsafe abortion and contraception at high risk and threatening the life of the pregnant woman.

Family TBA is someone who has been appointed by a large family to attend a birth in that family. Trained TBAs are family TBAs who have received short training courses through the modern health care sector to improve their skills. So, starting in 2007, the government initiated a partnership program by village midwives and traditional birth attendants aimed at reducing maternal and child mortality and morbidity. This statement reveals that the higher the number of
deliveries assisted by TBA, the more high risk that will potentially endanger the safety of the mother and baby. This is because the traditional birth attendants do not have enough ability and knowledge to handle obstetric complications and emergencies (EMOC) that occur during and after labor. Then, between midwives and doulas, they offer physical, emotional, and ongoing support while simultaneously encouraging patient autonomy. However, disagreements between them also occur from the Middlemiss study in the UK, differences in the role of doulas and midwives and identify potential for conflict if the role of doulas is misunderstood. Some experts have identified antagonistic attitudes towards doulas that create challenges for midwives and lead to inter-professional conflicts in the dynamics between midwives and doulas. In Canada, this misconception, midwives and nurses fear that doulas will take over their roles and “grass” jobs.

Death that occurs in a hospital is a referral for labor handled by TBA. Furthermore, in some cases TBAs called on midwives when their mother’s condition was severe. At this time, there are 329 TBAs in Kotabaru District. Their presence is spread in 21 sub-districts. Meanwhile, only 220 midwives served. The coverage of childbirth assistance by health workers is 68.2% which has not increased and has not reached target 95% from 2014 to 2017. Based on this problem, this research is intended to know the implementation of the partnership program between midwives and traditional birth attendants in Kotabaru District.

Materials and Method

The study design uses an explorative qualitative approach. A total of 9 participants consisted of 3 village midwives and 6 triangulation informants. This study was conducted at the Berangas Public Health Center in Kotabaru District, South Kalimantan Province. The selection of research locations was taken through considerations, among others: First, coverage of delivery assistance by health workers in the last 3 years had not met the District target of 95%. Second, they have the highest number of traditional birth attendants from the number of midwives. And, third, they have an ongoing partnership program indicator.

Data collection uses in-depth interviews, and semi-structured interview guides. Processing data with content analysis. The aspects studied include the system of implementing partnerships, namely 1) Human Resources, funding, facilities, and data collection and mapping of traditional birth attendants; 2) Fostering of traditional birth attendants; Written Agreement for Midwives and TBA; and the role of TBA; and 3) Support of Village Heads and Community Leaders.

Sources: Health Office Report, 2017
Analysis of Results

Human Resources: Thirteen midwives were obtained: 1 coordinating midwife and 12 other midwives serving in the village and in the puskesmas who were also double the task of fostering villages that did not have a midwife. From the interviews, information was obtained that 1 midwife served 2 to 3 villages at a time, because other villages that did not have midwives to cover all villages in their work area.

“..Serving three villages, meaning one village has three regions: Rampa Kapis, Batu Tunau and the Coal Mining Company.” (IU2) “Each place only has a few empty villages” (IU1, IU 3)

Interview for six triangulation informants, we obtained a statement that three midwives were still not living in the village but were willing to come at any time if needed.

“..do not live in the village every day, if called they are willing” (KD, M) “there is no residence in Berangas village, but if anyone wants to give birth, they are ready to come” (BK)

Half of the midwives, residing in districts and villages, have areas with a geographical area that vary by a distance of 25-30 km.

“I live in urban areas for about 30 minutes from Berangas Village because my children go to school in there” (IU3) “...back and forth to the village, but don’t stay overnight” (BK, M)

Midwives as MNH service providers and partners in implementing partnerships still lack adequate capacity. In terms of management, there are still two villages that do not have midwives. They also caseload to serve other programs. Type of inpatient health centers located in isolated areas.

Facilities and Infrastructure: Access and difficult terrain is also an obstacle. It must be taken on foot. Medical equipment is very unnoticed, so they add unsafe ingredients to the baby’s umbilical cord.

Funding Source: Specific funds for partnerships do not exist. Companion funds come from Health Operational Assistance (BOK). The funds according to them are insufficient because they are considered too little. Disbursement of funds is not routine every month but has to wait a long time.

Written Agreement for Midwives and TBA: Information from two people revealed never made a written agreement. Only an oral request to call the midwife if there is something

“..nothing.. we just talked..” (IU1, IU2)

Even they do not know the information about the partnership. The coordinating midwife stated that the agreement had not been made, it was still in the planning stage and had not been implemented.

“..up to now has not been implemented, because many other health programs take precedence” (BK)

TBA will call the midwife, if the baby has been born and delivery has been completed just to cut the baby’s umbilical cord.

“..because I am not allowed to cut the umbilical cord with a knife and concoctions” (DB)

Fostering of TBAs: Fostering shamans only through refreshing once a year and not all of them are invited. Midwives provide guidance on useful knowledge.

“Guidance and refreshing shamans have been carried out ..This year is only once, this year just once” (BK, TM)

Different from the 3 other triangulate informants who claimed to have never known and were never invited to refreshing the shaman.

“..never really meetings, try to be invited to meetings” (DB, DT, KD)

The Role of TBAs: Only one midwife informant who collaborated and applied the transfer of roles with TBAs.

“..if at my place, TBA tells me that pregnant women will give birth.. we usually join together to help until parturition “ (IU1) “they usually massage, make herbal concoctions, and midwives care.” (IU2)

Other different information TBAs are not partners, refuse cooperation and complete change of role. Only ever accidentally help together give birth.

“..Ever..she only held the abdomen, if part of the birth ..of course midwife”(IU3)”. Postpartum mothers still visited by midwives.” (BK, DB, M)
Midwives and TBAs seem to compete and look less harmonious. “...they (midwives) hold mother’s full...if her signs of birth appear, you call me, I better go home” (DT) it can be concluded that TBA not partnered still does not work together so that their role is still helping birth and the baby independently.

Support of Village Heads and Community Leaders: Real support was provided from the village head and community leaders, but information about the partnership program was not yet optimal. During this time they made requests to give birth with midwives at the health center.

Discussions

Human Resources: Resources hold an important influence in the implementation of health care systems, especially partnerships. Resources include implementing personnel, infrastructure, service facilities, and funding. Midwives are competent health workers who are stationed and should reside 24 hours in the work area of the puskesmas. One of the factors that caused the community to choose to be assisted by a dukun is the distance between the community’s house and the dukun in the adjacent village and the TBA is always 24 hours. While many of the midwives reside in areas farthest from the reach of the community.

Facilities and Infrastructure: Geographical conditions make it difficult to call midwives so that pregnant women choose TBA who are domiciled around their homes. To be able to realize the partnership, childbirth must be assisted by midwives, the government must be able to facilitate adequate health facilities and ensure the availability of quality midwives in each village and easy access to services.

Funding Source: The availability of a budget plan for the Birth Waiting Home which is a temporary residence for pregnant women who will give birth until the postpartum period including their babies and their companions (husband/family/cadre).

Written Agreement for Midwives and TBA: A written agreement between the midwife and the dukun is made together, in accordance with the implementation manual which contains information on the mechanism of reference for pregnant women, the referral mechanism for labor cases, the mechanism for distributing labor costs and the schedule for regular meetings. In line with the results of research by Rochmayanti the partnership did not go according to expectations and targets despite having a memorandum of agreement between them.

Fostering of TBAs: TBAs are also not equipped with knowledge of detection of danger signs in pregnant women, maternity, postpartum and newborn babies as well as ways of referring midwifery. In terms of benefits, some TBAs want to follow the call so that they don’t help their own deliveries anymore. But the appeal is not optimal so that they are still many who help deliveries unsafe.

The Role of TBAs: In the period of childbirth: remind the family to prepare transportation to the midwife, prepare safe delivery facilities such as clean water and clean cloth, and accompany the mother when giving birth. Some things in the puerperal period are: making home visits and motivating mothers to use contraception after giving birth, and motivating referrals if needed and reporting to midwives if if the prospective acceptor wants to use contraception.

Support of Village Heads and Community Leaders: The support of community leaders is needed in collaboration between midwives and TBAs. This support includes socialization and direction through village meetings, mediation between midwives and TBAs and helps influence other parties such as posyandu cadres, village officials, and TBAs to take an active role in the partnership. Some other village heads did not yet know information about the program.

Conclusions

Some obstacles in implementing the partnership program are midwives and TBAs on the utilization of SBA and strengthening the role of each available resource. Funding management from Jamkesmas, DAK and other fund allocations needs to be maximized so that the community realizes that safe delivery with midwives and in health facilities is accompanied by TBAs, not obstacles or concerns from families and communities. Training of skilled TBAs needs to be considered as a refresher in the skills of their childbirth practices under the supervision of the District Health Office, the priority of areas that are difficult to reach.

Risk Factors and Criminogenic Needs of Indonesian Inmates

Hasnida, Etti Rahmawati, Juliana Irmayanti Saragih, Namora Lumongga Lubis

Faculty of Psychology, Faculty of Public Health, Universitas Sumatera Utara, Indonesia

Abstract

This research was the initial stage of the main research. It aimed to get the constructs about risk factors and criminogenic needs of adult individuals committing crimes in the field, people of North Sumatera using Qualitative approach through Grounded Theory. Six hundred and nine participants were involved with a variety of respondents based on criminals (inmates) and not criminal such as the general public and significant persons who were considered to have had a lot of contacts and understood the reasons for adult individuals committing crimes. In general public and inmate respondents, the interview method was used to collect data about risk factors for committing a crime resulting in imprisonment and criminogenic needs that can be used as a solution to overcome recidivist. While the significant persons, the focus group discussion was used to obtain the field data. The results found eight factors: economic, social, personality, family, educational, prohibited substance, spiritual or religious, and criminal justice system.

Keywords: Adult inmates, criminogenic needs, construct, grounded theory, risk factors.

Introduction

In Indonesia, risk assessment and needs assessment for inmates began to take effect with the issuance of Regulation of the Minister of Law and Human Rights of the Republic of Indonesia No.12 of 2013 concerning risk assessment and needs assessment for inmates and correctional clients. This assessment was introduced in 2012 through collaboration between the departments of the New South Wales State prison and the Indonesian Directorate of Corrections. The instrument used to predict the level of risk and needs was Asesmen Risiko Residivisme Indonesia (RR-I) which was an adaptation of the Level of Service Inventory-Revised.

Risk assessment and needs assessments studies conducted in Indonesia, as far as researcher known, still use instruments from western countries. There were no risk and criminogenic needs assessment instruments of inmates that refer to the risk principle and criminogenic needs principle based on the characteristics of Indonesian adult inmates (Indonesian version) which have good psychometric qualities. The purpose of this study is to identify precisely and deeply what factors are behind an adult prisoner in North Sumatera to commit a crime. The factors obtained will later be used as a predictor of an inmate committing repeated crimes.

Research Method

This study used a qualitative approach through the exploration of constructs about the risk factors and the criminogenic needs of inmates. The method of analyzing data through Grounded Theory was used as a strategy to explore the phenomena that want to be studied by exploring new concepts or theories from field data. The interview method was used in the data collection process. Respondents in this study were divided into three groups, namely 500 general public, 102 inmates, and seven informants who were considered to understand the problem of criminal acts consisting of two religious leaders, one lawyer, one prosecutor, one police officer, one prison officer and one law faculty lecturer with criminology specialization. All respondents were asked
to answer the open questions put forward, namely, “in your opinion, what are the reasons behind someone committing a crime or crimes that causes them to go to jail”? The data obtained in this interview process were then analyzed using coding techniques.

**Data Analysis Method:** The initial stage of the coding process was open coding, the second stage is axial coding, and the final stage, the selective coding. This stage was also called the determination of the main factor of the research.

**Results and Discussion**

**Respondents’ demographics background:**
Respondents who participated in this study were 609 people, having diverse demographic backgrounds with the aim of obtaining more comprehensive data. Demographic descriptions based on gender, marital status, ethnicity, age, employment status, and final education are presented in Table 1.

The majority of respondents involved in this study were male (58.8%), and more than 50% (369) of the total respondents had married status. Respondents had an ethnic background that varied greatly with the majority of Batak and Javanese tribes which is around 59.4% (362) and 17.2% (105), around 4.3% did not provide information about ethnic groups. Based on age, more than 85.7% of respondents came from early adulthood and middle adulthood age groups, about 3.4% were not willing to provide information about age. The educational background of the respondents also varied from not completing elementary school to doctoral level. The majority of respondents have a senior high school (38.9%) and a Bachelor (36.5%) education level. Viewed from the status of employment, most respondents work as private employees (31.2%) and entrepreneurs (23.6%).

**Criminal background:** The results of the field data text unit in the form of keywords related to the background of someone committing a crime shows in table 2.

Discussion

Lumenta, Kekenusa, & Hatidja\(^5\) showed that the total population and unemployment had a direct effect on crime, while the number of industries and poverty had an indirect effect on crime; unemployment was a factor that had the greatest direct positive effect on crime, followed by educational and moral factors factors with a direct influence with\(^6\). The type of crime committed by the community, namely theft, embezzlement, fraud, and persecution, had a background of poverty\(^7-8\).

Liquor also greatly affects a person’s thinking power which in turn could cause people to commit criminal acts. The forms of crime that often occurred due to the influence of alcohol are murder, persecution, and rape\(^18\), theft, hijacking\(^19\). The results of a survey conducted by the BadanNarkotikaNasional (National Narcotics Agency)\(^20\) in 2016, 18 provinces in Indonesia found that certain types of drug could lead to excessive aggressive behavior on users and often resulted in behavior or acts of violence. Some even commit criminal acts such as stealing and selling drugs. In addition, in the effort to get drugs, users commit fraud and sell themselves.

Some descriptions of the personality of criminals were relatively high intellectual abilities, difficulties in controlling the inner drive, easily suspicious, acting without thinking and unstable emotions\(^21\). Listwan, Piquero, & Van Voorhis\(^22\) then attempts to explain the relationship of personality to criminal behavior. In subsequent studies, he also stated that the type of aggressive personality directed a person to commit repeated acts of crime (recidivism). In addition to personality types, other factors that were expected to direct a person to commit a crime were psychological problem or disorder\(^23\).

Adult individuals received their first education from their families during childhood. Tangkudung\(^24\) conducted a study on the role of family communication in preventing juvenile delinquency. Seventy-nine teenagers aged 13-18 years were respondents of this study. By looking at the intensity of communication, attention, and children’s needs, the results of the study found that parent communication with children was at a very good level, so it could prevent teenagers from committing illegal acts.

In addition to social norms or customary norms, religion was one of the rules that could control individuals in behaving in society. Wahyun\(^25\) conducted qualitative research to see the role of religious education
in preventing deviant behavior. Research respondents were principals, teachers, and fourth-grade students. The results showed that the implementation of teaching practices such as prayer, juz’ Ama reading, and spiritual giving are effective enough to prevent deviant behavior in elementary school students. Other research on the role of Islamic religious education in family and society was examined by Nasution. The results of the study concluded that the application of religious education (tauhid, aqidah, worship, morality, and sharia) in the family in adolescents could shape them in actual behavior.

Research showed that low education could become an individual background in committing a crime. The influence of age, education, income, and number of family dependents towards thievery crime rate in prisoners was the study of Maulana. 66 inmates who were committed thievery crimes in LapasKlas 1 Kedungpane in Semarang City were the respondents of the study. The results of multiple regression analysis showed that of the four independent variables, namely age, education, income and number of family dependents, only the age variable that was not significant. Educational variables had a negative and significant influence, the income variable had a negative and significant effect, the number of family dependents had a positive and significant relationship while the age variable had a significant negative effect.

An elements of law enforcement such as police, prosecutors, judges, and even prison officials had recently been in the spotlight of the Indonesian people. Police who act without conscience (misusing the power they had) were often found, it was uncommon for prosecutors to extort and amend cases just to get material benefits, court decisions that are often not accepted by the public. Such conditions were exacerbated by the behavior of law enforcement officers who were less praiseworthy and carried out actions that tarnish themselves and their own institutions. The bribery case that occurred in the Supreme Court was one sign that law enforcement in Indonesia was indeed faced with a big problem.

**Conclusion**

The findings in the field showed eight factors namely economic, social, personality, alcohol and prohibited substances, family, spiritual or religious, education and the criminal justice system that was behind an adult individual committing a crime and imprisoned for his actions.

Abstract

Vitamin D plays a role in supporting macrophage activation via vitamin D receptor. Polymorphism of Fok1, vitamin D receptor gene, can show the different level of susceptibility to pulmonary tuberculosis (PTB). This research aimed to analyze the comparison of polymorphisms of the Fok1 region of the vitamin D receptor (VDR) gene and vitamin D status in patients with type 2 diabetes mellitus (T2DM) with PTB. A descriptive comparative study of adult T2DM patients seeking treatment at the endocrine clinic, internal medicine clinic, and pulmonary clinic in two government hospitals in the city of Surabaya. The result showed that F allele frequency (63.3%), f allele (36.7%), FF genotype variation (40.0%), Ff (46.7%) and ff (13.3%) in T2DM group with PTB while in T2DM group without PTB obtained frequency of F allele (54.8%), f allele (45.2%), variation of FF genotype (33.3%), Ff (46.7%) and ff (20.0%). Polymorphism in T2DM group with PTB (60.0%) and DMT2 group without PTB (66.7%). Plasma vitamin D levels were found median (IQR) 20.26 (0.78) ng/ml in the T2DM group with PTB and 20.18 (1.25) ng/ml in the T2DM group without PTB. There were no differences in polymorphism in the frequency of F and f alleles, FF genotype variations, Ff, ff in the Fok1 region of the VDR gene, and the average vitamin D level between T2DM patients with and without PTB. Further research is needed on the linkages and gene interactions encoding macrophage activation proteins.

Keywords: Fok1 region polymorphism, vitamin D level, type 2 diabetes mellitus, pulmonary tuberculosis, PCR-RFLP, DNA Sequencing.

Introduction

Diabetes mellitus (DM) is one of the factors that influence the pathogenesis of tuberculosis (TB) in immunocompromised conditions. The condition of DM is a decrease in the patient’s immune response, which in turn can facilitate the occurrence of infection by Mycobacterium tuberculosis can develop into TB disease1. DM is one of the main risk factors with a three times greater relative risk of TB, reported in 22 countries with a high prevalence of TB including Indonesia2. Populations with DM have a three times higher risk of experiencing TB compared to populations without DM. About 15% of TB cases are globally associated with DM, most people with DM accompanied by undiagnosed TB or late diagnosis3. Reports from research in several countries said the prevalence of DM among TB patients was found to be 1.9% to 35%, while the prevalence of TB among DM patients was found to be 1.7% to 36%4,5. It is estimated that more than a quarter of people with DM have latent TB infections, studies in Mexico found prevalence of 51.3% and in Singapore 28.2%6,7.

Single Nucleotide Polymorphisms (SNPs) in the VDR gene show different levels of vulnerability and resistance in different subjects and populations. One of the SNPs associated with TB is polymorphism in the VDR gene which is located in exon two, which is a transition to T to C (ATG to ACG). There are two potential translation initiation sites in exons that can be
identified by the Fok1 endonuclease restriction enzyme, the individual with the C allele (called F) initiating translation on the second ATG codon and the absence of three-NH2 terminal amino acids from the overall length of vitamin D receptor proteins. Individuals with T alleles (indicated by f) initiate translation of the first ATG codon and synthesize the entire length of the vitamin D receptor protein (full-length with 427 amino acids).\textsuperscript{8,9}

This research aimed to elucidate the polymorphism of VDR gene and vitamin D concentration in T2DM patients with PTB in Surabaya city, Indonesia.

Materials and Method

Research with a descriptive comparative study on subjects from endocrine polyclinic outpatients, internal medicine clinics and pulmonary disease clinics in two government hospitals in Surabaya City was conducted in October 2017 to January 2018, samples consisted of 45 patients each of T2DM with and without PTB.

PCR-RFLP test and DNA, DNA isolation on cell pellets was carried out as directed in QIAamp® DNA mini and Blood Mini Kit (Qiagen, cat. no. 51104) Amplification of DNA isolation results for VDR gene with Fok1 primer with forward sequences 5’AGC TGG CCC TGG CTCT3 TGA CAC ‘and reversed 5 ‘GAA ATG ACA TGC TTC TTCT3’ to produce DNA products at the target 267 bp. The PCR conditions for all reactions were 35 cycles for denaturation of 95°C for 1 minute, annealing 57°C for 30 seconds, and extension at 72°C for 30 seconds. Electrophoresis was performed with 3% agarose gel in 0.5 x TAE solution and ethidium bromide. RFLP product description in the form of T allele (f) in the form of fragments measuring 69 bp and 198 bp as well as nonpolimorphic images C (F) allele consisting of one fragment, 267 bp and heterozygous Ff gives a description of the three fragments 267 bp, 198 bp and 69 bp. Furthermore, DNA sequencing was examined to confirm the results of cutting on the VDR gene using a reverse primer.

Vitamin D examination using an ELISA from DBC Diagnostic Biochem. Vitamin D calculation uses a 4-parameter immunoassay. In this study vitamin D levels were said to be deficienced if found (<20 ng/ml), insufficiency (20-30 ng/ml) and sufficiency (> 30 ng/ml).\textsuperscript{10}

Results

Averaged age sample 51.91 years ± 7.93 years, with proportion > 50 years (62.2%) in T2DM with PTB, whereas T2DM group without PTB average age was 55.78 ± 7.36 years, with proportion > 50 years (77.8%), the greater proportion was female, (53.3% and 88.9%). From laboratory measurements and examinations, T2DM group with PTB had lower BMI, SBP, and DBP, whereas average FBG, 2hPBG, and HbA1c were higher than T2DM group without PTB (Table 1).

The results of PCR-RFLP using Fok1 restriction enzymes show that is a band intersection in variations genotypes FF, Ff, and ff genotypes

Figure 1, ELISA plasma vitamin D examination showed median (IQR) of vitamin D levels in T2DM group with PTB higher than T2DM without PTB (20.26 (0.78) ng/ml vs. 20.18 (1.25) ng/ml).
Polymorphism is a variation of DNA sequences that give rise to genetic diversity in a pool gene. The amino acid sequence in proteins was determined by information contained in genes compiled by DNA. Genes that have different sequences was considered polymorphic has neutral effect on biological functions, but some conditions can cause disturbance of biological functions. This changes in arrangement DNA that encodes proteins. So that genetic polymorphism was different form of same allele in the population. “Normal” alleles was referred to as wild type alleles, while their variants called polymorphic or mutant alleles. Polymorphism was different from mutations because frequency of occurrence higher than repetitive mutations. As per provisions, the polymorphic locus was occupied by at least two alleles, each frequency of occurrence of more than 1%. Alleles whose frequency of occurrence less than 1% was repeated mutations.

The results of this research found that no difference in genotype variation of Fok1 polymorphism VDR gene in T2DM patients with or without PTB. In India (2013), 110 active PTB patients who reported proportion of Fok1 genotypes as follows FF (46.36%), Ff (41.82%), ff (11.82%). The results of this study stated that there were no differences in genotype variation between patients and controls. The frequency of FF genotypes from the Fok1 polymorphism VDR is higher than the mutant type. Also in line with Fok1 polymorphism research of pulmonary TB patients in Egypt reported FF genotypes (30.0%), Ff (50.0%) and ff (20.0%). As well as a study in Iran of TB patients reported the proportion of Fok1 genotypes each FF (52.4%), Ff (39.3%) and ff (8.3%). These results also reported no difference between genotype variations between cases of PTB with controls. Research in North Sumatra Indonesia of PTB patients reported the proportion of FF genotypes (35.5%), Ff (55.3%) and ff (9.2%), these results indicate there was no association between Fok1 genotype variation and the incidence of PTB (p = 0.311).

Different results were found in Fok1 polymorphism of T2DM patients in Morocco, stated FF genotype 49.43%, Ff (45.45%) and genotype ff (5.11%) The results of the study found an association between genotype ff and T2DM risk (p-value=0.018). Similarly, research in Santiago de Chile of T2DM patients and without diabetes received each proportion of FF genotype variation (17.3% vs 22.0%) Ff (62.3% vs 47.0%) and ff genotype (20.2% vs 30.8%). The results of the study found the risk of T2DM especially in the F allele genotypes Ff and FF (p-value = 0.0361).

Some studies on vitamin D status of T2DM patients showed varied results, among others, studies in Morocco received an average vitamin D level of 26.07 ± 13.03 ng/ml with normal vitamin D status of 31.0%, insufficiency of 29.0% and those with deficiency as much as 40%.
Vitamin D levels showed a significant difference between T2DM patients and controls (p-value<0.001)\(^\text{16}\). Study in China of T2DM patients reported a proportion of 20.14% of vitamin D 25 (OH) D deficiency, 62.27% of insufficiency and 17.59% of normal\(^\text{18}\).

Fok1 polymorphism research of T2DM patients and vitamin D status in Morocco results of vitamin D measurements based on the variation of genotype obtained FF (28.18 ± 12.72 ng/ml), Ff genotype (28.61 ± 12.82 ng/ml), and ff genotype (25.83 ± 17.49 ng/ml) with p values in the comparison of FF vs Ff genotypes (p = 0.774) and FF vs ff (p = 0.083). These results indicate there was no relations between vitamin D levels and Fok1 genotype\(^\text{16}\). Research in Santiago de Chile of T2DM patients received vitamin D deficiency (<20 ng/ml) based on variations in genotype namely FF genotype (16.6%), Ff (59.0%) and ff (24.4%)\(^\text{17}\).

Some of the results of the research on TB patients with DM were obtained as follows: A research on 2017 in hospitals and TB clinics in urban and rural areas in China received a median vitamin D level of 12.1 ng/ml. Normal vitamin D status 2.3%, 14.1% insufficiency, 53.9% deficiency and severe deficiency of 29.7%\(^\text{19}\). Another study in South India reported a vitamin D level of 13 ng/ml in the range (8-20) ng/ml lower when compared with TB patients with a diagnosis of new DM and TB patients without DM. The results showed that there was a significant relationship (p = 0.026) between the three groups\(^\text{20}\). Study in Tanzania reported a low vitamin D status (<75 nmol/l) reaching 50.0% with an average age of 43.5 years and an average BMI of 20.5 kg/m\(^2\) when compared with DM patients with low vitamin D status, only 29.7% with an average age of 43.5 years and an average BMI of 28.5 kg/m\(^2\), no correlation between low vitamin D status between the two groups (p-value = 0.22)\(^\text{21}\).

There are differences in the prevalence of vitamin D status in various regions has different risk factors. Vitamin D deficiency is influenced by various factors such as lifestyle, genetics, traditions, and activities so that further research, multifactorial, and multigene interrelation needed and macrophage activation interactions in the incidence of T2DM comorbid TB.

**Conclusion and Suggestion**

From this study there were no differences in the frequency of F and f alleles and FF genotype variations, Ff, on Fok1 regional polymorphism in the VDR gene between T2DM with or without PTB, and there was no difference in vitamin D level status with PTB in T2DM patients. Further research is needed on the relationship and interaction of genes encoding macrophage activation proteins.

An Overview of Socio-Cultural Factors on the Utilization of Antenatal Care Services in Bajonese Pomalaa, Southeast Sulawesi

Fatmah Afrianty Gobel¹, A.M. Multazam², Andi Asrina², Ella Andayanie²

¹Senior Lecturer of School of Public Health, ²Lecturer of School of Public Health, Muslim University of Indonesia, Makassar

Abstract

Maternal and infant mortality rate is one indicator of health status in one region. These can be seen from the low utilization of antenatal care (ANC) service which influenced by socio-cultural aspect. This study aims to obtain in-depth information about the influence of socio-cultural aspects on the utilization of antenatal care services in Bajonese Pomalaa.

This was a qualitative research with ethnographic approach. Six informants were interviewed. Data were obtained through observation, in-depth interviews and documentation.

Results shows that community are more prioritizing shaman to do their pregnancy check. They consider that shaman has certain rituals and more experienced than health workers. This causes a psychological impact where they feel more secure with their pregnancy after they were check by shaman.

The low coverage of ANC services is due to the fact that community is more entrusted their pregnancy check by shaman than health workers. It is suggested that health workers can develop partnership with shaman on assisting the community especially women during pregnancy and labor.

Keywords: Antenatal Care, Shaman, social, culture, Bajonese.

Introduction

Maternal and Child Health is one indicators that can be used to measures health status and prosperity of a country. Maternal Mortality Rate (MMR) and infant mortality (IMR) are two things that can be used as parameters to measure the success of health services in a region. Data from Health Ministry in 2015 shows that Maternal Mortality Rate (MMR) is 305 per 100,000 live births, while for Infant Mortality Rate (IMR) in 2016 is 25,5 per 1,000 live births. This data is still far from the target of Sustainable Developments Goals (SDGs) which is 70 per 100,000 live births for Maternal Mortality Rate (MMR) and 12 per 1,000 live birth Infant Mortality (IMR) by 2030¹,².

The high level of MMR and IMR in Indonesia is caused by the low utilization of maternal health service facilities. Socio-cultural conditions in each region also contribute, where there are still many areas where people still go to shamans to check their pregnancy and use shaman as a helper on delivering their child, especially in remote areas. This reality shows that there is linkages between socio-cultural and health aspect, where culture can form habits and responses toward health behavior and occurrence of disease in society³-⁴. This phenomenon also happens in the Bajo tribe in Coastal Area of Hakatutobu Village Pomalaa District Southeast Sulawesi.

Bajonese people still adheres to their culture and traditions due to maternal health seeking behavior, where society are tend to have more trust in shaman in doing their pregnancy check and giving help in delivering their child³. They believe that shaman has been possessed by their ancestral spirits which is called MboJanggo. Bajonese people assume that the shaman can solve their health problems through mantras which they believe can help smooth their pregnancy and delivery process⁵.
Based on this background, this research was conducted to find out how socio-cultural factors as a determinant factor in the utilization of maternal health services in Bajo Tribe, Pomalaa District. This research aims to obtain in-depth information related to socio-cultural aspects in the utilization of maternal health services in Bajo Tribe, Pomalaa District.

**Materials and Method**

This research was conducted in Hakatotobu Village, Pomalaa District, South East Sulawesi. This was a qualitative research with ethnographic approach as a procedure to describe, analyze, and interpret elements of a cultural group such as behavioral pattern, belief, and language that develops from time to time.

Information was obtained through observation, in-depth interviews and documentation. Observations were made by observing and make some notes about how Bajonese people behave towards utilization of maternal health care services during pregnancy and childbirth. In-depth interviews were conducted to obtain in-depth information about socio-cultural aspects, traditions and beliefs of Bajonese people related to pregnancy and childbirth matters. Documentation was carried by collecting data, recording and reviewing every information that are considered to be important and associated with this research.

This research involves six informants which consist of four common informants, which are pregnant women, maternity women and postpartum mother, midwives as key informants and shaman as supporting informants.

**Results and Discussion**

Based on the indepth-interviewed and observation, it shows that in Bajonese society shamans are society’s first priority when they want to do health checks related to pregnancy and to handle their delivery process. Bajonese considered that shaman has more experience than health workers (midwife), they also feel more comfortable interacting with shaman because they think that shaman is more familiar and all ritual that performed is not conflicted with customs that they believe.

The ritual that performed by shamans for pregnant women is called “mabheta” which intend to provide safety during pregnancy for mother and their child. Although this ritual is perform only by giving spells on the thread and then tied to the wrist of pregnant woman, but it contains very deep meaning because they believe that it can protect them from evil spirit during their pregnancy. This ritual is performed by shaman at pregnant women’s first visit. Bajonese people believe that this ritual can keep them away from the dangers and evil spirits that can harm their pregnancy. That is the reason why pregnant women will directly come to shaman as soon as they know that they are pregnant.

From all informant statements it can be concluded that socio-cultural factors have an enormous contribution to the low utilization of antenatal care services in Bajonese Pomalaa, Southeast Sulawesi where shaman have more dominant role than health workers (midwife). In this study, shaman is considered as the main health service provider. Although at the end there are some pregnant women who will go to midwife for pregnancy check, but they will prioritize their first pregnancy check by shaman, so does when they seek help for their delivery process. Society assume that shamans can provide spells for safety during pregnancy and delivery.

This results were similar with a study about Behavior of delivery assistance by shaman in Karawang regency which shows that almost all people believe in sahaman’s ability in helping delivery process, because the shaman is considered to have a reliable spiritual power\(^6\). In rural areas, most pregnant women still believe in shaman to help their delivery.

Result of previous study stated that Maternal and Child Health problems related to socio-cultural community is becoming problems that require a more in-depth and specific study in each region and certain ethnicities\(^7\). This because one of the most dominant determinants that encourage mothers to choose shaman for pregnancy check and getting help for delivery process is due to cultural factor which has passed down through generations, where society still rely on shaman in giving health services including pregnancy service\(^6,7\).

The pattern of cultural behavior during pregnancy and childbirth which passed down through generations provides a conceptual framework for understanding the essence of all human behavior, including behavior on the selection of service providers for maternal and child health. So it can be understood that each cultural community has its own perspective and different behavior, that is why cultural factors should be getting attention from various related sectors to increase coverage of mother and child health services\(^8\).
The main health problem in Indonesia is low public health status, which can be seen from the high number of maternal and infant mortality rates and also there are still many indicators of maternal health services (KIA) that is still not ideal\textsuperscript{7,9}. Maternal mortality and morbidity problems are not inseparable from socio-cultural and environmental factors in the society where they live\textsuperscript{10,11}.

The low utility of existing health facilities in rural area is often cause by society’s belief in their culture which is still preserved until now, resulting in the low coverage of health services in general and also maternal and child health\textsuperscript{12,13}. Various factors that influence the utilization of health facilities for ANC (Antenatal Care) examination, have an impact on the low coverage of ANC (Antenatal Care). The utilization level of health facilities is different in every society, including in coastal communities which have a strong belief in local culture.

This statement can be proven from the results of research that has been carried, where most pregnant women prefer shaman than midwife on their health seeking behavior related to their pregnancy check and delivery help. This is cause by cultural factors and society’s high belief in shaman’s knowledge and experience. Selection of helper during pregnancy and delivery can also be seen from the observation conducted during the research, where there are 14 pregnant women, which nine of them doing pregnancy check on shaman with their average pregnancy age is above four months old, while the rest five pregnant women doing their pregnancy check to midwife\textsuperscript{14-19}.

**Conclusion**

1. Socio-cultural factors still plays an important role in Bajonese community, where they still perform certain ritual when it comes to health seeking behavior.

2. The low coverage of ANC services is due to the fact that community is more entrusted their pregnancy check by shaman than health workers, although there are still some people who also go to health care facilities.

Utilization of Mother and Child Health Services in Bajo Transport in the Coastal Area of Hakakutobu Village, Pomalaa District

A.M. Multazam¹, Fatmah Afrianty Gobel¹, Ella Andayanie¹, Andi Asrina¹
¹Lecturers of Universitas Muslim Indonesia

Abstract
One of the causes of the still high maternal mortality rate (MMR) and infant mortality rate (IMR) is due to the low utilization of antenatal care (ANC) services, especially by people in remote areas. The low utilization of ANC can be influenced by many factors. This study aims to obtain in-depth information related to the utilization of maternal and child health services in the Bajo tribe in the coastal area of Hakakotubu Village, Pomalaa District in terms of economic aspects, family support and community beliefs. This research is a qualitative research with ethnographic approach. Data obtained through observation and in-depth interviews. Informants in this study were 15 people. Data analysis through three channels, namely data reduction, data presentation, and drawing conclusions. The results show that the low utilization of ANC services is due to the economic limitations of the community so that they find it difficult to access ANC service facilities. Lack of support from her husband’s main family also makes mothers not motivated to take advantage of ANC services. The high level of community trust in traditional birth attendants as pregnancy examiners and birth attendants is due to their high confidence in the ability of traditional healers during hereditary and cultural influences related to rituals they must undergo during pregnancy and childbirth.

Keywords: Antenatal care, economy, family support, belief, Bajo.

Introduction
Maternal and child health is an indicator of a country’s health status. Based on the World Health Statistics 2017 Monitoring Health for the SDGs by WHO, around 830 women die every day worldwide due to complications of pregnancy and childbirth in 2015. The SDG target is to reduce the global maternal Mortality Rate (MMR) from 216 per 100,000 births life in 2015 to be less than 70 per 100,000 live births in 2030¹.

Indonesia’s Health Profile in 2017 shows that the percentage of maternity mothers assisted by health workers in the health care facilities of Southeast Sulawesi Province is only 60.35%, relatively low compared to other provinces in Indonesia. Pomalaa District maternal mortality rate is 3% and infant mortality rate is 5%. For the achievement of K1 of 80.9%, K4 of 71.6%, delivery by health workers 68.3%, postpartum visits (KF3) 60.59% and neonatal visits (KN3) 60.59%. PWS-MCH data Hakakotubu village showed a maternal mortality rate in 2014 of 2 deaths due to bleeding and in 2015 a case of 1 and the infant mortality rate assisted by a TBA in 2015 was 2 cases. Coverage of K1 in 2013 was 38%, in 2014 it was 42%, in 2015 it was 40%. The K4 target is 95% while the K4 coverage for 2013 is 30%, in 2014 it is 33%, and in 2015 it is 39%. The target of deliveries by health workers is 90%, while the coverage of deliveries by health workers in 2013 is 28%, in 2014 38% and in 2015 40%. The childbirth visit target (KF3) is 90%, neonatal visit is 90% while the achievement of childbirth visit (KF3) and neonatal visit (KN3) for 2013 is 40%, 2014 is 50%, in 2015 is 45% ⁶. Village Achievement Hakakotubu is still far below the Renstra standard compared to other villages in the sub-district.

Materials and Method
This research is a qualitative research with an ethnographic approach that aims to get in-depth information about the Utilization of Maternal and Child Health Services in the Bajo Tribe in the Coastal Area of Hakakotubu Village, Pomalaa District. This research was conducted in March 2018. Data were obtained through observation and in-depth interviews. There were 15 research informants consisting of ordinary informants...
(pregnant women and post-partum mothers), supporting informants (traditional birth attendants and midwives) and key informants (community leaders). Data analysis through three channels, namely data reduction, data presentation, and drawing conclusions.

**Results**

**Economy:** Economy is the entire amount of family income obtained to meet daily needs that can affect the use of ANC services. The interviews found information that: 1. The majority of the main sources of income of informants’ families are from seafood (fishermen) where the average daily income is Rp. 100,000 which is only enough to meet their daily food needs, so they have difficulty if they have to incur additional costs for examining pregnancy in health care facilities. 2. If the informant has a pregnancy check at the puskesmas, they are charged a certain fee at each visit so they feel heavy about the costs. 3. Two informants stating that they prefer to have a pregnancy check up by a shaman, because the fees charged are in accordance with their abilities, the form of payment does not have to be in the form of money, but can be in the form of goods. 4. Three informants who stated they did not want to go to a health care facility because they had to pay additional transportation costs to go there, whereas if they were examined by a dukun they only waited at their home, because the shaman would come to their home. 5. Informants prefer to go to a shaman because with payment according to their respective abilities and is only done once, the shaman not only checks their pregnancy but carries out postpartum care.

**Family support:** Three people The informant stated that they did not get support from their husbands during their pregnancy. The informant said that their husbands did not have time to deliver to the health workers because they were busy working. 2,3 Two informants stated that their husbands did not want to take them to have their pregnancy examined because the location of the health service facility was far from their home.

**Community Confidence:** Four informants stated that they were more confident to have a pregnancy check up and give birth in a dukun because they considered shamans to be more skilled and experienced. 3 Two informants expressed public confidence in the ability of shamans not only as a helper during pregnancy and childbirth but could also help for those who have difficulty getting pregnant. In addition, healers are also believed to have the ability to keep away from spirits. 4 Three informants prefer to check the pregnancy to the dukun because of emotional closeness, where the dukun is one of the figures considered important in the daily life of the Bajo people.

**Discussion**

**The Economy:** Economy is the overall income derived from the work carried out by the head and family members. The level of the household economy affects all aspects of the lives of family members, including health aspects. The higher the level of the economy in a household, the greater the chance of accessing and utilizing health services, and vice versa. Families with a low economic level cannot afford to provide funds for antenatal care and preparation for birth, because their income runs out just to meet their daily needs. This can also indirectly have an impact on the lack of nutritional intake in mothers and babies during pregnancy and childbirth. Unlike families with adequate economic capacity, they can carry out routine pregnancy checks, plan deliveries to health workers and make other preparations related to pregnancy and childbirth so that the condition of the mother and baby can be optimally maintained.

The economic status of the Bajo is very minimal and even tends to be below the poverty line. The location of settlements that are above the sea resulted in the majority of them depending their daily lives on marine products both for sale and for their own consumption. The maximum income they can get from selling seafood in a day is 100,000, and even then it will usually be used up to pay off debt to. To increase family income, the wives sometimes collect waste to be sold even though the results are not much. For daily consumption, if they don’t have side dishes then they only consume rice sprinkled with salt.

Unlike the case when checking the pregnancy and childbirth with the help of a shaman, they are not charged a certain nominal. Shamans are sufficiently rewarded according to the ability of mothers who can be in the form of money or goods, so that the community does not feel burdened in terms of financing. According to Gamelia about the reasons for antenatal care and childbirth assistance, explained that subjects who use the services of a dukunberanak are because the cost of conducting a pregnancy check-up and birth attendant at a dukun are lighter than examining a midwife, the fee to the dukun is Rp. 10,000 often do not even set a price,
as sincere as giving. It also obtained the ease of making payments which can usually be repaid. According to Kotler and Armstrong there are many factors that influence the decision to use goods and services differently for each individual. These factors are; (a) cultural factors, (b) social factors, (c) personal factors, and (d) psychological factors. This theory also applies to the Bajo people related to the use of health services, where the economic condition of the family has an impact on the lack of utilization of the ANC.

**Family Support:** Support or motivation is something that supports the formation of a person’s actions or behavior. Support is anything that refers to encouragement and efforts to satisfy the needs of life or to achieve certain goals. Support is a reason for someone to act in order to meet their needs. During pregnancy and childbirth, a mother does not live alone but lives in a social environment with a complex family, community and culture that is rich in diversity both in terms of culture and tradition. In fact the main role of the husband’s family has a very big influence for pregnant women including the utilization of health services. Snehendu B. Kar’s theory concludes that a person’s health behavior is determined, among others, by the presence or absence of support from the surrounding community (social support). People who live in an environment that upholds the health aspect will have a high enthusiasm to make various efforts related to health care and vice versa.

During pregnancy until delivery, a mother needs various forms of support, especially from her husband. The lack of husband support can have a variety of negative effects including the lack of a loving bond between the mother and baby, including in the aspect of health care during pregnancy and carrying out checks on health care facilities. The greater support gained during pregnancy, the greater the chance for mothers to use ANC services.

The results showed that the support of husband and family during pregnancy and childbirth in the Bajo tribe community was still very minimal, because their culture was still very thick with patriarchal culture. They assume that everything related to pregnancy and childbirth is the responsibility of a mother/wife. In daily life a husband only functions as a breadwinner while the task of educating and raising children is left entirely to his wife. This is in line with research conducted by Titaley et al. which shows that social support has a significant effect on the utilization of ANC services.

Observation also shows that the husband and family prefer to encourage the mother to check the pregnancy and assist the delivery process to the dukun rather than to the health service facility because they assume that the dukun is far more experienced than the health worker. This also applies even if pregnancy and childbirth complications occur. These results are in line with research conducted by Reskiani, et al. Showing that there is a relationship between family support and the utilization of ANC services at Antang Health Center. Pregnant women who use ANC services because they have adequate family support, where the husband/family reminds mothers about the schedule of antenatal care and takes the pregnant woman to the puskesmas to check her pregnancy.

Husband’s support is very important during pregnancy because sometimes the wife is faced with situations of fear and solitude, so that the husband is expected to always motivate and accompany pregnant women. Besides the support provided during pregnancy can also reduce anxiety and restore the confidence of expectant mothers during pregnancy. This is in accordance with the concept of standby husband, the husband’s awareness of the danger signs of pregnancy and the husband’s readiness to accompany his wife to a health service for pregnancy checks needed at each pregnancy check-up visit, the husband should always accompany his wife so they know the condition of his wife’s pregnancy.

Good support from her husband can provide positive motivation for mothers in checking their pregnancy. Actual forms of actions that can be taken by the husband during the process of pregnancy to delivery include delivering a wife for antenatal care, meeting nutritional needs, inviting a wife to do light exercise, helping to do daily chores, preparing for labor costs, participating in choosing a place to give birth to his wife, accompany or accompany his wife during childbirth, and remind his wife to provide exclusive breastfeeding. The involvement of the husband from the beginning of pregnancy until delivery and the postpartum period will improve the behavior of the care of pregnant women so as to determine the success of the mother in pregnancy until the postpartum period.
Confidence: Beliefs are assumptions and beliefs that are considered correct by an individual or group, regarding concepts, events, people and certain things. Beliefs grow with the world view that is affirmed by the community, are considered positive and true, forming behavior in a predisposition, beliefs can still be changed depending on the interventions provided. Usually, beliefs tend to differ from one community group to another. This is conditioned by the customs or traditions adopted by the community. As seen in the Bajo tribe who believe in non-medical aspects of their health problems, shaman is a figure that is believed to be able to help health problems including for the health of mothers and children. In this study, the Bajo tribe entrusted the problem of pregnancy and childbirth to untrained birth attendants because it was a hereditary habit.

The tendency to prefer shamans for pregnancy and childbirth problems in the Bajo tribe is a challenge for local health workers. Feeling safe and comfortable when served by a shaman is a psychological factor felt by a mother who subjectively forms beliefs. It has become common in traditional societies who always rely on treatment based on their beliefs, as is the case with Bajo people who believe in dukun expertise in facilitating pregnancy and childbirth through certain rituals. The traditional Bajo community has taboos (pamali) which must not be violated for fear that there will be consequences. This conviction was strengthened because so far there had never been a case that they considered endangered the health and safety of pregnant and childbirth women as a result of being assisted by a shaman.

Linking Rosenstock’s theory of the Health Belief Model to the Bajo community with healthy behavior, the Bajo community does not feel any health problems during pregnancy and childbirth when assisted by a dukun, so that it does not change the perception, attitude and actions to find solutions in handling pregnancy and childbirth. Based on this theory, perceptions of health problems are influenced by three things namely; a) Health values in general, (interests and attention to health); b) Confidence in one’s vulnerability to health problems; and c) Confidence in the consequences arising from health problems13.

Changing the basic beliefs in utilizing health facilities such as the Bajo community requires attention in exploring problems, motives for change, and strengthening social factors and values that are hereditary. Likewise, various activities that are intended to be improved and developed through posyandu, puskesmas and counseling programs that are run separately. This needs to be attention because all of these are efforts to tackle health problems that stem from behaviors that do not harm health.

Conclusion
The inability of the community’s economy, resulting in them preferring to have a pregnancy check up and deliver a birth assisted by a dukun rather than a midwife or to a health care facility. 2. Husband and family support for mothers during pregnancy and childbirth is still very minimal. 3. The Bajo community’s belief in dukunbinun because it is a hereditary habit, and they do not feel any health problems during pregnancy and childbirth when assisted by dukunberanun.

Influence of Customer Value on BPJS Patients with IUR Cost Satisfaction in Hospital of Makassar City

Marwah Thaha¹, Amran Razak², Indar², Fridawaty Rivai³

¹Postgraduated Student Faculty of Public Health, ²Professor of Health Administration and Policy Department, ³Lecturer of Hospital Management Department, Faculty of Public Health, Hasanuddin University

Abstract

Hospital as a provider of service of health to the public should be able to improve the quality of service because a good quality of services will be able to generate customer value or good impression in the patients or satisfaction, as the purpose of service of the public which is to satisfy the public. The aimed of the study is to determine the influence of customer value on BPJS Patients with IUR cost Satisfaction in Hospital of Makassar City. The type of research is quantitative analytic method using the approach of cross-sectional, held pad a July to August 2019 in the city of Makassar. The population of the study are BPJS patients that use IUR cost or the difference in cost over the service that they receive in the year 2019. Total sample as many as 30 people were obtained using the technique of purposive sampling. Data collection is done through interviews using a questionnaire. Data were analyzed using a test correlation Pearson on SPSS then presented in the form of tables and narrative. The result shows that there is a correlation between customer value with the satisfaction of BPJS patients use IUR costs at hospital of Makassar with p = 0.001 and the value of Pearson Correlation (r) = 0.701. Based on the results of the research can be concluded that the satisfaction of patients affected by customer value and 70.1% of satisfaction of patients is determined by customer value in patients BPJS use IUR costs at the hospital of Makassar city.

Keywords: Iur cost, BPJS, satisfaction.

Introduction

Health becomes a necessity that is fundamental to society. The need is what makes the community feel the need to maintain health and obtain health services. In line with the increasing demands of society towards servicing the medical cause people to become more selective in choosing a hospital. Changes are caused also by further increasing education and state socio-economic society that give rise to the demands of the community to get good service and quality. Indonesian government through the Ministry of Health since 1st January 2014 held health insurance for the community through the Badan Penyelenggara Jaminan Sosial (BPJS), so the government shall provide the services of health that quality.¹

Ministry of health is a right fundamental human being that must be met by the government, things are contained in Law No. 36 the year 2009 about Health Article 15 which states that: “The Government shall be responsible on availability environment, structure, facility health both physically and socially for people to achieve the highest degree of health”² Under the terms of it, the government is obliged to provide facilities or services health through BPJS Health with service that is of quality, in order to meet the needs of patients. Public interest in the BPJS program is shown by the amount of community interest in being a participant in the BPJS program. Based on the data month September 2014 the number of participants BPJS Health in Indonesia as much as 127.3 million inhabitants (65%) and continues to increase, the month of November 2017 recorded 183 579 086 participants or approximately (70%) and in September 2018, the number of participants reached 201,660,548 people, and on February 1, 2019, reached 217,549,455 people. By the numbers, 217 million inhabitants of this, meaning that the number of participants BPJS Health have reached 81.8% of the total population of Indonesia is around 265 million inhabitants, as the data are quoted from page official BPJS.³ Data BPJS South Sulawesi shows that in the year 2019 the number of participants
BPJS Makassar City as much as 500,061 participants PBI and 857,262 participants of non-PBI. In general, the number of total participants JKN in Makassar that as many as 1,357,323 people. Data BPJS health of South Sulawesi in 2019, especially in the 4 (four) regency/municipality comprised of District Barru, Pare-pare, Pinrang and Sidenreng Rappang which is under the office branch cities Parepare, noted that as many as 863,053 people users JKN, on in January up to July, and there are 15% of patients using the IUR fee, to the the nonparticipants as many as 183,587 people by using the IUR cost as much as 23%. Things that indicate that high expectation or expectations of the services on the service of health who qualified with the consequences of the service to pay the difference in price of a standard right services that are acceptable by the patient. BPJS program health in the ministry, would not be separated from the financing of health, because the cost of healthcare is the number of funds that must be provided to organize and or take advantage of the various efforts of health is needed by individuals, families, groups and communities.

The research that is done on the quality of service, value for the customer and the satisfaction of patients at Home Hospital General in Regency Bandung, Indonesia obtained the results of the study indicate that there is the effect that significant to the quality of service at value for customers and satisfaction of patients, where the services are supplied by hospital can improve implications of customer value on patient satisfaction. The creation of positives rating of the customer on the service that they receive is a necessity, so it can be understood that the creation of customer value is a comparison between the perception of the service that is received with expectation before getting the service it. If expectations are met, means the service that has been giving a quality that is beyond the ordinary and also will lead to satisfaction were high. Conversely, if the expectation is not achieved, it means that the quality of service does not meet what is expected. Based on the description at the top then the researchers are interested to do research on the influence of customer value (assessment of customers) to the satisfaction of patients BPJS that use IUR costs in Hospital of Makassar City in 2019.

Materials and Method

The type of research is using quantitative Method of descriptive-analytic with the approach of cross-sectional study. This research was conducted in Makassar City. The population in the study is that BPJS patients that use IUR fee or the difference in cost over the service that they receive in the year 2019. Samples were obtained by using the purposive sampling and get 30 people respondents. Data are collected through interviews by using questionnaire. The data that collected are characteristics of respondent, BPJS class and class of the treatments are used, customer value, the perception of the IUR cost patients BPJS and satisfaction of patients. Analysis of the data is done by univariate and bivariate

Results

Results of the study showed that the group age most is the group aged 36-45 years as many as 6 people (23.1%), while the group age most bit is the group 76 years and above as much as 1 (3.3%). Respondents education are Bachelor as much as 14 people, Magister as much as 1 (3.3%) and other 8 (26.7%) persons. Class participation BPJS that most lots are class I as many as 20 people (66.7%). Class II as many as 4 people (13.3%) and class III as many as 6 people (20%). Patients BPJS are taking class care that 1 level is higher than the class of membership. So that class I patients who increased their class of care to VIP there was 20 people (66.7%). Class II rise into the class I as many as four people (13.3%) and class III rising levels into grade II as many as six people (20%).

The result of the test using SPPS obtained value of \( p = 0.001 \) and the value of the coefficient of Pearson Correlation \( (r) = 0.701 \). It is can be interpreted that the customer values affect the satisfaction of patients BPJS using lir costs in the hospital of Makassar City where 70.1% of satisfaction of patients are determined by customer value.
Discussion

Regulation of the Minister of Health No. 51 the Year 2018 defines that IUR cost is an extra cost that is paid if participants at the time of obtaining the benefits of ministry of health that can lead to abuse of the service. While that meant the difference in fee is an additional fee that is paid if participants at the time of obtaining the benefits of ministry of health which is higher than the right. Special increment costs, Article 10 paragraph 5 Permenkes 51/2018 regulate that participants JKN-KIS only can go up one level much higher than the class that became due. Chief of Bureau of Law and Organization of the Ministry of Health of the Republic of Indonesia Sundoyo explained that the purpose of the con fee and the difference in cost for participants Guarantee of Health National (JKN) which was held BPJS Health as the control of quality and cost, as well as preventing the misuse of the service facilities of health in the service of JKN.

The value of the customer (customer value) is the difference between the value of customer total and charge customers total in which the value of customer’s total is a set of benefits that are expected by customers of products or services specified and charge the customer the total is a set of costs which are expected by consumers who incurred to evaluate, acquire, use and discarding products or services. Value customers and the loyalty of customers is very important and useful for the improvement of services of the service. Customer value or customer perceived value is customer perception of the value where the company must consider the value in developing products and services so that it is in line with what the customer expects. Monroe states that the value of the customer is the ratio between profit or benefit that is perceived by the sacrifices incurred.

The satisfaction of customers is the response of customers to the discrepancy between the level of interest before and the performance of real-time that he felt after use. The satisfaction of customers is influenced by perceptions of the quality of service, quality of product, price and factors that are personal and that is the situation for a moment. The satisfaction of customers is the response of customers to a discrepancy between the level of interest before and the performance of real-time that he felt after use. One of the factors that determine the satisfaction of customers is the perception of customers regarding the quality of services that focuses on five dimensions of quality of services. The quality that is perceived as directly has the effect of positively towards the satisfaction of customers as a whole. The satisfaction of customers as a whole will impact negatively on the complaints of customers and impact positively on the loyalty or loyalty of customers.

Levels of satisfaction were obtained by the customer is usually highly related closely to the standard quality of the goods or services are enjoyed and services other form of service pre-sales, the current transaction and after-sales. The level of satisfaction is a function of the difference between the appearance of the felt with expectations. Patients are satisfied after receiving services that meet their expectations, the patient decides to provide an assessment of services and acts based on satisfaction. So the value of service quality is the most important part and a measure of patient satisfaction for the hospital.

Assessment of patients to care nurse comes from the experience of patients. The aspect of patient experience can be interpreted as a treatment or action of a nurse who is or has been experienced, felt and borne by someone who uses nurse services. aspects of the satisfaction of the patient is very determined on a model or engineering services, where the provider of services provide care professionally, so that the recipient of service feel satisfied on the service that they receive, and will give you a sense of confidence to hospital as one of the places receiving services are special. The satisfaction of patients who seek treatment at home sick will have an impact on the number of visits to patients at the hospital. Visits were so this by itself will increase the sources of income for hospital.

Results of the research showed that customer value effect is significant to the satisfaction of patients, where 70.1% of satisfaction of patients obtained from the customer value. It is in line moved at the research that is done by Alimuddin, et al. rgery Surabaya obtain results that there is a direct influence of the customer value to the satisfaction of 0.845. Soit can be interpreted that the direct influence of customer value on satisfaction is very significant and positive. Then increasingly higher levels of the value of customer service hospital, getting high is also the satisfaction of the customer and vice versa. The results of the research is also supported by research that is conducted by Maya Utami Ikasari, Sri Sutyoko and Sendhang Nurseto (2013) who find that the variable value of the customers influences the variable patient’s satisfaction. If the level of assessment of customers
(customer value) higher then getting high also the level of satisfaction of the patient’s homesick, especially in patients BPJS using Iur costs. This is because the patient chooses a class of care that is more than their participation certainly with the hope that the service will get better.

**Conclusions**

The study is concluded customer value or assessment of customers is significantly affecting the satisfaction of patients BPJS use IUR costs at home sick of Makassar. As for the advice that can be given are hospital need to improve the quality of service, attitude of social officers and factors other that can be re-established as well as increase customer value to satisfaction of patients can be further improved so that helped increase the loyalty of patients which resulted in increased profits hospital.

Abstract

Background: Malnutrition during pregnancy and early childhood causes delays in physical growth, the motor development, and cognitive development disorders.

Objectives: This study aims to Determine the factors that influence motoric, cognitive and socio-emotional development of children aged 18-24 months in Jenepontodistric.

Method: This study is an analytical study with cross-sectional approach. Samples consisted of 32 children aged 18-24 months. Child development was measured using the Caregiver Reported Early Childhood Development Index (CREDI) instrument. Statistical analysis to test the factors that influence motoric, cognitive and socioemotional development using an unpaired T-test with a significance level of 95%.

Results: This study reported that of 32 children born to mothers aged 20-35 years (68.8%), <20 and >35 years (31.3%) with a primary education level of 34.4% and 65.6% intermediate level. Bivariate analysis found that factors affecting the motor development were birth weight (p = 0.004), cognitive development influenced by maternal age (p = 0.021) and birth weight (p = 0.000) and socioemotional development influenced by maternal education (p = 0.050), breastfeeding (p = 0.010) and stimulation (p = 0.004).

Conclusion: The factors that influence motoric development are birth weight, cognitive development influenced by birth weight and maternal age, while maternal education, breast feeding, and stimulation Affect socioemotional development.

Keywords: Motoric development, Cognitive, and Socioemotional, Children aged 18-24 months.

Introduction

In 2010, an estimated 33% of children aged 3 and 4 years in countries of low and middle income, 80.8 million children fail to meet basic standards in cognitive development and or socioemotional.¹ In 2013, the national prevalence of malnutrition in children under five years-less by 19.6%, which means heavy-less nutritional problem in Indonesia is still a public health problem of high prevalence approaching. Among the 33 provinces, three provinces, including the very high prevalence categories, namely West Sulawesi, West Papua and East Nusa Tenggara.²

The Cognitive development of children is influenced by genetic and environmental factors. The child has the potential of genetically cognitive development. However, environmental factors, such as adequate nutrition and the ability of parents to improve food and stimulating home environment also has a positive effect on cognitive development of children³. Optimal health education in the mother can optimize the growth and development of children.⁴

Adequate support to the development of a child when a child can effect motoric development, language, cognitive, social, emotional and behavior, influencing the long-term health and reduce health inequalities and socioeconomic.⁵ In children suspected of having developmental delays or disorders, medical evaluation should be done and development (development assessment) so that early intervention can be done immediately (ealy intervention) on the child.⁶
Based on the phenomenon of the above results, the main purpose of this study was to determine the determinant factor of motor development, cognitive and socio-emotional in children aged 18 to 24 months in Jeneponto Indonesia.

**Research Method**

This study consisted of children whose mothers enrolled in trials of Moringa leaf powder supplements provided prenatal and postnatal district Jeneponto. Children of mothers who were enrolled in the trial and be eligible to participate in the study of child development when children aged 18 to 24 months time recruitment selection. We chose one district and call mom at random to participate in the study of child development between December 2018 to January 2019, and get as many as 32 children aged 18-24 months. The sample size is limited by those who were not in place when the data collection was done as well as funding constraints.

Child development was assessed using Caregiver Reported Early Childhood Development Index (credi). Credi is a simple device, low cost reported by the caregivers or child care givers, for the household survey. To monitor and measure the child’s development, two research assistants trained in the local language setempet Credi and anthropometric measurements for children and adults, and other study procedures.

We did a statistical analysis to examine the factors that influence a child’s development using an unpaired t test with significance level of 95%, and a linear regression model that is tailored to the characteristics of mothers and children with a significance values at p <0.05.

**Results**

**a. Maternal characteristics, prenatal and child development:** The relationship between mother and child development characteristics are presented in Table 1. This study found that children whose mothers aged 20-35 years scored significantly higher on cognitive development CREDI (p = 0.021) compared with children whose mothers aged over 35 years. Children whose mothers complete high school education earned scored significantly lower on socio-emotional development (p = 0.05) compared to children whose mothers completed primary education. Maternal body mass index, Moringa leaf powder supplementation and second-trimester anemia status did not significantly affect any of the scales of child development.

**b. Characteristics of children, follow-up and development of children:** The relationship between the characteristics of children, follow-up and development of children are presented in Table 1. In this study, it was found that children who had birth weight ≥2500 grams have significantly higher scores (p = 0.004) in motoric development, and p = 0.001 on cognitive development than children who had birth weight <2500 g. Children who were breastfed exclusively had lower scores were significantly (p = 0.01) in the socio-emotional development compared with children given non-exclusive breastfeeding.

c. Factors affecting the development of motoric, cognitive and socioemotional children ages 18-24 months

The results of multiple linear regression analysis (Table 3) to test the independent variables that most influence the high score between maternal characteristics of child development characteristics of children. In this study it was found that all of the variables examined in linear regression simultaneous effect on motoric development (p = 0.001), cognitive development (p = 0.000), and on socio-emotional development (p = 0.001). The results that the birth weight of 28.5% a negative effect on the development of motoric (p = 0.003, t =-3.283), and 65.1% negative effect on cognitive development (p = 0.000, t =-5.348). Giving stimulation 65.1% negative effect on cognitive development (p = 0.035, t =-2.234), and a negative effect on the development of socioemotional 48.4% (p = 0.002, t =-3.519).

**Discussion**

**Effect of Age Mothers with Children’s Cognitive Development:** In this study, the results obtained with p value = 0.021 which means there is an influence between the characteristics of the mother’s age with cognitive development in children. A child requires special attention to the optimization of growth. Optimizing the development of the necessary interaction between
children and parents, especially the mother’s role is very beneficial to the overall process of development of children because parents can immediately recognize the disorder as early as possible the process of development of their children.\textsuperscript{7}

If adjusted to international opinion, then an early age in Indonesia are those from birth (age 0 years) until well into the early primary school level. However, some studies show that since the time of conception (in the womb), the developing fetus and have proven to do stimulation to develop a variety of sensitivity and basic abilities.\textsuperscript{8}Given the 80% growth and brain development in children pasa currently developing an early age, at the age of 1 year of brain growth reached 70% of the adult brain, and in the age of 3 years of a child’s brain has reached 90% of the adult brain. Thus, this period should be best utilized to improve the intelligence of children.\textsuperscript{9}

The influence of birth weight with Motor and Cognitive Development of Children: Prenatal and natal factors that affect the development of children one of whom is the birth weight. An estimated 10-15% of premature infants with low birth weight or impaired development, as well as infants born with very low birth weight 3-4 times greater risk for experiencing a developmental disorder. Babies with low birth weight have a brain disorder that can be observed through MRI and a greater risk of an abnormal signal by a larger amount. Besides infants with low birth weight, premature and very low birth weight had serum CRP levels were higher.\textsuperscript{10}

According to Piaget, the first stage lasts Cognitive Development in children from birth until the age of 2 years is a sensory motoric development. At this stage the baby to build an understanding of the world by coordinating sensory experiences (sensory) them, such as seeing and hearing) with motoric movement (physical) they, like grabbing, or touched, because that is called sensorimotor. At the beginning of this stage, the baby showed no more than a reflective pattern for adapt with the world, towards the end of this stage, babies showed a pattern more complex sensory-motor.\textsuperscript{11}

The results of previous studies which stated that infants with a history of premature or low birth weight risk of impaired cognitive development and motor development and research shows that babies born with low weight the potential to have a developmental disorder in the future.\textsuperscript{12} Babies born with low birth weight, especially in infants born with very low birth weight, may have abnormalities in brain structure. Abnormalities of the brain in infancy can affect the child’s development in the future.\textsuperscript{13}

Effect of Breastfeeding with socioemotional development Children: Breastfeeding is one of the environmental factors are known to provide a variety of nutritional and immunological advantages in infants.\textsuperscript{14}

The American Academy of Pediatrics recommends breastfeeding for human use as an ideal source of nutrition for infant feeding. Infant formula is the second choice and third choice of soy formula.\textsuperscript{15}

In this study showed that breastfeeding for 6 months had a significant influence on socio-emotional development in infants aged 18-24 months. The development of socio-emotional during infancy and early childhood is described as the ability of children who thrive on experience, control and express feelings, establish connections close interpersonal and secure, investigate the environment and learn, all within the scope of the family, society and culture.

Some studies in the encyclopedia concluded that breastfeeding is not a panacea, but as a mother can breastfeed optimally, the infant or child they will get many benefits, one of them for psychosocial and emotional development in children.

The influence of Stimulation with socioemotional development Children: The development of socioemotional during infancy and early childhood is described as the ability of children who thrive on experience, control and express feelings, establish connections close interpersonal and secure, investigate the environment and learn, all within the scope of the family, society and culture.

Results of research on the behavior of giving stimulation to the 32 mothers found that children were stimulated high by their parents have higher scores were significantly ($p = 0.004$) on the development of socio-emotional compared to children who are less stimulated by their parents.

According to research results Supinah, mostly by 53% stimulation skills are good mothers and produce the majority of children aged 2-3 years at 71% had the appropriate gross motor development. Analysis Spearman rho rank generating value calculated at 0.687
indicates that the stimulation skills of mothers with gross motor development in children aged 2-3 years have a strong closeness. That is a good or bad skill in stimulating her mother will be very influential in his gross motor development.

**Conclusions**

Based on research that has been done above, it can be concluded that factors affecting motor development is birth weight (p = 0.004), cognitive development is influenced by maternal age (p = 0.021) and birth weight (p = 0.000) and the development of socioemotional affected by breast feeding (p = 0.010) and providing stimulation (0.004).

**Ethical Clearance:** Ethical clearance was issued by the Health Research Ethics Committee of the Hasanuddin University School of Public Health, and subjects were asked to sign an agreement before being included in the study.

Analysis of Human Platelet Antigen (HPA) in Thrombocytopenia Patients

Rachmawati Muhiddin1, Nelly1, Asvin Nurulita1, Tutik Harjianti2, Moch Hatta3, Mansyur Arif1

1Department of Clinical Pathology, 2Department of Internal Medicine, 3Department of Microbiology, Medicine Faculty Hasanuddin University, Makassar, Indonesia

Abstract

Human Platelet Antigen (HPA) is a form of immunogenic polymorphism of platelet membrane glycoproteins. Human Platelet Antigen can cause platelet alloimmunization response will be clinical manifestations of immune thrombocytopenia, such as Fetal Neonatal Allo-immune Thrombocytopenia (FNAIT), Post Transfusion Purpura (PTP), and Platelet Transfusion Refractory (PTR), Idiopathic Thrombocytopenic Purpura (ITP). The aim of this study to research on seroprevalence (genotype and frequency) of Human Platelet Antigen (HPA) in Patients with Non-Immune and immune Thrombocytopenia.

A Cross sectional study was conducted to 66 patients with thrombocytopenia, Samples were collected during the period Mei-July 2019, and HPA genotypes were identified in buffy coat blood samples. Samples were examined by PCR examination to detect HPA genotype at Medical-Research Center Laboratory/Medical Faculty of Hasanuddin University Hospital, Makassar. Data was analysis by the statistical tests used were Independent-t, Mann-Whitney, Chi-Square and Fisher Exact tests. The results of the test were significant statistically if the p-value <0.05.

Result. From 66 patients thrombocytopenia, ages 19-82 years, 41 (62.1%) women and 25 (37.9%) men. 31 (47.0%) patients were non immune thrombocytopenia and 35 (53.0%) were Immune Thrombocytopenia. The highest HPA frequency (100%) was HPA-1b, 2a, 4a were obtained in both non-immune and immune thrombocytopenia. In this study, there were frequency of HPA 1b, 15a, in both non-immune and immune thrombocytopenia where was not found in the normal population in Makassar (in our research before). Frequency of HPA-4b (2.8%) was obtained in the population of immune thrombocytopenia that was not found in non-immune thrombocytopenia. The Positive distribution HPA-3b was found to be significantly higher in the Immune group (22.9%) than in the Non-Immune group (3.2%) (p <0.05).

Conclusion: The frequency of HPA-3b was found to be significantly higher in immune thrombocytopenia than non-immune thrombocytopenia.

Keywords: Human Platelet Antigen, Non immune, Immune, Thrombocytopenia.

Introduction

Thrombocytopenia is a platelet count less than normal, the normal platelet value is 150,000-400,000/μL. The mechanism underlying thrombocytopenia is due to suppression of platelet production, increased platelet consumption and platelet lysis or damage through immune or non-immune reactions. Thrombocytopenia causa immune is one of the immune diseases characterized by platelet counts of less than 100,000/μL without other causes of thrombocytopenia, with or without a decrease in other haematological parameters (based on consensus results of the International Working Group (IWG) panel in 2009 which published the provided guidance).

1 Decreased platelet count is caused by platelets bound by antibodies, especially IgG, which originate from the patient’s own body. 2 The aetiology of immune thrombocytopenia is still unclear, environmental and genetic factors play an important role in pathogenesis. 3

Human Platelet Antigen (HPA) is a form of immunogenic polymorphism of platelet membrane glycoproteins. The HPA nomenclature has now identified 21 HPA bineal systems, generally composed by Single
Nucleotide Polymorphism (SNP) in genes that encode the glycoprotein membrane that is relevant except for one arranged single amino acid substitution. 4, 5

Platelet plasma membranes consist of many glycoproteins (GP) and phospholipids. The most platelet glycoproteins are GPIIb-IIIa, GPIa-IIa, and GPIb-IX. Twenty-four HPAs have been identified serologically, and the molecular basis of 22 of them has been identified. Twelve HPAs are grouped into six binucleotides (HPA-1a/1b, 2a/2b, 3a/3b, 4a/4b, 5a/5b, and 15a/15b). Higher frequency alleles are defined as “a” (such as HPA-1a) and low-frequency alleles “b” (such as HPA-1b). 6 The frequency of the HPA genotype varies between populations and different ethnic groups. 4, 5, 6

Human Platelet Antigen can cause platelet alloimmunization response which can cause clinical manifestations of immune thrombocytopenia, such as Fetal Neonatal Allo-immune Thrombocytopenia (FNAIT), Post Transfusion Purpura (PTP), and Platelet Transfusion Refractory (PTR), Idiopathic Thrombocytopenic Purpura (ITP). 5, 7, 8 Establishing an HPA system pattern is the basis for diagnosing and managing risk and managing the diagnosis. 4, 5, 9 Knowledge of the HPA genotype and frequency of antigens in a population is important, especially for the supply of appropriate blood components for patients with PTR. 4, 8

Pai SC, et al., have conducted HPA-1 through-6 and HPA-15 allele genotypes in 998 platelet donors by PCR-RT method at 6 blood service centres in Taiwan, the results of the study showed based on the frequency of HPA-15b alleles. and HPA-3a, which have the most important role as causative factors, FNAIT, PTP, and PTR followed by HPA-2,-6,-1,-5, and-4. Besides, HPA-4b and HPA-5b are also considered to cause immunogenicity. 8

Data on the genotype and frequency of HPA in populations in Indonesia do not yet exist, especially in Makassar, so researchers want to research on seroprevalence (genotype and frequency) of Human Platelet Antigen (HPA) in Patients with Non-Immune and immune Thrombocytopenic. Researchers hope the results of this study can be the basis for further research, especially in the management of diseases associated with platelets.

Method

Samples and DNA extraction: Blood samples were collected from 66 patients Thrombocytopenia, 31 patients were Non-Immune Thrombocytopenia and 35 patients were Immune Thrombocytopenia. The hematologic examination was performed with a Sysmex automatic haematology analyser. DNA was prepared from whole blood in ethylenediamine tetra acetic acid (EDTA) by standard Method. The genotypes of HPA-1 system were determined using the polymerase chain reaction sequence-specific primers (PCR-SSP) method designed by Skogen et al. and the SSPs were used to discriminate between the alleles encoding the six major HPAs in a series of patients and normal blood donors. The thermocycler program consists of an initial step of 94°C for 5 min, followed by 32 cycles of 94°C for 30 s, 65°C for 60 s, 72°C for 60 s, and a final extension step of 72°C for 10 min. The PCR products (15 μL) were subjected to gel electrophoresis on standard 1.5% agarose gel containing 0.5 μg per ml of ethidium bromide. The typing results were examined under UV light transillumination.

Statistical analysis: Statistical analysis was performed using SPSS version 12 statistical package for windows. Allele and genotype frequencies were calculated by direct counting.

Results

In this study, 66 samples study were obtained, with a diagnosis of thrombocytopenia, ages 19-82 years, 41 (62.1%) women and 25 (37.9%) men. In this study, an analysis of the frequency and genetic HPA of non-immune thrombocytopenia and immune thrombocytopenia also carried out an analysis of the haematological parameters of platelets, leukocytes, and haemoglobin

Discussion

In this study, 66 study samples were obtained, with a diagnosis of thrombocytopenia, ages 19-82 years, 41 (62.1%) women and 25 (37.9%) men. Non-Immune Thrombocytopenia was 31 (47.0%) patients, immune Thrombocytopenia was 35 (53.0%) patients, consisted of 24 (36.3%) patients with primary immune thrombocytopenia, and 11 (16.7%) patients with secondary immune thrombocytopenia.

Based on the age of the subjects in the Immune group significantly lower than the age in the Non-Immune group (median and mean) (p <0.001). while the distribution of women had more Immune (80.0%) compared to Non-Immune (p <0.001). This study was appropriate with previous research by Grace, et al, (2012) showed that immune thrombocytopenia generally occurs at a young age and is completely healed, and a small portion continues into adulthood. In this study it was found that there were significant differences in the gender, where women higher than men, this is under research by Andrés E et al. Andrés E, Immune thrombocytopenia often occurs in young adults, especially women in the third or fourth decade. Female dominance shows that sex hormones can play a role in various aspects of ITP.

In this study also carried out an analysis of the haematological parameters obtained Leukocytes mean lower in Immune than in Non-Immune but statistically not significant (p> 0.05). In this study the comparison of the mean Haemoglobin was significantly lower in Immune than in Non-Immune (p <0.05) and the Thrombocyte mean was significantly lower in Immune than in Non-Immune (p <0.05). In non-immune patients, leukocytes range between 300-98,000/μL. Increased leukocytes due to the response to infection and also the neoplasm process in leukaemia patients and thrombocytopenia occur due to the inflammatory response an increase in platelet consumption, whereas in neoplasms the hematologic malignancies of thrombocytopenia occur due to suppression of thrombopoiesis. In patients with immune thrombocytopenia caused by platelet lysis by an immunological response, an anti-HPA antigen reaction to platelet HPA occurs. The mechanism of these differences still requires further research.

In this study, the frequency of HPA-1a was (87.0%), 1b (100%), 2a (100%), 2b (96.7%), 3a (87.1), 3b (3.2%), 4a (100%), 4b (0%), 5a (38.7%), 5b (0%), 15a (16.1%), 15b (0%). The frequency and genotype of immune thrombocytopenia of HPA-1a (85.0%), 1b (100%), 2a (100%), 2b (94.2%), 3a (82.9%) 3b (22.8%), 4a (100%), 4b (20%), 5a (20%), 5b (0%), 15a (5.71%), 15b (0%).

In this study found the frequency and genotype of non-immune thrombocytopenia patients as follows HPA-1a (87.0%), 1b (100%), 2a (100%), 2b (96.7%), 3a (87.1), 3b (3.2%), 4a (100%), 4b (0%), 5a (38.7%), 5b (0%), 15a (16.1%), 15b (0%). The frequency and genotype of immune thrombocytopenia of HPA-1a (85.0%), 1b (100%), 2a (100%), 2b (94.2%), 3a (82.9%) 3b (22.8%), 4a (100%), 4b (20%), 5a (20%), 5b (0%), 15a (5.71%), 15b (0%).

The results of this study showed positive results on HPA-1b both non-immune thrombocytopenia (100%) and immune (100%), while the results found in Muhiddin R showed no frequency of HPA-1b was found in normal donors. In this study also found the frequency of HPA-4b was not found in non-immune thrombocytopenia but found in HPA immune thrombocytopenia (20%). In this study, the frequency of HPA-15a was found in both non-immune thrombocytopenia (16.1) and immune thrombocytopenia (5.7). This study shows that in percentage there is a difference in HPA-3b and HPA-15a in non-immune and immune thrombocytopenia with frequency and genotype in the normal population in Makassar.

The results of this study differ from those found by Pai SC, et al., having conducted HPA-1 through-6 and HPA-15 allele genotypes in 998 platelet donors, the results of the study showed based on the frequency of HPA-1b and HPA-4b, and HPA-15a in non-immune and immune thrombocytopenia with frequency and genotype in the normal population in Makassar.

In this study a statistical analysis of the differences in the frequency of HPA-1a, 2b, 3a, 4a, 4b, 5a, and 15a, in non-immune and immune thrombocytopenia, but not significantly.

Positive HPA-3b distribution was found to be significantly higher in the Immune group (22.9%) than in the Non-Immune group (3.2%) (p <0.05). How the mechanism of these differences still requires further research.
**Conclusion**

In conclusion, the highest HPA frequency 1b, 2a, 4a were obtained in both non-immune and immune thrombocytopenia. In this study, their frequency of HPA 1b, 15a, in both non-immune and immune thrombocytopenia was not found in the normal population in Makassar. Frequency of HPA-4b is obtained in the population of immune thrombocytopenia that is not found in non-immune thrombocytopenia. The frequency of HPA-3b was found to be significantly higher in immune thrombocytopenia compared to non-immune thrombocytopenia.

The Application of Nesting and the Light Protective Cover of Incubator to the Stability of Oxygen Saturation and the Pulse of Low Birthweight Babies in the Newborn Intensive Care Unit in RSU Undata Palu, Central Sulawesi

Andi Fatmawati Syamsu1, Aminuddin2

1Postgraduate Program of Medical Faculty, Faculty of Medicine, Hasanuddin University, Makassar; 2Senior Lecturer of Poltekes Kemenkes Palu. Indonesia

Abstract

Background and Objectives: During the care period of low birth weight babies (LBWB) at the Undata Hospital, Palu, the nests used consisted of blankets that could change the low birthweight baby (LBWB) and the thin layer incubator cover which still allow lighting to penetrate the incubator. Thus, the researchers initiated to use phlanyl and darco nests and thick incubator covers and observed the effects on the physiological stability of LBWB.

Materials and Method: The study was conducted at the Undata Palu Public Hospital in 2018. Total subjects were 12 LBWB consisting of 7 males and 5 females. The research design was One-group Pretest-Posttest (Single Group Before and After Intervention) because it could collect more reliable data that it was conducted the same subject with two different tests (before and after the intervention). Paired-sample t-test was a statistical test used for a single group that proposed two different tests.

Results: The total means of oxygen saturation before and after intervention were 93.20% (CV = SD = 6.26%; variant = 39.18%) and 96.32% (CV = SD = 3.70%; variant = 13.70%), respectively. The total mean of heart rate before and after the intervention was 93.20% (SD = 6.26%; variant = 39.18%) and 96.32% (SD = 3.70%; variant = 13.70%). There was a significant difference between the oxygen saturation before and after the intervention (p = 0.012 <0.05 significance level) and no significant difference before and after the intervention (p = 0.012 <0.05 significance level).

Conclusion: The nest from phlanyl & dacron and thick incubator cover were proven increasing oxygen saturation of LBWB and not proven to provide a useful contribution in lowering the LBWB pulse. It was probably due to the temperature of LBWB as a confounding factor.

Keywords: Nesting, incubator cover, developmental care, physiological response, low birthweight baby.

Introduction

Based on the Indonesian Demographic and Health Survey in 2007, the infant mortality rate in Indonesia was 34 per 1000 births with a neonatal mortality rate of 19 per 1000 live births (Wijaya, 2009). LBW prevalence was less than 11.1% in 2010 to 10.2% in 2013. Variations between provinces were very striking from the lowest in North Sumatra (7.2%) to the highest in Central Sulawesi (16.9%). For the first time in 2013, data was collected on the length of the baby born, with the National rate of <48 cm short-born babies was 20.2%, varying from the high in East Nusa Tenggara (28.7%) and the lowest in Bali (9.6%)1.

A number of studies have revealed that stress reduction in newborn babies can be obtained in the Newborn Baby Intensive Care Unit which includes the provision of low light, low sound, warmth, soft touch, pain control, lamping and nesting2, adjusting the humidity levels of incubators for LBWB during the first two weeks of age since LBWB was born, temporarily held the infants in the incubator until it had adjusting temperature ability to the changes in ambient
temperature, giving an incubator cover to protect his eyes from the light\(^3\).

The baby’s body position affects stress on LBWB. Supine position has the opportunity to reduce 40% of infant mortality due to infant suds syndrome and prone position to support neuromuscular development, especially the neck and head muscles. Based on the empirical facts as observed, the researchers applied nests that mimicked the condition of the mother’s womb made of phlanyl delicate material containing pieces of cloth (darco) with a length of approximately 121-132 cm and can be adjusted to the baby’s body length. Dacro materials are more elastic and can be adapted to the baby’s posture. The cover of the incubator used was made of a thicker cloth fabric that resembled a dark blanket and covered the entire surface of the incubator, thus preventing the direct lights entering the incubator\(^2\).

Based on the background of the problem stated above, the purpose of this study was to examine the effect of phlanyl and darco body position support media and thick protective light incubator cover on oxygen saturation and pulse Low Birth Weight Babies in Newborn Intensive Care Units (NICU) at Home Undata General Hospital, Palu, Central Sulawesi.

**Materials and Method**

**Research location:** The study was conducted in the Newborn Intensive Care Unit of Undata Hospital in Palu City from January 1\(^{st}\) to May 2018.

**Research Design:** The experimental design chosen in this study was One-Group Pretest-Posttest (Single Group Before and After Intervention).

**Population and sample:** The number of samples was determined using differences test of a paired-group. (Dawson and Trapp, 2001-not in the reference) stated in the equation:

\[
 n = \frac{\left[ (Z_{\alpha/2} + Z_{1-\beta}) \sigma \right]^2}{(\mu_1 - \mu_2)^2}
\]

Where:

- \(n\) = number of samples
- \(\mu_1\) = mean score group 1
- \(\mu_2\) = mean score group 2
- \(Z_{\alpha/2}\) = significance level 5%
- \(Z_{1-\beta}\) = 80% test power
- \(\sigma\) = difference in variation of 2 samples

The minimum number of samples needed in this study are:

\[
 n = \frac{[(1.96 + 0.84) \times 0.28]^2}{(0.24 + 0.52)^2} = 9 \text{ (rounded up)}
\]

**Statistical analysis:** Analysis of the data used in this study consisted of univariate and bivariate analysis.

1. **Univariate Analysis:** Univariate analysis is the analysis of the characteristics of the descriptive variables studied (Hastono, 2007). The characteristics of the descriptive variables observed in this study were gestational age, birth weight, and body weight during the study by calculating the mean, median, standard deviation (SD), and minimum and maximum values at a significance level of 95\% \((\alpha = 0.05)\).

2. **Bivariate Analysis:** This study used a paired sample t-test which compared two different tests in the same single group (Siswosudarmo, 2015). Oxygen saturation and pulse were analyzed by collecting data on mean, median, standard deviation (SD), and minimum and maximum values at a significance level of 95\% \((\alpha = 0.05)\). In this study a comparison of oxygen and pulse saturation in 12 LBW samples were conducted by using a nest of blankets and incubator cover made from thin material and nest made from phlanyl and darco and thick incubator cover.

**Research ethics:** All research subjects were treated according to human ethics guided by the Standards of Ethical Nursing Research published by the Association of American Nursing Scholars. Ethical research approval for the research subjects was examined and approved by the Health Research Ethics Comission of Health Polytechnics, the Ministry of Health of Yogyakarta as stated in the Research Ethics Decree with Registration Number N0. L.B.01.01/KE-02/XXIX/711/2017, and written permission statement from parents or legal caregivers of the research subject.
Results

Effects of Physiological Reactions

Teory | Low oxygen levels, less comfortable | High oxygen levels are more comfortable | Low pulse because low temperatures | High pulse because of high temperature |

Result | Confirmed the theory | Confirmed the theory | Not Confirmed the theory | Confirmed the theory |

Effect of nest on oxygen saturation.—Babies were comfortable-oxygen saturation increased.

Effects of non-test on heart rate — babies became stressed-their oxygen saturation decreased.

Body temperature drops, oxygen saturation rises.

The thin cloth covering the incubator caused an increase in the beam of light that hits the baby, increasing the stress on the baby. Stress in babies causes lower oxygen saturation.

The thick cloth covering the incubator caused the light to be reduced to reduce stress on the baby. Thus, his heart rate decreased.

Pulse frequency is strongly influenced by physical activity and other situations that can cause the body’s metabolism to increase such as increases in body temperature and anxiety or stress.

Table 2: Normality of oxygen saturation and pulse rate of LBWB (n = 12).

</table>
The results of the normality test data show that oxygen saturation and pulse rate in the test group 1 (nesting with roll blanket and incubator cover made of thin cloth) and test group 2 (nest made from phlanyl and dacro and thick incubator cover) were normally distributed so that paired t test was used as a parametric test in this bivariate analysis. This is evident from the value of p> 5% significant level.

Description of physiological reaction data comparison of total mean oxygen saturation and pulse before and after intervention is shown in Table 3.

Table 3: Total mean oxygen and pulse saturation levels before and after the intervention (n = 12).

Table 3 shows the total oxygen saturation level of group 1 (nesting with roll blanket and incubator cover made of thin cloth) at 93.20% (SD = 6.26%; variance = 39.18%), while the total mean oxygen saturation level of group 2 (nest made from phlanyl and dacro and thick incubator cover) at 96.32% (SD = 3.70%; variance = 13.70%).

Bivariate analysis before and after intervention: Bivariate analysis was performed to calculate the difference in the average of total oxygen saturation and pulse before and after the intervention. Table 9 shows the total mean oxygen saturation of LBWB before and after intervention. The total oxygen saturation before intervention was 93.2% (SD = 6.26%), while the total oxygen saturation after intervention increased by 96.317% (SD = 3.70%).

Table 4: Total mean of oxygen saturation at LBWB before and after intervention

</table>

The difference in total oxygen saturation before intervention and after intervention is 3.1167% shown in Table 10. In Table 10, there were significant differences in oxygen saturation before and after intervention. This was observed from the range of confidence values (CI) not exceeding zero (lower limit =-5,4006; upper limit =-, 8327; p = 0.012 <real level 0.05). Thus, nest made from phalyl/dacron and thick incubator cover made a significant influence on the increase in oxygen saturation compared to the nest of blankets and thin incubator covers.

Discussion

Nurses have an important role in creating a stress-free care environment. The environment of care can be created through the treatment of growth and development. In this study, the care aspects of developmental care provided included thick-incubator cover to reduce the lighting and installation of nests with dacron materials to support the baby’s body in a flexed position, provide comfort, maintain normality of the torso, and support self regulation.

Oxygen saturation states the percentage of oxygenated hemoglobin in the blood. The important role of hemoglobin is to bind oxygen in each molecule. Hemoglobin is a protein compound that has four globin and porphyrin polypeptide chain subunits, each of which contains heme. Heme itself contains one iron atom in the form of ferro, so that one hemoglobin molecule has four iron atoms that will bind four oxygen molecules. Therefore, if the hemoglobin level in the blood decreases, it can reduce the value of oxygen saturation. This is presumed as a temperature factor affecting the increase in the value of the test pulse (after intervention) compared to the group before intervention. Body temperature factors may be expressed as confounding factors (a confounding factor) on comparisons between groups before intervention and after intervention in this study. Nevertheless, the average value of total oxygen saturation after the intervention experienced a higher increase than the group before the intervention.

Body temperature data 12 LBWB is important included in the general data above (Table 2). Body temperature data need to be measured as a confounding factor which explains why the pulse of the treatment group is higher even though given nest made from phlanyl/dacron and incubator cover made from thicker than before intervention. The body temperature data on LBWB given rolled blanket nest and thin layer cover were measured using paired t-test. Effect of body temperature on the pulse of LBWB given nest made from phlanyl/dacron and thick incubator cover measured using paired-t test.

Conclusion

Nest made from phlanyl & dacron and thick incubator cover proved to be significant in increasing physiological stability of LBWB judging from the increase in LBWB oxygen saturation even though it was not proven to significantly increase the LBWB pulse rate compared to before intervention. Further research on the application of nest made from phlanyl and dacron and thick-coated incubator cover in the Infant Birth Care Unit is needed in order to support the improvement of developmental care approach for reducing neonatal mortality.

Abstract

Case detection in the TB control program in Majene Regency is still low. This study aims to increase active case detection through counseling to housewives using flipchart containing social determinants of tuberculosis. This study uses a quantitative method with 200 survey respondents selected using the zig-zag method. Quantitative data were analyzed using the statistic Wilcoxon signed Ranks Test. The results of the average score of knowledge before 41.86 and after intervention 102.34 with a value of \( p = 0.000 \) and attitudes showed there were differences before and after the intervention where the value of \( p = 0.000 \) then the detections of cases by mothers and cadres were measured after three months of intervention increased by 100%. Discussion and conclusions; knowledge of attitudes and case-detection actions before and after the intervention increased on average so it can be concluded that the FGD intervention model with counseling was very suitable to be applied to increase the knowledge of mothers detection TB cases.

Keywords: Case Detections, Social Determinants, Empowerment.

Introduction

West Sulawesi Province has also implemented the DOTS strategy as an effort that believed to be effective in stopping the spread of TB, but the results have not been able to reduce the incidence of TB in West Sulawesi Province. Early case detection such as pulmonary tuberculosis can prevent and break the chain of transmission by making early detection and early treatment is prevention and treatment efforts that must be carried out simultaneously (parallel) and is simultaneous in nature\(^1\). At present, the incidence of tuberculosis is quite high as much as 395 per 100,000 inhabitants (Sulbar TB report. The description of the high incidence that has not been matched by high detections demands that the local government look for the right case detection method and can be scientifically accountable. The idea of detection a case that links social determinants with the flow of TB events is in line with the recommendations of the 2016-2020 RAN for TB Research\(^2\).

Majene Regency is the location of the research. This regency is the center of the Mandar ethnic royalty besides that Majene Regency for 3 years carrying out a strategy but always showing low TB cases detection and never reach the target, seeing that in 2014 the target was set at 80% but the case detection was only 67%, and in in 2015 the target was set at 90% but coverage was only 72%, so in 2016 the target was set at 90% and achievement was only 75\(^3\).

As explained earlier in this paper, the cause of tuberculosis is Mycobacterium tuberculosis but the battery is not enough for someone to become ill. With the method of focus group discussion (FGD) using a flip sheet with the concept of Mandar culture as a promotion/communication media, it can give an idea of the level of knowledge and attitudes of respondents regarding TB. Based on the above concept, the researcher tried to understand the differences in the increase in knowledge and attitudes of respondents before and after being given health education regarding TBC with flip sheet.
media with a concept that described the condition of the Mandar ethnic real estate in the Rangas urban village.

### Materials and Method

**Location and Research Design:** This study was carried out in the Rangas urban village, Banggai District, Majene Regency, West Sulawesi in January-November 2018. The type of research is operational research, with a quasi-experimental design.

**Population and sample:** The population in this study were all housewives who were in the area of the Rangas Community Health Center, Banggai Sub-District, Majene Regency, West Sulawesi. Sampling selected using purposive cluster sampling with a sample size of 258 people, from the selected sample size refers to 10% of opinions and also refers to SEM modeling, an analysis tool that requires a minimum of 100-200 samples so that 200 samples were taken in this study. Residing in Rangas Urban Village, and is willing to take part in this research as a respondent.

**Data collection Method Data:** Data collection was carried out by researchers using questionnaires (age, sex, education, family income, respondents’ knowledge and attitudes about TB, which were carried out before and after treatment in the form of Focus Group Discussion (FGD) with flipchart method. The results of this study presented in the form of tables and narratives

**Data Analysis:** Data analysis performed was univariate, bivariate analysis with the Wilcoxon signed Ranks Test

### Results

**Sample characteristics:** Table 1 shows the results of univariate analysis, based on sex, showing the highest number of female respondents was 58.5%. Age shows the highest number of respondents in the age group of 31-40, which was 62.5%. The level of education shows the highest number of respondents at the Elementary School level, which was 62.5%. Based on the work, most respondents work as housewives who sell their husband’s haul was 31.5%. The family income per month for most respondents in the group of Rp.500,001-Rp.1,000,000 was 43.0%.

Source: Primary Data, 2018

Based on the research variables, the distribution of respondents based on the level of knowledge and attitudes of respondents regarding TB shows that there were 58.5% of respondents who have a sufficient level of knowledge about TB, and based on the variable attitude of respondents regarding TB there are 75.5% of respondents who have a fairly good attitude, Table 2.

Based on table 2, Ranks have a negative level of 586.0 and the number of positive levels was 18524.0. In table 3, the value of Z =-11,375 and the value of p = 0.000 <0.05, then H0 is rejected, so it can be concluded that there was a difference in knowledge of TB before and after FGD with the flipchart method or it can be interpreted that there was an effect flipchart method for increasing knowledge about TB in respondents.

In table 4, Ranks were negative 141.0 and positive numbers are 2634.0, and in table 5 are Z = -6.879 and p = 0.000 <0.05, so Ho is rejected, this can be interpreted as different attitudes before and after FGD with the flipchart method or it can also be interpreted that there is the influence of the FGD with the method of flip sheeting on the attitude of the respondents.

Discussion

The relationship between the level of knowledge and the incidence of Tuberculosis in the community is very close. Courtwright and Tumer (2010) suggest that in addition to increasing knowledge about tuberculosis, it can change one’s mindset and stigma so that prevention or treatment for TB patients can work well. According to the Indonesian Health Profile in 2008, the number of new positive cases of Acid Resistant Basil TB (BTA) in the age group 0-14 years in Indonesia amounted to 1861 cases.

Based on some of these researchers, it can be said that the promotional media in the form of efficient flip sheets increases the knowledge of respondents regarding TB. The statistical Wilcoxon signed Rank test showed that there was an increase in respondent’s attitudes before and after the intervention in the form of focus group discussions using flip chart media as a promotional medium that contained positive and easily understood things by respondents. Study also explains this, where flip sheets are used as a communication medium to improve the attitude of respondents who previously have also been tested in other pilot locations.

Research that is corresponding obtained by Miller, wherein his research also uses flip sheets as one tool using the flip chart method as a promotional media. The results of this study were also supported by previous research which suggested that by promoting TB on flip chart media, or electronic media can increase people’s knowledge about TB. According to Deepa Makesh also researched the treatment of tuberculosis using two Method and one of which was used as flip chart media as a promotional medium, which after the approach was made through the media, the respondents’ knowledge increased compared to before.

A similar study carried out in Banyumas-Indonesia, also stated this, that after counseling and counseling through media back ships could significantly increase mothers’ knowledge about pulmonary TB in children. Based on some of these researchers, it can be said that the promotional media in the form of efficient flip sheets increases the knowledge of respondents regarding TB.
or media promotion to change or increase the stigma and attitude of the respondents. Croft et al. conducted a survey of the level of knowledge and attitudes about tuberculosis and leprosy in two regions in Bangladesh, the results showed that there were significant differences between regions that received a 2-year education program in the form of day/night mass information programs run from jeeps using flipcharts, loudspeakers and two locally developed slide series that show simple stories about leprosy and TB sufferers who receive successful treatment.

A person’s attitude and knowledge are interrelated so that in other studies, it is said that the low level of knowledge about TB can affect behavior in seeking patient health and maintaining the transmission of disease in the community. The high level of knowledge a person can cause changes in one’s perceptions and habits, behavior based on knowledge will last longer than those not based on knowledge.

**Conclusions**

This study concludes that based on the Wilcoxon signed Rank Test conducted the results showed that there was an increase in respondents’ knowledge and attitudes after being given intervention in the form of focus group discussion (FGD) using promotional media in the form of a back-note with ethnic Mandar concepts.

Accelerative, Effective and Efficient Tuberculosis (TB) Response to TB Elimination on 2035 in Medan Year 2017

Syarifah¹, Tukiman¹

¹Public Health Faculty of Sumatera Utara University

Abstract

Indonesia includes the rank of two highest TB loads in the world. Incidence rate of TB in the city of Medan High, the case of TB drug resistance (RO) highest in North Sumatra, low cure rate, high drop out. Research aims to excavate 1) implementation of the mitigation program TB 2) implementation process 3) community participation and NGOS in TB countermeasures program. Research, qualitative study of research informant includes head of health office, head of Puskesmas, manager of TB Private Hospital, physicians of private Practice and clinic, NGO engaged in the response of TB. Data is gathered through in-depth interviews with informant. Processing and analysis of data is done through the stages of creating transcripts and analyzed by content analysis. The results showed that the policy of TB’s handling was appropriate, the implementing actors were right, all the Puskesmas has been implementing the DOTS strategy, but still many people who do not know Puskesmas serve TB for free. Hospital support and physicians of private practice in the reporting of low TB cases resulted in many cases missing, impacting the increased cases of TB MDR so that government burden in the reduction of TB is getting heavier while TB budget is still Dominated by foreign donors. NGOS have played a role in the management of TB but the coordination is not maximized, in the implementation of there are still overlapping reporting activities to the stakeholders is not smooth, Public Private Mix already exists but has not played a lot. In order to reach the elimination of TB year 2035 the Municipal health Department of Medan has compiled a regional action plan (RAD) Countermeasures TB Regulation status of the mayor. It is recommended that RAD should be implanted accordingly, right from the internal and external environment and the accuracy of the accelerometer, effective and efficient process to the elimination of TB.

Keywords: Accelerative, effective, efficient, elimination TB 2035, tuberculosis (TB).

Introduction

In North Sumatra the prevalence of TB of 110,666 with a rate of 794/100,000 inhabitants, a TB incident of 68,828 with a rate of 501/100,000 inhabitants and deaths from TB of 5,714 with a rate of 41/100,000 inhabitants, case detection rates, issuing form a number of 22,961 (33, 3%)¹-³. MDR-TB figures are estimated at 2% of all new TB cases (2620 cases) and 20% of TB cases with retreatment (42 cases), with a total of 2662 cases. As of March 2016 ⁴ changed found 356 TB MDR cases in Rsup HAM. It is noted that TB MDR increases due to inadequate countermeasures for TB. It is known that the treatment of TB MDR is longer and costs much greater, the effects of adverse reactions are very severe and can transmit TBMDR in the surrounding people. Adviesraad’s average celebrity success figure of TB MDR treatment for the last 4 years is about 37% of the global target of the latest celebrity milestone of celebrities national TB program.

Although nationally demonstrating increased developments in the discovery of cases and levels of healing, achievements at the provincial level still show disparity between regions. The discovery of the case of Medan City increased from 5776 cases in 2014 to 6541 cases in 2015.⁵ The probability of higher TB drug resistance in hospitals and private sectors that have not been involved in national TB control program as a result of high non-compliance and drop out rate of treatment because it was not prepared High DOTS strategy. Data from private service providers is not included in the data on national TB control programs.

While in the hospital in Medan, the new data available comes from about 41% of hospitals that have
implemented the DOTS strategy. The number of TB cases in the city of Medan in 2015 reached 350 cases. Case of TB proportions child of all cases TB reaches 5.4%. This figure is a partial description of the overall case of actual TB of children considering the high case of overdiagnosis in health facilities accompanied by a low reporting of health care facilities.6

Furthermore, the support by the Government to expedite the process is seen among others with the issuance of circular letter from the Ministry of State with No 440/4838 Bangda, on 26 October 2016 to all the governor of Indonesia to Provide accelerated TB response support. Furthermore, in the standard of Minimal service (SPM) health in 2016 is also more firmly stated in the 12th Standart of health services people with TB.7

It is necessary to do research that aims to: 1) Excavate the implementation of TB countermeasures program that has been conducted by the city health agency Medan. 2) Digging process implementation of TB countermeasures program. 3) to explore public and NGO participation in TB countermeasures program.

Method

Research Design: Research is a qualitative study to explore more in-depth policies implemented in TB’s countermeasures program in Medan City to obtain an effective and efficient TB countermeasures strategy. Qualitative Data was collected to explore the policy implementation of policy makers in TB program of the Medan city. Further excavated the role of NGOS and engaged in TB in the program of TB.

Location: This research was conducted in Medan because Medan is the capital city of North Sumatra province with the problem of TB which is quite complex from the heterogeneous population aspects, health services both government and private, as well as TB programs that conducted by NGOS.

Informants: Informant of this research: Head of Health service, head of P2P section, Head of Infectious diseases section as a manager of TB policy and NGO engaged in the response of TB KNCV, JKM, Aisiyah, Buddha She Chi.

Results

Implementation of TB Countermeasures program in Medan Health office: DOTS strategy is a national strategy that has been set in the TB countermeasures program, data shows that all Puskesmas in the city of Medan have been executing the DOTS strategy. However, the difficult practice to implement this strategy is an independent practitioner (DPM) and a private hospital. There are pros and cons between government programs and private physician practices in this regard, such as informant:

“Doctors of independent practice still uphold their diagnosis with photo Thorax/Roentgen While the government is with sputum. In the case of government treatment with the DOTS system and free but DPM with paid. When the case comes first to DPM especially with the low-economic social-then visit only a few times, Karen is unable to pay, it will be released. Patients who after this drug will inevitably spread the case to the surrounding environment so that the incidence of TB cases is still increasing and more severe when severe then the case of visiting health care services and there are those times it has suffered TB RO.

However, funding regulation for TB countermeasures has been aimed at increasing the role of the Government by having compiled the regional Action Plan (RAD) of TB in Medan city which will be strengthened by the legal status to be the rule of Mayor (PERWAL) . In RAD, it has been determined that the case of TB is not only addressed by the Department of Health but must be addressed with cross-sector related, private, educational institutions synergize and set targets for access, executor and funding sources so that when donor assistance has been reduced, the government burden is ready to respond.

Coordination and synergy of the program has begun to be improved both among government health services and DPM where it is currently in case of notification of cases in accordance with Permenkes No 67 year 2016 on the response of TB that each physician must make a report (A mandatory notification) of tuberculosis. It has been done training activities of MN-TB based Android
in Medan City, is expected through this network of TB cases found at DPM can be immediately reported in the Puskesmas in the working area and expected through this network no longer exists Loos to follow TB cases.

Communication process in the implementation of TB countermeasures program in Medan:
Communication process between health centers with hospitals, clinics and DPM who do not want to report a case of TB to Puskesmas even though the notification rules have been in the invitation. To overcome the loss to follow then inevitably the deputy Supervisor (Wasor) TB must fetch TB reports by visiting one by one health facilities, because non-governmental health services consider them not required to report a phrase:

“We have to pick up reports to non-governmental health facilities because they do not feel obliged to report TB cases to the Puskesmas”

Related to communication between hospital Adam Malik as a reference to TB case with Puskesmas and vice versa from Puskesmas to hospital Adam Malik has not run smoothly which resulted in case of missing or drop out. This can occur in the case of TB RO which after TB RO patients submitted to the treatment Puskesmas such as the expression of an informant of Puskesmas officers:

“TB patients who have undergone treatment for approximately 2 weeks, do not want to go to the Puskesmas anymore because of the severe side effects of the drug so the family decides to bring medication to DPM and feel it is getting healthier.”

Family patients with emotional tone say: “Why we have a cure to the Puskesmas when making the body feel sick, we come medicated because it wants to be healthy.”

This Data indicates that the communication between the officers and patients is not maximized where the officers do not have to support the patient to bring to the HOSPITAL Adam Malik because the SOP has been explained that if the problem is experiencing the drug side effects immediately Consultation with the clinical expert team (TAK). “The drug given by the officer is the drug from Puskesmas”

Meanwhile, it is known that there is no TB RO drug from Puskesmas. The above Data indicatess that both vertical and horizontal communication have not been well-done due to the role of the individual and the ability of the intertiller in accordance with the SOP, it is as the same as the results of this study.9

Community and NGO participation in TB countermeasures program

Like the following informant phrases: “JKM starts from the preparation of community mobilization, forming a cadre then there TOT. At the same time we strengthen the community leaders and religious figures so that there is special training for religious leaders there are special training for community leaders. Then there is also training for PMO of the patient’s family.”

The results of previous research conducted by9,10 showed that the discovery of cases in NGOS and Puskesmas officials still scramble because of incentives given to find different cases between NGOS. Bambang’s research in Bantul Regency declares the discovery of cases by officials of formalities and administrations.

As for the training of community leaders according to the informant that focuses on advocacy as said the informant:

“Advocacy is done in order to understand TB at once will be the lower-level advocate. From village and district level to district and Regency and provincial level”

Aisyiyah NGO: This organization has been involved in the response of TB gained funding, training and other supporting facilities. The organization is engaged in health but not in the TB program is called to suspend TB because it has facilities and human resources such as the following informant phrases:

“Organization: Aisyiyah, formed from Aisyiyah Center with the establishment of TB CARE Community Team 2009.”

Gain trust from the government through the GF program participating in TB program. This Program was named Community TB HIV Care Aisyah North Sumatera. Initially the main task in response to TB is like the following informant phrases:

“Looking for suspect TB and these cadres bring TB patients to the Puskesmas. Aisyiyah cadres exist in each sub-district and Kelurahan in Medan. In addition to searching for Suspeck, the Institute also conducts
training in drug monitoring (PMO). The essence of the program is that the patient does not end up with 6 months of medication.” Almost the same study conducted

Nevertheless, since the last 2 years, this foundation has begun to handle the TB RO called the Supporter Patient (PS), namely

“The healed TB patients were used as supporters for other TB patients. Currently, this foundation already has 3 PS, each of the PS accompanying 3 patients. In addition in the year 2015, this Foundation has also set up a stopover house to accommodate TB RO patients who should get treatment in the RS referral Adam Malik.”

Research results of Erna M DKK In 2015 indicates that in the case of the treatment of TB RO still found a drug that has expired, after confirmed with the officer that the year 2014-2015 is indeed too much drug in the drop, but already Stated at that time all drugs should be withdrawn, apparently there are also circulating.

LSM Buddha Tse Chi: The participation of NGOS in the TB program actually originated from the movement of this Organization in the field of social and health that has been under the center of the institution in cataract surgery. Subsequently this organization since 2015 began to move in the field of TB, feel called to handle TB cases because of the high number of TB in Indonesia.

“Since Indonesia is independent we already handle TB but why until now still many of the case, because people can not be overcome, people are uncomfortable to come to the Puskesmas, no lung doctor, not friendly, if come to a specialist doctor initially can but Because expensive finally broke down the drug.”

Based on the facts in the field, the organization coordinates with the city health office by expressing the intention to participate in TB countermeasures Program, no intention to bring religion, and not restrict an area. The head of Medan Health office that welcomes the idea of the foundation as below:

“The most difficult to enter the health workers are the Chinese, especially the ones in the area like Rame.”

For this, the foundation began to be interested in the prevention of TB by establishing TB clinic in the like crowded Puskesmas. But if further analyzed the informant to say the embryos in the handling of TB is actually already a few decades ago : “Cooperation with NGOS and PPTI, but this activity is not the way, because there is no doctor Who wants to practice guard in place. Research on Syarifah need to engage religious figures in TB response in Medan.”

Conclusion

1. Implementation of TB countermeasures in the city health office is already referring to the national strategy but has not been able to run the maximum, because not all health facilities, especially non-extrapding health facilities, private clinics and DPM complies with Established strategies.
2. The process of communication in the implementation of TB countermeasures program has not been maximally both vertical and horizontal communication impacting TB’s tougher response.
3. Already many NGOS are petrified in TB countermeasures program but the invention of the case is not maximal, TB insides, TB RO cases, TB DM, TB HIV and children are still increasing and need complex countermeasures.
4. The elimination of TB will be achieved if the control of TB is not only implemented by the Health office but is addressed along with other related sectors and refers to the regulation of the mayor of Medan No. 85 year 2017 on the regional action plan Response of TB City Medan year 2017-2022 (Medan City News year 2017 number 75).

Acknowledgement: Researchers thanked the University of North Sumatra who have given funds through the PNBP of North Sumatera University year 2017. Researchers are also grateful to the Jakarta City Health Office and the provincial Health office of North Sumatra which has provided secondary data and helped expedite the research process. Also to all informants who have been willing to provide data in accordance with the facts for the needs of this research.

Behavior of Tuberculosis Pulmonary Disease Prevention (Tb Paru) South Sulawesi

Herman

Health Polytechnic Ministry of Health of Makassar, Edi Sukamto (Health Polytechnic Ministry of Health of East Kalimantan), Syahida Djasang (Health Polytechnic Ministry of Health of Makassar)

Abstract

Diseases Tb. Lung is caused by the bacterium *Mycobacterium tuberculosis*, with the incidence rate in Indonesia ranks third after China and India and attacks all age groups of society. The purpose of this research is to know the behavior of disease prevention Tb. Lungs of Makassar City and the influence of disease prevention knowledge Tb. Lung from the aspect of controlling the source of disease Tb. Lungs, aspects Lung, and the aspect of increased endurance against the disease Tb. Lungs. The type of research is *analytic survey*. The study population is the people who live in the area of Makassar City. Samples of 335 people obtained by *multi stage sampling*. Data analysis was performed by simple regression test and multiple regression. Results of research that the behavior of disease prevention targets Tb. The lungs of Makassar City are generally good category. Lung effect on disease prevention behavior Tb. Lungs of Makassar City. Lung effect on disease prevention behavior Tb. Lungs of Makassar City r. Lung effect on disease prevention behavior Tb. Lungs of Makassar City. The lungs of the people of Makassar are the knowledge of the source of the disease Tb. Lungs.

**Keywords:** Knowledge, Control, Disease Sources, Agent Disease, Body Resistance and Behavior.

Introduction

The Commitment of the Government in order to decrease the case of Tb in Indonesia, it has been issued Decree of the Minister of Health of the Republic of Indonesia Number 364/Menkes/SK/V/2009 About TB Control Guidelines referring to *Directly Observed Treatment Short-course* (DOTS) strategy and implemented in all parts of Indonesia. DOTS strategy consists of 5 key components, namely: 1) Political commitment, with improvement and sustainability of funding. 2) The discovery of cases through microscopic sputum examination of assured quality. 3) Standard treatment, with supervision and support for patients. 4) Effective management and availability of OAT systems. 5) A recording and reporting monitoring system capable of assessing patient treatment outcomes and program performance. But issue Tb. Lung in Indonesia is still a serious problem because the case is still high and attacking all age groups.\(^1\) (Ministry of Health RI, Year 2015).

Case incidence Tb. Lung with BTA (+) in South Sulawesi Province (2013) reported as many as 8,902 cases found in male type as much as 5,259 cases (59.08%) and female gender 3,643 (40.92%). Bina field Disease Prevention and Environmental Health Makassar City Health Office (2014), the discovery rate of new cases of TB BTA (+) in 2013 as much as 72.44% (found 1,811 people from 2,500 mark), this number increased from 2012 with a number of 1,324 sufferers of 1,641 targets. When compared to the 2013 target of 70% then the achievement rate exceeds the target with the percentage of achievement of 72.44%.\(^2\) (Health Office Makassar, Health Profile Year 2014).

The results of research related to the interaction mentioned above are Media Y (2011) reported that the community of Padang Panjang City has a knowledge level about Tb is relatively good, but as a still assume that the cause of TB lung disease is related to things that ghiaib/magic and because of heredity; the public perception that the disease is a common cough, so that it relates to people’s lack of concern about the effects of pulmonary TB disease; and the behavior and awareness of some people for sputum examination and use of health service facilities is lacking. Untuk reduce the incidence
rate of disease Tb. Lung can be done by controlling the health behavior of the community. Noatmodjo\(^3\), states that *health behavior* is a person’s response to stimuli or objects related to healthy-sickness, illness, and factors affecting health-sickness (health) such as environment, food, drink and service health. In other words, health behavior is any activity or activity of an *observable* or *unobservable* person related to the maintenance and improvement of health.

Based on the above explanation, the purpose to be achieved from this research is the description of behavior about prevention of disease Tb. Lungs of the people of Makassar, knowledge of disease source control, control agent *penyakit*, and increased endurance of the patient against disease prevention behavior Tb. Lung and variable knowledge of dominant influence to behavior of disease prevention tb. Lungs of Makassar City.

**Research Method**

Based on the research design that will be used then the type of research is the *analytic survey*. Population referred to in this study is all masomism berdomisisli in the area of Makassar City either healthy or sick or suffering from disease Tb. Lung that has been diagnosed by the doctor. Samples referred to in this study are some of the people who have suffered from TB disease. Lung and who do not suffer Tb. Lung who is domiciled in the working area Pusekesmas Makassar as many as 335 people.

Sampling in this research is with *multi stage sampling technique* that is a way of sampling done by going through stages. The technique as follows:

a. The first stage, using all the existing districts within the city of Makassar are as many as 14 districts

b. The second stage, determining the number of samples per kecamatan by way of comparison of the number of cases Tb. lung to total population of Tb. pulmonary tuberculosis (+) multiplied by the number of samples to be studied (335 people).

c. The third stage, from the sub-district determined Puskesmas which has the number of cases number Tb. the highest lung as a place of data collection.

In this study, the variables to be analyzed consist of the dependent variable that is *tb disease prevention behavior. Lungs* and independent variables *i.e. Knowledge of disease source control Tb. Lung, Knowledge of disease agent control Tb. Lung and Knowledge of increased endurance against disease Tb. Lungs.*

Analysis technique in this research, used is simple regression test and double regression at error rate equal to 5%.
Research Result

Univariate Analysis

Figure 1 shows that out of 335 respondents in Makassar City who have Behavior of Communicable Disease Prevention Tb. Lung category less as much as 6 people (1.79%); sufficient category as many as 114 people (34.03%); good category as many as 181 people (54.02%) and very good category as many as 34 people (10.14%). Based on these data it can be concluded that most respondents have TB disease prevention behavior. Lung category GOOD.

Multivariate Analysis: This analysis aims to determine the influence of variables Penge Penguan Peng Sumber Peng yaki t, Knowledge Controller variables i a n Agent Diseases and knowledge variables Improved endurance against the variable Behavior Prevention Infectious Diseases Tb. Table 5. Show that the Influence of Knowledge of Disease Control Control on Behavioral Prevention Behavior Tb. Lung \( r = 0.948 \), Effect of Knowledge of Agent Control of Disease on Behavioral Disease Prevention Tb. Lung \( r = 0.867 \), and Knowledge of Increased Body Resistance against Disease Prevention Behavior Tb. Lung \( r = 0.900 \). Based on the coefficient of the correlation, it can be concluded that the knowledge of disease prevention tb. lungs that have the greatest influence influence are Knowledge of Disease Control, followed by Knowledge of Improved Body Resistance, and the last Knowledge of Agent Disease Control.

**Discussion**

1. **Disease Prevention Behavior Tb.**

   Figure 1 shows that out of 335 respondents in Makassar City who have Behavior of Communicable Disease Prevention Tb. Lung category less as much as 6 people (1.8%); sufficient category as many as 114 people (34.0%); good category as many as 181 people (54.0%) and good category as many as 181 people (54.0%). Based on these data it can be concluded that most respondents have TB disease prevention behavior. Lung category GOOD.

   Community behavior referred to in this research is to prevent the transmission of germs disease Tb. Lung is by closing the mouth with tissui or handkerchief at the time of coughing or sneezing, seeking treatment to doctors, clinics, Puskesmas if sick, eradicate germs cause disease Tb. Lung by cleaning the floor of the house with antibacterial every day, lighting the room home with enough eye rays, increase endurance by way of exercise at least 3 times a week, adequate rest at least 8 hours every day, eat a balanced diet, manage stress with well, do not consume alcoholic beverages, avoid drugs, avoid cigarettes and so on.\(^5^6\)

2. **Influence of Knowledge of Disease Control Control Tb.**

   Based on the results of research on tab 2 above it was concluded that the control knowledge s umber disease Tb. Lung effect on disease prevention behavior Tb. Lungs in the people of Makassar.

3. **Influence Knowledge Control Agent Diseases Tb.**

   The result of research tab 3 shows that Knowledge Control Agent Penyaki Tb. The lung has a disproportionate attitude to the TB Disease Prevention Behavior Tb. Lungs of Makassar City.Lungs that are known by the people of Makassar so that people can prevent transmission of TB disease.Lungs.

4. **Influence of Knowledge Increased Body Resistance Diseases Tb.**

   Results of the study showed that tab 4 Pen Knowledge ingkatan Body Endurance berpengaru h against Tb Disease Prevention Behavior. Lungs of Makassar City.Knowledge of increasing body endurance is an effort to increase body resistance against disease Tb.Lung is known by the people of Makassar so that people can prevent the transmitters of disease Tb.Lungs.

   Herda A\(^4\) there is a significant relationship between the level of knowledge with the compliance of patients with pulmonary TB in Pekakesmas Pekauman Banjarmasin, South Kalimantan . This means that the better the level of knowledge of the patient to the disease, the mode of transmission and treatment of TB Lung will be the better the compliance, and vice versa. Lung Glugur community of Medan.This means that the higher the level of knowledge of drug consumption the more obedient the patient in drug consumption or vice versa.

**Conclusion**

Based on the results of research and discussion on this study, it can be concluded that g behavior prevention behavior of TB Tb. The lungs of the people of Makassar are generally good category, knowledge of disease source control Tb. Lung effect on disease prevention behavior Tb. Lung of Makassar City, knowledge of disease agent control Tb. Lung effect on disease prevention behavior Tb. Lung of Makassa city r, knowledge of body resistance against disease Tb. Lung effect on disease prevention behavior Tb. Lungs of Makassar City, a variable that is very influential on disease prevention behavior Tb. The lungs of the people of Makassar City are the knowledge of controlling the disease source Tb. Lung, further knowledge of increased body resistance against disease Tb . Lung, and finally the knowledge of agent disease control Tb . Lungs .

Children’s Nutrition Status 7-12 Months Based on Age, Education and Job of their Mother in South Sulawesi

Hastuti¹, Hadju Veni², Citrakesumasari², Maddeppungeng Martira³, Tanziha Ikeu⁴, Abdullah Tahir²

¹Doctoral Student in Public Health, Hasanuddin University, Indonesia, ¹Senior Lecture Departement of Nursing, Anging Mammiri Nursing of Diploma, Makassar, ²Faculty of Public Health, Hasanuddin University, Indonesia, ³Child Departement, Wahidin Sudirohusodo Hospital, ⁴Department of Comunity Nutrition, Bogor Agricultural University

Abstract

The problem of malnutrition and malnutrition is one of the main health problems faced by developing countries including Indonesia. The incidence of cases of malnutrition is still very high, especially in South Sulawesi, although it is known until now that there are very many negative effects caused by malnutrition.

Purpose: Knowing the nutritional status description of children aged 7-12 months based on age, education and employment of mothers in Jeneponto Regency.

Method: This study uses a quantitative descriptive method with a cross-sectional design approach. Sampling with a total sampling of 131 people. The study was conducted in Jeneponto Regency, South Sulawesi.

Results: Based on the BB/U index, mothers aged 30-34 years had children with poor nutritional status of 1 person (2.7%) but the BB/TB index of mothers aged 25-29 years had children with normal nutritional status as many as 32 people (94.1%). Based on the BB/U index, mothers with elementary school education have children with good nutritional status as many as 32 people (97%), and educated mothers who do not complete elementary school have children with poor nutritional status of 1 person (5%). Based on the BB/U index, mothers who did not work had children with good nutritional status as many as 100 (90.9%) but based on the index BB/TB mothers who did not work had children with very thin nutritional status of 2 people (1.8%)

Conclusion: Mothers aged 30-34 years and mothers with education who did not complete elementary school had children with poor nutritional status, mothers who did not work had children with very thin nutritional status.

Keywords: Nutritional status of children, age, education, mother’s work.

Introduction

Malnutrition in children can cause several negative effects such as slow growth, prone to disease, decreased level of intelligence, and mental disruption. So that serious malnutrition can ultimately cause death¹. According to WHO, 54% of the causes of infant and toddler deaths are due to poor child nutrition. The risk of dying from a child who is malnourished is 13 times greater than a normal child². In general, the proportion of malnutrition and undernourishment in toddlers in terms of body weight according to age (BB/U) is less and worse nutrition 17.7%, while the percentage of nutritional status in South Sulawesi Province has decreased compared to 2013 even though it is still higher than national standards³.

In South Sulawesi there are four districts/cities with the most cases including Bone (16 cases), Pinrang (15 cases), Wajo (11 cases) and Jeneponto (8 cases) (Health Profile of South Sulawesi Province in 2008). In Jeneponto Regency in 2014 it was found that the percentage of children under five weighed 82.08% of the 36,127 toddlers available. Of the 29,652 toddlers
weighed found toddlers with good nutrition as many as 28,625 toddlers (97.64%), malnutrition as many as 687 toddlers (2.32%) and malnutrition as many as 16 people (0.04%)⁴.

Efforts to improve infant nutrition are based on that malnutrition at less than 2 years of age will have an impact on decreasing physical growth, brain development, intelligence, and productivity, and this impact is largely irreparable⁵. Micronutrients are needed for brain development during gestation and infancy. This is an important period for brain formation, laying the foundation for the development of cognitive, motor and socio-emotional skills during childhood and adulthood⁶.

Based on this phenomenon, the purpose of this study was to determine the nutritional status description of children aged 7-12 months based on anthropometric index BB/U, TB/U, and BB/TB in Bontoramba District and Binamu District, Jeneponto Regency.

**Materials and Method**

The design of this study used a quantitative descriptive method to determine the description of the nutritional status of children aged 7-12 months based on a cross-sectional approach. The total sample was 131 people from the Bontoramba and Binamu Subdistricts of Jeneponto Regency. The sampling technique is the total sampling method. Data on maternal and child characteristics were collected through direct interviews using questionnaires, while children’s nutritional status was determined based on anthropometric index (Department of Health, 2011), by measuring body weight according to age (body/age), height/body length by age (TB/U) and body weight according to height (BB/TB). To measure body weight, digital baby scales are used, while length boards are used to measure body length.

In table 3, it appears that the nutritional status of children is based on the BB/U index, so mothers with elementary school education have children with good nutritional status as many as 32 people (97%) and educated mothers do not complete primary school with 1 poor child (5%). Based on the TB/U index, the mothers who graduated from high school had 25 children with normal nutritional status (83.3%) and mothers who graduated from elementary school had 13 stunting children (39.4%). Based on the BB/TB index, mothers with elementary school education had children with normal nutritional status as many as 31 people (93.9%) and educated mothers who did not complete elementary school had children with very thin nutritional status of 1 person (5%).

Source: Primer Data, 2018

Based on the index BB/TB, mothers who do not work have children with normal nutritional status as many as 99 people (90%) and very thin nutritional status of 2 people (1.8%).

**Discussion**

**Characteristics of Respondents:** A person’s health status is influenced by four factors, namely behavior, health services, genetics and environment\(^7\). One of the things related to the environment is culture. Cultural factors influence a person’s health status according to the theory of nursing known as Sunrise Model\(^8\).

In this study the age of most children at the age of 7 months was 35 people (26.7%) and the least at age 11 months were 15 people (11.5%). This is consistent with a study that produces findings that age is one of the things that affects children’s development\(^9\).

The highest maternal age at the age of 30-34 as many as 37 people (28.2%) and the least at age 15-19 years as many as 13 people (9.9%).

The highest maternal education in the low education group was 33 elementary school and junior high school graduates (25.2%) and the lowest was 15 (11.4%) higher education (Diploma).

**Child Nutrition Status based on Mother’s age:**
In reality there are still many women who give birth at <20 years and > 35 years with normal nutritional status of children. This is due to the seriousness of the mother in caring for, caring for and raising her child. Adequate attitudes and knowledge of child nutrition will have an impact on the pattern of feeding given to children under five so that it influences the nutritional status of children under five.\(^10\)

Short child conditions can be prevented but cannot be cured so that improvement efforts are more emphasized on prevention efforts. The improvement efforts that have been made emphasize the identification and rehabilitation of children with severe malnutrition. Whereas the recent improvement efforts have been emphasized on prevention efforts through a combination of aspects of nutrition, disease and treatment/treatment\(^11\).

**Child Nutrition Status based on mother’s education:** According to the researchers’ assumptions, the influence of education on the nutritional status of children is due to the fact that the education in the research location is quite good but the education that
respondents have is still not practiced in everyday life. The higher the level of education, knowledge, skills there is the possibility that the better the level of family food security, the better the care of children, and the more families use existing health services and vice versa 12.

Someone who just graduated from elementary school is not necessarily less able to arrange foods that meet nutritional requirements than other people with high education. Because even if the education is low if the person is diligent in listening to nutrition counseling it is not impossible that his nutritional knowledge will be better. It’s just that it must still be considered that the level of education factors also determine whether or not someone is easy to absorb and understand the knowledge of nutrition they obtain 13.

A study also showed that there was no relationship between maternal education level (p = 0.646) and family income (p = 1,000) with stunting in toddlers 14. Although it is understood that increasing the ability of mothers through health education can be done to maximize growth and development of children.

One alternative with health education using the modeling approach that has been carried out by nurses is effective in increasing knowledge, practical ability, mother’s confidence in breastfeeding and stimulating babies, which in turn can optimize infant growth15. It was concluded that increasing maternal empowerment through health education improves baby growth 16.

Conclusion
As a health worker especially focusing on public health, it is very wise to prioritize promotive and preventive efforts without ignoring curative and rehabilitative efforts.

Abstract

Objective: This research aims to determine the social determinant factor related to the life quality of pregnant women in Polewali Mandar district.

Method: The research was conducted in July to December 2018 using a cross sectional study design. Sampling by sampling proportional random sampling with 399 peoples distributed in 3 districts and it is analyzed with multivariate logistic regression by backward elimination method.

Results: Mother aged 20-35 years (Adjusted Odds Ratio (AOR): 1.75 [1.15-2.66]), income over or equal to Regional Minimum Wage (Rp. 2.017.780) (AOR: 1.66 [1.01-2.73]) adequate information access (AOR): 1.89 [1.22-2.94]), domiciled in urban areas (AOR: 1.95 [1.27-2.99]) and those who have health insurance (AOR: 2.42 [1.417-4.126]) tend to have a better quality of life.

Conclusion: Life quality of pregnant women is influenced by maternal age, income, access to information, domicile and health costs. Therefore, women should be pregnant at an age that is not at risk and to maintain and improve the life quality of pregnant women, it is very important for pregnant women to be given adequate access to information, a good socio-economic environment and health insurance. This is a responsibility of family and needs to be supported by government policy.

Keywords: Social determinant, quality of life, pregnant mother, access to information.

Introduction

In the world, WHO estimates that there are 303,000 women died due to pregnancy causes, 2.7 million babies die during first 28 days of life. This condition is associated with a low-ANC globally; only 64% of women receive four or more antenatal (prenatal) treatments during their pregnancy. Though this ANC can reduce and prevent high maternal mortality rates. Therefore, we need quality health care for pregnant women. Pregnancy care requires equal and affordable health resources, but in reality it is not evenly distributed and not affordable.

The life quality of pregnant women is related to education, income, but based on data from the Central Statistics Agency of West Sulawesi in 2015 shows the low level of education as seen from the number of school dropouts aged 16-18 or not yet school 36%, and dependency is still high (56.74%). The life quality of

mothers and children is largely determined by early and comprehensive efforts. Health-related quality of life (HRQOL) has become increasingly recognized as an important result of medical care over the past two decades. In this research, the quality of life includes relativity and it is influenced by various factors such as expectations, life attitudes, physical, psychological and social effects, adequate and appropriate care, sufficient information, accessing health facilities and equal adequacy sources.

Until now, maternal mortality is still high, it is estimated 830 women died everyday due to complications of pregnancy or childbirth around the world. As much 99% of all maternal deaths occur in developing countries. Almost all of these deaths are related to low resources, and most can be prevented. Inequality as occur in West Sulawesi based on HDI in 2017, 64.3 ranked 31 after West Papua, Papua and NTT. While, the lowest HDI by district is Polewali Mandar are 62.35. This condition raises problems as a social determinant of health, especially for maternal and child health. As a result the maternal mortality rate is still high. Several studies related to the life quality of pregnant women have been conducted, but with different determinant and especially in Indonesia it is rarely done. This research was aimed to determine the health social determinants associated with the life quality of pregnant mother in Polewali Mandar district.

**Method**

This research was conducted in July to December 2018 by using a cross sectional study design. Sampling by cluster proportional random sampling. The sample was 399 pregnant mother distributed in 3 sub-districts in Polewali Mandar, namely Polewali, Pambusuang, Bulo. Data analysis uses multivariate logistic regression.

**Result**

Table 1 shows the characteristics of respondents. Most respondents at not risk on ages (20-35 years) (76.7%), more high school education (28.6%), generally they were not working or only housewives by 88.0. Furthermore, the dominant ethnic is Mandar (75.9%) and in general pregnant women do not have anemia (73.9%). The quality of pregnant mother tends to be almost equal in number between those who have high and low quality of life.

### Discussion

The problem of physical and psychological health for pregnant mother, childbirth, post-partum and breastfeeding were included as risks in pregnancy and childbirth that may arise and have a significant effect on the life quality of mothers. The social determinant of health is a condition in which people live and work, and this condition affects their chances to live in a healthy life. In March 2005, WHO established the Commission on Social Determinants of Health. The commission records determinants such as child development, sex, urbanization, employment, health systems, measurement and evidence, globalization, and social exclusion, as centers for addressing health inequalities as prevail in the world. Most respondents give birth at age 20-35 years which is very good for mother. Therefore, the age of pregnant mother determinetheir quality of life.

WHO emphasize to avoid four too in a pregnancy namely too young (pregnancy < 20 years), too old (pregnancy > 35 years), too many children (over 4) and too close (pregnancy distance < 2 years). As many 78 of 124 of women who died were very young, less than 25 years old. Furthermore, 26 of them were aged between 16 and 20 years and nearly 40% of women died during their first pregnancy and another 38% during the second or third pregnancy. At the other end of the spectrum are older women with a history of several pregnancies. In addition being responsible for their daily household, most of women die are laborers or farming workers in other countries. Some of them are migrant workers and even work until the last month of their pregnancy. Economically, employment is able to empower women to take responsibility for their health and facilitate access to health facilities. Therefore, income as comes from mother can affect the life quality of pregnant women. The results of research indicate that most pregnant women do not work and only as housewives. As a result, they do not have authority in obtaining health services, so the quality of life is below as expected. They with high levels of education will increase maternal knowledge, increase self-confidence and also increase awareness related with the use of health resources in the community for maternal health. However, it is found different in this study in which education does not affect the life quality of pregnant women. It can occur due to other important factors.

Health education media are all means or efforts to show messages or information to be conveyed by communicators, both print media, electronic and outdoor media, so that the target can increase their knowledge and ultimately it is expected can change their behavior towards positive health. One cause of efforts to control anemia in pregnancy must begin by providing health education for pregnant women and their partners, which reinforces mother statements during antenatal care. As results of distributing leaflet media as information can increases the understanding of pregnant women about high-risk pregnancies such as obstetric complications, bleeding and pre eclampsia. Therefore, it is necessary to develop promotional media to increase high-risk knowledge. Coupled with the development of social media is very useful to change health behavior. Some pregnant mother states that general complaint of pregnancy as a barrier to accessing health information. Several complaints that are often noted by respondents such as nausea and vomiting that can disrupt their daily routine activities. Some pregnant women also state that fatigue, and sleep problems and followed by lethargy throughout the day, so they do not have time to access information. Similar results were also found in this research, high media access tend to be a good quality of life than opposite.

Life quality of pregnant women in urban areas is better than rural areas. Generally, the rural women are considered to have poor health and higher mortality. This is because rural areas have poor access to perinatal care. In general, health resources are concentrated in...
densely-populated urban areas, while rural women tend to suffer from both their health and lifestyle. As result of Nasem’s (2011) research found that role limitations due to physical problems, perceptions of general health and also due to emotional problems had a significantly lower score in rural women compared to urban women. In this research, domicile has relation with the quality of life, mothers who live in remote areas often experience severe vulnerability. The availability and utilization of reproductive and child health services varies widely from country to country. It is important to understand the extent of poor and non-poor gaps in urban areas across the country apart from their urban poverty.

The level of public policy and financing, according to Egan et al. (2008) that social protection mechanisms and national health insurance schemes targeting marginalized populations, so that all groups can be reached. If a health system develops organically without government supervision, they can even provide services or support facilities for urban health services in remote rural areas. In this research, they had health financing both independently and those receiving aid. Also, in this research the available financing is related to quality of life. For the life quality of mothers to be better, it is expected to improve prenatal care, one of them by considering insurance factors that still need to be improved, as happened to low-income African-American women. It is intended to reduce limitations in obtaining health services.

**Conclusion**

As result and discussion mentioned earlier, it can be concluded that the life quality of pregnant women is influenced by maternal age, income, access to information, domicile and health costs. Therefore, should be the women to become pregnant at not risk age (20-35 years) and to maintain and improve the life quality of pregnant women, it is very important for pregnant women to be given adequate access to information, a good socio-economic environment and health insurance. This is a family responsibility and needs to be supported by government policy.

Implementation of Partnership between Midwives and Traditional Birth Attendants in Kotabaru District

Anggrita Sari¹, Adriana Palimbo¹,³, Angga Irawan¹, Sukamto², Isda Herlina⁴

¹Lecturer of Sari Mulia University, Banjarmasin, Indonesia, ²Senior Staff South Kalimantan Provincial Health Office, Banjarmasin, ³Student Doctoral of Public Health, Hasanuddin University, Makassar, Indonesia, ⁴Lecturer Public Health Center of Berangas, Kotabaru

Abstract

Background: Maternal and infant mortality ratio, in the Kota Baru high enough, one of them because of labor that much by the Traditional Birth Attendants (TBA). Midwives offer fewer deliveries and coverage has not reached the 95% target and fewer midwives than TBA.

Objectives: This study aims to know the implementation of the partnership program between midwives and traditional birth attendants in Kotabaru District.

Method: This study use da qualitative approach to the design of case studies, with purposive sampling technique. The number of the main informant as much as 3 people and informant triangulation 6 people. This research was conducted for 1 month consists of content analysis and data processing.

Results: The results show human resources are still lacking, inadequate facilities and funding partnership that is often paid late. Midwives and TBA is not made a written agreement, and over the role of the TBA will not be in accordance with regulations. The support from the village head and community leader that there is no information and the number of TBA partnering is still less.

Conclusion: Our findings conclude the importance of cross-program coordination and involvement in the District Health Office and across sectors at the District Government level. This participation is urgently needed from local stakeholders playing a major role in the successful implementation of maternal and child health programs.

Keywords: Midwives; traditional birth attendants; implementation of partnerships.

Introduction

Traditional Birth Attendant’s (TBAs), "dukun beranak" in Indonesia, has been around for a long time, and are still practicing labor and childbirth, where most deliveries occur at home and are not assisted by skill birth attendant such as midwives. This situation increases the risk of death for the mother and her baby.¹ TBA is a trusted employee in the family and community in all matters relating to women’s reproductive problems and their work is obtained from generation to generation.² Indonesia, which has a variety of tribes, customs, and cultures in the community, they are considered capable of providing emotional comfort and security to mothers during pregnancy check-ups, assisting mothers and caring for their mothers and babies after birth for up to 40 days. TBA’s knowledge of pregnancy and birth is so lacking that if complications arise they are unable to overcome them even realize it.³ However, in addition to providing technical assistance, TBA also practices unsafe abortion and contraception at high risk and threatening the life of the pregnant woman.⁴

Trained TBAs are family TBAs who have received short training courses through the modern health care sector to improve their skills.⁵-⁶ So, starting in 2007, the government initiated a partnership program by village midwives and traditional birth attendants aimed at reducing maternal and child mortality and morbidity.⁷ This is because the traditional birth attendants do not have enough ability and knowledge to handle obstetric complications and emergencies (EMOC) that occur during
and after labor. Then, between midwives and doulas, they offer physical, emotional, and ongoing support while simultaneously encouraging patient autonomy. However, disagreements between them also occur from the Middlemiss (2015) study in the UK, differences in the role of doulas and midwives and identify potential for conflict if the role of doulas is misunderstood. Some experts have identified antagonistic attitudes towards doulas that create challenges for midwives, and lead to inter-professional conflicts in the dynamics between midwives and doulas. In Canada, this misconception, midwives and nurses fear that doulas will take over their roles and “grass” jobs.

Death that occurs in a hospital is a referral for labor handled by TBA. Furthermore, in some cases TBAs called on midwives when their mother’s condition was severe. At this time, there are 329 TBAs in Kotabaru District. Their presence is spread in 21 sub-districts. Meanwhile, only 220 midwives served. The coverage of childbirth assistance by health workers is 68.2% which has not increased and has not reached target 95% from 2014 to 2017. Based on this problem, this research is intended to know the implementation of the partnership program between midwives and traditional birth attendants in Kotabaru District.

Materials and Method
The study design uses an explorative qualitative approach. A total of 9 participants consisted of 3 village midwives and 6 triangulation informants. This study was conducted at the Berangas Public Health Center in Kotabaru District, South Kalimantan Province. The selection of research locations was taken through considerations, among others: First, coverage of delivery assistance by health workers in the last 3 years had not met the District target of 95%. Second, they have the highest number of traditional birth attendants from the number of midwives. And, third, their has an ongoing partnership program indicator.

Data collection uses in-depth interviews, and semi-structured interview guides. Processing data with content analysis. The aspects studied include the system of implementing partnerships, namely 1) Human Resources, funding, facilities, and data collection and mapping of traditional birth attendants; 2) Fostering of traditional birth attendants; Written Agreement for Midwives and TBA; and the role of TBA; and 3) Support of Village Heads and Community Leaders.

Results
Characteristics of Participants: Characteristics explained the main informants were 3 midwives in each village in the Puskesmas area. And the triangulation informant consisted of 6 people selected based on competency and representatives who were aware of the partnership program. (Table 1).

Sources: Health Office Report, 2017
Analysis of Results

Human Resources: From the interviews, information was obtained that 1 midwife served 2 to 3 villages at a time, because other villages that did not have midwives to cover all villages in their work area.

“...Serving three villages, meaning one village has three regions: Rampa Kapis, Batu Tunau and the Coal Mining Company.” (IU2) “Each place only has a few empty villages” (IU1, IU3)

Interview for six triangulation informants, we obtained a statement that three midwives were still not living in the village but were willing to come at any time if needed.

“...do not live in the village every day, if called they are willing” (KD, M) “there is no residence in Berangas village, but if anyone wants to give birth, they are ready to come” (BK)

Half of the midwives, residing in districts and villages, have areas with a geographical area that vary by a distance of 25-30 km.

“I live in urban areas for about 30 minutes from Berangas Village because my children go to school in there” (IU3) “...back and forth to the village, but don’t stay overnight” (BK, M)

Facilities and Infrastructure: They are complete but some people are giving birth at home even though they are near to Puskesmas. Most of them do not have adequate electricity and clear water. Access and difficult terrain is also an obstacle. It must be taken on foot. Medical equipment is very unnoticed, so they add unsafe ingredients to the baby’s umbilical cord.

Funding Source: Specific funds for partnerships do not exist. Companion funds come from Health Operational Assistance (BOK). The funds according to them are insufficient because they are considered too little. Disbursement of funds is not routine every month but has to wait a long time. This is related to TBA not making an Accountability Letter (SPJ) and there are no reports on labor and childbirth period referrals.

Written Agreement for Midwives and TBA: Information from two people revealed never made a written agreement. Only an oral request to call the midwife if there is something

“...nothing. we just talked..” (IU1, IU2)

Even they do not know the information about the partnership. the coordinating midwife stated that the agreement had not been made, it was still in the planning stage and had not been implemented.

“...up to now has not been implemented, because many other health programs take precedence” (BK)

TBA will call the midwife, if the baby has been born and delivery has been completed just to cut the baby’s umbilical cord.

“...because I am not allowed to cut the umbilical cord with a knife and concoctions” (DB)

Fostering of TBAs: Fostering shamans only through refreshing once a year and not all of them are invited. Midwives provide guidance on useful knowledge.

“Guidance and refreshing shamans have been carried out ..This year is only once, this year just once” (BK, TM)

Different from the 3 other triangulate informants who claimed to have never known and were never invited to refreshing the shaman.

“...never really meetings, try to be invited to meetings” (DB, DT, KD)

The Role of TBAs: Only one midwife informant who collaborated and applied the transfer of roles with TBAs.

“...if at my place, TBA tells me that pregnant women will give birth.. we usually join together to help until parturition “ (IU1) “they usually massage, make herbal concoctions, and midwives care.” (IU2)

Other different information TBAs are not partners, refuse cooperation and complete change of role. Only ever accidentally help together give birth.

“..Ever..she only held the abdomen, if part of the birth ..of course midwife”(IU3)”.Postpartum mothers still visited by midwives.” (BK, DB, M)

Midwives and TBAs seem to compete and look less harmonious. “...they (midwives) hold mother’s full ..if her signs of birth appear, you call me, I better go home” (DT)

it can be concluded that TBA not partnered still does not work together so that their role is still helping birth and the baby independently. In fact, they consider midwives to be powerful over patients.
Support of Village Heads and Community Leaders: Real support was provided from the village head and community leaders, but information about the partnership program was not yet optimal. During this time they made requests to give birth with midwives at the health center. Their support is in the form of regulations, financial assistance, supporting facilities, and invitations to midwives and traditional birth attendants to work together.

Discussions

Human Resources: Resources hold an important influence in the implementation of health care systems, especially partnerships. Resources include implementing personnel, infrastructure, service facilities, and funding. Midwives are competent health workers who are stationed and should reside 24 hours in the work area of the puskesmas. One of the factors that caused the community to choose to be assisted by a dukun is the distance between the community’s house and the dukun in the adjacent village and the TBA is always 24 hours. While many of the midwives reside in areas farthest from the reach of the community.

Facilities and Infrastructure: Based on research by Pramono & Sadewo (2012), that geographical conditions make it difficult to call midwives so that pregnant women choose TBA who are domiciled around their homes. To be able to realize the partnership, childbirth must be assisted by midwives, the government must be able to facilitate adequate health facilities and ensure the availability of quality midwives in each village and easy access to services. Therefore, through a Government Regulation states that childbirth can only be done outside health care facilities if difficult to reach by the community.

Funding Source: The availability of a budget plan for the Birth Waiting Home (RTK) which is a temporary residence for pregnant women who will give birth until the postpartum period including their babies and their companions (husband/family/cadre). For Childbirth Assurance, the Health Allocation Fund (DAK) can be used to cover: operational costs, health workers and companions in RTK or official travel from home to RTK or from RTK to health service facilities. Of the 10% of the Village Fund Allocation (ADD) used to work on maternity guarantee programs, including the Health Operational Assistance (BOK) fund for promotive and preventive activities and funding for midwife and TBA partnership funds

Written Agreement for Midwives and TBA: A written agreement between the midwife and the dukun is made together, in accordance with the implementation manual which contains information on the mechanism of reference for pregnant women, the referral mechanism for labor cases, the mechanism for distributing labor costs and the schedule for regular meetings. In line with the results of research by Rochmayanti, the partnership did not go according to expectations and targets despite having a memorandum of agreement between them.

Fostering of TBAs: TBAs are also not equipped with knowledge of detection of danger signs in pregnant women, maternity, postpartum and newborn babies as well as ways of referring midwifery. So the TBA only has some knowledge to carry out his partnership role. In fact, for the treatment of the umbilical cord, TBAs still use herbs that are not useful and not clean. In terms of benefits, some TBAs want to follow the call so that they don’t help their own deliveries anymore. But the appeal is not optimal so that they are still many who help deliveries unsafe.

Support of Village Heads and Community Leaders: According to the research of Budiono, et al. (2012), the support of community leaders is needed in collaboration between midwives and TBAs. This support includes socialization and direction through village meetings, mediation between midwives and TBAs and helps influence other parties such as posyandu cadres, village officials, and TBAs to take an active role in the partnership.

CONCLUSIONS

Some obstacles in implementing the partnership program are midwives and TBAs on the utilization of SBA and strengthening the role of each available resource. Funding management from Jamkesmas, DAK and other fund allocations needs to be maximized so that the community realizes that safe delivery with midwives and in health facilities is accompanied by TBAs, not obstacles or concerns from families and communities. Training of skilled TBAs needs to be considered as a refresher in the skills of their childbirth practices under the supervision of the District Health Office, the priority of areas that are difficult to reach.

Socio-Cultural Transformation through the Process of Internalizing Values in Early Childhood Education in Makassar City (An Ethnographic Study of Education)

Juwanita Sahid¹, Nurul Ilmi Idrus², Hamka Naping², Munsi Lampe²

¹Anthropology Doctoral Study Program, ²Senior Lecturers of Hasanuddin University, Makassar, Indonesia

Abstract

The global idea of child education was declared through the Educational For All movement for the first time in 1990 in Thailand and then confirmed in the Dakkar Declaration in 2000. The study aim to examine in depth about the children value for PAUD institutions and the process of socio-cultural transformation through the process of internalization value to children. This research uses an ethnographic approach. Primary data obtained through in-depth interviews, and participant observation. The data was analyzed through a qualitative analysis procedure. The results of the study that changes in the application of the curriculum not only on one “Islamic value” but also universal values through child-friendly learning nuances of “Islamic”. There are nine indicators of basic Islamic values that are structurally internalized to children involve the three pillars of education (parents, educational institutions and the community), synergy and influence each other. There are supporting and challenges factors in implementing Islamic values in TK WU.

Keywords: Early Childhood Education, Transformation, Islamic values, ethnography.

Introduction

The global idea of children’s education was declared through the Educational For All movement for the first time in 1990 in Thailand and then confirmed in the Dakkar Declaration in 2000. At the level of early childhood education (PAUD), the role of educational institutions is very strategic to internalized moral values, cultural values and nationality value to the children. Now education faces the substance of the problems of globalization and the transmission of external values in national life. The orientation of new values has alienated city people from their roots, original culture. In a good and respectable family, their children can become foolish and unexpected, because the determinant of formation is no longer only parents, but the media, peers, education and even markets¹. Socio-cultural changes to education when children no longer belong to families, but belong to educational institutions and the environment. The development of communication technology, has totally changed the world culture. Global culture is known as MC Donald² culture.

In 2011, the Indonesian government launched the PAUD program, one village one PAUD program. PAUD is an instrument to overcome the deficit in the role of family or parents in children’s education.

A number of other relevant studies explain the position of this research, for example Baki³ study; Badruddin⁴; Rosdiana⁵; Priwardhani⁶; Amini⁷ and a number of other studies on education are portrayed using the perspective of anthropology, sociology, education, religion and so on. Despite the diversity of studies on early childhood education have been conducted by a number of researchers referred to, but there has not been a specific look at the transformation process in early childhood education.

The study of this transformation is a very relevant study using the anthropological approach. Spindler⁸ believes education as a whole process of development and adaptation, leading to the process of cultural transmission, including skills, knowledge, attitudes, values and beliefs and certain behavioral patterns. The study of how the reality of education in PAUD institutions in its development has also undergone a transformation, to capture the meaning of reality in the world of education using the ethnography as a method also experiences development. The views of Laksono et al.⁹ agree with the view of George Sprindler, that the ethnography of education is not only the ethnography of schools, but more extensive studies.
This research tries to reveal the process of transformation of values in “Kindergarten of WU” and how the strategy, the process of achieving educational achievement becomes an interesting reality revealed using the “ethnographic” approach. This research takes place in Kindergarten of WU as an educational institution with strong Islamic characteristics and this research location is an effort of resilience to current developments.

The general objective of this research is to examine in depth the phenomenon of transformation or socio-cultural processes working through the process of internalization in early childhood. The specific objectives, as follows:

1. In-depth study of the value of children for PAUD institutions in WU Kindergarten.
2. In-depth study of the process of socio-cultural transformation through the process of internalization of value in children.

**Method**

This research uses an ethnographic approach\(^\text{10}\). The research involved informants such as parents of students (mothers), grandmothers, teachers, school principals, foundation administrators, and baby sisters. Primary data obtained through in-depth interviews, and participant observation\(^\text{11}\). Qualitative data analysis through three processes (1) data reduction, (2) categorization, (3) data interpretation.

**Results and Discussion**

**Child Friendly Learning Based on Islamic Values:** Efforts to integrate the curriculum based on Islamic values and eight PAUD Standards in Indonesia. The level of development achievement includes basic competencies and indicators of religious and moral values, motor, cognitive, language, socio emotional and arts. The character or personality of the child becomes the main achievement of education initiated by WU. Basic Competencies are elaborated in daily activities based on the Koran and Hadith.

There are four principles of child-friendly learning indicators initiated by kindergarden of WU, namely 1) teachers as learning media\(^\text{12}\), 2) learning and playing, 3) creating learning spaces, and 4) schools are part of the daily lives of students.

There are at least five important aspects of child-friendly learning in WU Kindergarten, namely:

a) The teacher knows how to teach children with diverse backgrounds and abilities.

b) All children have the right to learn, regardless of physical, intellectual, social, emotional, linguistic or other differences.

c) In a friendly learning environment, everyone shares a vision of how children should learn, work and play together.

d) They believe that education should be inclusive, fair and non-discriminatory, sensitive to all cultures, and relevant to children’s daily lives.

e) A friendly learning environment, teaches life skills and a healthy lifestyle, so students can use the information obtained to protect themselves from disease. There is no violence against children and physical punishment.

Meanwhile, child-friendly learning has significant benefits, such as benefits for children, teachers, parents and the community.

**Internalization of Islamic Values of Students in Kindergarten of WU**

The social structure internalized in TK WU is formulated in nine points, namely:

a) Children are able to memorize a minimum of 20-30 short suras to a maximum target of juz 30.

b) The child is able to read, write, count and communicate simply in Indonesian.

c) Children are equipped with Islamic moral character education.

d) Children have discipline and independence.

e) The education system is integrated between religious and general sciences.

f) Extracurricular activities vary, planned, directed and systematic.

g) Islamic environment, safe and pleasant.

h) Teachers and human Resources who are friendly, dedicated and professional.

i) Facilities and Infrastructure support teaching and learning process activities.
The Internalization of Islamic values to children is divided into three, namely the value of monotheism, morals, and worship which is carried out in the initial semester for three weeks, using the method of reciting surahs in the Koran and the Hadith with the aim of being a process of habituation to students.

In addition to the family, school and teachers are important determinants of internalizing Islamic values to children. Schools are the second most significant institution in shaping children’s personality.

Factors that determine the internalizing Islamic values in early childhood are the environment, such as friendship. In this context, children tend to be more independent, innovative and experience the process of sorting good and bad subjectively. Bun, 27 years old, one of the parents stated:

“... actually what determines good or bad children is not just parents. Teacher or the meaning of school and the environment of his friends is also a big influence. Now what needs to be understood is, which children are more dominantly affected. These parents must understand, in order to balance. For example, don’t let the kids be locked up in the house all the time, or be told to play outside or continue to take care of school. Just be balanced. But many conflict. “

Early childhood has unique characteristics, both physically, socially, morally and so on. According to Aisyah, et al13 characteristics of early childhood include; has a great curiosity, is a unique person, likes to fantasize and imagine, the most potential time to learn, shows egocentric attitude, has a short span of concentration power, as part of social beings. According to Bredekamp and Coople13, some aspects of early childhood development such as physical, social, emotional, and cognitive aspects of each other are closely related. Child development and learning are children’s interactions with various contexts through play. The Internalization process here takes place through the play process.

All of these characteristics are very clearly seen in kindergarten of WU. Thus, each stakeholder (parents, teachers and community) is very important to pay attention to the characteristics of this early age. According to Piaget14, children have 4 levels of cognitive development namely sensory motor stages (between 0-2 years), pre-concrete operations (between 2-7 years), concrete operations (between 7-11 years), and formal operations (11 years and above).

After school, the family has the main functions of socialization and education, namely as the first institution in children’s education that designates the role of the family in shaping the child’s personality, through social interaction within the family. Children learn patterns of behavior, attitudes, beliefs, ideals and values in society in the context of the development of their personality. Internalizing values in children is an important process in children’s development. The role of the school (teacher or educator), family (parents and siblings) and the friendship environment must have a positive connection.

Integrated Education: Parent and Teacher Involvement: The form of parental involvement in this research is relevant to the Overlapping Sphere of Influence theory proposed by Epstein.15 There are six types of parental involvement, namely (1) parenting education, (2) communication, (3) volunteering (4) learning at home, (5) making decisions and (6) in collaboration with the community.

Parental involvement in education is very much needed at every level of education especially in PAUD institutions, where children are just starting to form character through the development of moral, religious, social and emotional values.16 The development of these values can only be achieved maximally with the existence of continuity between education at home and at school, not apart from the participation of parents.16 Research Park et al17 that parental involvement has a contribution to the development of cognitive aspects of children and other aspects of development.

The activities of the school committee are to provide education to parents of students through tarbiyah every Friday to harmonize the Islamic values given to children so that parents make habituation routed in their respective homes.

Hand over the role of children’s education to other parties, such as care for the maid or baby sister, then formal education is fully delegated to the school. The role of parents is also often replaced by other family parties, both siblings and grandparents. Child care patterns tend to distance between parents and children, because parents are busy working.

PAUD and Internalization of Islamic Values: The education system developed by TK WU is the integration of formal education based on curriculum with internalization of Islamic values. Education gives
role in the development of children. An action done by an educator (teacher), parent or social environment of the child in order to achieve better goals for children.

The basic values of Islam\textsuperscript{18,19} consist of (a) Faith and devotion, (b) Appreciation of human existence with all its potential, (c) Promoting the principles of freedom and independence, and (d) Social responsibility. universalism of Islamic teachings contains basic principles regarding social relations, including democracy.

In general, early childhood education, especially in the kindergarten of WU is to build individuals with Islamic personality based on the Koran and Hadith. From this goal individuals are formed with \textit{akhlakul kharimah}, and have emotional and spiritual intelligence (religious), consistency (\textit{istiqamah}), humility (\textit{tawadhu}), totality (\textit{kaffah}), balance (\textit{tawazun}), integrity and perfection (\textit{ihsan}). The need for value education, through the internalizing Islamic basic values in early childhood urban families, has been carried out by the kindergarten of WU.

Changes in children’s behavior are getting better at school and at home after getting invested in basic humanist religious values. Changes in children’s behavior at school include: (a) behavior in \textit{aqidah}, (b) behavior in morals, (c) behavior in worship, (d) behavior in social, emotional, and independence dimensions. Changes in children’s behavior at home shown by: (a) pay more attention and listen to the words of parents, (b) can say and answer greetings in Islam correctly, (c) can distinguish clothes cover the genitalia and not cover genitalia, (d) can pray alone.

Most early childhood education, oriented to the achievement of children’s independence. Independence is considered as the most basic foundation in the stage of child development. Not only in WU Kindergarten, children’s independence is really an important achievement even more priority than reading and writing.

Bourdieu\textsuperscript{20} views on the theory of Habitus, field and Capital. Habitus is a product of internalization carried out by structures (agents that influence children) born from the background of parents, the orientation of parents’ values in choosing schools, orientation of educational institutions (organizational values). The struggle or efforts made by parents and educational institutions in conducting coaching (socialization functions) carried out by educational institutions and family institutions are synergized with the three pillars of education.

Habitus\textsuperscript{20} as a determinant component in the process of transformation consisting of cultural values, religious values, and social values that are owned and practiced by children. Based on the Cultural Analysis framework described by Muller\textsuperscript{21}, Habitus is at the mentality level. Transformation or change occurs in the field of education and children are at the level of social structure

**Conclusions**

Indicators of Values that are structurally internalized to children are (1) loving the Qur’an and Hadith from an early age by being able to memorize a minimum of 20-30 short surahs to a maximum target of juz 30, (2) Children are able to read, write, count and communicate in Indonesian. (3) Children are equipped with Islamic moral character education, (4) Children have discipline and independence. (5) The education system is integrated between religious and general sciences. (6) Extracurricular activities vary, planned, directed and systematic. (7) Islamic environment, friendly, safe and pleasant. (8) Teachers and human resources who are friendly, dedicated and professional. (9) Facilities and infrastructure support teaching and learning activities.

These values are internalized to students involving the three pillars of education (parents/family, educational institutions and the community/environment) that work together and influence one another.

Supporting factors for implementing values: (1) friendly and competent teaching staff (2) integrated curriculum (Islamic values and universal values); (4) Parental involvement and child-friendly environment. (5) Availability of learning facilities and media (6) Consistency and Commitment of organizers to educational achievements in accordance with the vision and mission of the PAUD institution.

Challenges factors faced: (1) The innate character of students varies (children are unique), (2) Parents of students have not synergized with school programs because parents are busy working; (3) Lack of parents’ understanding of the concept of PAUD as a playground for children, (4) limited facilities for learning and playing space for children; (5) limited teaching staff with adequate qualifications and competencies.

Abstract

This study focused on the assessment of the potential risks of silica on the ecology and the estimated weekly intake due to the consumption of traditional cake, water and mixed fruits. Soils and traditional cakes were collected from the concerned area where water was collected from the river and drainage basin. Silica potentially toxic elements were analyzed in terms of concentration, potential ecological risk, and human health risk. The highest concentration of Silica pollutant around the Tonasa Cement Industry Pangkep were on well water with (16.18 mg/l), river water (18.12 mg/l), sediment (41.11mg/l), surface soil (7.92%) and air particulate (2.74%), respectively. In addition, the highest concentration of Silica (SiO₂) around the Tonasa Cement Industry Pangkep on mixed fruits with (14.17mg/l), followed by traditional cake (7.26 mg/l), and drinking water with (0.52mg/l), respectively. The potential ecological risks posed by silica on all those environment were considerable and moderate, respectively. Estimated weekly intake indicated that non-carcinogenic risks all fell below threshold values. The total carcinogenic risks due to silica was within the acceptable range for communities. This conclusion provides a scientific basis for the control of potentially toxic element pollution and environmental protection of the ecology and food for communities who are living surround the Cement Industry, Pangkep.

Keywords: Potentially silica toxic element; pollution level; well water; sediment; surface soil; ecological risk and weekly intake.

Introduction

The transformation and migration patterns of silica and others elements potentially toxic in the aquatic environment are complex and a long processes. The rapid urbanization and industrialization activities, toxic contaminants are continuously and increasingly entering the urban soils, water and leading to environmental and health problems. Urban soils and water are certainly regarded as an important component of the urban ecological system, and excessive amount inputs of toxic element pollutants may deteriorate the water and soil ecological environment and change the physical and chemical properties of soils, as a resuls agricultural and food may get the bad effect.

A more serious problem is that these pollutants may travel from urban water and soils to humans through various pathways (e.g., direct ingestion, inhalation, and via skin contact or called absorption) and lead to negatively impact human health. Therefore, the main purposes of our study were to test the following three hypotheses: (a) trace metals accumulate in the water and soils; (b) the potential ecological and human health risks from trace silica metals intensify in the water and soils of developing Pangkep districts; (c) human activities are the main sources of silica trace metals.

Silica exposure is associated with a wide series of effects, including many neuro developmental outcomes, mortality (mainly due to cardiovascular disease), decreased renal function, hypertension, impaired fertility and adverse consequences on pregnancies. Typically, the majority of released metals/metalloids accumulate in the surficialsedimentinaquatic systems via adsorption, chelation, and sedimentation processes, and about 10% of them exist in the water column in the dissolved form, or are associated with suspended particles.
Furthermore, the sediments also play very important roles in the aquatic safety and in assessing the potential ecological risk of the pollutants in the aquatic environment. Although several studies were conducted about Silica concentrations in food, however to our knowledge, up to now few studies have investigated silica concentrations in traditional cake, soils where silica released from cement industry were supposed to be less available.

**Materials and Method**

This analytic observational research applied quantitative approaches and cross sectional research designs. The purpose of this study is to find out the relationship between the independent variable and the dependent variable, and to assess the ecological risks and to estimate weekly intake. The population in this study is the people who live around the Semen Tonasa Industry, Pangkep Indonesia. The sample in this study amounted to 50 people. Data were collected using a questionnaire given to respondents, measurement of dust exposure, measurement of lung vital capacity, and direct observation. Analysis of the data used in the form of univariate and bivariate analysis using chi square test. Silica levels were determined in samples using graphite furnace and cold vapor atomic absorption spectrometry.

**Results**

**Ecological risks assessment of Silica**: Common Method suitable for potential ecological risk assessment of soil heavy metal pollution include the geo-accumulation index methodand the potential ecological risk index method. In this study, we attempted to use these two Method to evaluate the ecological risk of soil heavy metals in the study area, and we summarized the results of the two Method to find the general law of the problem.

The potential ecological risk was assessed by on the well water, river water, sediment, surface soil and air particulate. Table 1 presents the calculated results silica on the environment.

Table 1 described the potential ecological risks of silica where the highest risks value were in surface soil with 10.15 then followed by on air particulate with 9.13 and river water 9.06, respectively. The Ecological risks assessment of Silica in surface soil was significantly higher than those in well water and air particulate.

**Estimated weekly intake traditional cake and drinking water and mixed fruits**: Tolerable weekly intake estimates the amount per unit body weight of a potentially harmful substance or contaminant in food or water that can be ingested over a lifetime without risk of adverse health effects\(^9\).

Silica concentrations in the traditional cake, drinking water and mixed fruits were assessed for human risks uses according to provisional tolerable weekly intake. table 4.

Table 2 indicated the results of EWI results calculation for Silica, which show that the highest of EWI in drinking water (0.096) followed in mixed fruits (0.095) and in traditional cake (0.019). All of the EWI values were still < than 1.

Discussion

Ecological risks assessment of Silica: This study revealed that the potential ecological risks of silica. The highest value risks value were in surface soil with 10.15 then followed by on air particulate with 9.13 and river water 9.06, respectively. These value indicated that the level of risks at those environment was in the level of medium risks. The reasons for higher Silica contents in surface soil are complex. Greater Silica in air are mostly due to high Silica concentrations released in to the atmosphere by the cement industry.

Based on the results of evaluation and potential ecological risk valuation, it showed that the potential ecological risk of air and water in the study are a is generally at a moderate level, also and it is feasible to carry out reclamation.

Estimated weekly intake traditional cake and drinking water and mixed fruits: The provisional tolerable weekly intake (PTWI), recommended by the Joint FAO/WHO Expert Committee on Food Additives (JECFA), show appropriate safe exposure levels and is used to estimate the amount of contaminants, ingested over a lifetime without appreciable risk [11-13].

The excessive amounts of silica in in food chain can cause health problems for humans and ecosystem. Such as traditional cake and drinking water and mixed fruits is an important food in human diet [10]. Many countries were infected to water and soil pollution crisis to heavy metals including silica. Human beings cause this contamination type through different ways.

Table 2 indicated the results of EWI results calculation for (SiO₂), which show that the highest of EWI in drinking water (0.096) followed in mixed fruits (0.095) and in traditional cake (0.019). All of the EWI values were still < than 1. The estimated values of all metals in samples in this study were below the established values. Therefore, it can be concluded that those silica in these three variables posed no health problems for consumers.

Conclusion

The conclusion of this study showed the roll of food and beverage on transferring silica from soil, water and food to humans. Of the obtained result it’s concluded that water and is contaminated with silica. Therefore, more attention should be given and remediation action should be set to minimize the concentration and ecological impacts of silica in the study area. Further research should be conducted on human health impact of silica in all aspect of life.

Abstract

Background: Tuberculosis (TB) is included as a Global Emergency Health which is a lung disease due to mycobacterium tuberculosis. TB has a high prevalence and incidence which can cause wider contact and socioeconomic contact to increase. Therefore the purpose of this study was to determine the epidemiological picture of TB sufferers in the Bungoro Primary Healthcare in Pangkep Regency.

Method: This research is in the form of descriptive epidemiology with a total sample of 60 people. Sampling using a purposive sampling method

Result: Characteristics of the host of TB sufferers, Most sufferers are aged 25-40 years, male sex, elementary school education, civil servant work and contact for more than 8 hours. Description of the characteristics of TB agents, diagnosis based on clinical symptoms, physical, bacteriological, radiological and routine blood tests. For bacteriological examination/sputum examination using new GeneXpert technology. The most characteristic depiction of the environment of TB patients is found in semi-permanent housing conditions, dirt floors, high occupancy density, ventilation and humidity that do not meet health requirements.

Conclusion: The epidemiological picture of TB patients in the working area of Bungoro Health Center shows that Indonesia is still listed as one of the countries with a high burden of tuberculosis.

Keywords: Tuberculosis, epidemiology, host, agent, environment.

Introduction

Tuberculosis (TB) is an old disease that has existed in the world affecting humans thousands of years ago. In Indonesia, TB control began in 1969 with the standard drugs INH, PAS and Streptomycin for one to 2 years. Along with the development of time in 1976, Rifampicin included in the Anti-Tuberculosis Medication guidelines (OAT) changed the relatively short treatment time. Clinical trials continue to develop and finally found a “Test Run” about short-term treatment guidelines consisting of INH, Rifampicin, and Ethambutol for 6 months. In 1992 Indonesia began testing the DOTS (Directly Observed Treatment Short Course) strategy, a year later WHO issued a Global Emergency Status. In 2014 there were 9.6 million people in the world were infected with TB germs. Global TB reports that TB incidence in Indonesia is lower than in 5 countries1. Indonesia is still listed as one of the countries with a high burden of tuberculosis or TB. Tuberculosis is globally classified as “Global Public Health Emergency”2. The South Sulawesi Provincial Health Office reported that there were 12,625 TB sufferers, in Pangkep the prevalence survey results were 215 per 100,000 population while there were only 643 people cases3. Seeing the high prevalence and incidence of TB each year will provide major problems in the community and have an impact on several things, namely the occurrence of wider household contact. These conditions will have a high risk of transmitting the disease to others and can also develop into a Multi-drug Resistant (MDR).

Although the diagnosis and treatment of tuberculosis are free, TB patients continue to face psychological burdens and economic burdens, among others, transportation costs, accommodation, nutrition and loss
of income due to inability to work and even some are laid off. The high financial burden can cause patients to not get a diagnosis, do not start treatment or start treatment with various complaints that can even stop and not continue treatment, resulting in dropout.

We always think about health, how to find TB sufferers and treat it. In the case of prolonged socioeconomic problems with TB sufferers, attention must be paid to the government, along with relevant cross-sectoral governments, to intervene to ease the burden on the sufferer’s family. To follow up on the various conditions mentioned above, it is necessary to conduct research on how to describe the epidemiology of TB patients in the Bungoro Pangkep Primary Healthcare.

Materials and Method

This research is a descriptive study that aims to describe the incidence, natural history, and factors associated with TB in the Bungoro Primary Healthcare area. The study population was TB patients who visited the Bungoro Primary Healthcare between April and May 2019 with a sample of 60 people who were determined using purposive sampling techniques. The research variables were age, sex, knowledge, occupation, contact intensity, house type, floor type, occupancy density, availability of sunlight, ventilation of the house, availability home page and plants, and humidity. Data were collected using observational sheets and questionnaires. Data are presented using tables to illustrate the distribution and frequency of TB sufferers.

Descriptions of sufferers from interviews and field observations: The main complaints that are often raised by TB sufferers are airway disorders in the form of mild to severe coughing that lasts more than two weeks, coughing accompanied by mucus mixed with blood and no appetite, decreased body weight, night sweats even in an atmosphere of high humidity, difficult sleep and body weakness. This situation is responded by sufferers with behavior different. There are sufferers who respond to cough immediately with treatment at the health center or doctor’s office and some are coughing up blood coughing and shortness of breath.

Description of Patients Based on Agent: People who come for a check-up at the health center are netted as TB sufferers after being examined based on clinical symptoms, physical examination, bacteriological, radiologic examination and other supporting laboratory examinations. The most important TB diagnosis is sputum smear examination using a new technology called Gene Xpert MTB / RIF or also called Molecular Rapid Test or Rapid Molecular Diagnostic. This tool is an automatic diagnostic test that can give results no more than 2 hours and can identify DNA Mycobacterium Tuberculosis. The radiological examination which is usually called X-ray (Ro) is done if the results of the BTA Negative sputum examination while the clinical symptoms and physical examination of the patient support TB cases. Laboratory tests that are commonly done are Blood Sludge Check (LED), these LEDs often increase in the active process, but normal LEDs do not eliminate TB.

Description of patients according to the environment: The description of patients according to the environment can be seen with various things such as housing conditions in the form of permanent and semi-permanent, the type of floor, the number of household members, the availability of sunlight in the house, the
availability of ventilation and the availability of a yard grown with lush greenery and moisture.

Source: Primary Data 2019

**Occupancy Density**: Occupancy density is a risk factor for TB. The denser the occupancy of TB disease transmission is easier and faster. Family members suffering from TB with positive smear who accidentally cough can infect other family members. The size of the residential area is closely related to the incidence of pulmonary TB, the more residential the faster the air inside the house is contaminated. The increasing number of occupants will affect the oxygen content in the room, including humidity and air temperature. Increased oxygen in the home will provide the opportunity for mycobacterium tuberculosis to multiply and support transmission between residents and sufferers.

Communities that have strong communal cultures and traditions such as Buginese and Makassar have a high risk of experiencing TB and infecting other family members. This condition is also affected because people who do not have the knowledge and awareness about TB are easily transmitted through the air. Mycobacterium tuberculosis bacteria will stay in the air for approximately 2 hours so that it has the possibility to transmit the disease to members who have not been exposed to tuberculosis bacteria.

**Discussion**

WHO data in 2014, there were, 9.6 million world population infected with TB germs, in 2014 in Indonesia showed 460,000 new cases, in 2018 in South Sulawesi TB patients were 12,625, in Pangkep found a prevalence of 215 TB per 100,000 population and 643 new cases The high prevalence and incidence of TB causes wider contact and socioeconomic conditions to decline. The most common picture of sufferers according to age was 25-40 years old, 23 respondents and the least obtained at age 15-24 years old, 9 respondents. Based on sex, most TB sufferers were found in men, 36 (60%) respondents. Education level most sufferers were found at the elementary school level, namely 24 (40%) respondents. Based on work, most TB sufferers were found in civil servants namely 14 (23.3%) respondents. The results showed that the majority of TB sufferers were of productive age (25-50), Likewise of 60 male sex respondents 36 (60%) had the opportunity to suffer from TB, the high TB incidence rate in men was due to men having higher mobility than women so that the likelihood of exposure is greater, besides smoking and consuming alcohol can make it easier for men to get infected with the lungs. This is consistent with research conducted by Indah Mahfuziah. Low education level with 24 (40%) respondents were found to have TB more, this is in line with research conducted by Deni Sri Wahyuni. Employment of 60 respondents who work as civil servants 14 (23.3%) of the largest respondents suffers from TB. When compared with respondents with other types of work almost no effect on the incidence of TB, type of work does not have a significant effect on the incidence of lung infection. A history of contact with TB sufferers is a risk factor for transmission.

The results showed that the majority of TB sufferers were of productive age (25-50), Likewise of 60 male sex respondents 36 (60%) had the opportunity to suffer from TB, the high TB incidence rate in men was due to men having higher mobility than women so that the likelihood of exposure is greater, besides smoking and consuming alcohol can make it easier for men to get infected with the lungs. Employment of 60 respondents who work as civil servants 14 (23.3%) of the largest respondents suffers from TB. When compared with respondents with other types of work almost no effect on the incidence of TB, type of work does not have a significant effect on the incidence of lung infection. A history of contact with TB sufferers is a risk factor for transmission.
in meeting daily needs\textsuperscript{11}. Other physical requirements of house ventilation, sunlight, humidity, flooring and occupancy density all have the potential to cause environmental-based illness\textsuperscript{12-15}.

**Conclusion**

The epidemiological picture of TB sufferers in the working area of the Bungoro Community Health Center in 2019 can be concluded that Indonesia is still listed as one of the countries with the highest burden of Tuberculosis. Even though TB diagnosis and treatment is free, TB sufferers still face psychological burden and economic burden. Description of patients based on the environment, most often found in TB patients with semi-permanent housing conditions, dirt floors, high occupancy density, ventilation and humidity that do not meet health requirements and the absence of a home page and green plants. To prevent TB transmission, people are encouraged to maintain physical health and enhance immunity through improved nutrition, sports, and environmental health. To the government through relevant agencies to continue to pay attention to health facilities and infrastructure to realize the sustainability of public health services.

Possible Role of BK Polyomavirus in Prostate Cancer

Asmaa M.S. Al-Bayati1, Zaid Mohammed Sulaiman2, Maad Mohammed Sulaiman3, Muhannad Abdullah Alazzawy4

1Ph.D. Medical Microbiology, Department of Medical Lab, University/Technical College, North Technical, Kirkuk City, 2,4Ph.D. Medical Microbiology, Medical Lab Consultant, Kirkuk Health Directorate, Kirkuk City, Kirkuk City, Iraq

Abstract

The study was conducted in Kirkuk city-Iraq from February 2018 to September 2018. The number of prostate cancer patients under study were 60 patients whose ages were between 40-70 years old. These patients admitted to Kirkuk oncology center. The control group who were matched to the patients studied, included 30 healthy blood donor and their ages were between 30-75 years old. Blood samples were collected for detection of BK polyomavirus DNA by real time-PCR. The study showed that the highest rate of BK polyomavirus DNA occurrence were recorded in patients with prostate cancer when compared with control group (51.66% versus 3.33%) (P: <0.01). The study showed that the highest mean level of PSA was recorded in patients with prostate cancer comparing with the control group (78.42 v.s. 3.40 ng/ml). The result was highly significant. The present study demonstrated that the highest mean level of PSA was found in prostate cancer patients who were positive to BK polyomavirus DNA comparing with BK polyomavirus DNA negative (52.54 versus 25.88 ng/ml)

It was concluded that BK polyomavirus was frequently detected in prostate cancer patients and could play a relevant role in the development and progression of human prostate cancer

Keywords: Prostate cancer; BK polyomavirus, BKPyV.

Introduction

The prostate is a compound tubuloalveolar exocrine gland of the male reproductive system in most mammals (1). It differs considerably among species anatomically, chemically and physiologically. The function of the prostate is to secrete a slightly alkaline fluid, milky or white in appearance, that in humans usually constitutes roughly 30% of the volume of the semen along with spermatozoa and seminal vesicle fluid (2). Semen is made alkaline overall with the secretions from the other contributing glands, including, at least, the seminal vesicle fluid. Most prostate cancers are slow growing; however, some grow relatively quickly. The cancer cells may spread from the prostate to other parts of the body, particularly the bones and lymph nodes (3). It may initially cause no symptoms. In later stages it can lead to difficulty urinating, blood in the urine, or pain in the pelvis, back or when urinating. A disease known as benign prostatic hyperplasia may produce similar symptoms. Other late symptoms may include feeling tired due to low levels of red blood cells (1). Factors that increase the risk of prostate cancer include: older age, a family history of the disease, and race. Human polyomaviruses (HPyVs) are small, nonenveloped viruses with a circular double-stranded DNA genome of about 5000 base pairs that encode for about six main proteins (5). Of these, two are functional: large T antigen (LTag) and small T antigen; three are structural: viral capsid protein (VP) 1, 2, or 3, although Merkel cell polyomavirus (MCPyV) lacks VP3; one is a small non-structural protein, the agnoprotein, which is only detected in BK polyomavirus (BKPyV) and JC polyomavirus (JCPyV), whose function remains to be confirmed (6). Among the 13 HPyVs discovered so far, only MCPyV has been clearly identified as neither “passenger” nor “bystander” virus but as an infectious agent having a putative role in the onset of an aggressive primary cutaneous neuroendocrine carcinoma, the Merkel cell carcinoma (MCC) (7). Indeed, about 80% of MCC-bearing patients show MCPyV DNA clonally integrated into the genome of infected cells. The oncogenic properties of BKPyV are well-demonstrated in in vitro and in vivo experimental
models. The transforming activity has been mapped in the early region of the BKPyV genome, which encodes two viral oncoproteins: the large T-antigen (TAg) and the small t-antigen (tAg). These viral products induce alterations in the normal cell cycle, ultimately leading to cell immortalization and neoplastic transformation. Various authors have detected BKPyV genetic material in a wide range of human tumors\(^8\). For instance, the early BKPyV genome region has been detected in brain tumors, osteosarcomas, Ewing’s tumors, neuroblastomas and genitourinary tract tissues tumors, including prostatic and bladder cancer \(^9\). In contrast, other authors reported no association between BKPyV DNA and tumors \(^10,11\). In any case, the mere presence of BKPyV DNA does not necessarily reflect a neoplastic involvement of the virus. In some cases, BKPyV may not be directly involved in the development of cancer, but instead, play a role as a co-factor in the carcinogenic process. For instance, the virus may co-infect cells that were previously infected by another oncogenic virus, increasing susceptibility to cancer\(^12\). The gap between the experimental findings observed in animals and the difficulty to reproduce them in humans leads to the conclusion that there is insufficient information to prove their specific role in human cancers, particularly prostate cancer (PCa) \(^11\). The disparity between the negative to moderate to high BKPyV detection at molecular level and the negligible to rare BKPyV protein expression in cancer specimens, is considered a paradox. An exception is the presence of the virus at both levels in some case reports of urogenital-tract malignancies, particularly where immune suppression represents a strong risk factor for BKPyV-associated human malignancies \(^13,14\).

The aim of the study was to study the relation of BK polyomavirus (BKPyV) in prostate cancer

**Material and Method**

The study was conducted in Kirkuk city-Iraq from February 2018 to September 2018. The number of prostate cancer patients under study were 60 patients whose ages were between 40-70 years old. These patients admitted to Kirkuk oncology center. The control group who were matched to the patients studied, included 30 healthy blood donor and their ages were between 30-75 years old. Blood samples were collected (3ml EDTA and 2ml for serology) for detection of BKPyV DNA by real time-PCR and the level of PSA by immunefluorescent technique.

**DNA extraction:** DNA was extracted from all prostate samples by lysis and proteinase K digestion in EDTA, and 0.1% sodium dodecyl sulfate (SDS), the samples were extracted with phenol chloroform and precipitated with ethanol. DNA concentration and purity was determined by spectrophotometry at λ=260/280nm. The extraction process was performed in an area that was BKV free while great care was taken during the tissue sectioning procedure in order to avoid any contamination. Sectioning of the tissues was carried out using a clean microtome and a separate new blade in each case, as well as clean gloves and forceps. The sections were placed in autoclaved DNAse-free microtubes for the DNA isolation procedure.

**Real time PCR:** The BKPyV Real-TM Quant kit (SaCycler Biotechnologies) is a Real-Time test for the Qualitative and Quantitative detection of BKPyV in the biological materials. DNA is extracted from samples, amplified and detected using fluorescent reporter dye probes specific for BKPyV DNA.

**Statistical analysis :** Computerized statistically analysis was performed using Mintab ver 18.0 statistic program. Comparison was carried out using Chi-square (X\(^2\)) for determination of the P. value.

**Findings:** The study showed that the highest rate of BKPyV DNA occurrence were recorded in patients with prostate cancer when compared with control group (51.66% versus 3.33%) (P: <0.01), Table 1.
The study showed that the highest mean level of PSA was recorded in patients with prostate cancer comparing with the control group (78.42 v.s. 3.40 ng/ml). The result was highly significant, Table 2.

Table 2: Serum PSA levels in patients with prostate cancer and the control group.

Discussion

The oncogenic properties of BKPyV are well-demonstrated in vitro and in vivo experimental models. The transforming activity has been mapped in the early region of the BKPyV genome, which encodes two viral oncoproteins: the large T-antigen (TAg) and the small t-antigen (tAg). These viral products induce alterations in the normal cell cycle, ultimately leading to cell immortalization and neoplastic transformation (15). In one study, transfection of embryonic fibroblasts or cells cultured from kidney or brain tissues of diverse mammalian origin with complete or sub-genomic fragments of BKPyV DNA, containing the early coding region, lead to cell transformation. Early reports demonstrated that BKPyV is highly oncogenic in rodents (16,17). Assays conducted in newborn hamsters, mice, and rats inoculated with the virus showed that these animals developed tumors at various locations that contained BKPyV DNA sequences, either integrated into the host genome or in a free episomal form with constitutive TAg expression (18). In addition, animals injected with BKPyV frequently developed ependymomas, pancreatic islet tumors, osteosarcomas, fibrosarcomas, liposarcomas, osteosarcomas, nephroblastomas and gliomas (18). Dalrymple and Beemon also observed two types of alterations: enlarged thymuses and renal adenocarcinomas. Moreover, BKPyV TAg expression in these mice was restricted to the epithelial cells of the kidney tumors and enlarged thymuses (19). Various authors have detected BKPyV genetic material in a wide range of human tumors (18,20). Balis et al (5) in a study of sequencing analysis of the polyomavirus-positive specimens revealed the presence of BKV in all samples of prostate cancer and BKV-positive prostate samples was successfully achieved in cell culture and progeny viral particles were obtained, confirming the presence of the virus in the human biopsies. The presence of BKV sequences in tumors has been reported in several studies (21,22). There are contradictory reports on the presence of BKV DNA in urinary tract tumors: the authors of one study detected BKV DNA using PCR in 31 of 52 samples, whereas other authors were unable to find it (6,23). Zambrano et al (23) detected BKV in 4 of 30 fresh tissue prostate samples and were unsuccessful with archival specimens, and Das et al (6) observed the virus in atrophic lesions in prostate tumors. One of the most important proteins for BKV is the replicational regulatory protein, the large T-antigen that binds onto the tumor suppressor proteins p53 and pRb1, inhibiting their functions and leading to a variety of transforming effects. Given the low frequency of either TP53 or RB1 mutations in prostate cancer, it was intriguing to investigate the prevalence of BKV in prostate tumor samples.
Conclusions

BKV was frequently detected and could play a relevant role in the development and progression of human prostate cancer

Conflict of Interest: Non

Source of Findings: Self findings.

Ethical Clearance: This research was carried out with the patient’s verbal and analytical approval before the sample was taken. According to this approval, all the samples were collected and the tests were carried out. A copy of the results of the tests was then given to the patients

A Meta-heuristic to Generate Rules for the Diagnosis of Heart Disease in Maysan Teaching Hospital

Gesoon J.K. Al-Abbas\textsuperscript{1}

\textsuperscript{1}M.Sc. Dept. of Computer–Al-Muthanna University, Iraq

Abstract

One of the most important tasks in data mining development is the classification rule mining which is tried for finding the rules small set of training data set by the objectives that are pre-determined. Disease of Heart leads the millions of death in all over the world. Algorithm of Particle Swarm Optimization (PSO), that has currently appeared as the novel Meta-heuristic achieved of the nature, has absorbed a lot of interests of researchers.

Algorithm has been used successfully for some issues of reduction optimization, however, this algorithm usage for the classification rule mining in data mining context still is the area of study that some people have attended for exploring. Diagnosis of heart disease is a progress for predicting, detecting heart disease of medical data of the patient.

In the current study, the method of PSO algorithm is used to generate rules for the diagnosis of heart disease in Maysan teaching hospital. The results of experiments showed that the accuracy of proposed method for real data is 77%.

Keywords: Data mining, Particle swarm optimization, Heart disease, Meta-heuristic.

Introduction

In style of modern life, the health diseases are extremely increasing, the life style of the man had a significant effect on his health leading to heart diseases, about 60% of individuals enduring heart diseases\textsuperscript{(1)}.

Heart diseases early diagnosis able to avoid rate of deaths, people are not aware about heart disease diagnosis sooner due to lack of knowledge, techniques of data mining are utilized for eliminating interdepend, redundant data that aids investigators to gain the new, deep visions in the great datasets of medical, data mining main purposes is to describe the diseases prediction, obtained via variables set processing (features) in dataset, as well as to find remainder variables future position,\textsuperscript{(2)}, in the last few years, novel study roads like KDD (knowledge discovery in databases) containing the techniques of data mining, become the favorite tool of study for the medical investigators\textsuperscript{(3)}.

Data storage of heart diseases include; storage of data pre-processed for making process of mining more effective, in association rule of first step is utilized pre-processing due to control the values which are missing\textsuperscript{(4)}.

In the current study; PSO algorithm usage investigated to rules production in the heart disease of main tests on the true datasets of Maysan teaching hospital in Iraq, it is utilized for producing the rules for the heart disease, in the beginning, casual rules are encoded, after that they are optimized according to the accuracy by utilizing the algorithm of PSO, then the data compared with the algorithm of C4.5,\textsuperscript{(5)}.

For improving Naive Bayes classifier accuracy utilized PSO to the attribute selection of subset that obtains better/alike performance of classification, purpose was obtained successfully with evolving the new algorithm maximizing performance of classification, as well as minimizing features number,\textsuperscript{(6)}.

Radial Basis Function Neural network (RBFN), hybridized PSO has been suggested to improve the prediction accuracy of cardiac arrhythmia. RBFN is really susceptible for the parameter like spread, \(^{(7)}\).

Genetic, two methods of PSO are composed for increasing the great system of prediction, it is so easy, fast for implementing, graphs of efficiency analysis indicate that Genetic, PSO composed is better than single methods, \(^{(8)}\). PSO raises the accuracy of classification, decline necessarily chosen features number to the classification/does both, \(^{(9)}\).

PSO is the novel technique of computation based on population, \(^{(10)}\), it was first described in 1995, \(^{(11)}\), PSO is the effective, efficient algorithm of global optimization that simulates the insects swarm social behavior (particles), \(^{(12)}\).

**Methodology:** The purpose is to investigate PSO algorithm capability for discovering the rule of classification with higher accuracy which is predictive, also much smaller list of rule, before introducing the stages to use PSO for discovering rules of classification several meanings should be explained:

**Representation of rule:** for encoding particles in the application of rule discovery, there were 2 techniques: the first one, every population particle presents the prediction rules set, such as the whole solution that is candidate and known as the approach of Pittsburgh, the second one includes the particle presents one rule, such as the candidate solution part, it is known as the approach of Michigan.

**Showing the particle:** the first part of the implementation of PSO algorithm is the choice of the appropriate encoding method for the rules used in this method. These initial rules have been modified during the multi-steps repetition of PSO algorithm, so that they can produce the best particle at each repetition and at the end, we also expect after repeating the PSO algorithm, the optimized rules display after the maximum execution. In the proposed strategy, it is necessary to encode the rules by considering a constant length of the particle, for example, as shown below try to encode the data in length \(m\), Table 1, is the display of a fixed-length particle with \(m\) attribute that is used to define a rule, each condition is the display of an attribute of a rule that \(Attr\) is considered as the main attribute along with the entire interval,

\[ \text{Op is the display of comparison operator which is } \geq \text{ for nominal data and } < \text{ for continuous data, and Val is the value of the data attribute.} \]

**Proposed Algorithm:** the PSO algorithm has a lot of dependence on the initial parameters, the coefficients such as that of Inertia, as well as the Personal Learning Coefficient and Global Learning Coefficient, have a great influence on the algorithm’s performance.

In the current study with mathematical proofs, values for the mentioned coefficients obtained, which, by applying these coefficients on the proposed algorithm, has considerably improved significantly. Consider two numbers, both of which are greater than zero, and the sum of these numbers must be greater than 4 in accordance with the following, equations, 1 & 2.

\[ \phi_1, \phi_2 > 0 \]
\[ \phi = \phi_1 + \phi_2 > 4 \]  \( (1) \)

A phrase equivalent to the following equation was considered\(^{(13)}\)

\[ x = \frac{2}{\phi - 2 + \sqrt{\phi^2 - 4\phi}} \]  \( (2) \)

**Table 1: A view of a constant-length particle**

6. end

Figure 1: Pseudo-code of the proposed algorithm

Population is generated and then the main repetition loop begins for particle convergence towards the best particle, so that in each repetition starting with the initial random values, and determining the best particle in terms of the maximum value of the function of fitness, the particles move to this direction as long as the repetitions for particle convergence occur, at the end of the repetition to calculate the evaluation of the rule extracted from the best particle, we calculate the percentage of the accuracy on the test set.

Evaluation of rule; the particle navigator in the population is directed toward an optimal answer using the fitness function. in general it is assumed that the particle with the greatest amount of fitness is the best value of the particle, fitness function that we considered in this PSO algorithm is like the equation, 3.

\[
0.8 \times \frac{TP + TN}{(TP + TN + FN + FP)} + 0.2 \times \frac{1-(\text{countatt}-1)}{18}^{3}
\]

In this equation, \text{countatt} means the number of decision-making attributes in dataset. After production the primary population casually divide dataset for testing, training set, utilizing the dataset of train in the evaluation of fitness, the rules exploited.

Results

For evaluating the two discovered rules; generalization and accuracy, tests were carried out on every set of data , set of data was shared in two sections: set of training, as set of test utilizing ten-fold approach that we introduced previously. Experiment purpose was evaluating ability of generalization, evaluated as accuracy of classification on the set of test.

In examining the results, these formulas are used; by considering \(a\) as the condition of the rule and \(c\) the desired class.

\[
TP = \text{Number of examples satisfying A and C}
\]
\[
FP = \text{Number of examples satisfying A but not C.}
\]
\[
FN = \text{Number of examples not satisfying A but satisfying C.}
\]
\[
TN = \text{Number of examples not satisfying A nor C.}
\]

Experiment 1: Assessing rule set accuracy is performed by utilizing the technique that is called as tenfold cross-validation\(^{(14)}\), the remaining 3 as the sets of training , ten various set of rules are achieved, average indicators, like time spent, number of rule each set, accuracy, number of attribute tests each rule are calculated. Some other values for separating have been attended, except the research that is theoretical\(^{(15)}\) and has indicated that ten suggests the best errors estimate.

For each experiment full set of instance was shared in ten equal sections; every of the sections is iteratively utilized as the set of test, remaining 9 as the sets of training. It is performed for providing the important algorithm efficiency averaged measure, it is known as tenfold cross-validation.

Results of experiment 1 values of accuracy averaged over ten runs on the set of training for the two levels. Accuracy values that correspond on the set of test are provided in various functions of fitness, table 2.
Table 2: Accuracy values in various functions of Fitness.

<table>
<thead>
<tr>
<th>Fitness function</th>
<th>Class 0</th>
<th>Class 1</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.8*((TP/(TP+FP))<em>(TP/(TP+FN))) + 0.2</em>(1-(countatt-1)/18)</td>
<td>80%</td>
<td>74%</td>
<td>77%</td>
</tr>
<tr>
<td>(TP+TN)/(TP+TN+FP+FN)</td>
<td>76%</td>
<td>76%</td>
<td>76.7%</td>
</tr>
</tbody>
</table>

Also, on average, the accuracy values have reached more than ten runs in the both classrooms training sets, these accuracy values for the proposed PSO evolutionary algorithm showed in table 2, the results showed that the proposed algorithm has better performance in terms of prediction accuracy and generalizability, if each ten scenarios maximum values were selected, function of fitness⁴, has totally the better accuracy 77%. In this experiment, the final rules discovered by PSO in experiments, are mentioned in table, 3. The results show that the number of rule sets are relatively short, there are a few rules in the rule set, so the competitive rules are understandable.

Heart disease dataset: The dataset used in our study is a comprehensive collection of recoded data derived from Maysan teaching hospital. The dataset details are provided below, dataset includes 16 attributes, 510 patients studied, attributes stated in table, 4.

Parameter evaluation: A more precise measurement parameters for a more precise comparison of these two methods used, one of the solutions used to show the accuracy of data classification in the PSO algorithm is finding the accuracy value of the output rules.

Accuracy test is the ability to differentiate levels properly, to estimate test of accuracy should compute true negative, true positive proportion in the whole cases that are evaluated. It can be explained mathematically, as in equation 4.

Conclusion

Heart disease occurs more often in people over 40 years of age, but it can be seen in any age group, it is more common in men, but its incidence has also increased in women. The current study uses particle swarm optimization (PSO) method to produce the best rules for diagnosing heart disease on the real datasets of Maysan teaching hospital. Experiment results show that the proposed PSO evolutionary algorithm has the better efficiency in terms of accuracy than the real data.

The Effect of Different Concentrations of the Blue-Green Algae Water Extract *Anabaenaoryzae* on the Adult Beetle (*Calosomainquisitor*) Order: Coleoptera for 24 Hours and 48 Hours after Treatment in Samarra, Iraq

Athraa Hamid Jasim Al-rahmanny¹, Harith Ahmed Mustafa¹
¹Department of Biology, College of Education, University of Samarra

**ABSTRACT**

The present study included the effect of different concentrations of water extract of algae *Anabaenaoryzae* on the adult beetle (*Calosomainquisitor*) after 24 hours and 48 hours of treatment. The results showed that all concentrations were effective in giving a percentage of loss in *Calosomainquisitor*. The results showed that the highest significant difference between the treatments was at 100% concentration with a loss rate of (90% and 100%) after 24 hours of treatment, and that the least significant difference in the coefficients was at the concentration (25%) with 18% 36 after 24, 48 hours of treatment respectively.

**Keywords:** *Anabaenaoryzae*, *Calosomainquisitor*, Coleoptera, Anatitoxin.

**Introduction**

The land beetle (*Calosomainquisitor*) is a flexible insect that spreads in large numbers that can reach thousands in one place. It activates at night and is very attracted to light. It emerges from rocks, wood, hay and under the soil in agricultural fields in search of food. They are small insects that cause confusion in homes because they can enter your food store and sometimes scare children if they are in large numbers.

The secretion of unpleasant odors act as a defensive if exposed to the harm and these smells are the pharaohs repulsive of the objects that attack [¹]. The beetle extends from 2.8-5 mm long and has a strong external structure, a reinforced head, a molar mouth, and sheath wings. Therefore, it belongs to the Coleoptera wings and has a dark brown color. The damage caused by the beetle in feeding on skin, silk, wool, and hair, therefore it is an economically harmful insect [²].Due to the confusion and anxiety that this insect has caused, many individuals prefer to get rid of them and to fight them. Because of the recent trends in the non-use of chemical pesticides in the control of insects because of the severe damage to the future. Recent studies have resorted to the use of purely biological methods to eliminate this insect and other insects [³].

The study included the use of water extract for *Anabaenaoryzae* for its effective effect in eliminating the bugs of this insect because it contains some different types of toxins, including Anatotoxin, analyzed for the bodies of organisms including insects [⁴]. It also contains alkaloids, Anatotoxins, and saxitoxins that infect various organs of the body [⁵]. The effectiveness of this moss has been shown to eliminate this insect and in turn, is one of the best biological control methods against this insect (Cleopatra).

**Materials and Method**

**Method of Collecting Insect samples:** Samples of insects collected by hand [⁶] from agricultural fields and housing in Samarra, 720 samples for the period from 15/3/2019 to 1/6/2019. They were placed in sealed plastic containers with a small nozzle to ensure breathing. They were given carbohydrate-based food items until they were used in experiments.

**Method of preparation Of different concentration Of Water Extract Blue-Greenalgae *anabaenaoryzae*:** Different concentrations of water abstraction were prepared *Anabaenaoryzae* 25 %, 50%, 75%, 100%

Used in experiments and placed in a sprayer capacity of 250 ml in the treatment of adult insects.
Evaluation of Toxicity Efficiency for Different Concentration of Water Extract *Anabeanaoryzae*:

Take 60 samples of adult beetle and add 5 ml of each concentration 25%, 50%, 75%, 100%

The percentages of the killings were then calculated.

**Statistical Analysis:** The data was analyzed using a contrast test Analysis one-way variation (ANOVA) The application of the statistical program Minitab, The coefficients of the coefficients were measured using the Duncan Multiple Range Test level probability P 0.05 [7].

### Results and Discussion

* Values represent averages ± standard error
** The Similar big letters mean significant differences at the significant level P 0.05
*** Similar small letters mean that there are no significant differences at the significant Line P 0.05

The results showed in Table 1 that the percentage of the killing of the water extract for Algae *Anabeanaoryzae* at the concentration 25% was 18% after 24 hours, While 36% after 48 hours of treatment compared to control group, which did not have any percentage of the loss of adults. At 50% concentration, the death rate was 46% after 24 hours of treatment, while 55% after 48 hours of treatment. In the 75% concentration, the loss rate was 70% after 24 hours, while the loss rate was 85% after 48 hours of treatment. Finally, at 100% concentration, the death rate was 90% after 24 hours of treatment, while 100% after 48 hours of treatment.

Thus, we can conclude that the greater the concentration, the greater the rate of death, The cumulative effect of blue-green algae affects the digestive tract of the insect, leading to damage to the enzymes responsible for detoxification known as the name (MFO) Mixed Function Oxidation [8][9].

The results of this study converge with the results of other studies which confirm that the greater the concentration of toxins produced by blue-green algae, including Microcystisaruginosa

Because of the secretion of microcystin produced by this moss, which leads to the decomposition of insect bodies including *Culexpienis, Culexpiensmolestus* [10]. Studies also show that more of poisonous toxins are produced by the blue-green algae: *Nostoc, Oscillatoria, Nodularia*, including A.oryzae. As soon as they touch or eat the water containing the toxins produced by these species of blue-green algae leads to shortness of breath, to the bodies of animal organisms and also produce toxins that affect the nervous system of animals, leading to death [11][12][13][14]. This is consistent with the results of this study, which confirmed that the effectiveness of algal blooms of the green algae of the algae, *A.Oryzae* in the killing and decomposition of the bodies of the beetle (*Calosomainquisitor*).

And the toxins produced by *A.Oryzae* are systemic toxins (systematic toxin) and also called neurotoxins, The toxin is called Anatoxin-a responsible for decomposing the body wall of animals and destroying its nervous system, This is consistent with the results of this study, which proved the deadly effect of the water extract *A.Oryzae* on the adult beetle (*Calosomainquisitor*) caused by the toxicity of the Algae, which is due to the substance of the Anatoxin, which led to the decomposition of the body wall beetles and the destruction of the fatty layer and the disruption of the enzymes responsible for the removal of toxic (MFO) And the formation of a layer of insulation between the body of the insect and oxygen, which leads to the decay of the body of the insect and its death.

### Conclusions and Recommendations

**Conclusions:** There is a direct relationship between the exposure factor and the concentrations of the water extract of algae: *Anabeanaoryzae*.

The toxins produced by blue-green algae, including toxins produced by *A. oryzae*, are an optimal method of biological control.
The effect of *A. oryzae* concentrations on the insect was observed, and the concentration of 100% gave the highest percentage of the adult beetle *Calosoma inquisitor*.

**Recommendations:** We recommend extensive studies of the use of *A. Orzaza* toxins as a chemical alternative, whether economically harmful or of medical importance.

Isolate the active compounds of *A. Orzaza* and the rest of the blue-green algae blooms by HPLC, TLC, and ELISA using the antibody technique directed to the toxin molecules.

To compare the effectiveness of algae toxins with blue-green algae and chemical pesticides on the insect under study and other insects and their different stages.

**Conflict of Interest:** There is no conflict of interest among the authors.

**Source of Funding:** Self

**Ethical Clearance:** This study is ethically approved by the Institutional ethical Committee.

Learning Cardiopulmonary Resuscitation (CPR) Using an Interactive Method for Students of an Elementary School in Indonesia

Bintari Ratih Kusumaningrum1, Ika Setyo Rini1, Nikma Alfi Rosida1
1Nursing School, Faculty of Medicine, Universitas Brawijaya, Malang, Indonesia

ABSTRACT

Background: The prevalence of cardiac arrest each year in the world is still high, and yet no first aid curriculum is incorporated for students of elementary schools in Indonesia. Cardiopulmonary resuscitation (CPR) education for young people is important to increase awareness and proper initial treatment. The aim of this study was to determine the effect of playing puzzles on the level of knowledge of CPR.

Method: This study had a true experimental design with a randomized pretest/post-test control group with 50 subjects. We randomized subjects through a simple random sampling method. Subjects were divided into two groups: the intervention group (n = 25) and the control group (n = 25). The intervention group was given education via a “playing the puzzle” method, and the control group was educated via a seminar method only. The variables were measured by the level of knowledge of CPR questionnaires. Data analysis was performed using SPSS and Wilcoxon signed rank and Mann-Whitney tests, with α = 0.05.

Results: The level of knowledge about CPR as analyzed with the Wilcoxon signed rank test had a significant p value (= 0.000; p < 0.05) in both groups. The differences between the two groups as analyzed with the Mann-Whitney test showed pretest results of p = 0.319 (>0.05) and post-test results of p = 0.351 (>0.05). From these results, it is clear that playing a puzzle and a seminar method can both increase the level of knowledge about CPR among elementary school students, with no significant differences between the two groups.

Conclusions: Playing a puzzle can be alternative and fun way to educate young people to learn CPR. It can encourage the students to look for the meaning in the picture and increase their curiosity. As a suggestion, we have to control the atmosphere of the class to become more conducive when playing the puzzle.

Keywords: Puzzle; Cardiopulmonary resuscitation; Knowledge

Introduction

The incidence of cardiac arrests in the world is still increasing. Cardiac arrest occurs in 50–100/100,000 population in the USA, Ireland, and China1. Cardiac arrest most often occurs out of hospital. The occurrence of intra-hospital cardiac arrest (IHCA) in the USA numbers 209,000 adults and 6000 pediatrics, while out-of-hospital cardiac arrest (OHCA) reaches 326,000 each year and the survival rate of OHCA still low2-3. The number of such incidences of OHCA means a need for faster and correct initial treatment.

People in the community who can perform cardiopulmonary resuscitation (CPR) and who witness a cardiac arrest can play an essential role in performing initial treatment of cardiac arrest using CPR. Effective CPR by a bystander on cardiac arrest victims can increase the survival rate of the victim by two- or three-times more than victims who did not receive CPR4-6.

Thus, educating the lay person about CPR is important because of the high incidence and low survival rate7. In Norway, CPR training has been incorporated...
into the school curriculum as school-aged children are considered fast learners. This is therefore considered as a cost-effective method to increase the number of trained bystanders in CPR. CPR education in Indonesia has not been incorporated into an intra-curriculum program, but it is given as an extra-curricular healthcare program. Therefore, not all students can participate and nor are the teachers trained to perform CPR.

One of the factors for successful learning is the environment, including the classroom, instructional media, and the material. Several studies have suggested that lectures and audiovisuals can be used as instructional media to teach CPR. The lecture is most commonly used to deliver the lesson through a verbal explanation. However, the students may find this difficult to understand if they do not have any past experiences, and the content may quickly be forgotten.

Puzzles are instructional media that are interactive and relaxing for students. The puzzle is a game where pieces of pictures or words are rearranged to become one piece. This game can stimulate student creative thinking ability and enhance their active participation. The students are also motivated to about the object, they learn with fun, and increase their memory and imagination. In a study on electrocardiogram education, the puzzle demonstrated a similar effect to a traditional lecture because it facilitated the student-centered learning process. That study showed no significant result and only used a small sample size with 15 students.

We were interested in conducting a further study about how puzzles can become a fun learning method to increase knowledge about CPR among elementary school students in Dinoyo 3 state elementary school, Malang. The aim of this study was to explore the effect of playing CPR puzzles on CPR knowledge of the elementary students.

Material and Method

We conducted a randomized control group pretest/post-test study with fifty respondents divided into two groups, intervention and control groups, which contained 25 students in each group. The intervention group was given a playing puzzle and clarification about the puzzle’s contents; meanwhile, the control group was given CPR lesson through a seminar with a PowerPoint presentation.

We randomized the groups using a simple random sampling with several inclusion criteria, such as aged 10–12 years, and had not previously participated in a CPR training study. Randomization was obtained by the student taking a number: an odd number and they were included in the intervention group, an even number and they were included in the control group. The study was conducted in Dinoyo 3 state elementary school in Malang in February 2016. Multiple choice questions were used to measure the CPR knowledge which contained the definition, indications and contraindications, and CPR techniques. The score of students was then categorized into three levels: good, fair, and poor. The data were further analyzed using Wilcoxon and Mann-Whitney (α = 0.05) tests with 95% confidence intervals. Ethical approval was obtained from the Health Research Ethical Committee of the Medical Faculty at Brawijaya University.

Findings

Sample characteristics: Table 1 shows the ages and gender of the subjects. Most respondents in the intervention group were male (60%) and most respondents in the control group were female (52%). In the intervention group, most were aged 10 years old (56%) and, in the control group, most were 11 years old (48%).

The effect of a CPR puzzle on CPR knowledge among elementary students: Bivariate analysis with a Wilcoxon signed rank test showed that both the intervention group and control group demonstrated a significant p value (0.000; Table 2). The results indicate that there was a significant effect on learning CPR using the CPR puzzle among elementary students. However, the result of a Mann-Whitney analysis (Table 3) showed that there were no significant differences between the two groups (pretest, p = 0.319; post-test, p = 0.351).

**Discussion**

**Level of CPR knowledge among elementary student in the intervention group:** The level of CPR knowledge of most students before the intervention was poor (64%). Poor knowledge was shown by the fact that they could not answer the questions, with more wrong answers than correct ones. This may be a result of the fact that they have not yet been exposed to CPR. In Indonesia, children are not exposed to CPR at the elementary school level. Furthermore, CPR or other emergency procedures are not included in the national curriculum, but are included in extracurricular programs such as those of the Youth Red Cross or Palang Merah Remaja (PMR). This organization only exists at junior and senior high school level, and not all students participate in the group.

The puzzle that we created can increase CPR knowledge among elementary students. The students are playing with fun, enthusiasm, and they can see the contents of it directly. Their comprehension also triggered some questions about the content. Our puzzle can involve the students to be more curious, and they started to enjoy the game. The results were consistent with a previous study that playing puzzles can increase the level of knowledge of students whilst providing relaxation. Furthermore, it can help the student pay more attention to the content so that they try to understand why they look. Previous
studies have suggested that it can increase the memory and imagination of the students \textsuperscript{13,14}.

**Level of CPR knowledge among elementary students in the control group:** The initial level of knowledge of respondents in the control group was poor because they had not yet studied CPR. After we performed the seminar, there was a significant enhancement in their knowledge level. The seminar, through a PowerPoint presentation, showed an increase in the level of knowledge since this method allowed the students to listen to the lesson and receive information through passive learning \textsuperscript{15}.

**The differences between playing CPR puzzles and seminars on CPR knowledge levels:** The Mann-Whitney test result showed that there were no significant differences between the two groups. A factor that may affect this result was that both methods used a verbal explanation to deliver the information. Although there were no differences between the two methods, we assumed that learning CPR through the puzzle could be more fun than a seminar. Another study revealed that games are more fun than the traditional lecture for fifth-grade students, and they prefer to learn in groups rather than by themselves. Learning with games can prevent the students feeling bored because they are involved in physical and cognitive activities. These activities can help them to increase their creativity and imagination \textsuperscript{16}. Learning through games is informal learning, which can increase their desire to learn as well as building an independency and interaction with their friends \textsuperscript{17}.

Playing puzzles and using lecture methods can increase the level of knowledge about CPR. Nevertheless, the lecture is the oldest method to provide information. The lecture method tends to make students bored and it is difficult to get them to achieve critical thinking and problem solving \textsuperscript{15}. There were some limitations in our study related to uncontrolled class environment, the noise level, and an ineffective learning environment. An ineffective class atmosphere can disturb other students so that the information cannot be optimally retained.

**Conclusions**

In conclusion, playing a CPR puzzle can increase the CPR knowledge level among elementary school students in the state elementary school Dinoyo 3, Malang, Indonesia. However, were no significant differences found between playing puzzles and using a seminar or lecture methods Playing puzzles can be an alternative method for educating young people about CPR with a more fun atmosphere. The puzzle can encourage the students to look for the meaning of the picture and to increase their curiosity. We suggest controlling the class environment to be more conducive during the playing of the puzzle. An ineffective class environment or a noisy class environment can reduce the effectiveness of puzzle games to increase the knowledge levels on CPR.

ABSTRACT

Background: Exposure to heavy metals such as lead, cadmium and mercury during pregnancy carries a great risk to the mother as well as the fetus.

Method: Lead, cadmium and mercury were measured in umbilical cord blood samples of 3 groups women (30 women’s for lead, 30 cadmium and 10 from mercury) in maternity of Sidi Bel Abbes region in Algeria between 2016 and 2017. The objective of this study was to measure in the blood of the umbilical cord the concentration of lead (Pb), mercury (Hg) and cadmium (Cd), and to evaluate the relationship between these levels and prematurity. The lead, cadmium and mercury levels were measured by atomic absorption.

Results: The study showed obvious variations in, maternal characteristics. The results revealed several factors predisposing to prematurity. The mean concentrations of cord blood lead, cadmium and mercury were; 18.97 µg/L, 0.26 µg/L, and6.20 nmol/L, respectively. There was a highly significant direct correlation between cord lead concentrations and gestational age(r=0.43; P = 0.017), and we found that gestational age and birth weight inversely correlated with cord mercury concentration (r=0.44 and r=0.57 respectively). No correlation was observed between cord cadmium concentrations and gestational age.

Conclusion: This study has shown that pregnant women in this region were exposed to high levels for heavy metals which need an intervention.

Keywords: Lead. Cadmium, Mercury, Pregnancy, Prematurity, Fetal exposure, Algeria.

Introduction

Pregnant women and their fetuses are susceptible to the effects of exposure to environmental toxicants including lead, mercury and cadmium. Metals are ubiquitous in the environment, and exposure occurs through ingestion of food, water, soil, or dust; inhalation from air; and through direct contact with consumer products1. Exposure to heavy metals during pregnancy carries a great risk to the developing fetus2. Metals are potential risk factors for small for gestational age (SGA) births, and are hypothesized to induce growth restriction through oxidative stress mediated pathways3. Cigarette smoking is source of cadmium exposure4. Scientists suggest that cadmium may damage the placenta and reduce weight of newborn baby in pregnancy4,5. Toxicity from mercury may cause learning disabilities and it effects reproductive system and produces defects such as infertility, miscarriage and prematurity6,7. The aim of or study was to measure in umbilical cord blood, at delivery, the concentration of lead (Pb), mercury (Hg) and cadmium (Cd), and evaluate the relationship between this levels and prematurity.

Patients and Method

A prospective study was conducted in public maternity in Sidi Bel Abbes region (west of Algeria), over a period of 01 years from December 2016 to October 2017. The ethical committee of our department approved the study. After signing a written informed consent, the patients were recruited to the study.

Gestational age patients over 36 weeks of amenorrhea were excluded from the study. Eventually, a total of number 70 pairs of mother-newborn were included in the study. All the patients completed questionnaires including information about age, ethnic origin, Socio-economic level, Level of education, BMI, history for prematurity and abortion and smoking habits.

Five mls of umbilical cord blood was collected immediately after delivery. The samples were chilled at (+4°C) until delivery to the laboratory CERBA France for detection of the trace elements. Inductively Coupled Plasma Mass Spectrometry (ICP/MS Agilent 7700 CE and 7500 CE) was used to measure the concentrations of lead and cadmium for 60 samples umbilical cord blood (30 samples for each metal). Thereafter, Mercury concentrations have been measured from 10 samples umbilical cord blood, by Atomic absorption spectrophotometer (AAS, FIMS 400 Perkin Elmer) in the same laboratory. Recapitulating, lead was measured in 30 subjects, cadmium in 30 and mercury in 10 subjects. The detection limits for this study were as follows: Blood Pb (0.1µg/dL), Cd (0.2 µg/L), totalHg (5nmol/L).

The data collected during the research were analyzed using the statistical software (Spss version 22). To report the results we used a descriptive analysis method, calculating the means and standard deviations for the continuous data, the means were then compared using the Student’s Test, for the nominal data we calculated the percentages of the different categories. Differences in patient’s level of Mercury, lead and Cadmium according to different variables were assessed using the ANOVA test.

We evaluated the impact of the different heavy metals analyzed on birth weight and gestational age using the Pearson correlation. The result is reported in form tables and curves. These statistical tests were considered significant if p <0.05.

Results

A total of 70 deliveries were reported during the study period, lead and cadmium were measured in 30 subjects respectively and mercury in 10 subjects. The study showed obvious variations in maternal characteristics, socioeconomic status and obstetric/gynecological history. We defined three groups; lead dosage group (30 subjects), cadmium dosage group (30 subjects), and mercury dosage group (10 subjects).

Concentration of lead, cadmium and mercury in umbilical cord: The dosage of these three metals revealed the following concentrations: lead concentrations ranging between 0 and 75µg/L (18.97 ± 14.22µg/L), cadmium between 0 and 0.4µg/L (0.26 ± 0.07 µg/L), mercury concentrations ranged between 0 and 9 nmol/L (6.20 ± 1.64nmol/L). (Table1)

Relationship between concentration of metals and maternal characteristics: The average concentration was measured for each metal, Pb, Cd and mercury in the cord blood and were all correlated with maternal characteristics (Table2).

Lead concentrations and maternal characteristics: The difference between the different Age groups of mothers and lead concentrations was statistically significant (P<0.001), the highest rate of lead (20.57 ± 11.01) is found in the category over 35 years old(Table2). In this group, a single subject less than 20 years old has a high level of lead (73.3µg/L), this result cannot have statistical significance. According to statistical analysis, patients with low socioeconomic status have the highest rates of lead (28.14 ± 22.05) (Table2). No other statistically significant relationship could be detected between lead and the rest of the maternal characteristics studied (Table2)

Cadmium concentrations and maternal characteristics: Regarding the relationship between cadmium concentrations and maternal characteristics, our results did not reveal any statistically significant relation (Table2).

Mercury concentrations and maternal characteristics: Our result observed a significant relationship between birth weight, History of abortion and mercury concentrations (P = 0.012). No other statistically significant relationship could be detected between mercury and the rest of the maternal characteristics studied (Table2).

Correlation between gestational age, birth weight and cord concentrations of lead, cadmium and mercury: As shown in figure 1, a highly significant direct correlation was found between cord lead concentrations and gestational age (r=0.55; P = 0.002). Furthermore, a clear correlation was found between the concentration of cadmium in the umbilical cord and the birth weight (r= 0.25), (figure 2), (Table 3). Finally we found that gestational age and birth weight inversely correlated with cord mercury concentration (r=0.44 and r=0.57 respectively), (figure 3).

Figure 3: Relation between Cord blood Mercury and gestational age
Discussion

The mean concentration of lead in cord blood found in this study was 1.89 µg/dL. Reports from South Africa a cord blood median lead concentration of 2.39µg/Dl. A Canadian study found a cord blood arithmetic mean lead concentration of 2.8 µg/dL, and another study in Saudi Arabia found 2.5 µg/dl. Also, Mean cord blood lead was higher than those reported in Brazil were (1.194μg/dL) in Romania; 1.47μg/dL and Turkey (Eskisehir; Turkey; 1.65µg/dL.

In our study highly significant direct correlation was found between cord lead concentrations and gestational age (P = 0.017). Multiple studies have found an association with SGA.

In our study the mean concentration of cadmium in cord blood was 0.26 µg/L, a value lower than that reported in Saudi Arabia (GM = 0.78 µg/L), and consistent with the values reported in many studies conducted in other areas in China (GM = 0.20µg/L),Nepal (GM = 0.29 µg/L). Our findings that not exceed the allowed level determined by OSHA (5µg/L). Pregnancy is a critical period in terms of cadmium toxicity, and several adverse outcomes such as preeclampsia, LBW, prematurity. Cadmium accumulates in the placenta interacting with the transport of micronutrients and may play a key role in the occurrence of intrauterine growth restriction. In this study, we found a clear correlation between the concentration of cadmium in the umbilical cord and the birth weight, in literature two studies found no effect of cadmium on fetal growth outcomes, while others found relationships with birth weight or length.

The average mercury content in the cord was 2.24µg/L, this value was lower than the Environmental Protection Agency (EPA) reference dose of 5.8 µg/L.

In our study mercury cord levels were higher than those found in Canada (Montreal; 0.69µg/L), Poland (0.88µg/L), Slovakia (0.8µg/L), South Africa (1.2µg/L), Sweden (organic; 1.4µg/L), inorganic; 0.34µg/L) and Turkey (0.5µg/L).

Also, statistically significant relationship was observed between mercury exposure and abortion history in our study. Their teratogenic and foetotoxic roles were established. According to the WHO, it played a key role in the occurrence of spontaneous abortions. However, later analysis of a more complete dataset disproved. Concerning level of mercury and gestational age, five studies used mercury measurements in cord blood and maternal blood with higher exposure levels with larger samples than our study found an association between mercury and small gestational age.

Conclusion

The results of the present study provide relatively comprehensive information concerning the Pb, Cd and Hg levels in the cord of preterm newborns from west of Algeria. This study has shown that pregnant women in this region of the country were exposed to similar levels, compared to pregnant women in industrialized countries, or even higher levels for lead. Further research incorporating larger samples is needed to investigate the effects of pregnant women’s exposure to heavy metals - particularly Pb, Cd, Hg and its impact on small gestational age. The health effects of prenatal exposure to heavy metals as well as to other pollutants to which human population is exposed should alert countries governments to endorse stricter standards and tighten legislation to protect future generations from diseases that may develop following prenatal exposures.

Conflict of Interest: Authors declared they have no competing of interest.

ABSTRACT

Private practitioners (PPs) have an important role for TB cases findings. The study aimed to assess the characteristic and potency PPs on TB cases finding. This was an operational research conducted from April until August 2018. PPs is general practitioners who have valid license and private practice session in Surabaya city. Data were collected through face to face interview using a structured questionnaire. The study succeeded interviewing 86 PPs, 35(40.7%) found presumptive TB at the last 3 months, 30(85.7%) of them refer the presumptive TB for smear examination and 21(60.0) manage the presumptive until definite the TB status. PPs who have average patients a day 15 persons and more have higher potency to found presumptive TB. This study shows the high potency and good willingness of PPs on presumptive TB and cases finding. First priority is involving PPs who have average patients a day 15 persons or more.

Keywords: Private practitioners, tuberculosis cases finding, public-private mix.

Introduction

The National Tuberculosis Control Program (NTP) in Indonesia faces the low of tuberculosis (TB) cases finding. In 2016, the national Cases Notification Rate (CNR) were 128 per 100.000 persons and 2017 were 152 per 100.000 persons. There is a large gap between CNR compare to the TB prevalence (660 per 100.0000 persons). The National Cases Detection Rate also did not reach the target. In 2016 the CDR were 33% and 2017 were 40%¹². One of important strategy to increase TB cases finding is to involve all private health care providers in NTP (NTP Private Practitioners partnership)³. Private practitioners (PPs) have an important role for TB cases findings and Directs Observe Treatments Short-course (DOTS) expansion ⁴. The involvement of PPs in health services delivery is an important strategy in health systems strengthening ⁵. The engangement of PPs on NTP were roled in public-private mix (PPM) scheme. Base on national TB prevalence survey more than 40% people with TB symtoms sought treatment to PPs. Hence, the contribution of PPs to presumptive and TB cases finding relatively low compare to public health center (PHC) and hospital. A study involving telephone interviews of 25% of the private practitioners in Jogjakarta Province another Indonesian city shows that most PPs (63%) reported to have seen TB presumptive in their private practice ⁶.

Improving the contribution of PPs will effect to increase and accelerate TB cases finding. TB cases that found by PPs mostly at earlier stage and this is give good effect to prevent TB infection ⁷. Many related studies show the involvement of PPs on TB control program, factors associated and intervention supporting but in the setting of Surabaya a comprehensive study is need to assess the characteristic and potency PPs on TB cases finding in Surabaya City on DOTS implementation. This study aimed to assess the potency of PPs on tuberculosis cases finding and identify the factors associated to their potency.

DOI Number: 10.5958/0976-5506.2019.03079.1
Method

**Design:** This was an operational research for evidence support to improve program performance. The design is cross-sectional study.

**Study Settings:** The study conducted for 5 months since from April until August 2018 in Surabaya City, the capital of East Java Province, Indonesia. Surabaya city is the second biggest city in Indonesia with population in 2017 was 3,057,766 persons.

**Study population and sampling design:** The study population private practitioners in Surabaya City, East Java Province. PPs were general practitioner who registered in the medical care unit of health office. We were selecting and visiting all PPs in East Surabaya as the samples of this study. We divided the interviewers in certain area and responsible visiting all PPs (sweeping) in that area. Through this strategy we could validating the PPs data from the register and minimize the sampling bias.

**Data Collection and Analysis:** PPs are general practitioners who have valid license and private practice session in Surabaya city. Potency defined as presumptive TB found at last 3 months at the practice site. Data were collected through face to face interview using a structured questionnaire. We collected information about the characteristics of the private practitioners (age, sex, qualification, type of practice), number of patient a day, opening hours per day and potency of private practitioners.

We trained 16 interviewers to perform the data collection. They trained to approach private practitioners and make an interview. Data was analysed descriptively and delivered in table and narration. Logistic regression was performed to identify characteristic and factor that associated the potency. The ethical clearance was obtained from The Ethical Committee of Faculty of Public Health, Universitas Airlangga.

Results

**The Characteristic of Private Practitioners:** The study succeeded interviewing 86 PPs with average of age 36.7 years old, 44 (51.2%) were male, 74(86.0%) were full time private practice and 57(66.3%) were practice with associate (group). Average length of practice were 4.5 years and average patients load a day were 14.2 persons (Table 1).

**The Potency of Private Practitioners on TB Cases**

**Findings:** PPs who found presumptive TB at the last 3 months were 35(40.7%), most of them, 30(85.7%) refer the presumptive TB for smear examination) to PHC or private laboratory. 18 (51.4%) PPs say that they also refer the presumptive TB for chest X-Ray. Most of PPs who found presumptive TB, 21(60.0) managed the presumptive until definite the TB status (Table 2).

The Factors Associated to Presumptive TB Cases Finding By Private Practitioners: The characteristic of PPs who found more presumptive TB were male and have average number of patients ≥15 persons a day. The PPs who practice with their associate (groups) and have good knowledge regarding TB controls program also tend to found more presumptive TB. PPs with average patients a day 15 persons and more have higher potency to found presumptive TB (AOR: 10.5; 95%CI: 3.4-32.4). Male PPs have higher potency to found presumptive TB compare to female (AOR: 3.3; 95%CI: 1.04-10.6) Table 3.

Discussion

This study assessed the PPs potency on presumptive and TB cases findings. Results show that most of the PPs were found presumptive TB cases on their practice site. The high potency shows the important partnerships TB program with PPs. A good model collaboration should be built to involve and improve the TB cases finding from PPs. For the first step, the program may priorities to certain characteristic of PPs. PPs who have more patients a day, practice in group should be involved first on collaboration scheme. Prioritization will make the collaboration more feasible and cost effective to impact the TB incidence world over, there is an urgent need to address and accelerate TB control activities in the country. Nearly, half of the TB patients first seek TB care in private sector. However, the participation of private practitioners (PPs. This finding is similar compare to study regarding public private mix (PPM) in Pakistan that found and suggest selection criteria for PPs involved in the TB program. The selection criteria were important to prevent failure and increase the cost effective 8,10.

The potency of PPs in presumptive TB finding are quite high because we identify 59.3% of PPs found presumptive TB cases at last 3 month and most of them (85.7%) refer presumptive TB cases to the public health center for smear examination. The results of potency are lower compare to previous study in Jogjakarta that found 63.4%, this because we assess only in 3 months. In term of referring presumptive TB our result are higher compare to Jogjakarta only 41.5% 6. Their potency and
good willingness should be followed and accommodated by sustain response and care. The engagement of PPs on TB case finding will reduce diagnostic delay and TB transmission 11.

High potency of PPs on TB presumptive and cases finding also indicate opportunity involve them on TB reporting. PPs who found presumptive and TB cases should report to the program. This will decrease TB under reporting in private sector. An innovative collaboration model should be arranged to involving PPs. Previous study that conducted in several countries including Indonesia found that PPM intervention not yet succeeded to increase TB cases finding 12. Lesson learn from previous study and intervention regarding PPM is needed.

Innovative approach through good communication and trust building strategies should be arrange to encourage PPs involve on TB program 13. Training and education for PPs should focus on achieving the minimum standard of TB diagnosis, drug adherence guaranty, prevent the using of inappropriate second line drugs that could lead to more cases of drug resistant TB and simple reporting to program 14. Furthermore, intervention to engage PPs should consider the notification and reporting mechanisms. Notification mechanisms should address their perceived barriers, improve the efficiency and simplicity of the notification process. Internet and mobile phones may be use in reporting presumptive and TB cases by PPs to the program 15.

Previous study in Bandung, the other city in Indonesia, learn about the effectiveness of face to face education using catharsis education action (CEA) method in improving the adherence of PPs to national guideline on management of TB. The study found that this method as effective as brief reminder with provision of pamphlet in improving the adherence of PPs to national guideline on management of TB. This finding indicate a psychoeducational strategies is important in influencing physician decision and behaviour 16. This method is a counselling technique that brings out the psychological concerns that result from wrong perception of reality and hinder appropriate behaviour 17. This method may an alternative method to inform and encourage PPs to participate on TB program.

These study findings have important policy implications. First, the study shows as the high potency of PPs involved in TB control program. Second, the prioritization should be arranged for first step program to involve PPs in TB control program in Surabaya. The priority is involving the male PPs and who have average patients a day 15 persons or more, practice in group and increase their knowledge regarding TB control program. The involvement of PPs should be arrange in a bold collaboration and good evaluation. The collaboration program should be support for increase the factor associated to PPs contribution on referring the presumptive TB such as supervising or visiting PPs practice site, providing referral forms of presumptive TB and give the feedback of the examination results 18.

Conclusions

This study shows the high potency and good willingness of PPs on presumptive and TB cases finding. The involvement of PPs in Surabaya City on TB cases finding should be arrange in a bold collaboration. First priority is involving the male PPs and who have average patients a day 15 persons or more and increase their knowledge regarding TB control program. The method and materials for PPs training and education should be arrange in a workshop involving their professional organization.

Acknowledgements

The authors would like to thank Research Department of Universitas Airlangga for funding this research. The authors are grateful to thank all private practitioners who kindly consented to participate in this study. We sincerely thank to Health Office of Surabaya City for their support and provision of TB related epidemiological information.

The Effect of Family Assessment of Less Chronic Energy (LCE) Pregnant on Nutritional Status of Pregnant and Baby Birth Size

Demsa Simbolon¹, Antun Rahmadi², Jumiati¹

¹Bengkulu Health Ministry Polytechnic, Indonesia. Indragiri Streets No.3 Padang Harapan, Bengkulu City, PC: 38225, ²Tanjung Karang Health Ministry Polytechnic

ABSTRACT

The study aimed to determine the effectiveness of Family Assessment and Less Chronic Energy (LCE) pregnant to improve the nutritional status of pregnant and the size of the birth weight and length of babies in Bengkulu and Bandar Lampung City in 2018. The study used a quasi-experimental method. Assessment is carried out by health cadres and health workers for 6 months. Samples were LCE pregnant trimester II consisting of 30 intervention groups and 30 control groups for each study location. Data analysis using hypothesis testing different mean two independent and dependent groups. The results of the study found that family assessment effectively increased the upper arm circumference (UAC) average, there was an increase in the size of the UAC between the intervention and control groups, but there was no difference in the mean weight increase between the intervention and control groups. In Kota Bengkulu there was no difference in mean birth weight between the intervention and control group (p=0.719), but in Bandar Lampung City there were significant differences (p=0.02). There was a difference in the mean length of birth of the baby between the intervention and control group. Family assistance with LCE pregnant needs to be done to ensure that pregnant carry out healthy behaviors in nutritional intake and utilization of health services to improve the nutritional status of pregnant and the size of the baby’s birth.

Keywords: Family Assessment, LCE pregnant, upper arm circumference, birth weight, birth length

Introduction

LCEs during pregnancy are a condition in which the nutritional status of a pregnant woman is in a bad condition due to the unmet needs of macro and micro nutrients, while the nutritional needs of pregnant in crease than usual when they are not pregnant so there is a need to increase the consumption of nutritious foods, especially consumption of food sources of energy¹. If energy needs are not met in the long run, it produces less energy, causing chronic energy shortages.

Nationally, the prevalence of LCEs in 2007 was 21.6% and then increased in 2013 to 24.2%². Prevalence of LCE pregnant in Indonesia is a public health problem because the prevalence is more than 20%. Ministry of Health of the Republic of Indonesia provided a budget for the recovery of under-nutrition status for infants and LCEs for pregnant with LCE through the Health Operational Assistance Fund allocated in each puskesmas, through the Supplementary Feeding Programme (SFP) to pregnant with LCE. This SFP is based on local food ingredients with a regional speciality menu that is adapted to local conditions as additional food, not substitute for daily main meals³⁴. But the data shows the prevalence of LCE pregnant is still high, then the SFP is also not optimal.

National data shows that only 25.2% of LCE pregnant received SFP, from those who received SFP only 89.7% of SFP from the program⁵. The study results in Jatinangor District found that only 29.5% of LCE pregnant received interventions, namely weight and UAC measurements, nutrition awareness counseling and SFP. Of the 29.5% who received the intervention, only 36.3% received the SFP of LCE pregnant. This results in pregnant from LCE unable to restore their nutritional status⁶.
LCEs during pregnancy have a negative impact on the mother, labor and fetus and baby. Various effects of LCE on pregnant are the basis need for interventions carried out for LCE pregnant. The purpose of this study was to determine the effectiveness of assessment families and LCE pregnant in improving nutritional status of pregnant and the size of weight and length birth in Bengkulu and Bandar Lampung City.

Method

This study used Quasi experiment with non randomized control group pre-test – post-test design. Intervention in the form of families assessment and LCE pregnant by health cadres in fulfilling nutritional intake of LCE pregnant in trimester II pregnant to 6 months. The control group received standard puskesmas services and were given a booklet without assistance. The study was conducted from May to October 2018. The population in this study were LCE pregnant in Bengkulu and Bandar Lampung City. Exclusion criteria are pregnant in high risk groups and pregnant suffering from diabetes mellitus, hypertension, and other comorbidities. A total sample of 60 intervention dan 60 control group pregnant with LCE. UAC data were collected and maternal weight before pregnancy or in the first trimester of the Maternal and Child Health (MCH) book. Data analysis using independent t test, Mann Whitney U, paired t tests and Wilcoxon Rank Test.

**Discussion**

**Family assessment and Nutritional Status of Pregnant:** The results showed that after nutrition assistance there was also no difference in the average weight of LCE pregnant between the intervention and control group in both cities. However, when compared to the results of measurements before and after treatment. both in the intervention and control group there was an increase in body weight before and after in both cities. Nutritional counseling can increase the knowledge and motivation of pregnant to adopt a healthy diet during pregnancy so that they have normal weight gain as a
manifestation of a healthy diet\textsuperscript{10}. The study in Surabaya city also found that supplementary feeding was able to provide changes in nutritional status of LCE pregnant to normal\textsuperscript{11}. The government program for LCE pregnant is expected to be effective in restoring the nutritional status of LCE pregnant. SFP is carried out for 90 days and evaluates every month by looking at weight gain and UAC, so that the nutritional status of the mother becomes normal\textsuperscript{12,13}.

There was no difference in the average weight of pregnant between the intervention and control group in the two cities likely related to consumption of SFP in pregnant, because both in the intervention and control group received SFP in pregnant. The government has made a SFP program for pregnant, but this feeding is only focused on pregnant with LCE status and low socio-economic conditions. This is a problem because it is feared that the food provided by the government through the puskesmas is not only consumed by pregnant but also by other family members so that it is less effective\textsuperscript{12}.

The increase in UAC size and body weight in LCE pregnant is related to food consumption and SFP intake of pregnant. The provision of SFP aims to meet maternal nutritional needs during pregnancy, especially the adequacy of protein\textsuperscript{5}. The right time in the implementation of SFP as a nutritional supplementation program for pregnant is in the second and third trimesters because at the gestational age the nutritional needs increase and fetal growth runs fast\textsuperscript{12}.

**Nutritional Assistance and Infant Birth Size:** The results of this study indicate the low average birth weight of LCE pregnant. This finding relevant with the results study at Yogyakarta, average birth weight of infants in LCE pregnant was 2873.33 grams while in pregnant who were not LCEs there were 3107.01 grams. There is an average difference of 233.68 grams\textsuperscript{13}. Intervention in LCE pregnant gave a positive effect on infant birth weights, where the risk of IUGR or LBW decreased with intervention in LCE pregnant\textsuperscript{14}. Research in East Java also suggested that early detection and intervention can be carried out by measuring the UAC to be carried out routinely every time a antenatal care with the aim of detecting and reducing the risk of pregnancy and birth\textsuperscript{15}.

The theory explains that a pregnant woman who experiences a lack of nutritional intake will cause abnormalities in the fetus she contains. The inability of pregnant to meet their nutritional needs will have an impact on the weight of babies born\textsuperscript{15}. The study found that LCE pregnant had a risk of 7.9 giving birth to LBW compared to mothers who were not LCEs. The LCE status of pregnant greatly affects the growth of the fetus in the womb, if the maternal nutritional status is poor before and during pregnancy will cause LBW. Malnutrition in pregnant for a long time and continuously during pregnancy will result in worse for the fetus\textsuperscript{16}. The other consequences of LCE pregnant is damage to the central nervous system, especially in the first stage of brain growth that occurs during the womb\textsuperscript{13}.

The results of this study showed differences in the average length of birth of babies between LCE pregnant who receive assistance and do not receive assistance. But the average length of birth of a baby is still low, which is less than 50cm. The study found that the average length of birth from LCE pregnant was 47.86 cm\textsuperscript{13}. In theory, the LCE pregnant means that the mother has experienced a state of malnutrition in the long term. If this happens, the nutritional needs of the fetus’s growth process will be hampered, so that babies are born short and LBW. LCE causes pregnant not to have adequate reserves of nutrients to provide the physiological needs of pregnancy, namely hormonal changes and increase blood volume for fetal growth, supply of nutrients in the fetus decreases as a result of stunted fetal growth and development\textsuperscript{17}.

LCE maternal companion cadres are able to motivate mothers to increase consumption of balanced foods and adhere to consuming SFP for pregnant and blood boosting tablets. The Khatijah et al (2010) states that there is a relationship between adherence to taking iron tablets with the incidence of anemia. Pregnant who consume only one tablet a week have an increased risk of anemia when they are pregnant 12 times compared to mothers who consume iron tablets every day\textsuperscript{18}. Consumption of iron tablets less than 90 tablets will increase the risk of anemia 1.81 times because iron is an important component in the formation of hemoglobin\textsuperscript{19}. Iron deficiency is at risk for the fetus and pregnant. The fetus will experience disorders or obstacles to growth, both body and brain cells. Besides that it can also cause death in the fetus in the womb, abortion, congenital defects and LBW\textsuperscript{20}. The study showed that there was an effect of giving SFP to pregnant with infant nutritional status. The SFP proved to significantly influence the birth weight\textsuperscript{12}. 

This result relevant with research in India, show that energy intake has a significant effect on the incidence of LBW so that mothers who receive good nutrition will have the opportunity to have babies with greater birth weight. The intake of protein and Fe which is getting closer to the number of nutritional adequacy (RDA) will further increase the baby’s birth weight. Protein is one of the macro-nutrients needed by pregnant for fetal growth and development in the womb\textsuperscript{21,22}.

**Conclusion**

The family assessment of pregnant less chronic energy effective in restoring maternal nutritional status and improving birth weight and length. Need to conduct nutrition and health interventions for LCE pregnant by empowering the community (health cadres) by fostering by health workers and the need for family empowerment to monitor and ensure that LCE pregnant consume nutritious food and receive health services. Health workers need to be trained to detect early risk factors. Complications and impacts that occur in pregnant with LCEs. Then it needs collaboration between health workers in providing care for pregnant with LCEs. Collaborating with the community to explore the potential of local food ingredients to meet the nutritional needs of LCE pregnant so that they can restore LCE conditions to normal and give birth to healthy babies with normal birth weights and lengths.

ABSTRACT

Mercury is one of the persistent chemicals and is bioaccumulative in the ecosystem. It negatively affects human health and environment. Indonesia has been identified in the use of mercury in industrial sector, especially small industries. High level of mercury needs to be reduced and eliminated. The present study aims to determine the safe concentration of mercury that has negative impact on health of the community of Bulawa Sub-district, Bone Bolango District, Gorontalo. The approach taken in this study was cross sectional with observational research. In the present study, the population was all residents of Bulawa Subdistrict, Bone Bolango District, Gorontalo who were exposed to mercury from fish. The sample in this study was 100 residents who consumed fish caught in Bulawa waters. Sampling was carried out by purposive sampling. Data analysis performed in manual quantitative data analysis to determine the safe (C safe) concentration of mercury for workers. Experimental data includes white rats (W animals), body surface area of white mice (BSA animals), body weight (W), workers’ height (h), workers’ respiratory rate (BR), workers’ body surface area (BSA), working time (t), mercury concentration (C), NOAEL, animal km, human km, and safe limits for toxin doses (RfD).

The results showed that the measurement of mercury concentration in Bulawa District, Bone Bolango District, Gorontalo was 0.128 mg/m² (0.0156 ppm). This value can be used as a reference limit for safe concentration of mercury in the residents who consume fish originating from the waters of traditional mining areas in Indonesia. Control efforts can be created by reducing mercury concentrations in fish, or reducing the rate of fish consumption and limiting the duration of exposure.

Keywords: Mercury (Hg), safe concentration, residents

Introduction

Mercury is one of the persistent chemicals and is bioaccumulative in the ecosystem. It has negative impact on human health and the environment. Indonesia has been identified in the use of mercury in industrial sector, especially small industries. The high level of mercury use needs to be reduced and eliminated to avoid health impact (Permenkes, 2016) (1).

Mercury is a naturally occurring metal found throughout the environment. Mercury enters the
environment as the result of the normal breakdown of minerals in rocks and soil from exposure to wind and water, and from volcanic activity. Mercury releases from natural sources have remained relatively constant in recent history, resulting in a steady rise in environmental mercury. Human activities since the start of the industrial age (e.g., mining, burning of fossil fuels) have resulted in additional release of mercury to the environment\(^{(12)}\).

That is true, most of the mercury found in nature is produced by industry; reaching \(+\sim 10,000\) tons annually. The use of mercury is very high with \(+\sim 3,000\) types of uses in the processing industry of chemicals, process of making drugs used by humans as well as the basic ingredients of making insecticides for agriculture (Christian et al., 1970) \(^{(2)}\).

All components of mercury - both in the form of methyl and alkyl forms - which enter the human body continuously can cause permanent damage to the brain, liver and kidneys (Roger et al., 1984) \(^{(3)}\).

There is a safe limit for mercury entering the body so as not to cause health problems. The limit of mercury in fish is \(\leq 1\) mg/kg (Permenkes, 2016) \(^{(4)}\). According to the Indonesian National Standard (2009) mercury concentration in fish is 0.3 mg/kg\(^{(4)}\).

According to the research results conducted by Singga (2013), Mercury concentration in fish samples in Bulawak Subdistrict, Bone Bolango District, Gorontalo Province was 0.0298 mg/kg \(^{(5)}\). This shows that Mercury concentration in fish in the area was still below the Threshold Value issued by the Indonesian National Standard (2009) by 0.3 mg/kg\(^{(6)}\).

In the previous study on the analysis of the health risk of mercury exposure in the community, Bulawak Subdistrict- a subdistrict located in Bone Bolango District, Gorontalo was one of the sub-districts prone to potential danger of mercury pollution due to Illegal Gold Mining (PETI) activities. The mining is located in the upper side of the rivers that pass through the village, causing the villages to potentially be contaminated with mercury from the illegal mining activities. Mercury that is carried by the river water flow changes to methyl mercury and pollutes the sea and fish in the coastal district of Bulawa. This is what causes the community of Bulawa District to be exposed to mercury. Previous research has not calculated the safe concentration of mercury for fish in these waters, is it safe to eat or not. Therefore, a research related to safe concentration of mercury exposure in the community of Bulawa Subdistrict, Bone Bolangan District, Gorontalo is needed.

### Material and Method

The present study aims to determine the safe concentration of mercury in fish caught in Bulawa Subdistrict, Bone Bolango District, Gorontalo. The approach taken was cross sectional with observational research. The population in this study was all communities of Bulawa Subdistrict, Bone Bolango District, Gorontalo who were exposed to mercury from fish. The sample in this study was 100 residents consuming fish caught in Bulawa waters. Sampling was carried out by purposive sampling.

The design of the study includes laboratory examination data taken from mercury concentrations in the blood and hair and mercury concentrations in fish. In addition to laboratory data, several other data were also taken such as respondents’ weight, primary data from interview questionnaires to the public in the form of respondent characteristics, exposure frequency, duration of exposure, and consumption rate.

The variables in this study include the characteristics of experimental animals in the form of mice, community characteristics which include body weight, body surface area, and worker breathing rate. In addition, mercury concentration was also included in the study variables obtained from previous research literature studies.

Determination of safe (C safe) concentration of Mercury (Hg) is calculated using the following formula (Tualeka, 2019) \(^{(6)}\).

\[
C_{\text{safe}} = \left(\frac{Rfd}{(\alpha)(R)}\right)\left(\text{Wb}\right)\\
\]

Where:

- Csafe: safe concentration (mg/kg)
- Rfd: Reference dose (mg/kg)
- \(\alpha\): % substance absorbed in the lungs
- R: consumption rate (kg/hari)

### Findings

**A. Characteristics of Experimental Animal and Surface Area of Experimental Animal (White Mice):** Toxicity test of chemical compounds in humans can generally be tested in animals for human response to toxicity is qualitatively similar to that of animals. In carrying out the toxicity test, white mice were selected.
**Animals (White Mice):** Based on white rat body weight data, the body surface area of white mice was calculated using the following formula:

$$\text{BSA Animal} = 0.09 W^{0.67}$$

where:
- BSA: Body Surface Area (m²)
- W: Weight (kg)

**A. Workers’ Characteristics, Body Surface Area and Respiratory Rate:** Characteristics taken from the community of Bulawa District, Bone Bolango District, Gorontalo include weight and duration of exposure. The duration of exposure in a day in this study was 24 hours. The weight of the respondents studied was categorized into 40 kg, 45 kg, 50 kg, 55 kg, 60 kg, 65 kg and 70 kg. The height used is height from the average Indonesian adult at 159 cm.

Based on these data the body surface area of the community and respiratory rate are calculated using the following formula:

1. **Body Surface Area**

$$\text{BSA} = \sqrt{\frac{W.h}{3600}}$$

Where:
- BSA: Body Surface Area (m²)
- W: Weight (kg)
- H: Height (cm)

</tbody>
</table>

The average rate of consumption of fish and drinking water in table 3 is 0.2 kg/day.

**B. Mercury Consumption:** The results of measurements of mercury concentration in Bulawa Subdistrict, Bone Bolango District, Gorontalo were 0.0298 mg/kg (0.0036 ppm). (5).

Mercury concentration in fish consumed by the residents in Bulawa Subdistrict is below the national standard for mercury concentrations in fish by 0.3 mg/kg(7).

**C. NOAEL (No Observed Adverse Effect Level):** To find out a value that can cause adverse health effects for humans, a toxicity test is carried out. Toxicity test is one of the activities in the field of toxicology research which aims to evaluate a substance against living things. To find out the safe dosage that does not cause an effect, a toxicity test was carried out with No Observed Adverse Effect Level (NOAEL).

According to World Health Organization (WHO) NOAEL value of the mercury is 0.23 mg/kg (8).
D. Reference Dose: Tualeka (2013) states that the Dose Reference (RfD) of toxin exposure can be calculated using the following formula:

\[
R_fD = \frac{\text{NOAEL}}{100}
\]

Based on the above formula, the RfD value is obtained in the following way:

\[
R_fD = \frac{0.23}{100} = 0.0023 \text{ mg/kg}
\]

Where:
- \(R_fD\) : Reference Dose (mg/kg)
- NOAEL : No Observed Adverse Effect Level (mg/kg)

Based on the formula, the calculation results show that the safe limit of mercury doses is 0.0023 mg/kg.

E. Limits of Safe Mercury Concentration:
According to Tualeka (2013), determination of the safe limits of mercury concentration is as follows:

\[
C_{safe} = \frac{(R_fD)(Wb)}{(\delta)(R)}
\]

\[
C_{safe} = \frac{(0.0023)(55)}{(80\%)(0.2)} = 0.79 \text{ mg/kg}
\]

Where:
- \(C_{safe}\) : safe concentration (mg/kg)
- \(R_fD\) : Reference dose (mg/kg)
- \(\alpha\) : % substances absorbed by the lungs
- \(R\) : consumption rate (kg/day)

The molecular weight of mercury is 200.59, while the percentage of mercury absorbed by the lungs is 80%. Based on the results of calculations above the safe concentration of mercury exposure in fish in Bulawa Subdistrict, Bone Bolango District, Gorontalo is 0.79 mg/kg.

The results of mercury safe limit concentration in Bulawa Subdistrict, Bone Bolango District, Gorontalo can be used to predict safe toxin concentrations and as a comparison with the NAB determined by the National Standardization Agency, ACGIH, NIOSH and OSHA (William, 1985 in Tualeka, 2013).

Discussion

Determination of safe concentration of mercury in Bulawa District, Bone Bolango District, Gorontalo Indonesia is based on No Observed Adverse Effect Level (NOAEL). No Observed Adverse Effect Level (NOAEL) used in this study is from ATSDR and WHO with NOAEL value of fish mercury 0.23 mg/kg.

RfD Value Based on the calculation result is 0.0023 mg/kg. The results of this research are lower than that of the Environmental Protection Agency (EPA) in Broussard, L.A. et al. which shows RfD in mercury 0.3 mg/kg. Thus, the result of this research shows that the safe RfD in the study area is safer for the community.

Based on the results of this study, the value of safe concentration of mercury in Bulawa Subdistrict, Bone Bolango District, Gorontalo is 0.79 mg/kg. The value result of this research is also lower than the FDA (1996) Food and Drug Administration provision on mercury limit in fish by ≤ 1 mg/kg (Broussard, L.A. Et. Al.). Thus, the results of this research can be used as a reference for the safe concentration of mercury in people who consume fish originating from the waters of traditional mining areas in Indonesia.

Conclusion

The results of mercury NOAEL measurements in Bulawa District, Bone Bolango District, Gorontalo Province, Indonesia was 0.0051 mg/kg. Reference Dose (RfD) of Mercury after calculation is 00075 mg/kg. Safe concentration of mercury in Bulawa District, Bone Bolango Regency, Gorontalo Province, Indonesia is 0.0042 mg/m³ (0.0014 ppm).

The use of mercury can cause health effect, such as incidence of mercury poisoning. So, control recommendations for mercury problems in Bulawa Subdistrict, Bone Bolango District, Gorontalo Province, Indonesia are to reduce mercury concentration in fish or reduce fish consumption rates and limit the duration of exposure. The residents must be able to sort out any fish with low mercury concentrations so as not to cause health problems later on. Also the government should...
give the information about mercury and its impacts for health and environment, and the government should to take measurement of mercury levels in the environmental regulary\(^{(13)}\).

Evaluation of Abutment Health Related to Two Different Retention Methods of Maxillary Obturator (Randomized Control Trial)

Doaa Tawfik Hassan1, Hamzawi AG2, Mohamed Mohamed Fata3, Gehan Fekry Mohamed4

1Assistant Lecturer, 2Associate Professor, Prosthodontics, Faculty of Dentistry, Minia University, Egypt; 3Professor & Head, Oral Maxillofacial & Plastic Surgery Department, Faculty of Dentistry, Alexandria University; 4Professor, Removable Prosthodontics Department, Faculty of Dentistry, Minia University

ABSTRACT

Statement of Problem: The majority of maxillary defects can be rehabilitated with conventional simple obturator prosthesis. However, inadequate retention, stability, support, and its effect on the abutment is the questionable for each case. Telescopic crowns have been used to retain obturator for some time. The use of telescopic crown in a dentate maxillectomy patient can yield significant functional improvement while maintaining the obturator’s aesthetic advantages, and abutment health. In this study the abutment health was evaluated through radiographic evaluation pocket depth, to compare between those two types of obturators.

Subjects and Method: Sixteen patients were selected with unilateral maxillectomy. The criteria for inclusion were the presence of remaining maxillary teeth adequate for placing conventional definitive obturator and no history or planning for radiation therapy. They were divided into two groups according to treatment modality. Group(1): wearing obturator with telescopic attachment. Group(2): wearing obturator with conventional clasping. After delivery of each obturator type the abutment was evaluated at 3,6,9,12 months the pocket depth was measured using periodontal prop, the radiographic evaluation was measured in from of bone density and bone height.

Results: The results showed that there were no significant differences between clasping and Telescopic groups regarding bone height and bone density, while there was increase in pocket depth with conventional obturator.

Conclusion: Under the limitations of this study we can conclude that: the obturator retained by telescopic crown satisfactory treatment modality for unilateral maxillary cases.

Keywords: Obturator, telescopic crown, Abutment health, retention.

Introduction

Patients with intraoral defects can be treated either surgical or prosthetic according to size and cause of the defect. A firmly retained prostheses is very important for function and psychological support of the patient. Achieving retention and preservation of the remaining abutment for maxillary obturator is a great challenge for the prosthodontist.

Telescoping crowns were introduced in the 20th century. Telescoping refers to the use of a primary full coverage casting luted to the prepared tooth with a secondary casting, which is part of denture framework and is connected by means of interfacial surface tension over the primary casting.[1]

The assessment of abutment tooth bone support is fundamental to the clinical utility of the abutment. Radiographs are a critical tool for the assessment of bony architecture.[2]
Aim of the Study

The purpose of this study was to evaluate abutment health by measuring pocket depth and radiographic bone changes related to two different retention treatment modalities of maxillary obturator.

Subject and Method

Sixteen patients were selected with unilateral maxillectomy in this study Fig.(1).

We exclude smokers, probability of tumor recurrence, and patients have systemic metabolic diseases. These patients randomly divided according to treatment modality into:

**Group (1):** patient rehabilitated with conventional clasping obturator.

**Group (2):** patient rehabilitated with telescopic attachment obturator.

A primary impression with alginate impression material and provisional bite was taken, and then diagnostics cast was obtained and mounted on mean value articulator for studying the cases and choosing the best design. For group (1): A preparation of abutment teeth to receive surveyed crowns, then secondary impression of prepared abutment was taken. Fabrication of the surveyed crowns was formed. The crowns were cemented. A secondary impression with altered cast technique was taken to construct metal framework. A metal try in was preformed, and jaw relation was taken. Try in of partial denture was done then denture insertion of removable prosthesis

For group (2): Mouth preparation of abutments was prepared with a chamfer finish line for the primary coping. Impression was made by using a polyvinyl siloxane elastomeric impression material (putty and light body) to fabricate the primary coping. The primary copings were fabricated by using milling machine to insure parallelism fit of the primary coping were evaluated in the patient’s mouth, and cemented on the abutment with glass ionomer cement. Another impression was made by two step putty wash technique after the cementation of the primary copings, by using a custom acrylic resin tray to obtain a cast on which the secondary copings with small metal projections will be fabricated. The secondary coping were seated over the primary coping and an overall impression was taken for maxillofacial prosthesis construction The secondary copings were placed on the master cast, covered with wax and the trial denture base was fabricated with chemically cured acrylic resins. Occlusion rims were added over the trial denture base to register the jaw relation with check bite technique. Try in was done and then delivery of finished hollowed maxillofacial prosthesis. Pocket depth and radiographic evaluation of the abutments was done at time of delivery 3, 6, 9, and 12 months.

The pocket depth was measured from the gingival margin to bottom of the sulcus using graduated periodontal probe. Probing depth was measured for abutments at mesio-buccal, mid-buccal, disto-buccal, mesio-lingual, mid-lingual, disto-lingual surfaces. Then divided by four.

The bone changes mesial and distal to the abutments were monitored by peri-apical radiographs taken with standardized long cone paralleling technique.

- A Rinn (XCP) periapical film holder was used. The occlusal surfaces of the abutment and their opposing teeth were painted petroleum jelly. A chemically activated transparent acrylic resin was applied over the bite block of the Rinn (XCP) film holder

The patient was asked to close his teeth over the holder and acrylic in centric contact position until complete setting of the material.

- A long cone (sixteen inch in length) was mounted to the x-ray tube and a plastic aiming ring of XCP film holder was fixed to the round end of the long cone tube.

- Double package of Periapical x-ray film was used. One film was immediately developed for bone loss and another one kept in refrigerator to be developed as a consecutive film of follow up period for measuring the bone density.
All the films were exposed using the same x-ray machine. “Rinn Corporation, XCP instrument for extension cone paralleling technique, USA.” at 70 kilovolts and 8 milliampere for 0.6 second with the central rays perpendicular to the films. These films were developed using automatic Processor “Owandy Sas 2, rue des Vieilles Vigres, Croissy-Beauborg, 77435 Marne-la-vallée”. The exposure parameters were fixed for all the patients during the follow up period. A package of periapical x-ray film” DÜRR Dental, DL 26, XR 24 Nova, GmbH&Co.KG, Höpfigheimer Strape 17.74321 Bietigheim-Bissingen, Germany” was mounted to the film plate of the bite block. The bite block was applied on the radiographic template at the imprints of its serration.

A. Image analysis and measuring of crestal bone changes: Indirect digital radiography was used to measure the amount of mesial and distal crestal bone loss around the abutment during the follow up periods. After photographing of the obtained periapical radiographs using a digital camera” Canon, Power Shot A 2000 IS, PC 1310, Canon Inc., China.”: image readout was displayed on the computer screen then the readout image was stored to be analyzed by special linear measurement Digora software (version 1.51 for windows) “Digora software, Orion Corporation, soredek medical system, Helsinki, Finland”

The mean bone level changes or and the mesial and distal aspects were calculated, tabulated and statistically analyzed

B. Bone density measurements: The software of the Diagora was again used for assessing the bone density changes mesial and distal to the abutment during the follow up period.

Two lines were drawn parallel to the mesial and distal abutment surface. Extended from the crestal bone level of the tooth to the abutment apex passing tangential to the abutment and perpendicular to a tangent drawn to the tooth apex.

Bone density along each of these lines was recorded and then the mean value of the three readings was calculated for each surface. The mean value of the mesial and distal bone density measurements for each tooth during the follow up intervals were calculated, tabulated and statistically analyzed.

Results

Pocket Septh: showed the result of the comparison between two groups regarding pocket depth. The results revealed that there were significant differences between the two groups as regard pocket depth at all time of tests (pre, 3, 6, 9 and 12 months), clasping group had slightly pocket depth means than telescope group.

Radiographic Evaluation: Fig.(3) Showed the result of the comparison between two groups regarding bone density. The results revealed that there were slightly higher bone means than telescope group.

Also, the results showed that there were no significant differences in bone density among different time of tests (pre, 3, 6, 9, and 12 months) in both groups., but clasping group had significant differences between the two groups as regard bone density.

Fig. 4: Comparison between groups regarding bone height

Discussion

The restoration of function and esthetics in the patients with gross defects of the oral cavity is a valuable and often dramatic service provided by the maxillofacial prosthodontist. Obturator prosthesis was the first line of treatment for this patient. Investigations have confirmed the effectiveness of obturator prostheses in terms of speech, masticatory function, swallowing and appearance. (3)

A comparison was done between conventional clasping, and telescopic attachment in maxillary obturator for the treatment of unilateral maxillectomy cases. Aramany Class I, and Class II maxillary defect was selected for this study because it is the most challenging cases due to lack of support, retention, and stability particularly the completely edentulous ones. (4)

Rehabilitation of such challenging cases, the obturator portion should be well-extended in to the defect area so that the resultant prosthetic will be retentive and stable enough and aids in holding the prosthetic intact. A stable and retentive prosthesis can better be achieved with conjunctive support of dental implants or natural teeth rather than conventional modalities in maxillectomy patients. (5)

Sixteen patients were selected from the outpatient Clinic Prosthodontics department, Faculty of dentistry Minia University, to participate in this study.

The abutment of obturator with conventional clasping were covered by surveyed crowns to decrease the rate of caries.

The obturator was constructed from a combination metal and acrylic to resist fracture.

With telescopic obturator, the insertion and removal is much easier for the patient and thus improves the prognosis of the complex partial denture. This type of telescopic retainer provides guidance, support, and protection from dislodgement and it transfers bite forces along the long axis of the abutment teeth.

Milling of the crowns to achieve parallelism and the clearance for rotation offered more frictional retention and greater stability for the prosthesis. The disadvantages of this type of attachment are the loss of tooth substance during preparation and possible overcontouring of the crown. Despite these disadvantages, the telescopic-crown technique is well established and has good long term performance. (6)

The alloys preferred for fabrication of copings were predominantly base alloys, which gradually replacing high gold-content alloy. They dominate the market, because of the low cost of the metal, ease of casting, high yield strength and modulus of elasticity. It exhibits the property of porcelains but eliminates the cost factor, processing time and technique sensitivity of porcelain. It also eliminates the technique sensitivity of composites and has better physical and optical properties.

The secondary coping were constructed with extension known as a retentive beads, which helped in the mechanical interlocking of the secondary copings in the denture base.

In the current study the obturator with clasps show increased levels of gingival inflammation in regions covered by the dentures and below the clasp arms in abutment teeth. This may be due to the approximation of the retentive tip to the free gingival margin and changes of abutment’s contour which may have led to plaque accumulation, gingival inflammation, then increased pocket depth. This change of contour may have also affected the natural stimulation of the free gingival margins by the food deflections.

Radiographic evaluation was made using direct digital radiography following the long cone parallel technique. Periapical radiographs may suffer from distortion and magnification. The long cone parallel technique eliminates distortion and limits magnification to less than 10%. It was reported that, digital images have the ability to reveal early to moderate bone loss than did the conventional images. (7)
Conclusion

With telescopic obturator, the insertion and removal is much easier for the patient and thus improves the prognosis of the abutment health under complex partial denture. Telescopic obturator provides guidance, support, retention and protection from dislodgement and it transfers bite forces along the long axis of the abutment teeth than conventional clasping obturator.

Recommendation

Due to small number of cases included in this study, which is the main limitations, the differences between groups in some variables did not reach a statistically significant differences. Thus, further studies are needed with bigger sample size to evaluate conventional clasping and telescopic attachment in maxillary obturator for the treatment of maxillectomy cases.

Antibacterial Activity of Silver-Nanoparticles Synthesized Using Trichoderma Harzianum

Ehab Y. Jabber¹, Mohamed M. Abdul Hussein¹
¹Department of Biology, Faculty of science, Kufa University, Najaf, Iraq

ABSTRACT
Among the various methods used to synthesize nanoparticles is the biological method is best favorable. Fungi supply several advantages in this context. In this study, extracellular synthesis of silver nanoparticles from Trichoderma harzianum isolated from soil samples. The aim of this study is the biosynthesis of silver nanoparticles by Trichoderma harzianum and evaluating their biomedical action against multidrug resistant bacterium (MDR) of every gram positive & gram negative bacteria (Enterobacter spp. & Acinetobacter spp.). The characterization can be done with the help of XRD, SEM and AFM.

Keywords: Biosynthesis Ag-NPs, Trichoderma harzainum, Antibacterial activity, Nanotechnology.

Introduction
Nanotechnology is a wide field of science that represents the synthesis, characterization and application of materials¹², and nanoparticles are observed as fundamental building blocks of nanotechnology¹⁰. Microorganisms have been explored as possible biofactories for synthesis of nanoparticles like cadmium, sulphide, gold, and silver⁴,⁵. T. harzianum that’s found in all soils⁶. Silver nanoparticles are of interest because of the various properties e.g. size, shape⁷, resistance to antimicrobial agents by pathogenic bacteria that has which enabled it to be incorporated into antimicrobial uses⁸. The size range of silver nanoparticles are 1–100 nm⁴⁶. A fungus produces many of hydrolytic enzymes¹⁰,¹¹. Application of microorganisms is one of the most obvious methods among many bio-methods for nanoparticle production¹²,¹³. Ag-NPs have been extensively used for identification, treatment & drug delivery¹⁴,¹⁵. Physical and chemical methods are more expensive and in actuality toxic to the environment¹⁶. Growth of dependable, nontoxic and green techniques for synthesis of nanoparticles is the most essential to multiply their biomedical uses. One of the choices to achieve this goal is to use microorganisms to synthesize nanoparticles¹⁷,¹⁸. The functions of Ag-NPs as antiviral, antimicrobial, antitumor, and anti-inflammatory agents in which one use of silver ion or metal silver in addition to silver nanoparticles can be exploited in medicine for burn treatment, dental materials, etc.¹⁹. Using microorganisms in the synthesis of nanoparticles emerges as an eco-friendly exciting approach for production of Ag-NPs because of its low toxic, environmental compatibility²⁰.

Materials and Method
Isolation & identification of fungal isolates: In this present study, a total of 50 different fungal isolates had been obtained on isolate only T. harzianum from soil. The soil sample was collected via the usage of a sterile spatula and by serial dilutions were used for getting pure culture using (PDA) media. The medium was also a mended with antibiotic chloramphenicol (0.25 g/ml) to reduce bacterial contamination after serial dilution the petri dishes are incubated at temperature (28 ± 2 °C) for 5 days. Then the fungus isolates were recognized depending on morphological and microscopical examination by using field microscopy observations of lacto phenol cotton blue stained fungal specimen at 40×. To prepare the cell free supernatant from T. harzianum.

Biogenic of silver nanoparticles (Ag-NPs): Biological methods may be used to synthesize Ag-NPs without
the usage of any harsh, toxic and expensive chemical materials\textsuperscript{21,22}. For the biosynthesis silver nanoparticles only isolated \textit{T.harzanium} become used to synthesis of Ag-NPs through extracellular biosynthesis was grown by adding the fungal disk in a liquid PDB media and incubated at 28 °C for 5 days, the produced fungal was filtrate via using centrifuge and thoroughly washed 2-3 times by using distilled water to remove the residual media part and different particles, then 200 ml of cellular filtrate mixing with 20 ml AgNO\textsubscript{3} solution (1Mm).The consequent solution is incubated in shaking incubator at 150 rpm at 28 °C for 96 hrs. this step was prepared in dark condition to avoid any photochemical reactions \textsuperscript{23}. After incubation the color alteration, the supernatant was discarded, the pellet collection of nanoparticles were dried in oven at 40°C. The dried powder was collected cautiously and saved for further examination \textsuperscript{24}. 

**Characterization of silver nanoparticles**

**XRD Analysis:** X-ray diffraction was used to characterization of silver nanoparticle. Department of Geology, Faculty of Science/Baghdad University.

**SEM Analysis:** SEM was used to characterization the morphology of nanoparticles in electron microscope unit, Faculty of science/Kufa University.

**AFM Analysis:** Atomic force microscope (AFM) was used to characterization the silver nanoparticle. Department of chemistry Faculty of science/Baghdad University.

**Antibacterial activity of nanoparticles:** The antimicrobial activity of silver nanoparticles were tested against different kinds of pathogenic multidrug resistant bacteria of each gram positive and gram negative. For antibacterial activity agar well-diffusion method was followed, Muller-Hinton Agar (MHA) plates the usage of sterile cotton swabs. Agar wells were punched with sterilized cork borer. The wells were loaded with solution of silver nanoparticles, incubated for 24 hrs. at 37°C, after the inhibition zones have been measured in millimeter diameter \textsuperscript{25}.

**Results & Discussion**

**Biosynthesis of Silver nanoparticles:** Cell-free filtrate of \textit{T.harzanium} was incubated with silver nitrate, The color of the culture filtrate with silver nitrate modified from yellow to reddish brown after incubated in shaking incubator in 96 hrs., 28°C at 150 rpm, whereas the control did not exhibit any color alteration as in (fig.1). The advent of a brown color in solution as indicator for biosynthesis of Ag-NPs by the reducing agents including enzymes and proteins, etc. \textsuperscript{26}. The color exhibited through metal nanoparticles is a result of the coherent excitation of complete free electrons within the passage band, leading to (SPR) \textsuperscript{27}.

**Characterization of Ag-NPs:** Were characterized by using

**SEM analysis of nanoparticles:** SEM is used to decide the shape and size of biogenic nanoparticles, experimental results displayed well- dispersed nanoparticles with diameter of 64-100nm for silver nanoparticles biosynthesized using \textit{T. harzianum} with variable shapes most of them found in spherical shape as in (fig.2) \textsuperscript{28,29}.

![Fig. 1: Color of sample A) Crude cell filtrate of \textit{T. harzianum} before immersion of AgNo3 B) after immersion of AgNo3](image1)

![Fig. 2: SEM micrograph of biogenic silver nanoparticles](image2)
XRD analysis of nanoparticles: XRD showed that *T. harzianum* produced silver nanoparticles with average size 16nm (fig.3) the Ag-NPs biosynthesized from *T. harzianum* was 16.73 nm\(^2\)\(^9\).

![XRD analysis of biosynthesized nanoparticles size from *T. harzianum*]

AFM analysis of nanoparticles: AFM analysis presented the three dimensional form of silver nanoparticle, average diameter was 78.58 % from *T.harzianum* as in fig.4.

![AFM analysis of biosynthesized silver nanoparticle from *T. harzianum*]

Antibacterial Activity: Results showed that Ag-NPs has the capacity to inhibit the bacterial growth gram positive and Gram-negative bacteria. The inhibition zone was more in gram positive than in gram negative bacteria (table 1) & fig.6. The most important inhibition zone of Ag-NPs in Gram positive bacteria was 26.5 mm with concentration 1mg/ml, while the largest inhibition zone in Gram negative bacteria was 21 mm with same concentration, due to the fact the Gram-positive species containing a large amount of peptidoglycans, monolayer, the content of lipids more less than Gram-negative and have sensitive more to antibiotic from G- which have resistant to antibiotics. When increase the concentration of silver nanoparticles displayed increase in the antibacterial activity \(^{30,31}\). The antimicrobial effect due to the positive charge on the silver ion as its able to attract the negatively charged of microorganisms through the electrostatic interaction. This attraction possibly overcomes other factors, including size and shape, which could influence the bacterial cell death \(^{32,33}\).

![Atomic Force Microscopic analysis of biosynthesized silver nanoparticle from *T. harzianum*]

**Table 1: Inhibition Zones of different pathogenic bacteria by using Ag-NPs synthesized by *T. harzianum***

Incidence of Bacterial Vaginosis and Aerobic Vaginitis before and after Pessary Insertion in Indonesia

Eighty Mardiyan Kurniawati¹, Faria Toma¹, Harry Parathon¹, Gatut Hardianto¹, Azami Azinar Denas¹, Kartuti Deborah², Firas Farisi Alkaff³

¹Departement of Obstetrics and Gynaecology, ²Departement of Microbiology, ³Department of Pharmacology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo General Hospital, Surabaya, Indonesia

ABSTRACT

Background: Pelvic organ prolaps (POP) is the most common gynecological condition in women and its incidence increases with age. Among all treatments option available, the most commonly used was pessary treatment. However, the use of pessary has several side effects, and the most common one is leucorrhoea due to Bacterial Vaginosis (BV) or Aerobic Vaginitis (AV). This study aims to evaluate the incidence of BV and AV before and after pessary insertion in postmenopausal women with POP in Indonesia.

Method: This study was an observational analytical study conducted at outpatient clinic Department of Obstetric and Gynecology Dr. Soetomo General Hospital on August-October 2016. Subject of this study was postmenopausal women with POP who were about to be treated with pessary. Vaginal secretion samples were taken before pessary insertion and 4 weeks after insertion. Gram staining, microbiology culture, and pH evaluation was done for BV and AV evaluation.

Result: There were a total of 20 patients included in this study. The incidence of BV before and 4 weeks after pessary insertion was significantly higher (0 vs 16, p < 0.05), while the incidence of AV before and 4 weeks after pessary insertion was not significantly higher (1 vs 5, p = 0.29). There was a significant increase in the pH evaluation before and after pessary insertion (6.2 ± 0.62 vs 6.4 ± 0.53, p= 0.008). The most common microorganism found in vaginal swab was Escherichia coli.

Conclusion: BV incidence was significantly increased after pessary insertion in postmenopausal women with POP.

Keywords: Aerobic Vaginitis, Bacterial Vaginosis, Postmenopause, Pelvic organ prolapse, Pessary

Introduction

Pelvic organ prolap (POP) is the most common gynecological condition in women and its incidence increases with age. It is defined as the descent of uterus and vaginal walls through vaginal canal ¹. Not only causing discomfort, POP is also having a negative impact on quality of life.

Corresponding Author:

Treatment for POP is offered when the patients develop symptoms attributable to the prolapse that they find bothersome. Until now there are 2 available option for treating POP, which are conservative treatment and surgical treatment. However, surgical treatment is generally reserved when conservative treatment has failed. One of the conservative treatments for POP is the use of pessary. From many types of pessaries, ring pessary have been widely used as conservative therapy for women with pelvic organ prolapse because of its easiness for insertion and removal. Compare to surgical therapy, patients with pessary reported to experience similar improvement in micturition, bowel movements, and quality of life. However, the use of pessary has several side effects, and the most common one is leucorrhoea. A study in postmenopausal women...
using pessaries reported a significant increase in vaginal discharge, leukocytes, and parabasal cells which illustrate the presence of vaginal inflammation 4. The inflammation is caused by either Bacterial Vaginosis (BV) or Aerobic Vaginitis (AV) due to the changes in the vaginal ecosystem 4,5.

BV is a clinical condition which is characterized by changes in vaginal ecology that normally contains morphotype Lactobacilli spp flora into a mixture of flora, specifically a combination of anaerobic bacteria and Gardnerella vaginalis 6. AV, on the other hand, is a condition where Lactobacillus flora is disrupted, followed by signs of inflammation and predominance of aerobic bacteria composed of commensal or pathogenic enteric bacteria 6,7.

The composition of Lactobacillus in the vagina of each individual is different, and it depends on geographic location, race and ethnicity 8. In Indonesia, analytic studies examining the effect of the pessary insertion in pelvic organ prolapse patients on the incidence of BV and AV is scarce. Given the geography, race and ethnicity of Indonesian women that are different from other countries, this study aims to analyze the difference of BV and AV incidence before and after pessary insertion in postmenopausal women with POP.

Material and Method

This study was an observational study conducted from August to October 2016 at Department of Gynaecology Dr. Soetomo General Hospital Outpatient Clinic, Surabaya, Indonesia. Subject of this study was postmenopausal women with POP who were about to be treated conservatively with pessary. POP were diagnosed according to the Pelvic Organ Prolapse Quantification System (POP–Q) 9. Patients with intrauterine device, underwent hormonal replacement therapy, and had an uncontrolled diabetes mellitus were excluded from this study. Drop-out criteria for this study was patients whose pessary was expelled before four weeks of insertion and those who consumed antibiotics during the first four weeks of pessary insertion.

Vaginal secretion samples were taken before pessary insertion and 4 weeks after insertion. Gram staining, microbiology culture, and pH evaluation was done for BV and AV evaluation. BV was evaluated using Nugent criteria scoring system 10. AV was evaluated using microscopic diagnosis criteria 7. Microbiology culture was done in blood agar plate for aerobic organism and MacConkey agar plate for gram-negative aerob organism. Culture was done at the Clinical Microbiology Laboratory Dr. Soetomo General Hospital.

Acquired data was analysed using SPSS version 18.0. Data distribution was analysed using Shappiro-Wilk test. Incidence of BV and AV before and after pessary insertion was analysed using McNemar test. pH evaluation before and after pessary insertion was analysed using paired T-test. The p-value of < 0.05 was considered as statistically significant.

This study follows the principles of the Declaration of Helsinki. This study had received ethical clearance from Dr. Soetomo General Hospital before the study began. All subjects gave their informed consent prior to their inclusion in the study. Information for informed consent was given before subjects signed the informed consent. Details that might disclose the identity of the subjects under study were omitted.

Results

There were 26 patients with POP that met the criteria to be involved in this study. During the study period, 6 patients were dropped out from the study because of pessary expulsion and antibiotic use. The average age of the study subject was 63.8 ± 8.2 years. The menopause duration was 14.9 ± 8.5 years. Most of the study subjects were in the POP stage 3. There were 2 patients who had an intercourse during the first 4 week of pessary insertion (table 1).

Before pessary insertion, no patient had BV and only 1 patient were positive for AV. Four weeks after pessary insertion, 16 patients were positive for BV and 5 patients were positive for AV (table 2). From 16 vaginal swab samples of BV patients, none of the samples had *Lactobacillus* and *Mobiluncus*. Six samples had *Bacteroides/Gardnerella* as many as 5-30/visual field, and 10 samples had more than 30/visual field. No clue cell was found in all samples. The pH value of patients’ vaginal swab specimens before and after pessary insertion was significantly different (6.2 ± 0.62 vs 6.4 ± 0.53, p= 0.008). Microbiological culture of vaginal swab specimens showed that the most common microorganism before and after pessary insertion was *Escherichia coli*, and the second most common was *Staphylococcus coagulase negative* (table 3).

**Discussion**

**Characteristics of Study Subjects:** Subjects of this study were postmenopausal women ranging from 48 to 80 years. Previous study from South Korea found that the prevalence of POP increases with age and reach it peaks on the age of 75 years old 11. Majority of the patients had elementary education, followed by secondary education.
Educational level is known to correlate with individual hygiene and sanitation. A study involving 500 married non-pregnant women revealed a significant association between the incidence of Bacterial Vaginosis and level of education (p < 0.025) 12. Another study involving 85 sex workers also revealed that the level of education was significantly related to the incidence of sexually transmitted diseases 13.

Behaviors such as sexual intercourse, smoking and douching also have an effect on the incidence of BV. In this study, all patients did not smoke or douche. There were 2 patients that had sexual intercourse during the study, with a frequency of 1 to 2 times in four weeks. A prospective study involving 1248 women who did not initially suffer BV reported that the incidence of BV was associated with smoking, douching, and not using contraception, with risk factors for non-white races including decreased Lactobacillus-produced H2O2, having two or more sexual partners in in the past four months and have had sex more than 3 times a week 14.

Incidence of BV before and after pessary insertion: BV is a clinical condition characterized by changes in vaginal ecology, which in normal conditions contains morphotype flora Lactobacilli spp into a mixture of flora combined of anaerobic bacteria and Gardnerella vaginalis. It is defined as an abnormal vaginal ecosystem characterised by a decreased concentration of Lactobacillus and an increased concentration of anaerobic bacteria such as Bacteroides spp., Mobiluncus spp., and Gardnerella vaginalis. There are four bacteria related to BV, including Gardnerella vaginalis, Gram negative anaerobic rod bacteria, Mycoplasma hominis, and Mobiluncus spp 6.

Incidence of BV before and after pessary insertion in this study was statistically significant (p< 0.05). A case control study at Mount Sinai Hospital involving 44 women with POP using pessary with a control of 176 women found that pessary insertion significantly increased the incidence of BV (OR 4.37), where the incidence mostly occurred in the first 6 months after the insertion 5.

BV is evaluated based on Nugent criteria and/or the presence of clue cells 16. In this study, the diagnosis of BV is based on a decrease in the number of Lactobacillus and an increase in Bacterioides/Gardnerella like. In microscopic examination of vaginal swab specimens from patients with positive BV, Lactobacillus morphotype was not found, but Bacteroides/Gardnerella morphotype was found in large quantities. The absence of Lactobacillus in vaginal swabs in this study is most likely because subjects were postmenopausal women, hence the decrease in estrogen resulted in a decrease in the amount of Lactobacillus. This is in accordance with several studies which state that in postmenopausal women, the decrease in estrogen results in a reduced in glycogen metabolism in epithelial cells, which causes a decrease in the amount of Lactobacillus and an increase in vaginal pH 6 13. However, no clue cells were found in all positive BV specimens. We argue that the absence of clue cell formation in this study is likely due to fewer amounts of Gardnerella vaginalis compared to other anaerobic bacteria 16.

In this study, it was found that the average of vaginal pH before pessary insertion was 6.2 ± 0.62 and significantly increased to 6.4 ± 0.53 in 4 weeks after the insertion. An increase in vaginal pH will result in a shift in vaginal flora towards the mixed flora that causes BV and AV 17. In normal condition, the average pH of postmenopausal women is > 5.3 18. According to one of the Amsel’s criteria for the diagnosis of BV, vaginal pH had to be > 4.5 19. Therefore, Amsel’s criteria could not be used to diagnose BV in postmenopausal women.

Incidence of AV before and after pessary insertion: AV is an abnormal condition vaginal ecosystem with reduced concentration of Lactobacillus and increased concentration of aerobes such as Escherichia coli, Staphylococcus aureus, group B Streptococcus and Enterococcus. AV is diagnosed based on an increased leukocyte count of ≥10, decreased Lactobacillus, and the presence of parabasal cells and aerobic bacteria in vaginal swabs 7. In this study, AV is defined as an AV score of ≥3.

Incidence of AV post-pessary insertion was higher compare to pre-pessary insertion. However, the difference was not statistically significant. The result of this study is in accordance with a study involving 100 postmenopausal women, which showed an increase in leukocytes and parabasal cells at 2 weeks, 3 months and 6 months of pessary insertion. Pathological organisms tend to increase after pessary insertion although the increase is not significant.

The most common bacterial isolate in vaginal fluid culture was Escherichia coli. This finding is consistent with a study by Donders et al. which states that the most
common microorganism found in AV is *Escherichia coli*. A study by Hitti et al. reported that *Escherichia coli* was the only microorganism found in the vaginal fluid culture of women with vaginal infections.

**Conclusion**

Incidence of BV in Indonesia increases significantly after pessary insertion in postmenopausal women with POP, while AV incidence did not increase significantly.

ABSTRACT

Introduction: Mother, as the primary care provider for the baby, is expected to be able and independent in caring for the baby. Many factors can influence the independence of mothers in treating low birth weight babies. The purpose of this study was to develop a model of maternal independence in caring for low birth weight babies at home.

Method: This study used an explanation survey. The samples were 160 mothers who had low birth weight babies. The samples were obtained through purposive sampling. The data were collected through a questionnaire and analyzed using Partial Least Squares.

Result: The mother’s independence model is formed from maternal and health worker factors. The biggest effect is on the factor of health officers, with a statistical value of $T = 3.061$.

Conclusion: Factors of health workers in making visits after mothers and babies go home and the care needed to be considered in increasing the independence of mothers to care for low birth weight babies at home are discussed. Further research is needed in the model of visits of nurses by involving families to improve the ability of mothers to care for low birth weight babies.

Keywords: low birth weight, home care, independence of mother, model.

Introduction

Low birth weight babies are those born with a body weight of fewer than 2,500 grams; the number of low birth weight infants in Indonesia is still quite high. The figure accounts for more than 20 million babies worldwide or 15.5% of all births and 95.6% of them in developing countries. Low birth weight babies have a 20 times higher risk of being likely to die than a normal baby. In the long term, low birth weight babies have been associated with the probability of infection, malnutrition and higher disability conditions during childhood, mental deficiencies, and problems related to behavior and learning during childhood. The number of low birth weight babies births in East Java is 11.2% while Indonesia’s national figure is 10.2%.

Low birth weight babies are very susceptible to illness and death, especially in the first month to the third month after birth. Emerging health problems include hypothermia, lack of ability to consume nutrients and infections such as fever/infection, dehydration, shortness of breath, vomiting, and diarrhea. The health condition of low birth weight babies after returning home must be maintained properly because health problems are still prone to occur. The survey results in hospitals in Malang, East Java, Indonesia, show, on average, re-hospitalization of low birth weight babies as much as 10% in the first month after leaving the hospital. The mother, as the primary care provider for low birth weight babies, must have ability include knowledge, mental readiness, and skills in carrying out baby care. Research results in Indonesia show that mothers’ knowledge of maintaining a baby’s body temperature and warmth is 75.56% of mothers with insufficient knowledge.
Mothers who have low birth weight babies often experience obstacles in carrying out their roles both internal and external, including insufficient knowledge, stress, economic problems, and family and social support\(^9\)\(^{-12}\). Mothers need knowledge/information and care support from the environment from both health and family officers up to the first six months after birth\(^13\). Family support is very important to improve the ability and confidence of mothers in caring for babies, but family support in the care of low birth weight babies is sometimes less than optimal.

**Method**

**Research Design:** This study used explanatory survey design, which explains the factors that influence the independence of mothers in treating low birth weight babies after they are released from the hospital.

**Respondents:** This study was conducted on mothers who had low birth weight babies and had returned from treatment at a hospital or health center from September to December 2018 in Malang, East Java, Indonesia. This study involved 160 respondents obtained by purposive sampling. The inclusion criteria were mothers who gave birth to low birth weight babies (body weight less than 2,500 grams with a baby aged 0-2 months and infants who did not experience congenital defects).

**Data Collection:** Data were obtained by going to the home of mothers who had LBW based on the data obtained from the local health center. Data collection was done through questionnaires, interviews, and observations. Maternal factors included knowledge, stress, and family support. Mother’s knowledge about LBW care was measured using a modified questionnaire from LBW care consisting of 15 question item\(^2\)\(^{-14}\).

**Instruments:** The family support variable instrument was compiled based on a measurement questionnaire by Mercer\(^15\) with modifications adjusted to families who had LBW\(^16\).

Mother’s perception used the Parental Perceptions Questionnaire by Pasquali and Araújo\(^17\), which was simplified into 15 items of questions for mothers. Each question item used the answer on a five-point scale. The instrument of the ability of mothers to carry out treatment based on LBW care books and health manuals used a 5-point scale\(^4\)\(^,16\).

All instruments were tested for validity and reliability in a pilot study consisting of 15 respondents. Each item in the statement reached validity (\(r>0.529\)) and each questionnaire also achieved reliability (\(>0.8\)). The development of the independence model of mothers caring for babies with low weight was carried out through focus group discussions with informants who played a role in establishing a model of maternal independence, namely mothers representing respondents, health workers, and holders of maternal and child health programs. After collecting data, we conducted a Focus Group Discussion with respondents and health workers.

**Data Analysis:** Data were collected and analyzed using Smart PLS.

Figure 1: The results of the analysis on the development of a model for the independence of mothers caring for LBW babies at home
Discussion

Maternal factors in the application of independent care in treating LBW are shaped by indicators of knowledge, stress and family support felt by the mother in infant care. Knowledge is the result of knowing, and this happens after the person feels a certain object\textsuperscript{18}. Knowledge can also be defined as facts or information that we consider to be correct based on thoughts that involve empirical testings or based on other thought processes such as providing logical reasons or solving problems\textsuperscript{19}.

Almost all mothers had mobile communication media that could access the internet or asked neighbors who had given birth or from relatives. Mothers considered that information about baby care is the main requirement of postpartum mothers\textsuperscript{20,21}. There are four postpartum maternal needs, namely: information needs, psychological support needs, need to share experiences and need for practical and material support. Stressful condition of the mother will disrupt the daily activities of the mother, including the task of caring for the baby\textsuperscript{22}. Confusion, maternal pressure, and anxiety are signs of prominent psychological disorders when discharged from the hospital\textsuperscript{23,24}. This psychological pressure will be weighted by family environment factors, such as low family income and a large number of family members that are dependent on living costs\textsuperscript{25}.

The results of the study show that prevention of infection in LBW has the smallest number in the ability of mothers to prevent infection in the care of their babies, so there should be active efforts by health workers, both in the perinatology treatment room setting and those responsible in the area/village midwives, to actively counsel and assist so that the baby does not have the potential for infection and illness. LBW babies will experience 30% pain after taking care at home\textsuperscript{26}. The high birth rate of LBW and premature babies puts a burden on parents and a public health burden because of the impact of morbidity and mortality\textsuperscript{22}.

Family support is given by providing maternal needs and trying to prevent the risk of postpartum psychological stress during the postpartum period\textsuperscript{26,27}. In carrying out the role of a mother, a harmonious relationship between husband and mother-baby and with other family members is the most important factor\textsuperscript{28}.

Family support increases peoples confidence and their values, communication patterns and the role of the family as a lifestyle so that families are able to carry out their functions well\textsuperscript{29}. Health worker has a higher influence than the maternal factor. The indicator of health workers in this study is the number of visits and healthcare provided.

The visit of community health workers is highly expected and the results are proven to increase the interaction and communication of mothers and health workers so that they are able to effectively solve health problems for babies and infants, especially from the first month to the sixth month\textsuperscript{30}. Babies with problems or high-risk babies are vulnerable groups who must get special care and assistance, receiving visits so that mothers are not too stressed and are able to independently care for their babies\textsuperscript{31}.

The study employed a cross-sectional design. The data were collected in 2008 and 2009 in 44 different nursing homes from 250 nursing home patients who met the inclusion criteria.\n
\textbf{METHODS:} A sample of 202 cognitively intact nursing home patients responded to the Nurse-Patient Interaction Scale and the Hospital Anxiety and Depression Scale. A structural equation model of the hypothesised relationships was tested by means of Lisrel 8.8 (Scientific Software International Inc., Lincolnwood, IL, USA). The efforts of infant health services in Indonesia after the baby’s birth, according to the government’s program committee for the maintenance of the health of the first 1,000 days of life, comprised neonatal visits and postpartum maternal visits\textsuperscript{32}.

Baby condition monitoring and maternal assistance are also very important to maintain a conducive situation for the care of LBW babies\textsuperscript{33,34}. Good care will minimize the occurrence of LBW health problems, such as the risk of infection, poor nutritional intake and hypothermia problems. Independence in preventing hypothermia and fulfillment of infant nutrition is much better because the direct effects of this behavior can appear as a cold baby and weight loss, while infection prevention behaviors have a lag time for a decrease in endurance, infection, and illness\textsuperscript{35}.
Conclusion

The ability of mothers to care for LBW babies independently is very important to prevent babies from getting sick and dying. The most influential factor for the independence of mothers in the first two weeks is health workers. Mothers need guidance on knowledge, motivation and mentoring by health workers to be able to properly care for their LBW babies. This guidance is carried out by visiting the house at certain time intervals. The factor of family support is also important to help mothers carry out their roles and duties.

ABSTRACT

Introduction: The My Village My Home (MVMH) community-level tool was designed by the Maternal and Child Health Integrated Program (MCHIP) to provide the community and local health functionaries are a visual depiction of the immunization status of all infants born in a village. It ensures that every child receives immunization they need. In Indonesia, MVMH tool is used at the community level (called “Posyandu”). This research objectives is to evaluate My Village My Home (MVMH) method. It supports the Complete Basic Immunization Programme in Surabaya, Indonesia.

Method: This research was an observational study with cohort retrospective design. The exposure population of this research was Public Health Center (PHC) that has received MVMH training on March-April 2018 and the non-exposure population of this research was PHC that has not received MVMH training yet. It was determined by using simple random sampling.

Results: 80% of cadres in the group that had received prior training were well-informed and in the group that did not get training 85% had good knowledge of 5% enough, 10% less. Knowledge of mothers in the cadre group who received training was 85% good and in the group of cadres who did not get 75% good training. Both cadres and mothers in the group of cadres who received training and did not receive training had a good attitude.

Conclusion: Most of the cadre with or without training and mothers have good knowledge. They have a good attitude towards the My Village My Home.

Keywords: Evaluation, Immunization, My Village My Home.

Introduction

The incidence of Vaccine Preventable Disease with immunization such as measles in the East Java Province is still relatively high. It includes the number of measles cases suspects cases and positive measles cases1). The East Java Provincial Health Office data shows that the measles suspect cases were still found from 2012 to 2016 and continues increasingly. The highest measles suspect cases were recorded in 2016, amounting to 3,506 cases, and the lowest cases were recorded in 2012 with 398 cases. Numbers of positive measles cases are increase2-3).

Immunization is one of the most cost-effective public health interventions to prevent children from contracting vaccine-preventable diseases. Indonesia launched the Expanded Program for Immunization (EPI) in 1977. However, immunization coverage remains far below the United Nations International Children’s Emergency Fun (UNICEF) and World Health Organization (WHO) target of 80%4-5).
Low vaccination coverage often reflected services that were not easily accessible, uncomfortable, unreliable, or unfriendly officers. It may also be related to a lack of public trust in vaccination or vaccination services. The level of vaccination coverage in a given community depends on both service factors and the degree to which the public trust in immunization services. Most interventions purpose to raise vaccination coverage focus on improving services or on informing and motivating families.

The My Village My Home (MVMH) community-level tool is designed by the Maternal and Child Health Integrated Program (MCHIP) to provide the community and local health functionaries a visual depiction of the immunization status of all infants born in a village to ensure that every child receives every immunization they need. The MVMH tool designed for use at the community level by field-level workers, such as Auxiliary Nurse Midwives, Accredited Social Health Activists, and the community to efficiently and accurately track children’s immunization status. In Indonesia, MVMH tool used at the community level (called “Posyandu”) by under supervised immunization coordinator cadre at Public Health Center. The community leaders, cadres, volunteers, and health workers are allowed by MVMH to monitor the vaccination status of every young child in participating communities and reminder guiding, and motivational visits.

The MVMH shows information on all children less than 2 years of age in a community under the roof of a house. Each row (from bottom to top), composed of boxes, is indicative of one beneficiary, and each box indicates an antigen that is to be provided to the beneficiary.

The objective research is to evaluate My Village My Home (MVMH) method, and to support the complete Basic Immunization Programme in Surabaya, Indonesia.

Method

This research was an observational study with cohort retrospective design. It was conducted in Surabaya, since September to December 2018.

The Public Health Center (PHC) was the exposure population of this research that has received MVMH training from Faculty of Public Health Universitas Airlangga on March-April 2018 and the non-exposure population of this research was Public Health Center that has not received MVMH training yet. The MVMH tool is a large poster-sized record on which every infant in a community has his or her own row, with spaces for the child’s name, date of birth, and dates of each vaccination.

The data that had been collected was in form of primary data, that it was obtained from an interview between the cadres and mother of children under 2 years with questionnaires. Before the interview taken, respondents would be given this research explanation, they were asked to sign the informed consent. Prior to the interview, respondents were given an explanation and then asked to sign an informed consent. Then, the data that had been collected were analyzed descriptively and it was presented in the form of narration and tables that illustrated the investigated variables.

Results

The result of this research was the socio-demographic characteristics cadre and mother with children under 2 years, descriptive analyze for input, process and output components about My Village My Home in Surabaya.

Socio-Demographic Characteristics: The average age of mothers is 32.67 years with a range of 21-54 years, while the average age of Posyandu cadres is 47.58 years with a range of 25-68 years. Age distribution of respondents can be seen in table 1.

The results showed that all cadres in the two groups said that the MVMH was available at the Posyandu. The number and quality are in accordance with the standard. Posyandu still exists that does not have an area to attach to the Immunization House during the Posyandu schedule. In this study also identified the availability of the MVMH budget in each Puskesmas that was the location of the study. Most cadres said that the source of the budget came from the Puskesmas and was adequate.

Indeed the procurement of MVMH from the Puskesmas. A cadre who said that there was a budget from community self-help, was intended for stationery to fill in the columns in the MVMH.

The results showed that most Posyandu cadres in both groups said that filling in the MVMH for infants and children who did immunization at the Posyandu was at the end of every Posyandu activity. Filling the MVMH should be every time a newborn is born and every baby or child is immunized.

In the group of cadres who had received training, most said that monitoring of immunization schedules for immunized infants and children in Posyandu and Puskesmas was close to the Posyandu schedule (68.4%). While in the cadre group who did not receive training, most said that monitoring of immunization schedules for infants and children immunized in Posyandu and puskesmas was during the implementation of Posyandu (57.9%). More information is presented in table 6.

In the group of cadres who had received training, most said that monitoring of immunization schedules for infants and children immunized not at Posyandu was close to the immunization schedule (68.4%). Whereas in the group of cadres who did not receive training, (52.6%) cadres said that monitoring of immunization schedules for immunized infants and children was not in Posyandu, namely during the implementation of Posyandu.

Discussion

Immunization are important to reduce vaccine-preventable diseases in children, and consistent control of vaccine-preventable diseases depends on fairly high immunization coverage

A person’s behavior is influenced by 3 factors, they are predisposing factors, reinforcing factors, enabling factors. One of the predisposing factors that influence health behavior is knowledge. It is the basic foundation of attitudes and positive action of a person. It means that a person good knowledge would showed that attitude good. A person’s knowledge is very influential on the actions they take. Knowledge is the result of knowing something and knowledge occurs after someone senses a particular object. The sensation can be through the senses of sight, hearing, smell, taste, and touch. Most human knowledge is obtained through the ears and eyes.

Knowledge of cadres and mothers of toddlers about MVMH was measured by 8 questions about the description of the contents of the MVMH, those who played an active role in the MVMH, as well as the goals and benefits of the MVMH. Cadre in health volunteers, selected by the community, most of active cadres entirely female, although it may be a cadre of men. Mostly, training cadres or without training have MVMH good training.

Most of the baduta mothers accompanied with cadres with training have known about the MVMH while for mothers with cadres without training, 50% of mothers
do not know the MVMH. Most of the respondents who knew about the MVMH had sufficient knowledge about MVMH both for mothers with cadre with and without trainings. The 8 questions that were asked to the mother of baduta mostly answered incorrectly, this questions related to the purpose and benefits of the MVMH. One of question, namely “The home of immunization can be used as a means of communication between midwives, cadres, and the community regarding immunization” and “The MVMH provides an illustration of infant immunization status at the posyandu only”. There is a significant difference between mothers and cadres who have received training and mothers with cadres who do not receive training are related to whether or not the MVMH is available.

They inform and motivate about immunization to mothers and fathers during their regular visits as well as in meetings and other community activities. Although rarely needed, they also do home visits to motivate the parents of a child who has fallen behind in his/her immunizations.

The results showed that both cadres and mothers had good knowledge about MVMH because they had to be in every Posyandu while maintaining the existence and sustainability of the MVMH method therefore 3 all under-aged children were immunized in order to improve the Complete Basic Immunization Program in Surabaya.

ABSTRACT

Benzene is a liquid aromatic hydrocarbon compound that is clear, colorless, flammable, and volatile. This study aims to determine safe concentration of benzene at public gas stations workers around Diponegoro University Semarang. This is descriptive, observational, and cross sectional study. A total of 28 workers were then taken as sample. Data was taken in form of primary and secondary data, then analyzed manually through calculation of safe concentration of benzene after determination of weight, body surface of experimental animals, body weight body surface area, breathing rate of workers, benzene concentration, Animal Km, Human Km, highest dose of toxin without causing effect, and reference concentration of benzene for workers.

The measurement of average concentration of benzene in the air showed a value of 0.82 mg/m³ (0.25 ppm). This result is lower than benzene Threshold Limit Value according to Ministry of Manpower Regulation Number 5 of 2018 of 0.5 ppm. In contrast, manual calculation of safe concentration of benzene was 0.01 ppm. In conclusion, average value of benzene concentration is not safe for workers. Efforts to control benzene exposure in work environment are needed to ensure workers health such as use of Personal Protective Equipment in form of half mask respirators with organic vapor cartridges, consumption of CYP2E1 enzymes in beef liver and salmon meat, procurement of Golden Phothos or Boston plants, and inspection and regular monitoring of benzene exposure biomarkers in work environment.

Keywords: Benzene, Safe Concentration, Workers

Introduction

Benzene is a liquid aromatic hydrocarbon compound that is clear, colorless, flammable and volatile with a smell like gasoline. Benzene is carcinogenic to humans and associated with an increased risk of developing lymphatic and hematopoietic cancers, acute myelogenous leukemia and chronic lymphocytic leukemia(1). According to World Health Organization (2010), narcosis with symptoms of headache, drowsiness, confusion, and loss of consciousness is the effect of acute exposure to benzene(2). The effect of chronic exposure to benzene is cancer.

According to Agency for Toxic Substances and Disease Registry, there is a causal relationship between exposure to benzene in workplace as a major cause of increased leukemia. This is supported by National Cancer Institute and Chinese Academy of Preventive Medicine study conducted on 74,828 workers in China exposed...
to benzene. The risk of leukemia increases at average exposure of 10-24 ppm and cumulative exposure of 40-99 ppm/year\(^9\).

The benzene compound has value of Inhalation Reference Concentration for non carcinogenic effects by 3x10-2 mg/m\(^3\) (0.0086 mg/kg/day) and Cancer Slope Factor for carcinogenic effects by 2.2x10\(^{-6}\)-7.8x10\(^{-6}\) mg/m\(^3\) (0.1-0.34 mg/kg/day) that has been determined by Integrated Risk Information System U.S. Environmental Protection Agency\(^4\). The volume of benzene in oil and gas industry functions as an octane-enhancing solvent for gasoline products is about 1-5\(^0\). Occupational Safety and Health Standards states that exposure limit in working period is 1 ppm\(^6\). American Conference of Government Industrial Hygienists in 2012 recommended exposure to working period of 0.5 ppm\(^7\). In Indonesia, benzene Threshold Limit Value by Ministry of Manpower Regulation Number 5 of 2018 is 0.5 ppm\(^8\).

Semarang has the highest population growth rate in 2010-2017 at 1.72\%, especially Tembalang and Banyumanik sub-districts at 21.03\% and 14.03\%\(^9,10,11\). High number of population have impact on the use of motorized vehicles that reached 48,663 and 17,121 units\(^12\). It influences increase in fuel demand and availability of public gas stations around Diponegoro University.

The Ministry of Mining and Energy Decree Number 1585/K/32/MPE/1999 concerning Marketing Requirements and Domestic Gasoline and Solar Fuel Types states the gradual elimination of lead and substitution with benzene doesn’t reduce the carcinogenic effect because gas stations workers remain directly exposed to these compounds through inhalation, ingestion, and continuous contact with skin\(^13\).

Based on study conducted by Sukaisi (2018), there was an increase in lymphocyte content of public gas stations workers in Medan\(^14\). Content of lymphocyte in leukocytes is around 20-30\%. Leukocyte is the most sensitive cell to benzene exposure\(^15\). If leukocytes increase, leukocytosis will occur and trigger lymphocytosis which can cause enlargement of liver, spleen, and glands that are site of lymphocyte formation\(^16\). Winek et al. (1967) in the Agency for Toxic Substances and Disease Registry (2007) stated that fifteen male workers were exposed to benzene with concentration of >60 ppm, causing 80\% of workers have mucous membrane irritation and 67\% have shortness of breath for 3 weeks\(^3\). Thus, safe limits of benzene concentration need to be known.

Dimas Triyadi (2016) showed the measurement of benzene concentration at public gas stations on the highest value of 2.08 ppm\(^17\). This concentration exceeds benzene Threshold Limit Value. It is concluded to be unsafe that creates risk of causing non-carcinogenic and carcinogenic effects. This is supported by study in Korea that showing exposure to benzene in workplace as cause of increase in hematopoietic disease even though workplace environment had been improved\(^18\).

Based on previous study, no safe concentration has been calculated. This calculation is important to ensure the health of workers. Safe concentration of benzene was calculated by using Reference Concentration formula with No Observed Adverse Effect Level adjusting the research data so as not to cause health problems and carcinogenic effects on workers\(^19\). The author calculates the safe concentration of benzene by using Reference Concentration formula with No Observed Adverse Effect Level as safe limit of benzene concentration in workers of public gas stations.

### Material and Method

This study aims to determine safe concentration of benzene at public gas stations workers around Diponegoro University Semarang. This type of study was descriptive, observational, and cross sectional. The population was all workers at four public gas stations by 78 people. The sample was calculated using Slovin formula and proportional random sampling, taken by using a purposive sampling technique and inclusion criteria which resulted into 28 people.

The study began by collecting secondary data and primary data obtained through filling out questionnaires, weighing weight, and measuring concentration of benzene in the air directly inhaled by public gas stations workers with personal dust sampler and coconut shell charcoal. The variables were weight, body surface area of experimental animals, body weight, body surface area, breathing rate of workers, benzene concentration, Animal Km, Human Km, highest dose of toxin without effect, reference and safe concentration of benzene for workers. Data analysis was carried out by using quantitative data analysis manually to determine the safe concentration of benzene.
Findings

A. Characteristics and Body Surface Area of Experimental Animals: The experimental animals used was white mice (*Rattus norvegicus*).

The body surface area is calculated by using following formula.

\[ \text{BSA} = 0.09 \times \text{W}^{0.67} \]

B. Characteristics, Body Surface Area, and Workers Respiratory Rate: The characteristics were weight and length of work of workers. The average body weight is 58.57 kg and length of work is 6.5 hours/day. The average height of workers is the average height of Indonesian men 159 cm. The body surface area and respiratory rate of workers can be calculated using following formula.

1. The surface area of the workers body

\[ \text{BSA} = \sqrt{\frac{W \times h}{3600}} \]

\[ \text{BSA} = \sqrt{\frac{58.57 \times 159}{3600}} \]

\[ = 1.6 \text{ m}^2 \]

2. Workers' Breathing Rate

\[ \text{BR} = \frac{5.3 \ln W - 6.9}{24} \]

\[ \text{BR} = \frac{5.3 \ln W - 6.9}{24} \]

\[ = \frac{5.3 \ln 58.57 - 6.9}{24} \]

\[ = 0.6 \text{ m}^3/\text{hour} \]

<table>

</table>

The average body surface area and breathing rate of workers are 1.6 m² and 0.6 m³/hour.

C. Benzene Concentration: The average concentration of benzene in the air directly inhaled by public gas stations workers around Diponegoro University Semarang is 0.82 mg/m³. The formula and results of conversion from mg/m³ to ppm are as follows.

\[ C = 24.45 \times C \text{ (mg/m}^3) \div \text{molecular weight} \]

\[ C = 24.45 \times \frac{0.82 \text{ mg/m}^3}{78.11} \]

\[ = 0.25 \text{ ppm (< 0.5 ppm)} \]

The average benzene concentration is lower than benzene Threshold Limit Value. However, the benzene highest concentration reached 2.08 ppm. This exceeds Threshold Limit Value permitted in Ministry of Manpower Regulation Number 5 of 2018 by 5 ppm.

D. Animal Km dan Human Km: Determination of safe dosage of toxin in workers begins with calculation of Animal Km and Human Km.

1. Animal Km

\[ \text{Animal Km} = \frac{\text{W animal}}{\text{BSA animal}} \]

The results of Human Km are shown in Table 4 with average Human Km for public gas stations workers around Diponegoro University Semarang of 36.6.

E. No Observed Adverse Effect Level (NOAEL):
To find out the safe limits of concentration, No Observed Adverse Effect Level toxicity test needs to be carried out without causing any effects on experimental animals\(^{(20)}\). Swaen et al. (2010) stated that No Observed Adverse Effect Level benzene is 3.0 mg/m\(^3\) or 0.022 mg/kg obtained from following formula\(^{(21)}\).

\[
\text{NOAEL benzene} = \frac{3 \times 0.00013 \times 8}{0.1405} = 0.022 \text{ mg/kg}
\]

F. Inhalation Reference Concentration: In book Industrial Toxicology and Risk Assessment (2013)\(^{(22)}\), the safe limits of concentration on workers are calculated using formula from Shaw et al. (2007) as follows.

\[
\text{RfC} = \frac{\text{animal Km}}{\text{human Km}}
\]

The benzene Reference Concentration were obtained from No Observed Adverse Effect Level, average Animal Km, and Human Km are as follows.

\[
\text{RfC} = \frac{5.82}{36.6} = 0.003 \text{ mg/kg}
\]

G. Safe Concentration of Benzene: In book Industrial Toxicology and Risk Assessment (2013)\(^{(22)}\), safe concentration of benzene was calculated using formula used after obtaining Reference Concentration with No Observed Adverse Effect Level, average body weight, length of time worked, and breathing rate of workers as follows.

\[
\text{Safe C (mg/m}^3\text{)} = \frac{(\text{RfC})(W)}{(8)(\text{BR})(t)}
\]

\[
\text{Safe C (ppm)} = \frac{\# mg/m^3 \times 24.45}{\text{molecular weight}}
\]

\[
\text{Safe C (mg/m}^3\text{)} = \frac{(\text{RfC})(W)}{(8)(\text{BR})(t)} = \frac{(0,003)(58,57)}{(50\%)(0.6)(6.5)} = 0.059 \text{ mg/m}^3
\]

\[
\text{Safe C (ppm)} = \frac{\# mg/m^3 \times 24.45}{\text{molecular weight}} = \frac{0,059 \times 24.45}{78,11} = 0.01 \text{ ppm}
\]

Safe concentration of benzene at public gas stations workers around Diponegoro University Semarang was 0.059 mg/m\(^3\) (0.01 ppm). These results can be used to compare with benzene Threshold Limit Value permitted by Ministry of Manpower in 2018 and other institutions such as Occupational Safety and Health Standards, American Conference of Government Industrial Hygienists, or National Institute for Occupational Safety and Health then be basis for efforts to control benzene exposure in work environment to be safe for workers.

The average concentration of benzene reached 0.25 ppm and the highest reached 2.08 ppm; exceeding benzene Threshold Limit Value. The safe concentration of benzene was calculated based on Reference Concentration with No Observed Adverse Effect Level. In this study, the value of No Observed Adverse Effect Level benzene using white mice was 0.022 mg/kg. The same result was obtained by Swaen et al. (2010) with 0.022 mg/kg\(^{(21)}\). Meanwhile, this result is smaller than Agency for Toxic Substances and Disease Registry (2007) study which states 3 ppm for exposure through inhalation\(^{(3)}\). In conclusion, No Observed Adverse Effect Level benzene was safe for workers.

Benzene Reference Concentration obtained from value of No Observed Adverse Effect Level, average Animal Km, and Human Km is 0.003 mg/kg/day. This result is smaller than Integrated Risk Information U.S. Environmental Protection Agency in 2003 which was 0.0085 mg/kg/day\(^{(4)}\). This result is also smaller than study conducted by Salim (2012) and Hayat (2013) which were 0.01 and 0.0086 mg/kg/day\(^{(24,25)}\).
The safe concentration of benzene was 0.01 ppm. This result is smaller than benzene Threshold Limit Value and limit of benzene exposure set by Occupational Safety and Health Standards and American Conference of Government Industrial Hygienists by 1 ppm and 0.5 ppm\(^6,7,8\). The safe concentration of benzene in this study can be used as reference to determine the limits of benzene exposure in work environment so that it is safe for workers.

**Conclusion**

The average concentration of benzene in the air directly inhaled by public gas stations workers around Diponegoro University Semarang show a value of 0.25 ppm that it is still lower than 0.5 ppm as benzene Threshold Limit Value. Unlike that, the manually calculated safe concentration of benzene was 0.01 ppm. Thus, the average value of benzene concentration is not safe for workers. In addition, the highest benzene concentration reached 2.08 ppm; exceeding Threshold Limit Value and safe concentration of benzene. Therefore, efforts to control benzene exposure in the work environment are needed to ensure the health of workers.

Efforts to control benzene exposure recommended are the use of Personal Protective Equipment in form of half mask respirators with organic vapor cartridges to minimize inhalation of benzene exposure in the air, consumption of CYP2E1 enzymes in beef liver and salmon meat to reduce the concentration of benzene in the body, procure Golden Phothos or Boston ornamental plants to absorb and reduce the concentration of benzene in the air, and check and monitor benzene exposure biomarkers periodically in work environment to control benzene concentrations in the air\(^{23}\).

¹Department of Management, Faculty of Economics and Business, Universitas Airlangga, Surabaya, Indonesia; PhD Student in Department of Management, Faculty of Economics and Business, Universitas Brawijaya, Malang, Indonesia.; ²Department of Management, Faculty of Economics and Business, Universitas Brawijaya, Malang, Indonesia

ABSTRACT

The purpose of this study is to conduct literacy studies on phenomena that are becoming the main focus for universities in the world in an effort to improve the quality of internationally standardized education and get the best ranking in the world. The perspective used in conducting the literature review is to include strategic management theory, especially the concept of developing models or operations strategy frameworks as university strategic reconciliation reaches world class university.

The content of the operations strategy is an interaction between goals and operating performance decisions that pay attention to the translation of the resources they have. The important thing about the content of this operations strategy is an understanding of the importance of the role of operating performance goals and understanding the effect of operating performance goals in determining decisions based on organizational resource capabilities. One of the state universities which is an example in describing an operations strategy model is Universitas Airlangga. The main focus of Universitas Airlangga as one of the leading universities in Indonesia is to improve academic quality over time to reach the world’s top 500 ranking.

The expected theoretical contribution is to be able to complement the strategic management research and operations strategy and business process management in the management of universities in developing a specific framework regarding operating strategies as strategic reconciliation towards world class university. While the expected empirical or practical contribution, namely the uniqueness of the operations strategy framework developed by Universitas Airlangga towards world class university, is able to inspire and be adopted by other universities who wish to improve the quality and achievement of a world-class reputation.

Keywords: operations strategy, world class university, quality improvement, strategic reconciliation, competitiveness

Introduction

World-class universities, which are usually referred to as the most prominent research universities, have a very important role in developing competitiveness in the international knowledge economy. These universities play a key role in generating and disseminating knowledge, educating individuals who are highly skilled in leadership, and serving the needs of the community. In recent years, the development of world-class universities has been prominent in the strategic planning of various countries. Various development strategies at the national and institutional level have been developed and implemented in such a way as to achieve international or global scale quality.

In this context, Shanghai Jiao Tong University has initiated the International Conference for World Class Universities, to bring together university managers and leading researchers from all over the world to...
discuss issues related to world-class universities, in the context of increasing the number of countries and higher education institutions that face the challenges of achieving academic excellence. Universities in developing countries seek to improve their ability to improve the performance of their research to achieve and maintain their position and status throughout the world.¹

**World Class University:** World class university sometimes referred to as a global research university is an academic institution dedicated to creating and disseminating knowledge in various disciplines and fields, providing high-quality education at all levels, serving national needs, and advancing international public interest. The main attributes of world-class universities include the availability of qualified faculties, academically gifted students, excellence in research, quality teaching with international standards, high funding levels, and complete facilities. A world-class university is able to attract students who excel in the academic field and the most highly qualified lecturers (researchers and researchers), and also have access to abundant funding sources and offer a diverse (rich) learning and research environment, so that they can respond flexibly and appropriate to the changing demands of the international market.¹

In addition to the amount of funds needed, the problem of mentality to make changes is also another important thing. Hayward states that “Change will not take place without the general recognition within the university community that it is necessary. Part of the process of strategic planning is to get people to recognize the need for change.”¹⁴ Altbach suggests that many universities in various parts of the world have claimed to be universities that have reached world class; but the claim, actually does not have enough justification. According to him at least is a university that has fulfilled several relevant characteristics which indicate that it already has the status of a world class university.²

Nowadays economic growth and global competition that continue to increase are in fact influenced by science, which causes universities to play an important role. The rapid progress of science and technology in various aspects of life provides tremendous potential for the development of the country’s economy. In the World Development Report of 1998/1999 from the World Bank it was stated that there are four key strategic dimensions that complement each other in developing an economy based on science: corresponding institutionalization and economics, a strong foundation of human resources, a dynamic information infrastructure, and a system efficient national innovation.⁵

In this case the tertiary institution plays a central role in these four dimensions, especially in two respects, namely: building a strong foundation of human capital and an efficient national innovation system. universities support the state by building a global competitive economy from the aspect of developing a skilled, productive and flexible workforce and creating, implementing and disseminating new ideas and inventions and technologies.⁵

The world class university development strategy at the institutional level is directed at strong leadership, a clear vision of the university’s mission, goals and strategic planning clearly articulated in translating its vision into concrete targets and programs. universities that have aspirations to produce something that is better coupled in an objective evaluation/evaluation of their strengths and domains that require improvement, compile the achievements to be achieved, and design and implement plans that have been updated that will lead to improving the performance of universities to be better. But on the contrary, if the university is satisfied with the existing conditions, it is less ambitious to make things better in the future, so the final performance that is displayed is the higher lag of the college with competitors - other universities both at the regional level national, let alone international.³

**Operations Strategy:** The term operation is often interpreted as part of the organization creating and or delivering products and services. Every good organization engaged in manufacturing and services is certain to carry out the transformation process. Slack and Lewis state the reason for every organization trying to add value to the products and services produced to its customers is to satisfy the needs and demands of consumers for continuous quality improvement. In the transformation process, two important things that must be considered for good management are all types of resources and processes. Resources in this case are what types of raw materials, information, humans, building technology and other things that are right used to achieve organizational goals, while the process is how all these resources are organized to create products and services that consumers want.⁸

The operations strategy must reflect four perspectives: top-down, bottom-up, market requirements and operations resources.⁸
Figure 1: Perspective in Operations Strategy
Source: Slack and Lewis, 2015

The four perspectives that underlie the understanding of the formation of operating strategies in the organization to carry out the transformation process and create added value and make the organization have competitive advantages are (1) Top-down perspective where operating strategies should be interpretations or strategies at higher levels (in above) and the term “top down” reflects or gives meaning to what the organization manager wants to do, especially from the top management level; (2) The bottom-up perspective where the operations strategy should learn from day to day experience based on the operational experience of the company’s daily activities and the meaning of bottom up is that all operational improvement activities are carried out cumulatively according to the strategies produced in the top down perspective; (3) Perspective operations resources where operating strategies must build capabilities or operational capabilities based on the resources owned by the company.; and (4) The market requirements perspective where the operations strategy must satisfy the company’s market and the company’s perspective on its external conditions and how market demand influences the organization’s operations strategy.8

The results of strategic reconciliation between market demand and operating resources can be seen in the dimensions of operating performance in the form of quality, speed, dependence, flexibility and cost. These five dimensions will generally determine the competitive advantage of each organization where the organization can show qualities that exceed other organizations. Determining the exact dimensions of operating performance is strongly influenced by how well the organization understands the market which includes understanding of the needs of its customers, the position of the organization in the market and the activities of its competitors. These dimensions will then be used to determine strategic decisions in various areas or fields.8

An operations strategy matrix is a description of the operations strategy as a result of reconciliation between the objectives of the company’s performance and the area of decision making. This emphasizes the iteration between what is needed from the operation function (the relative priority given to each performance goal), and how the operation tries to achieve this through a series of choices made (and capabilities that have been developed) in each decision area. Any operation that claims to have an operations strategy might have some kind of story to tell to each iteration. This should explain exactly how the capacity strategy will affect quality, speed, dependency, flexibility or cost. This should be able to explain exactly how flexibility is influenced by capacity, supply networks, process technology and development decisions and organizations, and so on. In other words, the matrix helps the operations strategy to be comprehensive. Also, it is not possible for all vertices in the matrix to be of the same importance. Some iterations will be more critical than others. Which iterations are critical goals, of course, depend on the company and the nature of its operations, but tend to reflect the relative priorities of the performance goals and regional decisions that influence, or are influenced by, the company’s strategic resources.8

Towards World Class University in Indonesia: Several universities in Indonesia are currently competing to carry out various strategic efforts in order to achieve the criteria of world class university, including Universitas Airlangga which is one of the state universities in Indonesia that is targeted to become one of the world-class universities like other universities. One of the state universities which is an example in describing an operations strategy model is Universitas Airlangga. The main focus of Universitas Airlangga as one of the leading universities in Indonesia is to improve academic quality over time. Globalization is not considered an obstacle but as an opportunity to carry out the development of education, research, and various public services. Universitas Airlangga continues to innovate to actualize the integration and collaboration of various disciplines, especially in the fields of health.
economics, humanities, social sciences, local wisdom, and science and technology. The aim is to strengthen each other’s disciplines so that they can continue to exist and contribute to society, not only at the national level but also at the international level. Universitas Airlangga pays attention to entrepreneurship-based research to realize national independence supported by the efficiency and effectiveness of human and natural resources.

In order for Universitas Airlangga to become a world class, Universitas Airlangga must continue to strive to be the best. This has clear implications for the quality of higher education. The difference between universities and their academic excellence depends on maintaining a long-lasting and prolonged level of academic excellence and education. University competitiveness is influenced by the support of those who manage and have an interest in the institution. The world-class quality expectations that Universitas Airlangga wants to be ranked in the top 500 universities in the world, have not been able to be realized by Universitas Airlangga, where until 2018 Universitas Airlangga is still ranked 700th in the world. Therefore, it is necessary to carry out research that is expected to be able to provide a clear model or strategic framework of operations as Universitas Airlangga’s strategic reconciliation in order to achieve world-class universities (top 500 of the world) so as to enable Universitas Airlangga to face the challenges and problems that are expected. later able to be adopted by other world-class universities. Some important questions that need to be explored to develop a model or operations strategy framework are how to develop the status of a world-class university; how to face the same problems and challenges experienced by other world-class universities; what is the market demand faced; what is the stiff competition with other universities; what is the availability of operating resources that can be seen from the dimensions of operating performance in the form of quality, speed, dependence, flexibility and cost; and what is the strategic decisions in various fields.

Referring to the answers of several participants who are strategic decision makers at Universitas Airlangga, they will be able to describe a model or framework regarding operating strategies as strategic reconciliation towards world class university. The uniqueness of this operations strategy model is expected to be able to inspire later and be adopted by other universities who wish to improve the quality and achievement of a world-class reputation.

### Conclusion

World-class universities, which are usually referred to as the most prominent research universities, have a very important role in developing competitiveness in the international knowledge economy. These universities play a key role in generating and disseminating knowledge, educating individuals who are highly skilled in leadership, and serving the needs of the community. The main attributes of world-class universities include the availability of qualified faculties, academically gifted students, excellence in research, quality teaching with international standards, high funding levels, and complete facilities.

The content of the operations strategy is an interaction between goals and operating performance decisions that pay attention to the translation of the resources they have. The important thing about the content of this operations strategy is the understanding of the importance of the role of operating performance goals and understanding the influence of operating performance goals in determining decisions based on organizational resource capabilities. business carried out by the organization. The strengths and weaknesses of resources and business processes are always understood before carrying out these strategic decisions.

One of the state universities as an example in describing an operations strategy model is Universitas Airlangga. The main focus of Universitas Airlangga as one of the leading universities in Indonesia is to improve academic quality over time. Globalization is not considered as an obstacle but as an opportunity to carry out the development of education, research, and various public services. The phenomenon of Universitas Airlangga’s performance problems arises when viewed from the context of ranking on the basis of several indicators assessed on aspects used by the Higher Educati()ons Ministry and applied and treated equally on all universities in Indonesia, both State Universities and Private Universities. The ranking is still in the level of quality competition with all universities in Indonesia. To achieve the target of world-class universities, it is necessary to know the empirical conditions of Universitas Airlangga in the global or international scope. The world-class quality expectations that Universitas Airlangga wants to be ranked in the top 500 universities in the world, have not been able to be realized by Universitas Airlangga, where until 2018
Universitas Airlangga is still ranked 700th in the world. Therefore, it is necessary to carry out research that is expected to be able to provide a clear model or strategic framework of operations as Universitas Airlangga’s strategic reconciliation in order to achieve world-class universities so as to enable Universitas Airlangga to face the challenges and problems that are expected. later able to be adopted by other world-class universities.

The expected theoretical contribution is to be able to complement the strategic management research and operations strategy and business process management in the management of universities in developing a specific framework regarding operating strategies as strategic reconciliation towards world class university. While the expected empirical or practical contribution that is the uniqueness of the operations strategy framework developed by Universitas Airlangga towards world class university is able to inspire and be adopted by other universities who wish to improve the quality and achievement of a world-class reputation.

ABSTRACT

Introduction: Problems with coronary heart disease (CHD) can be prevented by involving the family. The purpose of this study is to develop an anticipatory persuasive model by adolescents as an effort to prevent CHD by families.

Method: This study using observational analytic study with the cross-sectional approach. The sample was 180 students aged 16-18 years who have families with CHD. The variables of this study were adolescents as a source of messages, dimensions of message strength, family characteristics, persuasive promotion, anticipatory attitudes and prevention of CHD. Data collection used a questionnaire. The analysis used descriptive analysis and testing of structural models were done with Partial Least Square.

Results: The promotion of family persuasiveness, Family characterization factors affects the prevention of CHD through a family anticipatory attitude. influence the prevention of CHD directly. Persuasive promotion does not affect the prevention of CHD if not through anticipatory attitudes. Improved family prevention of CHD is better after more positive anticipatory attitude changes following persuasive promotions. The new discovery of the research is a model of persuasive anticipative promotion by adolescents as an effort to prevent CHD.

Conclusions: The anticipatory attitude of the family is an important factor in preventing CHD by the family following persuasive promotion. The training program, in collaboration with schools, is a way to make adolescents as health cadres for families in the prevention of CHD.

Keywords: Persuasive Promotion, Anticipatory Attitudes, Prevention of Coronary Heart Disease

Introduction

The 2013 Riskesdas¹ data showed that the highest prevalence for cardiovascular disease in Indonesia was coronary heart disease (CHD), which amounted to 1.5%. The most appropriate interventions for CHD are primary prevention or early prevention by eliminating altered CHD risk factors. The community must begin the quality of healthy life with an awareness of the need to change self-behavior for the better by implementing a good lifestyle². Knowledge, attitudes, perceptions, motivations, family support and sources of information are factors that play a role in secondary prevention measures of CHD risk factors³.

Preventive behavior requires knowledge enhancement activities that can be carried out through health promotion. The promotion of sustainable cardiovascular health and disease prevention is very important, and the family is the central entity in this process. The mechanism that contributes to the importance of families for the promotion of cardiovascular health is family system interdependence⁴. Based on this research, it can be explained that health promotion is not only the responsibility of health workers but can be also done by family members, one of whom is a teenager. Adolescents
can persuade parents by becoming a sharing friend for parents by being an agreeable discussion partner, so as to provide input to parents as long as the delivery is polite and adapted to the capacity that adolescents have. The previous study\textsuperscript{4} showed that intergenerational communication and learning by empowering different generations by appreciating their knowledge is very effective in the transfer of knowledge.

Adolescents’ ability to persuade families in internal promotional activities is expected to convince families in anticipating CHD events. Persuasive methods are more effective in improving attitudes. Learning does not have to be from older people\textsuperscript{5}. Promotion by adolescents with the aim of family members at risk of developing CHD is a form of family support. Family support is one of the factors that greatly influence positive behavior\textsuperscript{6}. Through a promotion with a persuasive approach by adolescents, it can generate anticipatory attitudes to prevent CHD by the family. Based on this, the purpose of this study is to develop adolescent anticipatory persuasive promotion models for efforts to prevent CHD by the family.

Method

The study design was observational analytic with the cross-sectional approach. The population of this study was adolescents undertaking high school education in Bangkalan Regency. The total sample of 180 adolescents aged 16-18 years was taken by cluster simple random sampling technique. The variables of this study were adolescents as message sources, message strength dimensions and family characteristics as exogenous variables. Persuasive promotion, anticipatory attitudes, and prevention of CHD were endogenous variables. Data collection was done using a questionnaire. The analysis used descriptive analysis and testing of structural models with Partial Least Square (PLS).

Results

Construct Validity Test Results: The results of the construct validity test to find out a valid indicator in explaining the latent variables are explained in Table 1. It is known that adolescent sex and content dimensions do not significantly measure latent variables.

Figure 1: Structural Model
Discussion

Adolescent factors as a source of messages have a significant influence on the promotion of persuasion by adolescents in the prevention of CHD. Adolescents are required to have good knowledge and communication skills. Parents are no longer the main source of knowledge for children. Scientific and technological knowledge in the information society has reduced the role of parents as knowledge authorities. Emotional closeness due to family factors is an important factor in communication to convey the desired message. The message delivered must be a message designed to foster attention, able to be understood, clear and in accordance with the family need, provide practical information and the facts and offer recommendations.

The message strength, content and time dimension has a significant influence on the promotion of persuasion by adolescents in the prevention of CHD by families. This is certainly contrary to the principle of communication states that one aspect of communication is the aspect of message content. The message becomes very valuable when the family needs it. Because of the dimension of time, the information has value. The communication process should be a message that meets the rules of relevance. Timeliness (time) of events involves things that have just happened or have just been stated.

The message must be planned well, and according to one’s needs and the message must attract the recipient’s personal interests and needs and generate satisfaction. Persuasive communication theory is known as the Monroe motivational sequence which states that the message of persuasive communication must be well designed so that it has appeal in the eyes of the communicant.

The level of family education contributes to the promotion of persuasive adolescents in the prevention of CHD. Cognitive is also called a perceptual component, which contains beliefs that influence information from others. Culture is a universal experience so there is no exact same culture. Culture is filled and determined by human life itself without realizing it. Family resilience increases if per capita income increases per month and family-owned assets increase. If income is lacking, the tendency for the family to focus is to meet economic needs compared to parenting, communication, the application of educational norms or increased knowledge. Families play an important role in all forms of health promotion and risk reduction. The health promotion model in Pender’s nursing practice explains the family. Service provider groups are important interpersonal sources that influence health promotion behavior.

Persuasive promotion by adolescent influences family anticipatory attitudes in the prevention of CHD. Persuasive promotion variables by adolescents consist of several indicators: ability to build trust, to provide information and to persuade, willingness to remind parents of their responsibility in preventing disease. Health promotion accompanied by motivation by community leaders is more effective in changing attitudes and behavior compared to leaflets.

The effect of persuasive promotion influences anticipatory attitudes. Persuasion is an attempt to change individual attitudes by incorporating ideas, thinking, new opinions and even facts through communicative messages. Promotion is able to increase public anticipation by increasing knowledge and attitudes in preventing disease because of trust in the promoter.

The results show that family characteristics influence the prevention of CHD. The function of healthcare or care (the healthcare function) is to maintain the health condition of family members in order to continue to have high productivity. This function was developed as a family task in the field of health. The continuity of family functions is closely related to its characteristics. Family characteristics that influence the prevention of CHD are education, family type, attitude, a culture of healthy living and income. Different levels of education directly or indirectly affect the mindset, the point of view and acceptance of the client for the treatment actions he has received. There is a positive relationship between education level and disease prevention behavior. Mother education associated with disease prevention.

Family type is the dominant factor influencing the behavior of disease prevention. The attitude of the family is considered as a general predisposition to respond or act positively or negatively to an object or person accompanied by positive or negative emotions. Family-Centered Nursing Theory family support is one of the factors that influence a person’s behavior in making decisions more precisely. Income levels can affect someone in healthcare because someone with a high income can launch healthcare activities.
behavior affects the behavior of other family members in dealing with health problems. Financial support improves the welfare of pregnant women.

Behavior is a function of predisposing factors, namely factors that exist within the individual in which there is an attitude of the individual. Attitude is said to be an evaluative response. Evaluative response means the form of reaction that is expressed as good and bad values, positive-negative, which then crystallizes as a potential reaction to the object of attitude. To improve the ability of families to prevent CHD, it is necessary to change family attitudes about CHD from negative to positive and manifest these in action.

The persuasive promotion model by adolescents influences the prevention of CHD by the family. Persuasive promotion affects family attitudes more anticipatively, which illustrates the family’s response to the importance of preventing CHD. Promotion carried out by adolescents as members of the family makes it easier to deliver messages because of their emotional closeness. The family, groups and healthcare providers are important interpersonal resources that influence, increase or decrease the desire for health promotion behavior.

**Conclusion**

Adolescents as a source of messages are an important factor in efforts to prevent CHD for families, even though the effect is indirect because it has to go through persuasive promotion by adolescents and family anticipatory attitudes in the prevention of CHD. Empowerment of adolescents as family members is quite effective in promoting the prevention of CHD using a persuasive approach.

Adolescents have an important role to play in changing the anticipatory attitudes of families in the prevention of CHD through promotion using a persuasive approach. Anticipatory attitude is the key to improving the family’s ability to prevent CHD. The study identified a model of anticipatory persuasive promotion by adolescents in efforts to prevent CHD by families, composed of the following components: adolescents as the source of the message, message strength dimension, family characteristics, persuasive promotion, family anticipatory attitudes and prevention of CHD by the family. Persuasive promotion by adolescents makes family anticipatory attitudes more positive so as to increase the prevention of CHD by families.

Risk Factors of Gonorrhea Infection among Indirect Female Sex Workers (IFSW) in Indonesia 2015

Frans Landi¹, Nuning Maria Kiptiyah²
¹Master of Epidemiology Study Program, ²Department Epidemiology, Faculty of Public Health, University of Indonesia, Depok

ABSTRACT

Background: Chlamydia trachomatis is the most common cause of curable bacterial sexually transmitted infection (STI) worldwide. Indirect Female sex workers (IFSWs) are the key population to be affected by sexually transmitted infections (STIs). In Indonesia, little is known about Chlamydia infection in most at risk population. This study aimed to know the risk factors of gonorrhea infection among IFSW in Indonesia 2015.

Method: This research uses Cross Sectional study design. This study used secondary data based on the Integrated Biological and Behavioral Survey (IBBS) 2015. The study population was 3,153 IFSWs who registered in the IBBS 2015 in 13 districts and cities Indonesia. The study sample was derived from an eligible population that met the inclusion criteria=813 responden.

Results: The results show the prevalence of gonorrhea among IFSWs was 9.4%. Gonorrhea infection is associated to Chlamydial infection (OR=4.29 ; 95%CI=3.124–5.891) and age (OR=1.52 ; 95%CI=1.104-2.096).

Conclusion: IFSW who also suffer from chlamydial infection and are <28 years old are more at risk to gonorrhea infection. For this reason, IFSW infected with chlamydia and young people must be treated thoroughly and prioritize safe sex to avoid gonorrhea infection. Gonorrhea infections among IFSW warrant the need to strengthen intervention efforts.

Keywords: gonorrhea, chlamydia, Indirect Female Sex Workers, Integrated Biological and Behavioral Survey

Introduction

Sexually transmitted infections (STIs) are a major public health problem worldwide, affecting quality of life and causing serious morbidity and mortality. STIs have a direct impact on reproductive and child health through infertility, cancers and pregnancy complications, and they have an indirect impact through their role in facilitating sexual transmission of human immunodeficiency virus (HIV) and thus they also have an impact on national and individual economies. More than a million STIs are acquired every day. In 2012, an estimated 357 million new cases of curable STIs (gonorrhoea, chlamydia, syphilis and trichomoniasis) occurred among 15–49 year-olds worldwide, including 78 million cases of gonorrhoea ¹

The prevalence of STIs in FSW in Indonesia has not been systematically observed and is only measured sporadically. In Indonesia, based on research conducted in 9 provinces, prevalence is 28.6%², while based on 2013 STBP data the prevalence of gonorrhea in WPSTL is 17.7%³. Gonorrhea is a bacterial exudative infection caused by Neisseria gonorrhoeae, a fastidious gram-negative bacteria. N. gonorrhoeae was first described by Neisser in 1879, and is a gram-negative, nonmotile, non-spore-forming diplococcus, belonging to the family Neisseriaceae ⁴. Untreated gonorrhea can cause serious and permanent health problems in both women and men. In women, gonorrhea can spread into the uterus or fallopian tubes and cause pelvic inflammatory disease (PID)⁵. Some epidemiological data have suggested that gonorrhea contributes to increased HIV transmission. (Puspitosari, et al., 2014). More than that, increased resistance to most antibiotics used to treat gonococcal infections has been reported worldwide, raising concerns about the eventual development of untreatable gonococcal infections with serious sexual and reproductive health consequences ¹.
Gonorrhea transmission is related to sexual behavior, such as having multiple sex partners, unsafe sex and and lack of knowledge. Indirect Female Sex Worker (IFSW) are a population at high risk for STIs. In certain geographical areas STIs is transmitted by IFSW which acts as a core group to customers as a bridging population and will then transmit to their partners in the general population. Compared to Direct Female Sex Worker (DFSW) who openly work as sex workers, IFSW generally covers their work as sex workers and this has an impact on supervision and access to health services and which results in the vulnerability of IFSW to STI. Based on the estimation of the key population of HIV in Indonesia in 2016, the number of key population of FSW was 226,791 people and the number of WPS customers was 5,254,065 people.

Sex work is usually classified as “direct” (open, formal) or “indirect” (hidden, clandestine, informal). Direct FSW are typically women who do define themselves as sex workers and earn their living by selling sex. Indirect FSW are women for whom sex work is not the first source of income. They may work as waitresses, hairdressers, tailors, massage girls, street vendors, or beer promotion girls and supplement their income by selling sex on a regular basis or occasionally.

To achieve target of Indonesia free prostitution in 2019, until the end of 2018 the Ministry of Social Affairs and Regional Government has closed 151 of the total 168 prostitution localization in Indonesia and repatriated more than 20.00 Female Sex Work. On the other hand, the closure of localization has resulted in the loss of income from the FSW, since most of them are the backbone of the family, they also have difficulty finding other jobs, because they get the stigma from the community. There are several facts found related to the situation after the closure of places of localization. WPS do not change professions, but only move to new locations such as boarding houses, massage places, streets or graves. Thus in the future it is predicted that the number of IFSW will increase due to the possibility of DFSW turning into IFSW.

Several risk factors and indicators are associated with differing prevalence gonorrhea infections including sex, age, geography, membership in a vulnerable group, high-risk sexual behaviors, and biological and epidemiological factors and recommendations as well as implementation considerations (e.g., population groups, testing and case management. Several previous studies have shown an associated between gonorrhea infection and several factors including: age, marital status, education level, chlamydial infection, consistency of condom use, age at first sexual intercourse, duration of sex work, number of client, use of drugs before sexual intercourse, dan STI information.

The aim of this study was to determine the prevalence of gonorrhea and identify factors associated with gonorrhea infection in Indirect Female sex worker in Indonesia 2015

### Materials and Method

The design of this research was cross sectional study by using secondary data sources from the 2015 IBBS. The independent variables in this study were age, marital status, chlamydial infection, vaginal douching, duration of sex work, number of customers, drugs use before sexual intercourse in the last 3 months, and STI information, while the dependent variable is the incidence of gonorrhoea infection. The target population in this study were all IFSW in 13 districts dan cities in Indonesia. The inclusion criteria in this study were IFSW who were 15 years of age or older who had commercial sex with at least one customer in the last month and were at the survey site at the time of the survey team’s visit, while the exclusion criteria in this study namely incomplete or missing data. The minimum sample size is 508 respondents, after the exclusion criteria were carried out, the total sample in this study was 1,955 respondents. Statistics data analysis using computer software included univariate, bivariate (chi square) and multivariate (regression logistics prediction factor model).

### Results

Based on table 1 above, it is known that the prevalence of gonorrhea in IFSW in 13 districts and cities Indonesia is 9.4%. Bivariate analysis was conducted to assess the correlation between independent varibales and gonorrhea infection as independen variable. From the results of chi-square test, the correlation among both variables can be examined by looking at the $p$ value and Odd Ratio (OR). If the value of $p < 0.05$ and OR $> 1$ or $< 1$, then both variables have a significant correlation. Based on Chi-square test results, there is a significant correlation between age ($p$ value= 0.000 ; OR=1.81 ; 95%CI=1.328-2.474), marital status ($p$ value= 0.001 ; OR=1.71 ; 95%CI=1.244-2.359), chlamydial infection ($p$ value=0.000 ; OR=4.49 ; 95%CI=3.280-6.148), duration of sex work ($p=0.022$). Whereas the variables that did not have a significant relationship with the incidence of gonorrhea ($p> 0.005$ ; OR=0.69 ; 95%CI=0.512-0.941).

Bivariate analysis is also used for variable selection that enters to multivariate analysis. variables that have $p$ value $<0.25$ are included in multivariate analysis. As for the variables entered into multivariate analysis were : age, marital status, chlamydial infection, condom consistency, vaginal rinse, length of work, and STI information. Then multivariate analysis was carried out using logistic regression with the backward analysis

From the final result of multivariate analysis using logistic regression by removing one by one the variable with p>0.05, it is known the variables that having correlation with gonorrhea infection in Indonesia are age (p value=0.010 ; OR=1.52 ; 95%CI=1.104-2.096) and chlamydial infection (p value=0.010 ; OR=4.29 ; 95%CI=3.124-5.891). Chlamydial infection variable is the most significant factor since it has the largest OR value.

Discussions

Based on the results of the study, it is found that gonorrhea prevalence among IFSW in Indonesia is 9.4%. Multivariate analysis showed a significant predictor of gonorrhea infection in IFSW are age and chlamydial infection. IFSW <28 years old had a risk of 1.53 times for gonorrhea infection compared to those aged ≥ 28 years. IFSW with chlamydial infection were 4.29 times at risk of gonorrhea compared to those who did not suffer from chlamydial infection. The results of statistical tests it is known that the age variable has a relationship with the incidence of gonorrhea in the IFSW, the results of this study are in line with the research conducted by Afriani on Female Sex Workers in 16 City and Districts in Indonesia in 2011, where IFSW aged <29 years had a risk of 1.53 times being infected with gonorrhea compared to those aged ≥29 years (OR: 1.53; 95% CI: 1.30-1.79)\(^{11}\).

Young people are a critical target group for sexually transmitted infections (STI) surveillance due to their particular behavioural and social related vulnerability. Gonorrhea is the most common sexually transmitted infection in young people ages 15-24 years\(^5\). One explanation for the observed age disparity in STI is immature reproductive and immune systems in younger adolescents\(^19\). Young age is related to changes in sexual hormones for the maturity of sexual organs, sexual hormones can increase sexual drive so that it affects sexual behavior at a young age. Young IFSWs are susceptible to gonorrhea because they are more sexually active and usually the younger IFSWs are more attractive so that they get more buffets, this is related to the higher number of sex partners which is a risk factor for gonorrhea.

Based on the results of the study, chlamydial infection variable is the most significant factor for gonorrhea infection among IFSW in Indonesia. Similar results were reported in other studies conducted among FSWs Yangzhou and Changzhou, China, was known that female sex workers who suffer from chlamydia are a risk factor for gonorrhea infection (p value=<0.01 ; OR=1.99 ; 95%CI=1.43–2.79)\(^{15}\). Sexual transmission is the primary route of gonorrhea infection and chlamydial infection, As all these infections share the similar mechanisms of transmission, infection by one organism offers more potential opportunities for others. Chlamydia trachomatis is an obligate intracellular parasite, this parasite causes infection in columnar epithelium. Symptoms that arise are caused by inflammation in endocervical gland, which produces mucopurulent or endoservical secretions. If infected, endocervical tissue will usually swollen and reddish\(^17\). The presence of inflammation in the reproductive tract is the entry point for other sexually transmitted infections, including being the entry point for neisseria gonorrhea bacteria.

Conclusion

Gonorrhoea is the second most common bacterial STI after chlamydia and results in substantial morbidity and economic cost. Because and gonorrhea and chlamydia are usually asymptomatic, screening is necessary to identify most infections. Screening of all sexually active women younger than 28 years old and women with risk factors such as multiple partners. STI screening and treatment in high-risk groups is a form of intervention to prevent further complications and spread of the diseases. Screening and treatment of chlamydial and gonorrhea infections in female sex workers aims to prevent complications, spread the disease further and co-infection, especially at the young IFSW.

Limitation of Study: This study used a cross sectional study design so that there was no clear temporal time relationship. In addition, not all variables were examined so that they were still unable to explain thoroughly about other risk factors related to the association of chlamydia infection among IFSW. Bias information that might occur in this study are questions that explore information that has long happened (retrospective).

Occupational Stress Due to Additional Tasks of Procurement of Goods and Services in Provincial Health Office, East Java, Indonesia

Hafidh Maulana¹, Mochammad Bagus Qomaruddin², Oedojo Soedirham²

¹Health Promotion and Behavioural Sciences, Master Program of Public Health Sciences, ²Department of Health Promotion and Behavioural Sciences, Faculty of Public Health, Universitas Airlangga, Indonesia

ABSTRACT

Hospitals under the coordination of the Provincial Health Office do not have particular employees to manage the procurement of goods and services so that the task charged to the existing employee as an additional task. Among them, 56.25% were health workers, and 43.75% were non-health workers. Preliminary studies show that 100% of procurement officials in the Technical Implementation Unit (well known in Bahasa as Unit Pelaksana Teknis, UPT), Health Office, experience job stress and it potentially continuously occurred, specifically in the UPT of East Java Provincial Health Office as the locus of this research, if it not adequately controlled. Therefore, this study aims to understand and explore the sources of work stress on employees who concurrently become procurement officials in hospitals at the East Java Provincial Health Office. This study uses qualitative-approach and the data analyzed using content analysis. The study was held during April and May 2019 by collecting data from six people who met the inclusion criteria through in-depth interviews to understand the job stressors experienced by procurement officials. Job stress on procurement officials originates from workloads, role conflicts, unfit person jobs, stagnation of roles, and interpersonal demands. Furthermore, findings of the sources of work stress on procurement officials, can be considered as a strategy for organizational approaches.

Keywords: job fit, job stress, role conflict, role stagnation, work-related stress, workload.

Introduction

Nine hospitals under the supervision of the East Java Provincial Health Office did not have officials to procure goods and services. Consequently, procurement tasks charged as additional tasks to employees of each hospital. This additional task must be completed together with their primary task. Among them, 56.25% are health workers, and 43.75% are non-health workers.

Preliminary study conducted by measuring the stress level of the work of procurement officials in the UPT of the East Java Provincial Health Office. The results of the preliminary study show that 100% of procurement officials at the Health Office UPT experience job stress with variations in stress levels: very low (8.34%), low (41.66%), moderate (41.66%) and high (8.34%).

Research on work stress on employees is essential to understand the sources of work stress. By understanding the sources of work stress, organizations can precisely determine stress control strategies. Thus, this study aims to explore and understand the sources of work stress on employees who concurrently become procurement officials in hospitals at the East Java Provincial Health Office. The findings in this study will make hospitals begin to consider the prevention of stress with an organizational approach rather than just individual oriented by increasing stress coping skills.
Method

Research Design: This research is a descriptive study with a qualitative approach because they can produce descriptions of phenomena of additional assignments experienced by hospital employees will be a concern in this study. The qualitative approach in this study aims to explore the source of stress felt by employees.

Sample: This research involved 6 individuals who experienced the phenomenon of additional duties as procurement officials at least 1 (one) year. The informants of this study were considered to represent 9 (nine) hospitals in terms of the size of the budget and the specialization of the hospital.

Data Collection: The data collected through in-depth interviews using semi-structured interview guidelines (Table 1). Before the interview, informants asked for their willingness to sign an informed consent form. Open questions are used to allow participants to express their detailed experiences and perceptions. Informants were asked to disclose and explain their experiences and perceptions of work stress and asked further questions related to the answers given by them. The duration of each interview varies from 30 to 60 minutes until no new information identified.

Table 1: Interview Guideline

Location and Duration of Research: The research was conducted at the hospital under the coordination of the East Java Provincial Health Office, from April to May 2019.

Data Analysis: The analysis step refers to Miles et al.\(^2\) including data reduction, data display, and conclusion drawing. Data reduced by making a summary by choosing the main things, focusing on important things, looking for themes and patterns, and discarding what is considered unnecessary. The presentation of data is done using narration and directed so that the reduction data can be organized, arranged in a relationship pattern so that it is easy to understand, can be concluded to achieve the research objectives.

Results

From the results of in-depth interviews with procurement officials, several causes of stress can be identified, including workload, role conflict, unfit person jobs, role stagnation, and interpersonal demands.

Workload: The majority of procurement officials feel a high workload due to multiple positions held. One of the informants (A4) completed an additional and the main task at home to pursue a monthly deadline. Another informant (A6) claimed that additional work as procurement was very time-consuming, even though they also had to fulfill their primary duties in serving patients. Following are interview quotes that support:

“My main task is to serve patients. This procurement seems to be time-consuming. I have to meet the provider; eventually, the patient could be neglected.” (A6).

The workload feels increasingly heavy with the deadlines set. One informant (A4) claimed to be hunted to complete procurement tasks because of deadlines every month. If he does not meet the deadline, it will disrupt the service in the hospital. Following are interview quotes that support:

“Yes, I am hunted for deadlines every month. If I do not finish the job this month, I cannot order items for the following month.” (A4)

The workload of procurement officials is increasingly heavy with the variety of variants for each type of item purchased. The workload of procurement officials felt to be very high, as perceived by the informants as follows:

“My task is that all procurement starting from fuel, consumption, maintenance, medical devices, medicines, reagents.” (A3).

Some procurement officials feel a high workload because they do not have a staff who can help documenting all procurement activities. The following are excerpts of interviews that support:

“The workload that burdens me is typing procurement documents. I do not have the staff. That is why I feel that my time is being consumed a lot.” (A6).
Role Conflict: All informants stated that the procurement tasks took up almost all of their daily time compared to their primary tasks. The majority of them have difficulty dividing roles because they are required to carry out their primary duties, and it ultimately makes their workload more difficult because the main task cannot be abandoned.

Procurement work is work that cannot be postponed. If postponed, it will have an impact on the continuation of services in their agencies. Thus, the majority of them carry out procurement tasks every day, not their primary task. The following are the results of interviews that support:

“It has been three years, I want to get out of procurement but I cannot. Then I have never learned about my profession” (A4)

On average, those who are current procurement officials are already involved in the structure of the previous procurement manager. As previously stated (A4), they had tried to get out of the procurement manager but could not. The following interview supports:

“I have been a procurement officer for six years. There has never been rolling. Replace once a year. “(A3)

Interpersonal Demands: Stress is experienced because the relationship with co-workers occurs in the majority of procurement officials at the UPT Dinkes. Procurement officials have tried to explain the dual conditions of their positions, but procurement officials feel uncomfortable with other staff. As they feel the following:

“So sometimes I also clash with friends in the pharmacy. Even though the leadership has said that I am if I hold a position.” (A4)

Discussion

The management of the procurement of goods and services puts hospital staff into procurement officials with various stressors namely workload, role conflict, person job unfit, stagnation of roles, and interpersonal demands.

Job stress felt by procurement officials is influenced by the high workload in the procurement of goods and services. Quick et al.3 conclude that overloading work, time pressure, and changing tasks or activities is one of the most significant sources of work stress for people in many jobs and organizations. The high workload experienced by procurement officials is due to many things, among others: multiple positions held, deadlines for completion of work, types of procurement of goods and services that are very diverse and absence of procurement staff or assistants. Ilies et al.4 mentioned that the single most consistent factor associated with stress in the workplace is the amount of work, followed by the shadowing deadline. Incompatibility between the number of employees’ needs and the number of jobs will increase the workload of employees because employees are forced to do multiple jobs so that they have the potential to cause stress5.
Procurement tasks prevent them from carrying out their primary tasks in a focused and maximal manner so that many jobs were neglected and they had not finished. This condition corresponds to a study that showed that work stress not only harms individuals but also harms the organization\textsuperscript{6,7}.

The role conflict affects the occurrence of stress on officials of the procurement of goods and services. These results correspond to the conclusions of Jin et al.,\textsuperscript{8} stating that role-conflict could increase work stress among Chinese correctional staff. Previous research shows that role stress reduction is associated with reduced overall job stress, and that work stress decreases, in turn, can be associated with higher job satisfaction\textsuperscript{9}.

In addition to workload and role conflict, the person-job factor is unfit to influence work stress events in procurement officials. Person-job fit can be explained as employee perceptions of how well they fit or match their job position in terms of knowledge, skills and abilities to successfully perform the tasks expected of them\textsuperscript{10,11,12}. Deniz et al.,\textsuperscript{13} revealed that paying attention to person-job fit and adjusting employees to organizations is an essential factor in reducing work stress. Procurement officials claim they do not understand the specifications of medical goods and services because they have no medical education background, which makes them always anxious when there is an audit by the auditor regarding the specifications of the goods. The gap between employment and educational background is stressful since inappropriate educational backgrounds can also lead to work stress\textsuperscript{9}.

The majority of procurement officials claimed to intend to leave the procurement management structure at their UPT. These results are in line with Kristof’s\textsuperscript{10} conclusion that person-job fit also influences job satisfaction and in turn, the commitment and intention of employees to leave their jobs. A research\textsuperscript{12} confirms that the person-job fit has the most significant impact on employee turnover intentions.

Stagnation of roles also affects the incidence of stress on procurement officials. Pareek\textsuperscript{14} identifies the stagnation of roles as one of the conditions responsible for work stress. Pareek\textsuperscript{15} defines role stagnation as the feeling of being “trapped” in the same role as is the recognition of most procurement officials that they have tried to get out of the procurement tasks but cannot. The stagnation of the role experienced is feared to have a negative impact in the future. Srivastava\textsuperscript{16}, in his study, revealed that stress arising from role ambiguity and role stagnation is the most correlated with anxiety.

Interpersonal demands from coworkers also influence job stress events for procurement officials. Procurement officials experience stress because they are often required to carry out their primary tasks. These demands relate to the dual role experienced by procurement officials. This condition is in line with the statement of Quick et al.,\textsuperscript{3} that stress due to interpersonal demands is somewhat broader and more personal than stress due to the demands of the role.

**Limitation:** This qualitative research has limitation. The limitation is the sample size representing a small number of procurement officials in Indonesia. So that the findings of this research could limit the generalization to other regions. Therefore, the results of this study must be interpreted with caution when applying them to procurement officials in other regions of Indonesia.

**Conclusion**

The findings of this study clarify that procurement officials have experienced work stress and need more attention from the supervisor and works stress prevention strategies required with an organizational approach. Recruitment or assignment of functional employees who specifically handle the procurement is an urgent matter to eliminate role conflict and role stagnation. The formation of a management team for the procurement in hospitals is expected to reduce workload. Technical competency training for procurement official can reduce the person job unfit. Understanding of the stressors faced by procurement officials in hospitals makes us think of developing strategies that are not only focused on increasing stress-coping skills on individuals but rather a more preventive organizational strategy.

Healthy Reflection of Behavior Modification Strategies on Snatch Lift Technical Performance for Students of the College of Physical Education and Sports Sciences

Haidar Hassan Karam¹, AlaaKhaldoun Ziedan²
¹Researcher, ²Supervisor, College of Physical Education and Sports Sciences, University of Al QADISIYA,

ABSTRACT

The strategy adopted by the subject teacher in the development of the skilled performance level of the students in the effectiveness of weightlifting (snatch). Behavioral modification strategies have positively contributed to post-tests in developing the skill performance level of weightlifting (snatch). The strategy of controlling the troublemaker has helped educating the students better than other strategies.

Keywords: Healthy Reflection, Behavior, Snatch Lift

Introduction

The diversity in the application of teaching strategies in the field of physical education to learn lessons and receive information through modern strategies that would provide the teachers with the opportunity to know the capabilities, abilities, tendencies and desires of the learners. Further, such modern strategies that would motivate the learner to gain expertise and knowledge are better than using response-based teaching strategies that are limited in achieving the outputs of the educational process[1].

Research Problem

The aim is to develop an educational curriculum that includes modern information received by the student through using an educational booklet and special pictures of the snatch lift technical performance.

Objectives of the Research

To identify a number of behavior modification strategies (Reinforcement - Punishment - Exclusion - Formation - Control of the troublemaker) and its impact on the cognitive acquisition.

Recognition of the effect of some behavior modification strategies (Reinforcement - Punishment - Exclusion - Formation - Control of the troublemaker) in the snatch lift technical performance of students in the first grade in the College of Physical Education and Sports Sciences at Al-Qadisiyah University.

Methodology

The researcher has adopted the experimental approach through designing compatibility groups.

Material and Method

The current research sample consisted of (160) students of the construction and technicians sample from the students of the College of Physical Education and Sports Sciences at Al-Qadisiyah University.

To determine the types of behavior modification strategies, the researcher, through the agreement with the supervisor and the committee to approve the subject, decided on the selection of behavior modification strategies, which are (Reinforcement – Punishment – Exclusion - Formation – Control of the troublemaker). The researcher has initially prepared the measurement phrases, which were (90) phrases divided into two positive and negative parts.
Chi\(^{(2)}\) test was used to identify the valid phrases. The results showed the validity of seventy-nine (79) phrases to represent the types to which they belong.

Experimental tests were carried out for the experimental sample groups in the technical performance of the snatch lift in the weightlifting hall at the College of Physical Education and Sports Sciences at the University of Qadisiyah. The researcher relied on evaluating the snatch lift technical performance of the student. The researcher has appointed the same conditions and the manner in which the tests were conducted in order to achieve the same conditions when carrying out the remote tests. Performance was recorded in accordance with the specifications and conditions specified for the tests and were presented to the experts.
The work was commenced by dividing the sample into five experimental groups. The first group (D) acts as a sample of the reinforcement strategy. Through the educational activities and the students’ standing before the subject teacher as well as assuring the students’ understanding of the technical aspects of the performance. Further, the teacher’s performing for the initial position of the snatch lifting. Through the applied activity, the initial position will be applied correctly and the cooperation among the group members to implement the skill specified by the teacher as well as working on enhancing the correct performance through verbal or physical reinforcements [3].

The second group (e) represents the strategy of punishment. Through the educational activity and the students’ standing before the subject teacher as well as assuring the students’ understanding of the technical aspects of the performance.

The third group (f) represents the strategy of exclusion. Through the educational activity and the students’ standing before the subject teacher as well as assuring the students’ understanding of the technical aspects of the performance. Further, the teacher’s performing for the stage of the second withdraw and the full extension of the snatch. In the applied activity, the student will apply the second withdraw and the full extension correctly and the cooperation among the group members to implement the skill specified by the teacher as well as working on excluding the individual from the supporting environment. That will be by excluding the student away from the colleagues or by applying the performance and then excluding the student from the tool used (shift) and making him/her performing of the training by a stick, or by giving his colleagues a certain weight while the student’s having a weight less than colleagues.

The fourth group (C) represents the formation strategy. Through the educational activity and the students’ standing before the subject teacher as well as assuring the students’ understanding of the technical aspects of the performance

The fifth group (g) represents the strategy of controlling the troublemaker. Through the educational activity and the students’ standing before the subject teacher as well as assuring the students’ understanding of the technical aspects of the performance. The cooperation among the group members to implement the skill specified by the teacher as well as working on giving the students a week before the lecture and an instructional booklet containing an explanation of all the technical performance of the snatch lift. In addition, using of the pictures contained inside the booklet before giving the lecture in accordance with the curriculum prepared and the methodology followed by the subject teacher [4].

Table (5) shows that the fifth experimental group (control of the troublemaker) exceeds other experimental groups.

Discussion

The researcher explains that the reason for the success of the fifth experimental group (control of the trouble maker) on the rest of the other experimental groups in this skill is due to the type of skill given. This means that there is a set of skills can be divided in learning. Among these skills is the high skill of snatch; as it is a difficult skill in terms of technical performance, in particular, it cannot be learned only after fragmentation into parts easier for the student method of performance. After learning each part of them, they are linked to complete the technical performance or skill in all parts and the difficulty of this skill. This has been done in this strategy (Controlling the trouble maker), which requires the division of the skill parts, the technical performance of the snatch and distribution to each individual within the experimental group. In this strategy, the student is responsible for learning each stage of the technical performance of the snatch and then move to the other part until the skill is taught entirely.

The researcher also believes that one of the reasons for the excellence of this group in the level of technical performance of the snatch of the students (control of the trouble maker) is represented in the use of a worksheet for each student through the knowledge material and illustrations of the technical stages of the snatch for each student for the part given by the teacher about the skill. In addition, helping to improve the performance of good students and high-level students are vulnerable.

Conclusions

1. The strategy adopted by the subject teacher in the development of the skilled performance level of the students in the effectiveness of weightlifting (snatch)

2. Behavioral modification strategies have positively contributed to post-tests in developing the skill performance level of weightlifting (snatch).

3. The strategy of controlling the troublemaker has helped educating the students better than other strategies.

Recommendations

1. The necessity of using the behavioral modification strategies to help develop the skill performance of an effectiveness of weightlifting (snatch) and other games to raise the level of skill performance of students.

2. Teachers should be encouraged to use behavior modification strategies and adopt them in teaching different subjects.

3. Setting up workshops and holding courses for teachers and students to train on the concept of behavior modification strategies.

Evaluation of Serum Lysyl oxidase and Calreticulin as Biomarkers in patients with Chronic Kidney Disease

Haitham S. Hamadi1, Mohamed I. Hamza1, Arif S. Malik1

1Department of Chemistry and Biochemistry, College of Medicine, University of Al-Nahrain, Iraq

ABSTRACT

This study was carried out to determine the level of lysyl oxidase and calreticulin in CKD patients and correlate the serum level of those markers with routine markers such as urea, creatinine, phosphorus, albumin, duration, stages and causes of disease. A total 65 patient with chronic kidney disease were studied among them (32) female and (33) male patients and (26) healthy as control of them were (13 females, 11 males). Their ages (patients and controls) were ranged from (18 – 70). Blood samples were collected from patients and control to evaluate serum levels of (serum Urea, Creatinine, calcium, ionized calcium, phosphorus, albumin, lysyl oxidase and calreticulin). The level of lysyl oxidase in patients and control was (19.82 ± 12.96 ng/mL and 27.73 ± 9.48 ng/mL respectively with a significant difference (p=0.013) and the level of calreticulin was patients showed higher serum level of CRT (8.64 ± 7.43 µg/L) than controls (3.46 ± 2.68 µg/L) with highly significant difference (p=0.003). serum urea, Creatinine and phosphorus level was highly significantly increased p value <0.001 in patient CKD as compared to the controls. Where calcium and ionized calcium normal in both groups. The significant decrease of Lysyl oxidase enzyme level in patients with chronic kidney disease and the significant increase of serum calreticulin in patient with chronic kidney disease in advance stages (stage 4 and stage 5). Lysyl oxidase have significant correlation with urea and have no significant correlation with other routine biomarkers used in present study also have no significant relation with duration of dialysis. Calreticulin have significant correlation with phosphorus and have no significant correlation with other routine biomarkers used in present study also have no significant relation with duration of dialysis. Phosphorus have significant negative correlation with albumin and creatinine.

Keywords: Chronic kidney disease, Lysyl oxidase, Calreticulin

Introduction

Chronic kidney disease (CKD) has become a public health problem. The definition of CKD was introduced by the National Kidney Foundation (NFK/KDOQI) in 2002 and later adopted by the international group Kidney Disease Improving Global Outcomes (KDIGO) in 2004. The definition of CKD requires a decrease in kidney function with a glomerular filtration rate (GFR) of less than 60 mL/min per 1.73 m2 and/or kidney damage for 3 month or more. Kidney damage refers to pathologic abnormalities documented by biopsy or imaging, alterations in urinary sediment or proteinuria (proteinuria/creatinuria > 200 mg/g, albuminuria/ creatinuria > 30 mg/g).1

Lysyl oxidase (LOX): LOX plays a key role in promoting fibroblast-to myofibroblast activation in skin, heart, liver, kidney, and lung fibrosis. The conversion of fibroblast-secreted collagen into insoluble fibers by LOX contributes to the accumulation of stiff extracellular matrix ECM and thereby contributes to the progression/persistence of fibrosis. In addition to elastin and collagen, LOX can oxidize lysine within a variety of cationic proteins, suggesting that its functions extend beyond its role in the stabilization of the extracellular matrix. Indeed, recent findings reveal that LOX markedly influence cell behavior including chemotactic responses, proliferation, and shifts between the normal and malignant phenotypes. Recent investigations demonstrated that the biological role of LOX has already extended beyond the oxidation of ECM proteins. Indeed, several reports describe its influence on cell proliferation, intracellular signal responses, cell migration, and tissue development and reveal that it may act as an antagonist or a protagonist of malignant processes. In chronic renal injury the biological consequences of Hypoxia induce
factor (HIF) activation are different, and negatively impact clinical outcome, that is, promote fibrosis, ultimately leading to the development of end stage renal disease. This may occur through increased expression of ECM-modifying genes, such as LOX and Plasminogen activator inhibitor (PAI-1), functional co-operation with transforming growth factor (TGF)-β1, promotion of epithelial to Mesenchymal transition (EMT), and Through modulation of renal inflammation⁴. Present study provide a basis for modulating tissue fibrosis, possibly by pharmacological modulation of the enzyme lysyl oxidase or suppression of peripheral TGFβ present study provide a basis for modulating tissue fibrosis, possibly by pharmacological modulation of the enzyme lysyl oxidase or suppression of peripheral TGFβ present study provide a basis for modulating tissue fibrosis, possibly by pharmacological modulation of the enzyme lysyl oxidase or suppression of peripheral TGFβ The results of the present study provide a basis for modulating tissue fibrosis, possibly by pharmacological modulation of the enzyme lysyl oxidase or suppression of peripheral TGFβ⁵. Also a link between LOX disturbance and disease has been reported in fibrotic processes, connective tissue disorders, neurodegenerative pathologies, tumor progression and metastasis and cardiovascular diseases, making it an attractive pharmacological target⁶.

On other side our data suggest that uric acid may exert its profibrotic effects through upregulation of LOX. This notion is based on the observations that uric acid increased fibronectin protein in cultured rat renal proximal tubule cells in a LOX-dependent manner and RNA interference of LOX attenuated the effects of uric acid on ECM formation in vitro, which was associated with a substantial reduction in fibronectin protein synthesis. Moreover, we found that LOX was significantly increased in fibronectin deposited in the kidneys of hyperuricemic mice, which substantiates the notion that lysyl oxidase may play a role in the development and progression of hyperuricemia induced renal injury. Although initially identified by their ability to cross-link ECM protein, LOX has also been shown to carry out intracellular functions and display an extended range of biological activities including the regulation of ras and NF-B signaling⁶. Recent reports indicate that LOX interaction with the transcriptional repressor Snail induces renal fibrosis⁷. It is plausible that a uric acid-induced increase in the expression of lysyl oxidase in tubular epithelial cells enables promotion of ECM assembly. However, the molecular events underlying ECM cross-linkage are complex, and because of the recently limited understanding of LOX protein maturation, localization, and function, its role in fibronectin synthesis via modulation of other molecular pathways, such as the Notch or TGF-β signaling pathways, awaits further investigation⁸.

**Calreticulin (CRT):** Calreticulin and also called Calregulin is a highly conserved endoplasmic reticulum chaperone protein which participates in various cellular processes. It was first identified as a Ca²⁺-binding protein in 1974⁹.

Calreticulin (CRT) is a 46 KDa multifunctional protein predominantly located in endoplasmic reticulum (ER) and highly conserved in diverse species⁸. Physiologically, CRT was first described as an endoplasmic reticulum protein responsible for Ca²⁺ homeostasis and glycoprotein folding; currently, CRT is recognized as a multifunctional chaperone detected in other cellular compartments, as well as extracellularly, where it is involved in cell proliferation, phagocytosis, apoptosis, adhesion, and innate and adaptive immune processes including cancer cell elimination by immunogenic cell death and fibrosis. CRT overexpression is linked to various pathological conditions including chronic inflammatory diseases, autoimmunity, fibrosis-related disorders, and malignant evolution⁹. The role of calreticulin outside of the endoplasmic reticulum is also extensive, including functions in wound healing and immunity¹⁰. Therefore, calreticulin has important implications in health and disease¹¹. The calreticulin concentrations were 400 ± 200 ng/mL (95% CI: 350–600 ng/mL) for healthy participants¹². ER is an important organelle for synthesis, folding, and transportation of secretory proteins. These functions are carried out by molecular chaperones which facilitate correctly protein folding and assembly. CRT is one of the well-characterized lectin-like ER chaperons for many proteins¹³. Recent evidences indicated that CRT is involved in quality control process during protein synthesis, including integrins, surface receptors, and transporters¹⁴. The concept that CRT might be involved in cell adhesion is based on the regulation of focal contact via multiple mechanisms¹⁵. It is clear that the extracellular matrix (ECM) molecules are important for focal contact formation. Several studies elucidated that alteration of CRT levels affects cell adhesion on various ECM¹⁶,¹⁷. Papp et al. implicated that CRT plays a role in the control of cell
adhesiveness through regulation of fibronectin expressions and matrix deposition. These studies provided evidences that CRT plays a critical role in cellular adhesiveness. ER stress refers to physiological or pathological states that result in accumulation of misfolded proteins in the ER. ER stress plays a pathogenic role in diseases associated with the accumulation of misfolded proteins, such as conformational diseases like Alzheimer’s, Parkinson’s, and Huntington’s diseases. Further, ER stress is also associated with a wide range of other conditions, including ischemia/reperfusion injury, diabetes, and atherosclerosis. Accumulating evidence suggests a pathophysiological role of ER stress in the kidney. Calreticulin (CRT) overexpression in tubular epithelial cells (TECs) induces endoplasmic reticulum (ER) stress and cellular apoptosis mechanisms. In human kidney biopsies, markers of ER stress in glomeruli have been identified in various noninflammatory and inflammatory glomerulopathies. Folding-competent states are maintained by classical chaperones, for example, the glucose-regulated proteins (GRP94) and (GRP78), and lectin-like chaperones, for example calreticulin. Renal fibrosis is the common anatomical denominator underlying the progression of CKD of various causes. There are studies indicated that calreticulin (CRT) is among the proteins that are consistently up-regulated from the earliest stages of the process of renal fibrosis(CKD is the end result of several renal and systemic diseases, its common anatomical feature is progressive development of fibrosis,) even before the extracellular matrix (ECM) begins to accumulate. Up-regulation was confirmed at the protein and mRNA levels and was localized exclusively in tubular epithelial cells (TECs). The ability of CRT to affect so many aspects of fibrosis indicates that decreasing CRT levels may represent a novel targeted and effective treatment against fibrosis and CKD. The mechanisms of fibrosis development in various organs may have pathways shared in common or differing in a tissue specific manner. It is therefore possible that in organs other than the kidney the fibrotic process could be also targeted by reduction of the levels of CRT.

Subjects, Materials and Method

Subjects and Study Design: This case control study was carried out on a 76 patients age ranged from 18 to 70 years, consist of patients diagnosed as CKD, all patients are under hemodialysis compare to 26 healthy persons as controls were enrolled serially in the study. The control subjects were taken from the same socioeconomic population who matched for their age and body mass index (BMI) with the cases. All persons in control group were have normal kidney function. All patients were attended from the Imamian Al-Khadhemiyan Medical City (dialysis unit) in Baghdad and Al Sader Teaching Hospital in Mysan. Patients and controls were with a comparable age.

Exclusion Criteria: patients with
- Heart failure
- Liver disease
- Elderly patient above 70 years

Sample Collection: 5ml of blood were taken from each patient and control, serum was centrifuged at 2000 rpm for 5-10 minutes.

The basal levels of serum Calreticulin, Lysyl oxidase, Urea, Creatinine, eGFR, total calcium, Phosphorus, ionized calcium and serum albumin measured.

Material

Measurement of Calreticulin CRT: Serum calreticulin was measured by Elisa kit supplied by Kono Company which intended for quantitative determination of calreticulin in serum.

Measurement of Lysyl Oxidase LOX: Serum lysyl oxidase was measured by Elisa kit from Elabscience Company.

Discussion

This study showed that CKD patient have lower value of LOX (19.82 ± 12.96 ng/mL) than that for control group (27.73 ± 9.48 ng/mL), (P value =0.001) Highly significant this is shown in figure (1-1).

In present study there is a significant difference in patients CRT (8.64 ± 7.43 µg/L) and control (3.46 ± 2.68 µg/L) (p=0.003) as show in figure (1-2) this results agreement with finding of showing substantial (50%) reduction in the expression of CRT reduced the development of tubulointerstitial fibrosis at a comparable level through regulation of inflammation, transcriptional activation, transforming growth factor β1-associated effects, and apoptosis and establish that CRT is critically involved in the molecular mechanisms
that drive renal fibrosis progression and indicate that inhibition of CRT expression might be a therapeutic target for reduction of fibrosis and chronic kidney disease development. CRT is a calcium binding protein which is present in the endoplasmic reticulum of the cell, and also may have a nuclear function. It regulates gene transcription via its ability to bind a protein motif in the DNA-binding domain of nuclear hormone receptors of sterol hormones that is may be the cause increasing the CRT up regulate\textsuperscript{24} the same study suggest that CRT have role in the expression of parathyroid hormone in the molecular level this my express the positive correlation between the CRT and the phosphorus as figure (1-3). In addition the renal cell destruction may lead to leak of the intracellular CRT. CRT have no significant difference between the duration of dialysis table (1-1) (p > 0.706).

\textbf{Lox:} Lysyl oxidase; CRT: Calreticulin, different small litters indicate significant difference
Conclusion

The significant decrease of Lysyl oxidase enzyme level in patients with chronic kidney disease and the significant increase of serum calreticulin in patient with chronic kidney disease in advance stages (stage 4 and stage 5) suggest that these two markers have association with pathology and can use them as a biomarkers in diagnosis of late stages in patients with chronic kidney disease.

Lysyl oxidase have significant correlation with urea so may can use it as early diagnostic biomarker in chronic kidney disease.

Calreticulin have significant correlation with phosphorus suggest a relationship of it with change in the parathyroid hormone during chronic kidney disease.

There is no relation between lysyl oxidase and calreticulin with duration of dialysis suggest that they have no relation with disease progression.

Differences in Consumption of Flavonoid Phytochemicals Toward Total Cholesterol and Ldl-Cholesterol Levels in Dyslipidemia and Non-Dyslipidemia Groups of Minangkabau Ethnic Women

Hermita Bus Umar¹², Diah M. Utari³
¹Faculty of Public Health, University of Indonesia, West Java, Indonesia; ²Department of Nutrition, Health Ministry Polytechnic of Padang, West Sumatera, Indonesia; ³Department of Public Health Nutrition, Faculty of Public Health, University of Indonesia, West Java, Indonesia

ABSTRACT

Introduction: Dyslipidemia is the primary risk factor for cardiovascular disease. Prevalence of dyslipidemia in Indonesia is still high, which is related to lifestyles such as unhealthy diet. Flavonoids are one type of phytochemical that is abundant in fruits, vegetables, nuts, and flavors that have a preventive effect on degenerative diseases.

Purpose: To determine differences in flavonoid phytochemical consumption of total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C) in dyslipidemia and non-dyslipidemia groups of Minangkabau ethnic women.

Method: The study design was comparative cross-sectional, examination of lipid levels of TC and LDL-C was carried out to determine dyslipidemia status. Subjects consisted of 72 women with dyslipidemia and 74 women with non-dyslipidemia. Interviews on food consumption used a food consumption frequency questionnaire (semi-quantitative food frequency questionnaire).

Results: The mean TC and LDL-C were higher in the dyslipidemia group, there was an inverse correlation between flavan 3-ols, flavones, flavonols, antocyanidins and isoflavones with TC and LDL-C. There were significant differences in flavonols and antocyanidin consumptions among the dyslipidemia and non-dyslipidemia groups (p < 0.05).

Conclusion: The flavonoid consumption can improve dyslipidemia status (TC and LDL-C).

Keywords: Dyslipidemia, flavonoid, total cholesterol, low-density lipoprotein cholesterol

Introduction

Dyslipidemia is a disorder of lipid metabolism which is characterized by an increase or decrease in lipid fraction in plasma, which is the primary risk factor for cardiovascular diseases such as coronary heart disease.¹² The prevalence of dyslipidemia in Indonesia is still high, based on the 2013 National Basic Health Research survey results, that prevalence of dyslipidemia in people over 15 years old obtained total cholesterol (TC) above normal at 35.9%. Low-density lipoprotein (LDL) is not optimal at 60.3%. Based on sex, LDL cholesterol (LDL-C) in females is higher than in males.³

The cause of dyslipidemia consists of factors that cannot be modified such as age, sex, family records, and modifiable risk factors including food intake. Unhealthy diet is associated with abnormal lipid profiles such as increases in LDL-C and TC which can be at risk for cardiovascular disease. From various studies, a high-fiber consumption from vegetables, fruits, nuts, and seeds⁴⁻⁹, consumption of antioxidant vitamins and flavonoids are related to the reduced risk of cardiovascular disease.¹⁰⁻¹³
Food phytochemicals are commonly found in plant foods such as fruits, vegetables, grains, and tea. Consumption of flavonoids is consistently associated with protection from chronic diseases, including cardiovascular disease, cancer, and neurodegenerative diseases. A large group of phytochemicals is polyphenols, mostly consisting of flavonoids which are secondary metabolites of plants found in cereals, vegetables, fruits, flavors, and spices.14-17

In recent years, flavonoids have been recognized as compounds with a strong biological activity which also play a role in the prevention of chronic diseases including cardiovascular diseases.18 Food flavonoids have biological effects, such as anti-oxidant and anti-inflammatory properties. Flavonoid types such as flavan-3-ols and proanthocyanidins have been associated with a reduced risk of cardiovascular disease by increasing the release of endothelial nitric oxide and inducing vasodilation.17 Several epidemiological studies have found a relationship between flavonoid intake and lower risk of cardiovascular disease. Flavonoids can also prevent damage and oxidation of LDL.18 This study aims to determine the differences in flavonoid phytochemical consumption toward TC and LDL-C levels in the dyslipidemia and non-dyslipidemia groups of Minangkabau ethnic women.

**Materials and Method**

The design of this study was a comparative cross-sectional study, which compared phytochemical consumption between groups with dyslipidemia and non-dyslipidemia. The study was conducted on Minangkabau ethnic women in Koto Tangah District, Padang City, West Sumatra Province, Indonesia. Prior to the study, screening lipid levels (TC and LDL-C) was carried out to determine dyslipidemia status. The number of samples in each group were 72 women with dyslipidemia and 74 women with non-dyslipidemia. The inclusion criteria consisted of women aged 20-44 years who came from Minangkabau ethnic based on the ethnicity of their parents coming from the Minangkabau tribe without any mixed marriages with other ethnic groups; exclusion criteria were women who were pregnant, suffering from chronic diseases (heart disease, diabetes mellitus, and kidney disorders), and those taking anti-cholesterol medicines regularly.

Data collection included interviews, and laboratory tests, namely examination of TC and LDL-C levels. Interviews on food phytochemical consumption used a semi-quantitative food frequency questionnaire (FFQ) in the last three months. The dyslipidemia status was determined based on the National Cholesterol Education Program (NCEP) Adult Treatment Panel III classification guide, which is a total cholesterol level of > 200 mg/dl and/or an LDL cholesterol of > 130 mg/dl. A database for Indonesian food composition was in accordance with the Indonesian Food Composition Table in 2017, while a flavonoid database was added from USDA. Data processing of consumption patterns applied the modified Minang cuisine FFQ program and the 2007 Nutri Survey program. The independent t-test and Mann Whitney were taken to determine differences in the average consumption of flavonoid phytochemicals in the dyslipidemia and non-dyslipidemia groups. Pearson’s and Spearman’s correlation tests were used to determine the relationship between phytochemical consumption with TC and LDL-C. The results were stated statistically significant if the two-way test got p-value ≤ 0.05.

**Results**

Of the number, the total of those who met the inclusion criteria and were willing to voluntarily participate in the study were 146 people consisting of 72 people as the dyslipidemia group and 74 people as the non-dyslipidemia group. The normality test showed that TC and LDL-C levels were normally distributed. The mean TC and LDL-C levels in both groups can be seen in Table 1.

**Table 1: The Mean TC and LDL-C Levels of Minangkabau Ethnic Women**

<table>
<thead>
<tr>
<th>Group</th>
<th>The Mean Cholesterol Level</th>

<td>213.38 ± 33.63</td>
</tr>
<tr>
<td>Non-dyslipidemia</td>
<td>167.68 ± 19.77</td>
</tr>
</tbody>
</table>

Based on the lipid fraction in Table 1, the mean TC and LDL-C levels in the dyslipidemia group were higher than the non-dyslipidemia group.

Table 2 shows the average consumption of flavonoids in the non-dyslipidemia group was higher (117.7 mg) than the dyslipidemia group (107.27 mg),
except in the flavanones class. Statistically, there were significant differences in the average consumptions of flavonols and antocyanidin between the two groups (p-value < 0.05). However, overall, there was no difference in flavonoid consumption between the two groups.

**Discussion**

A study conducted on four ethnic groups in Indonesia found that the prevalence of dyslipidemia in the Minangkabau ethnic group was higher than that of the other. Another study stated that consumption pattern of Minangkabau ethnic likely uses coconut milk as a source of saturated fat, but also uses various flavors and spices which are a source of antioxidants.

Antioxidants can be obtained from various food phytochemical sources, one of which is from abundant flavonoids found in vegetables, fruits, flavors, and spices. Based on its chemical structure, food flavonoids are generally categorized into the main subclasses: flavonols, flavones, flavanones, flavan-3-ols, anthocyanidins and isoflavones. Many epidemiological studies show that food flavonoids are associated with lower incidence of degenerative diseases such as cardiovascular disease. Flavonols shows a protective effect against type-2 diabetes in the Framingham Offspring cohort study, and anthocyanidins, flavan-3-ols, flavones and flavanones individually are associated with lower mortality caused by cardiovascular disease in the Cancer Prevention Study II Nutrition Cohort.

In this study, the mean TC and LDL-C was higher in the dyslipidemia group. Flavonoid consumption in the non-dyslipidemia group was higher than the dyslipidemia group, except for flavanones whose consumption was
almost the same between the two groups. The types of flavonoids with the highest average consumption in both groups were flavanones whose main source in this study was citrus fruit. Most types of Hesperetin and Naringenin flavanones are found in citrus fruit. The mean isoflavones are also high in the non-dyslipidemia group, which in this study the main source is mainly from tofu and tempeh. Isoflavonoids are a very distinct subgroup of flavonoids. Isoflavonoids are mostly found in soybeans and other leguminous plants. 

Table 2 shows that, statistically, there are differences in the consumption of flavonoids in the flavonols and antocyanidin groups in both groups (p-value < 0.05). In this study, the flavonols group with the highest average was from quercetin flavonoids found in lettuce, and from the onion, garlic, and turmeric flavors; while, kaempferol flavonoids are obtained from spinach. Flavonol intake is found to be associated with a variety of health benefits that include antioxidant potential and a reduction in the risk of vascular disease. Quercetin and its derivatives can prevent oxidative damage in various systems, including those with clear relevance to atherosclerosis. 

The most consumed group of antocyanidin is delphinidin flavonoids obtained from eggplant. Qui et al reported that anthocyanidin supplements (160 mg) compared to the placebo group given for 12 weeks improved LDL and HDL levels from 120 subjects with hypercholesterolemia. 

Overall, the average consumption of flavonoids was 112.56 ± 37.16 mg, which results are higher compared to other studies on antioxidants in Minang cuisines with an average consumption of flavonoids at 105.0 ± 48.0 mg. In this study, there was no difference in total flavonoid consumption in both groups, which were also supported by previous studies.

In this study, there were significant differences in phytochemical consumption in the flavonols and antocyanidin groups with dyslipidemia. From the fraction of the lipid profile, there was an inverse correlation between consumption of flavonoids with TC and LDL-C levels, meaning that increased consumption of flavonoids was associated with lower TC and LDL-C levels.

A study conducted between Mediterranean and non-Mediterranean groups found no significant difference in the average total flavonoid intake between non-MED countries (373.7mg/day) and MED countries (370.2mg/day) observed. In non-MED areas, the main contributors were proanthocyanidins (48.2%) and flav-3-ol monomers (24.9%) and the main food sources were tea (25.7%) and fruits (32.8%). In the MED region, proanthocyanidins (59.0%) are by far the most abundant contributors and fruits (55.1%), grapes (16.7%) and tea (6.8%) are the main food sources. This study showed similar results for total food flavonoids intake, but a significant difference in the intake of flavonoids, food sources and some characteristics between MED and non-MED countries. 

A study conducted on Japanese women found that total flavonoid intake was inversely correlated with plasma TC concentration (TC) (r = -0.236, P <0.05) and plasma LDL-C concentration (LDL-C) ((r = -0.220, P <0.05) , the main source of flavonoid is onion and the isoflavone is tofu. A population study in Australia also show an association between consumption of flavonoids and the risk of coronary heart disease. 

At the molecular level, flavonoids can contribute to the reduction of the risk of coronary heart disease by affecting oxidation of LDL, fat plaque, and hypercholesterolemia. Studies in Haitian-American and African-American ethnic groups show that increased consumption of flavan-3-ols and flavanone is associated with lower LDL in the group with no diabetes. Flavonoids from old garlic extract flavor can reduce TC and LDL-C by 5-10% in hypercholesterolemic patients. 

A meta-analysis study shows that turmeric and curcumin which contain a high level of flavonoids have an effect on decreasing LDL-C and TC levels. A study shows that orange juice (750 mL/day), which was also high in flavonoid level, improved blood lipid profile in hypercholesterolemic subjects. Naringenin-type flavonoids given in supplement form during the 8-week trial were found to reduce LDL concentrations by 17% in the hypercholesterolemic group compared with the healthy control. 

**Conclusion**

There are differences in the consumption of flavonoids for the flavonols and antocyanidin groups in the dyslipidemia and non-dyslipidemia groups of Minangkabau ethnic women. The consumption of flavonoids is inversely correlated with TC and LDL-C levels, then it can be concluded that consumption of
flavonoids can improve the status of dyslipidemia (TC and LDL-C). The next researcher is suggested to analyze the flavonoid phytochemical consumption directly through blood test.

Dental Caries and Treatment Needs in Relation to Nutritional Status among Kindergartens Children in Tikrit City, Iraq

Hind Thyab H. AL-Nassary¹, Ahlam Taha Mohammed¹

¹Department of Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Dental caries is the most common infectious and widely spread disease affecting children in early age. Nutrition may be one of the important factors affecting dental caries. The aim of this study was to estimate the prevalence and severity of dental caries and treatment need in relation to nutritional status among kindergartens children in Tikrit city.

Materials and Method: The sample consisted of 580 kindergarten children aged (4-5) years old (329 boys and 251 girls) from Tikrit city. Dental caries was recorded by using dmfs/dmft indices, while dental treatment need was recorded according to criteria of (WHO). The assessment of nutritional status was achieved using anthropometrics measurement (height and weight) according to body mass index indicator.

Results: The prevalence of dental caries was 86.03 %. Caries experience was higher among 5 years than 4 years and higher among boys than girls, with statistically no significant difference between age and gender. The higher percentage of examined children were in need of one surface filling. According to nutritional status (BMI indicator), the mean value of ds and dmfs were higher among children with undernutrition than among other children, with no significant difference (P >0.05).

Conclusion: A study reported a high prevalence of dental caries among kindergartens children, thus there is an increase need of a preventive program among preschool children in Tikrit city in Iraq.

Keywords: Dental caries, treatment need, nutritional status, kindergarten children, Tikrit city.

Introduction

Dental caries is “a multifactorial, transmissible, infectious oral disease caused primarily by the complex interaction of cariogenic oral flora with fermentable dietary carbohydrates on the tooth surface over time”(1). It is the most prevalent infectious chronic disease affecting all ages in both genders and all races (2). The process of dental caries develop as soon as the tooth erupt in the oral cavity (3). Dental caries develop in the oral cavity at any site where a biofilm develops and remains for a period of time (4). Epidemiological studies in different geographical location in Iraq reported high prevalence of dental caries among children (5,6). Treatment of dental caries has been considered as one of the important factor for both general and oral health (7). The type of dental treatment become more complicated as well as increases with age (8-16). The oral cavity is the mirror of nutritional status of the body (17), so nutrition is considered as integral component of the oral health. Good nutrition is important to avoid many common health problems (18). There is a continuous synergy between nutrition and the integrity of the oral cavity in health and disease, this independent relationship revealed that good oral health promoting good nutritional health and vice versa (19). In Iraq, several epidemiological studies among kindergarten children has been conducted in different geographical location, regarding the dental caries and treatment need in relation to nutritional status. Yet, no previous study conducting among kindergarten children in Tikrit city. Therefore, this study was designed and conducted.

Material and Method

This cross sectional study was conducted among kindergarten children aged (4–5) years old, 580 child (329 boys and 251 girls) in Tikrit city in Iraq. Examination started at the 1st of December 2018 till the end of February 2019. Prior to data collection, permission was obtained from the Ministry of Education,
the purpose of the study was explained to kindergarten authority to ensure full cooperation, also a special consent has been distributed to the parents to obtain permission for including their children in the study. A representative sample was taken, they were randomly selected from kindergarten. Eleven kindergartens had been examined in Tikrit city. Children with systemic disease and uncooperative children were excluded. The age of the child was taken according to the last birthday by WHO (1987) (39). Dental caries and dental treatment needs were recorded according to criteria of WHO (21,20). The assessment of the nutritional status was performed using anthropometrics measurement according to body mass index indicator (BMI) (22).

**Result**

Table (1) revealed the total sample distribution by age and gender. The prevalence of dental caries was (86.03%), total girls recorded higher prevalence of dental caries compared to total boys. Children at 5 years old found to have higher percentage of dental caries than 4 years children, Table (2). Dental caries severity represented by dmfs and its component (ds, ms, fs) was illustrated in the Table (3). Mean value of dmfs was higher among 5 years than 4 years children, and was higher among girls than boys, with statistically no significant differences for both age and gender (P > 0.05). Decays component (ds) represented the highest percentage followed by missing component (ms) and then filled component (fs). Mean value of (ds) among 5 years was higher than among 4 years, and in girls was higher than boys, these differences found to be statistically not significant. The higher percentage of examined children were in need of one surface filling followed by two or more surface filling, pulp care and then fissure sealants as revealed in Table (4). Regarding nutritional status, mean value of decay component (ds) and dmfs were higher in children with under nutrition than among other children, with no significant difference, this was illustrated in Table (5). No significant inverse correlation was found between ds, dmfs and nutritional status, Table (6).

Discussion

This oral health survey was designed to evaluate dental caries and treatment needs in relation to nutritional status among kindergarten children in Tikrit city in Iraq. There was no previous epidemiological studies concerning this age group in Tikrit city, the collected data was intended to use as a base line data for a comparison with other Iraqi studies in other governorates and in different parts of the world, and could be used in evaluating possible future oral health preventive program for preschool children in Tikrit city.

The prevalence of dental caries was found to be 86.03 % for kindergartens children, this percentage was higher than that reported by some studies (5,11,15,16, 27,30,31,32), while it was lower than that reported by others (25,26,29). Considering age, caries experience found to be higher among 5 years than among 4 years children, this finding is in agreement with the other studies (5,6,8,11,15,16, 27,30,31,32). This result attributed to accumulative and irreversible nature of dental caries (33).

In present study girls showed higher caries percentage than boys with no significant difference between them, this result in agreement with some studies (5,11,32,34,35). This finding may be attributed to earlier deciduous teeth eruption in females than males of the same age group, so females deciduous teeth exposed to cariogenic factors earlier. While this finding comes in disagreement with other studies (6,15,24,30,36,37,38).

The results of this study showed that (ds) fraction was higher than (ms) and (fs) component of dmfs index, this is an indication for poor dental treatment, and (ms) fraction was higher than (fs) , this indicated that even if treatment is present it was directed toward extraction rather than restoration, this result is in agreement with result of other studies (5,6,10,14,24).

Most of the children of this studies were in need of one surface filling, that is to say in need for restorative
treatment to prevent progression of dental caries, followed by two surface filling, pulp care and fissure sealants. This finding agree with results reported by (6,8,39,40), in which one surface filling was higher percentage needed by the samples. Caries experience (dmfs) and decay component (ds) were higher among children with under nutrition than other children. No significant inverse correlation was found between ds, dmfs and nutritional status. Increase in the prevalence of dental caries attributed to nutritional deficiency which increase tooth susceptibility to caries development by changing in the tooth formation or in the hard tissues quality of the tooth that can be affected by nutrition (34). Numerous studies reported that there is no association between malnutrition and dental caries (38,41). While many other Iraqi studies reported direct association between malnutrition and dental caries on the same age group(6,14,30).

**Conclusion**

This study reported a high prevalence of dental caries among kindergartens children in Tikrit city. Caries experience in deciduous dentition increasing as increase in the age, thus there is an increase need of a preventive program among preschool children in Tikrit city in Iraq.

Evaluation of Implant Stability in Three Implants Supported Milled Bar Mandibular Overdenture Cases: A 1-Year Follow-up Clinical Trial

Hussein Abdel Hady Hussein¹, Amr Mohamed Ismail Badr¹, Emad Mohamed Tolba Mahmoud Agamy¹, Gehan Fekry Mohamed¹

¹Prosthodontics Department, Faculty of Dentistry, Minia University, Minia, Egypt

ABSTRACT

Purpose: The aim of this study was to investigate the stability of three implants supported by a milled bar, which carries two different attachment systems and submitted to immediate loading.

Methodology: The current research was a prospective study conducted according to split-mouth design with random allocation of the tested attachments. Two types of attachments were used, OT Equator and OT Cap attachment. A total of 8 completely edentulous patients were divided into 2 Groups according to OT Equator position. CBCT was used for the planning and construction of the surgical stent. A milled bar with the attachments was fabricated prior to implant placement. Each patient received three implants in the interforaminal region, connected with a milled bar. On one side of the bar; OT Equator attachment was used, while the other side was supplied with OT Cap attachment. Overdenture was delivered at an average time of 10 to 15 days after implantation. Follow-up period was 12-months after loading. Implant stability was evaluated using Osstel™.

Results: The results revealed that; there were no significant differences between all groups at implant placement time and at 12-months period for all implants and through different time intervals until the follow-up period was finished.

Conclusion: The results of the current study indicated an increase in implant stability and due to splinting of the implants by using immediate loading protocol. Splinting of the implants using a rigid bar appears to be a successful treatment option that could be considered for treating the completely edentulous patient.

Keywords: three implants, rigid bar, milled bar, OT equator, implant stability, supported overdenture.

Introduction

The reduced stability is the most critical problem that faces Complete denture. In the last decades, using implants for improving denture stability and retention has become a common and useful protocol.¹

Using two implants or more in the interforaminal region to support mandibular overdenture has been proved to be a successful treatment modality for edentulous patients.² ³ ⁴

In the case of using three-implant to support overdentures, the anterior implant may act as an indirect retainer by preventing the movement of the anterior portion of the denture towards the tissues.⁵

However, in general; splinting implants with a bar, are usually increase the amount of support, stability, and retention.⁶ A custom-made bar could be milled to develop guide planes which provide resistance against denture rotation and lateral forces.⁷ Custom-made bars are also allowed to follow the ridge shape as well as adding attachments above.⁸

Therefore; the purpose of this study is to investigate the implant stability in 3 implants supported milled bar mandibular overdenture submitted to immediate loading.
Material and Method

Study Protocol: The current research was a prospective study conducted according to split-mouth design with random allocation of the attachments. A total of 8 completely edentulous patients in the mean age of 58 years were selected with problems in the retention and stability of mandibular dentures.

Each patient received three implants in interforaminal region. These implants were connected with a milled bar. OT Equator attachment was found on one side of the jaw while the other side was supplied with OT Cap attachment.

The eight patients were randomly divided into two groups based on the location both types of attachments to Group A and Group B. Additional randomization was carried out regarding the site of the third implant either right (Group 1) or left (Group 2) central incisor area. These randomization steps aimed to eliminate the effect of preferred chewing side and or muscular power differences that may affect the amount or frequency of load falling to the implant.

Radiographic Procedures: For each participant, the existing mandibular denture was used as a Radiographic stent. Ten gutta-percha markers of 2mm diameter each were attached to the labial and buccal region.

A CBCT scan was done using the dual scan technique. The patient’s position was adjusted using the Frankfort plane and the office floor as a reference point. The denture was positioned on a pad of cotton to ensure scanning fitting surface without artifact.

Planning for implant placement: Dicom files were imported in the software. Virtual denture was merged with the patient data using gutta-percha markers in the 3D virtual model extracted from CBCT. These data were used to plan the insertion of the three implants.

A prosthetically driven Planning using the denture fitting surface as a guide was made and implants were virtually inserted, so abutments emerge in a good position. Three implant positions were selected; the canine region bilaterally and central incisor position of one side of the mandible with random allocation of the middle implant.

A 3D model of the cast with holes compatible with the implant analogue was printed. The analogues were secured in their position into the cast using a thin film of cyanoacrylate adhesive material. (Figure 1)

Figure 1: Showing the position of the implant analogue in relation to surgical stent.

Prosthetic procedures before surgery: The connection between bar and implant was made using OT Equator Passive Bar System® - “Elastic Seeger” made by Rhein83® (Rhein83 SRL, Bologna, Italy). The purpose of the Elastic Seeger is to create a passive connection between implants and bar. The Elastic Seeger will correct small imperfections created by the 3D printing process, surgical placement of the implant or laboratory casting process, which reduces the risk of the implant bar not seating passively.

The titanium equator abutments were screwed into the analogues. The Milled cantilever bar (with 8 mm cantilever length) was constructed using castable connectors and connected to a plastic connection which placed above each titanium abutment. Then the waxed-up bar was milled to ensure parallelism.

This study was used two attachment systems, one of them was (OT Cap Castable and OT Equator Castable). Each patient received 2 OT Equator Castable and 2 OT Cap Castable (one attachment between the implants and the other distally at the cantilever area).

Surgical Procedures: The surgical protocol for implant placement was the same for all patients according to the flapless technique to minimize post-surgical edema.

For each patient; three implants (Dentium®, Implant System) was used. These implants had a standard size (3.6 mm × 12 mm). A minimum of 35 N/cm torque was determined to be satisfactory at implant insertion to ensure primary stability.
Prosthetic procedures after the surgery: The primary resonance frequency (RF) was measured before screwing the abutment. The further measurements were made using the (OsstellTM, Model 6.0, Gothenburg, Sweden) at 1 week, 1-3-6 and 12-months periods after the installation of the implants. The Magnetic transducer (Smartpeg, Type 7) was screwed using a plastic screwdriver, and the ISQ value was recorded. The plastic probe of the OsstellTM device was placed proximal to the labial side of the transducer without contacting the peg until the machine registered the ISQ value. Two additional ISQ values were obtained, with the transducer loosened and retightened each time to improve precision. A single representative implant stability value was computed by averaging the three ISQ values. (Figure 2)

![Figure 2: Showing the plastic probe of the OsstellTM device](image)

Equator titanium abutments were screwed to the implants immediately after implant placement. The verification of the bar position was checked and adjusted. The milled bar attachment complex was screwed to the equator abutments. (Figure 3)

![Figure 3: Showing Bar in position immediately after surgery](image)

The new constructed mandibular overdentures were delivered to the patients after an average time of 10 to 15 days after implantation. The same dental technician made all dentures for standardization. The nylon inserts selected for the present study were of pink color for both systems and with nearly similar retention strengths (Ball: 9.31 N (950 gr.); (Equator: 11.76 N ~1200 gr.). The riders were picked up intra-orally.
The recall visits and follow-up procedures were carried out with a mean of 12 months after prosthesis delivery. In these visits, the denture, bar and equator titanium abutment also were removed.

**Results**

For each implant position, the results revealed that; there were no statistically significant differences between two groups at T0 and at T5 period for the right and left implants and through different time intervals. The same results were found by comparing right and left implants at the same group.

The mean stability for right and left implants decreased during the first month from 7-15.7% for the right implant and 1.5-16.9% for the left implant in comparing with implant insertion time. After that, implant stability was increased up to twelve months follow-up.

There was a tendency of higher ISQ values for Group B than Group A during follow-up, however, with no significant differences. There were no significant differences between different time intervals of follow up for all groups. (Table 1)

Another comparison was made regards to the para-symphyseal implant. The results revealed that; there were no statistically significant differences between two groups at T0 and at T5 for the para-symphseal implants and through different time intervals. Therefore, implant stability was increased up to twelve months follow-up. High primary stability had been achieved for all implants at the para-symphseal position for different groups at insertion times. (Table 2)

**Discussion**

It is important to consider using three implants with a rigid bar. Using a rigid bar may decrease follow-up and maintenance efforts than a prosthesis with solitary implants and increases the amount of support, stability, and retention.12,13

Some authors recommended the splinting of implants with a rigid bar for better stress distribution.14,15 However, other authors postulated that solitary implants to reduce axial stresses around implants and supporting structures.16 This controversy was solved partly by the work of...

several authors who found a better distribution of stress around splinted implants than solitary implants. 17,18

In addition to choosing adequate implant number, the splinting the dental implants immediately after surgery using a rigid bar is mandatory for obtaining success with immediate loading. 10 This treatment option also may decrease bone loss in comparing with solitary implants. 19,20

The mechanism behind the decrease of ISQ value during the first three months and the further increase of ISQ (3–12 months) in the present study are probably related to the process of bone formation. 21 The justifications for this fact may be related to the bone adaptation after lateral compression during implant insertion, the process of bone remodeling and the marginal bone reabsorption. 10

After twelve months, the average ISQ values were increased. The probable justification is that a well-developed, mineralized, and dense bone was formed during the remodeling period. However, it was assisted by other factors such as the splinting with a rigid bar, the distribution of occlusal overload and proper maintenance of the retention nylon cap. This is coinciding with the finding of da Silva et al, (2012). 10

Conclusion

Within the limitations of this study; the results of the current study indicated a positive effect of splinting on implant survival and implant stability using immediate loading protocol. However; types of attachment over the bar has no effect on implant stability. Splinting implants immediately loaded using a rigid bar appears to be a viable treatment modality that could be considered for the rehabilitation of edentulous patients.

Study Limitation: Future clinical research with long-term follow-up is recommended to evaluate implant stability using different attachments and bars designs.

The most obvious limitations of this study were the small sample size and short follow up period. Fewer participants than intended were included because the strict inclusion and exclusion criteria restricted recruitment. Longer follow-up time and larger groups are suggested for future research.

The present study had insufficient power to measure survival differences between immediate and conventional loading protocols. It also had inadequate power to compare between splinting and solitary situations.

Source of Funding: Self-funding

Ethical Clearance: The protocol was structured by following the Declaration of Helsinki 22 and was approved by the Ethical Committee of the Faculty of Dentistry – Minia University (Egypt). The study steps benefit and risks were explained to each patient, and informed consent was obtained from all participants.

Conflict of Interest: The authors declare that there is no conflict of interest regarding the publication of this paper.

ABSTRACT

Background: Stress urinary incontinence is the prevalent type of urinary incontinence among women. The Tension Free Vaginal Tape – transobturator (TVT-O) and anterior colporrhaphy with Kelly’s plication procedures are the public surgical options by Gynecologists for treatment of stress urinary incontinence.

Aim of Study: To evaluate the outcome of Tension Free Vaginal Tape- transobturator (TVT-O) surgical procedure in comparison to anterior colporrhaphy with Kelly’s plication surgical procedure in treatment of stress urinary incontinence among adult women.

Patients and Method: A comparative prospective interventional study conducted in a period of 11 months; Feb, 2016 – Jan, 2017 on convenient sample of 20 women with stress urinary incontinence which categorized into two groups (Kelly’s group: 10 women surgically operated with anterior colporrhaphy with Kelly’s placation) and (TVT-O group: 10 women surgically operated with a Tension Free Vaginal Tape trans-obturator approach). The patients in both groups compared regarding to age, parity, severity of stress incontinence, presence of cystocele and its grade according to certain classifications and complications. The patients were followed up for six months.

Results: There was a significantly higher cure rate for women underwent Tension Free Vaginal Tape-transobturator surgical operation than the cure rate of women underwent anterior colporrhaphy with kelly’s plication after one month (P= 0.009) and after six months (P=0.005).

Conclusions: The outcome of trans-obturator tape procedure in treatment of stress urinary incontinence among women was better than outcome of anterior colporrhaphy with Kelly’s plication after one and six months of follow up.

Introduction

Stress urinary incontinence (SUI) is a major health problem that affects millions of women throughout the world. It is estimated to affect 15% to 35% of women in the general population (1). However, the prevalence may be higher as many females with SUI do not seek help for fear of embarrassment (2). SUI as defined as a ‘complaint of involuntary loss of urine on effort or physical exertion (e.g. sporting activities), or on sneezing or coughing’ (3). It is usually caused by weakness or damage to muscles and connective tissues of the pelvic floor, compromising urethral support, or by weakness of the urethral sphincter itself (4). Overall, 30% of women develop SUI within five years after their first vaginal delivery. SUI impairs the quality of life (QOL) in women suffering from it and is associated with significant social and financial costs and depression (5). The staggering number of procedures to treat SUI reflects a lack of consensus on an appropriate intervention for this problem (6). Anterior/posterior colporrhaphy with Kelly’s plication (CA-KP) is one of the conventional methods performed in the treatment of...
SUI. Although it is an old method and the success rate is lower in the long term, it has been a popular method in some clinics among gynecologists and urologists (7). However, in today’s surgical practice, it is well-established that performing an anterior repair or Kelly plication for the treatment of SUI is substandard care. The failure rates are high and recurrence is common (6). In 2001, Delorme described a new route of inserting the tape, which the author called transobturator taping (TOT), in which the tape was inserted through the obturator foramina (8).

In 2003, de Leval introduced a modified technique called TVT-O, in which the tape is inserted in a reverse route, in through a vaginal incision and out through the obturator foramen (inside out) (9).

The transobturator route may be associated with damage to the obturator nerve and vessels in an anatomical dissection model, the tape passes 3.4 cm and 4.8 cm from the anterior and posterior branches of the obturator nerve, respectively, and 1.1 cm from the most medial branch of the obturator vessels. Consequently, nerve and vessel injury in addition to bladder injury and vaginal erosion remain a potential complication of the procedure. Studies have reported cure and improved rates of 80.5% and 7.5% respectively at 17 months (10). The aim of this study is to evaluate the outcome of Tension Free Vaginal Tape- transobturator (TVT-O) surgical procedure in comparison to anterior colporrhaphy with Kelley’s plication surgical procedure in treatment of SUI among adult women.

Patients and Method

Study Design and Setting: A comparative prospective interventional study, conducted in Al-Eliwa Maternity Teaching Hospital during a period of 11 months; Feb, 2016 – Jan, 2017.

Study Population and sample size: The included patients were adult non pregnant female patients complained from genuine stress incontinence (history of urine leak with increase intra-abdominal pressure such as coughing sneezing laughing - positive cough stress test), complete their family, with failed of conservative treatment, body mass index < 30 kg/m², and cystocele of grade 0, I, II (according to Baden - walker Halfway system) (11). Patients with history of chronic lung disease, psychological disease or neurological disease, with organomegally, hysterectomy, history of previous surgery for urinary incontinence, and history consumption of some drugs such as benzodiazepine anticholinergic were excluded from this study. Each patient after evaluation by history, examination was sent to urodynamic study in Ibn-kuff hospital to confirm the diagnosis of genuine stress incontinence and exclude other type of incontinence.

A total of 20 patients were enrolled during this period. The patients were also sent full investigation including GUE, RFT, RBS. Urinary tract infection was treated. Fitness for anesthesia was confirmed and informed consent was taken from patients. As for treatment, the patients were assigned into two groups

- **Kelly’s Group:** Included 10 patients underwent Anterior colporrhapy with Kelly’s plication.

- **TVT-O Group:** Included 10 patients underwent Tension Free Vaginal Tape –transobturator approach TVT-O. No cystocele repair was done in TVT-O group.

In TVT-O group, the tape was of Boston scientific obtrazyx type which Has license from ministry of health.

Patients in both groups compared preoperatively in term of stress incontinence severity according to stamey classifications as the following (12):

- **G0:** Continent
- **G1:** Loss of urine occur with sudden increase in intra-abdominal pressure (Coughing, sneezing, laughing).
- **G2:** Leak of urine occur with lesser degree of physical activity (Walking, standing erect from sitting position or sitting up in bed).
- **G3:** Urine is lost without any relation to physical activity or position.

Surgical procedures were performed by the same experienced surgeon. Seventeen patients received spinal anesthesia and three patients received general anesthesia. Spinal and general anesthesia was used according to the patient and anesthesiologist’s preference. There was no difference between general and spinal anesthesia except the ability to ask the patient to cough after tape insertion to insure continence in some patients.

Postoperatively, patients were evaluated subjectively by Jacobs and Blaivas classification (Table 1) and objectively by cough test one month and six months after operation and also for complications including intra operative complications, short term voiding difficulty, denovo urgency, denovo dyspareunia, infection.

Statistical Analysis

The data analyzed using Statistical Package for Social Sciences version 25. Outcomes of analysis were arranged in scales variables in categorical variables. Chi square test was used for comparison between categorical data (Fishers exact test applied when expected variable was less than 20% of total). The level of significance (p value) was set as ≤ 0.05.

Results

In this study, there was no statistical significant differences (P ≥ 0.05) in age, parity, mode of delivery, menopausal history, Stamey classification and Cystocele Grade between study groups. All patients in kelly’s group were overweight compared to 60% of patients in TVT-O group and this difference was statistically significant (P= 0.025) as shown in table (2).

Discussion

Testing the quality evidence of surgical procedures in treatment of stress urinary incontinence in females which is dependable on outcome, satisfaction of surgeons and patients, those are the golden standard used as base in selection of an appropriate surgery (13). Present study showed that after one and six months follow up, the outcome of TVT-O procedure was significantly better than anterior colporrhaphy with Kelly’s plication procedure in surgical treatment of SUI of women. These findings are similar to results of Azab et al (14) study in Egypt which found that TVT-O procedure is significantly better than anterior colporrhaphy with
Kelly’s plication procedure in treatment of SUI in women, but they reported no significant difference between two surgical procedures regarding complications. However, the findings of the current are inconsistent with results of Sohbati et al study in Iran which was reported no significant difference in outcome between two procedures (5).

The cure rates of TVT-O procedure of SUI for women after one and six months follow up in present study was (100%). This finding is in agreement with results of Al-Taweel et al (15) study in Canada which stated that the TVT-O procedure is safe and effective surgical management procedure for SUI among women.

The current study cure rate of anterior colporrhaphy with Kelly’s plication procedure after one months was (50%) and after 6 months was (30 %) subjectively. While objectively, cure rate was after one month was (70%) and after six months (50%). These findings are inconsistent with results of Pelusi et al study in Italy which found that cure rate of Kelly’s plication procedure in women with SUI 88.5% after period of 6 – 12 months (16). This inconsistency might be due to difference in women characteristics and difference in methodology and sample size between different studies. In Iran, Zargham et al reported that cure rates of Kelly’s plication procedure after three days and 12 months were 62% and 54% respectively (17). It was obvious that in the current study and other studies, that cure rate of anterior colporrhaphy with Kelly’s plication procedure drop down in evaluation after long time. The success rate of surgical operations used for women with urinary incontinence is related to lower complications, ability to control urine and improved quality of life of the women (18) (19)(20) (21).

The clinical significance of the current study is the helping of Surgeons and Gynecologists to choose the appropriate surgical option for treatment of SUI among women and adding more information on outcome of TVT-O procedure and anterior colporrhaphy with Kelly’s plication procedure. In conclusion, the subjective and objective outcome of tension free vaginal tape – transobturator procedure (TVT-O) in treatment of SUI among women was better than the outcome of anterior colporrhaphy with Kelly’s plication after one and six months of follow up.

Evaluation of Some Enzymes, Hormones, Other Related Biochemical Parameters in Sera and Follow up of Women after Treatment of Breast Cancer

Jamal A. ALJabbar Attawi1, Nazar Ahmed Naji Abed.2

1Medical Technology Institute in AL-Mansour, Middle Technical University, Baghdad, Iraq; 2Department of Chemistry, College of Science, Tikrit University, Baghdad, Iraq

ABSTRACT

Carbohydrate Antigen (CA 15-3) is a carbohydrate called mucin containing protein antigen. The pregnancy hormone of human chorionic gonadotropin (HCG) is a complex glycoprotein, the glycoprotein-type α-subunit and the β-subunit. This biochemical marker may be elevated in patients with breast cancer. For programmed cell death, caspases are cysteinyl aspartate-specific proteases. To study the relationship between CA 15-3, β-HCG, caspase-3, serum IgG, IgM, ferritin and alkaline phosphatase in patients with various stages of breast cancer.

Key words: Carbohydrate Antigen (CA 15-3), β human chorionic gonadotropin (β-HCG), Immunoglobulins IgG, IgM, Caspase-3, Ferritin and Alkaline phosphatase (ALP).

Introduction

A great deal of attention has also been given to the prognostic value of CA15-3 level in breast cancer. Levels of CA15 -3 may provide useful information for breast cancer diagnosis and therapy.1 There is a significant increase in CA 15 -3 production in many people with cancerous breast tumors.2 Serum CA 15 -3 levels with clinicopathological parameters in women with metastatic breast cancer and tumor marker elevation were correlated with increased several metastatic sites.3 Serum nucleosomes have been reported to give a positive correlation with CA 15-3 in patients with breast cancer.4 Caspases play a central role in this apoptotic process by activating DNases to stimulate nucleosomal DNA fragmentation.5

(β-HCG) has been implicated in breast tumorigenesis.6 Human breast cancer cells and tissues contain HCG/luteinizing hormone receptors, which are very important for apoptosis and activation of these receptors, leading to increased cell differentiation and apoptosis.7 It has been shown that HCG’s apoptotic effect on breast cancer cells is mediated by activation of the apoptotic mitochondrial pathway going to lead to the cleavage of caspases-3 and -9.8 Apoptosis occurs when intrinsic or extrinsic caspase pathways are activated in cell death programs, so that most of the signaling pathways activated by anticancer drugs eventually lead to caspase activation.9 The growth of tumors is the end result between cell proliferation and cell lack by apoptosis. Several death-inducing signals that can activate caspase-3, including chemotherapeutic agents and radiation. Due to its location in the cascade pathway of protease, caspase-3 was considered to be directly correlated with apoptosis.10 Caspase-3 are used not just as a indicator for treatment response prediction, but as a therapeutic target whether directly or from other proteins connected to apoptosis.11

After an immune challenge, the first immunoglobulin (Ig) produced is adaptive IgM, which was considered an early diagnostic tool for cancer detection.12 For early diagnosis, the level of serum immunoglobulin was important. IgG and IgM have been increased in breast cancer women from stage I to IV.13 Natural IgM has a direct cytotoxic effect on tumor cells, recognizes tumor-modified cell surfaces that develop during tumorigenesis.
and it activates complement to destroy nascent transformed cells.\textsuperscript{12} The silencing of IgG1 reduced the formation of colony, survival, progression of the cell cycle, migration and invasion in cells of prostate cancer. The silencing of IgG1 also reduced the amount of the proliferation marker and induced apoptotic caspase-3 marker formation.\textsuperscript{14}

The gradual increase in breast cancer serum ALP activity is an indicator of metastasis. Women with breast cancer generally have ALP activities higher than normal healthy women.\textsuperscript{15} Bone is perhaps the most frequent site of distant breast cancer metastasis. Early detection and diagnosis of bone metastasis is therefore helpful for treatment in patients with breast cancer.\textsuperscript{16} The most accurate biomarkers for predicting bone metastasis in breast cancer were elevation of ALP and CA15-3 with reduced hemoglobin.\textsuperscript{17}

Increases in serum ferritin levels in malignancy and high serum ferritin levels in various cancers are associated with poor survival.\textsuperscript{18} The connection between ferritin and many cancer-related pathways, either directly or indirectly, such as cell proliferation, evasion of growth suppressors, inhibition of cell death, angiogenesis, invasion and metastasis. In cancer cells, increased ferritin might be correlated with development of cancer.\textsuperscript{19} Downregulation of ferritin resulted in an increase in caspase-3 activity as an apoptosis marker.\textsuperscript{20} Several forms of cancer can associate with iron overload. Estrogen (E2) disrupts homeostasis of the iron intracellular. E2 changes the intracellular iron status and the potential for cell growth in breast cancer that has been treated with an increase in E2.\textsuperscript{21}

\textbf{Materials & Method}

Fifty four women with newly diagnosed breast cancer were divided into 34 (stage I) and 20 (stage II) patients with age range (25 -59) years, other 54 women with benign breast mass (pathological control) with age range (19 -60) years, other fifteen patients selected from fifty four patients with breast cancer after the end of the six cycles of therapy were seen at center of breast cancer in Al - Amal National Cancer Hospital in Baghdad/Iraq from January, 2018 till September, 2018. Other 54 women were considered as a normal healthy control. The final diagnosis was checked for cytology, histopathological study (biopsy) and mammograph, according to the classification of the Union for International Cancer Control (UICC 1997). The cases were classified according to Tumor Node Metastasis (TNM) classification and tumors were diagnosed in most cases as invasive ductal and invasive lobular and are presented in Table 1 according to (American Cancer Society, 2017).\textsuperscript{22}

Blood samples were withdrawn from all patients and allowed to coagulate at room temperature then centrifuged at 3000 rpm for 10 min. The resulting sera were separated and manually assay have been done. (CA 15-3), (β-HCG), Caspase-3 IgG, IgM, ALP and Ferritin have been detected. CA15-3 ELISA kit is a solid phase enzyme-linked immunosorbent assay.\textsuperscript{23} The HCG quantitative test is based by (ELISA).\textsuperscript{24} Determination of human caspase-3 by ELISA Kit.\textsuperscript{25} Determination of serum IgG, IgM, the procedure consists in an immune precipitation in agarose between an antigen and its homologous antibody.\textsuperscript{26} Colorimetric determination of ALP.\textsuperscript{27} While the method of ferritin measurement was by (ELISA).\textsuperscript{28}

\textbf{Statistical Analysis:} Students’ t-test was used to determine the mean value for parameters whether it
was significantly different in women with breast cancer, pathological control and normal healthy control p<0.05 was considered significant.

**Ethical Aspects:** According to Iraq’s ethical guidelines, the informed consent was obtained from all patients included with the study protocols.

**Results**

The prevalence of breast cancer is found to increase with age, approximately 25.9% of females between 40-49 years and 44.4% of females between 50-59 years. Table (2) shows that serum (CA 15-3), (β-HCG), caspase-3, IgG, IgM, ALP and ferritin level of women with breast cancer was significantly increased in comparison with normal healthy control (p<0.0001, respectively). Serum (CA 15-3), IgG, ALP and ferritin were no significance in comparison normal healthy control with pathological control (p<0.234, <0.503, <0.684, <0.90 respectively), but serum β-HCG, caspase-3 was significantly increased and significant decrease of IgM level in comparison normal healthy control with pathological control (p<0.05, <0.0001, <0.05, respectively). In post-therapeutic study, the results were decreased in the serum (CA 15-3), (β-HCG), IgG, IgM, ALP and ferritin level after treatment when compared to their level before treatment in women with breast cancer (<0.05, <0.001, <0.0001, <0.001, <0.0001, <0.05, respectively), while there was a significant increase in the (CASP3) level of these parameters before and after treatment (P< 0.0001). (Figure 1,2,3).

Table 2: Showed, CA 15-3, (β-HCG), caspase-3, IgG, IgM, ALP and ferritin values for sera of normal healthy control, pathological control and women with breast cancer (stage I and stage II) before and after treatment with (mean ± SD)

Discussion

The CA 15-3 is a tumor marker that is often expressed in people with breast cancer. It is play a crucial role in diagnosis, monitoring response to therapy, early detection of metastasis. There is significant an increased production of CA 15-3. Results were consistent with that reported by [Wu SG, et al.2014]. A great deal of attention has also been given to the prognostic value of CA15-3 level in breast cancer. Levels of CA15-3 may provide useful information for breast cancer diagnosis and therapy. The deregulation of caspases associated in the regulated apoptotic cascade, resulting in the release of DNA or nucleosomes into the circulation of the blood, an essential aspect of the development and progression of cancer. Serum nucleosomes have been reported to give a positive correlation with CA 15-3 in patients with breast cancer. It is been concluded from this study that serum nucleosomes showed a positive correlation with CA 15-3 in breast cancer patients.

Hormone (β-hCG) has been implicated in breast tumorigenesis. Results indicate it to be protumorigenic or stimulate the growth of cancer cells. In breast cancer, there was a significant increased in production of β-HCG. Results were consistent with that reported by [S K Sengodan, et al. 2017]. (β-hCG) has been implicated in breast tumorigenesis. Luteinizing hormone (LH)/HCG receptor expression, it has been recorded to also be higher in normal breast tissue than those in breast cancer. Human breast cancer cells and tissues contain HCG/luteinizing hormone receptors, which are very important for apoptosis and activation of these receptors, leading to increased cell differentiation and apoptosis.

It is been concluded from this study that serum IgG and IgM increased therefore, detected serum immunoglobulin level was important for early diagnosis breast cancer. Results consistent with that reported by [Matsumoto H, et al.2015]. For early diagnosis, the level of serum immunoglobulin was important. IgG and IgM have been increased in breast cancer women from stage I to IV. IgM can eliminate breast cancer tumors through different mechanisms such as apoptosis. These results were consistent with the results by [Mariana D, et al 2015]. Natural and adaptive IgM can eliminate tumors of breast cancer in cancer patients through different mechanisms, such as apoptosis. The silencing of IgG1 reduced the proliferation marker and formation of the apoptotic marker such as caspase-3. Results were compatible with that reported by [Yawen Xu, et al. 2016]. The silencing of IgG1 reduced the formation of colony, survival, progression of the cell cycle, migration and invasion in cells of prostate cancer and formation caspase-3 as apoptotic marker.

Results indicated that women with breast cancer have ALP activities generally higher than normal healthy women. The gradual increase in serum ALP activity with breast cancer is an indicator of metastasis. Results were compatible with that reported by [A. K. Singh, et al.2013]. The gradual increase in breast cancer serum ALP activity is an indicator of metastasis. Women with breast cancer generally have ALP activities higher than normal healthy women. The most accurate biomarkers for predicting bone metastasis in breast cancer were elevation of ALP and CA15-3 with reduced hemoglobin.

There are relationship between ferritin and many pathways related with cancer and elevated ferritin in cancer cells may be related with cancer progression. Results were compatible with that reported by [Min P.BS and James R C. 2015]. The connection between ferritin and many cancer-related pathways, either directly or indirectly. In cancer cells, increased ferritin might be correlated with development of cancer. This study can be concluded that elevated ferritin in cancer cells may be related to cancer progression. Several forms of cancer can associate with iron overload. Estrogen (E2) disrupts homeostasis of the iron intracellular. E2 changes the intracellular iron status and the potential for cell growth in breast cancer that has been treated with an increase in E2. Ferritin low regulation led to an increase in caspase-3 activity as an apoptosis marker.

Conclusion

It is been concluded from this study that levels of CA 15-3, β-HCG, IgG, IgM, alkaline phosphatase and ferritin may provide useful information for breast cancer diagnosis and therapy. There are a significant increase in CA 15-3, β-HCG, Caspase-3 IgG, IgM, ALP and ferritin production in many people with with breast cancer. Patients with breast cancer increased the deregulation of caspase-3 and elevated CA15-3. Hormone (β-hCG) has been implicated in breast tumorigenesis. HCG/luteinizing hormone receptors, which are very important for apoptosis and activation of these receptors, leading
to increased apoptosis. The link between ferritin and many cancer-related pathways, such as cell proliferation and inhibition of cell death.

Arthroscopic Coblation for Temporomandibular Joint Disc Release

Khaled I Barakat¹, Diaa El Saied²
¹Professor and Head, ²Assistant Lecturer, Oral and Maxillofacial Surgery Department, Faculty of Dentistry, Minia University

ABSTRACT

Temporomandibular joint diseases are common and one of the most important methods of modern treatment are arthroscopy, which many scientists since the use and until now go to develop in the techniques used for it. The aim of this study is to confuse the results of the use of coblation devices in the operations of TMJ disc release. The study was conducted on the number of 12 patients who were diagnosed by research diagnostic criteria for TMJ and arthroscopic surgery to release disc and place in proper anatomic position then follow up for 2 months. Our results show that highly success rate 91.6% with increase in jaw function. We conclude that coblation give an effective results for arthroscopic joint surgery

Keywords: Temporomandibular joint, Arthroscopy, coblation, disc release

Introduction

Temporomandibular joint (TMJ) internal derangement (ID) is the most common forms of temporomandibular disorder. Patients with TMD may present with a cluster of joint and muscle disorders characterized primarily by pain, joint sounds, and improper jaw function. The first treatment modality of those patients is conservative methods such medical treatments, physiotherapy & splint therapy. In the past when conservative method fail surgical methods is performed through open joint surgery techniques such as arthrotomy, disk repositioning, diskectomy and condylotomy that are invasive and have many complications and their outcomes or success rate still not satisfactory. So that many efforts continued to replace these invasive techniques with another treatment modalities that are less invasive and probably more effective such as arthroscopy (ARSCOPY) which had proved reliable and encouraging results.

Accordingly different ways has been discovered with excellent results, such as arthroscopic disk release with disc-repositioning or suture techniques (discopexy), synovial coagulation, chondroplasty, discoplasty, fibrous debridement and eminectomy. McCain, was first one described TMJ anteriorly disc release to move the frontal and medium correlation in the region of the frontal and medium capsule and pterygoid muscle, release the displaced disc then the disc is placed in a position posterior and subsequently in a favorable connection with the condyle. Disc release could be accomplished to various with the hand tools and monopolar or bipolar electrocautery (diathermy) probe, radiofrequency coblation and laser systems while the others with rotary mechanical shavers. In past the most common technique used for disc release act on using electrocautery diathermy for generating electric stream from the dynamo which is through the tissue among two electrodes, that finding from great temperature (400º-600ºC) play role in cutting the tissue and simultaneously seals the blood vessels. The characteristic of this proceedings in comparison to conventional manual manners is the lowest danger of intra-operative bleeding and smaller period of surgery. Meanwhile, this process is connected with addition post-operative suffering referred to the spread of thermal injury caused to great temperatures utilized.
In 1995 the arthroscopic coblation instrument triggered a revolution in the development of arthroscopic devices for orthopedic arthroscopic surgery, radiofrequency electrical freightage throwing through saline solution produces a plasma with enough power to destroy great bonds necessitate in soft tissue molecules than that induced using electrocautery, treatment theoretically decreasing risk to healthy tissue and reduction suffering. The significant characteristic of the coblation an established is the reduce temperature (lower than 40°C) recognized to the all around tissues, with the lower potential of topical damages when compared with others and without inadvertent damage to adjacent tissues. Many researchers observed that the coblation was additional appropriate, extra careful, supplementary influenced, and lower harmful than conventional hand tools, revolving mechanical shavers, and electrocautery and they reported improved results and prevention of recurrence by using arthroscopic Coblation. Also they found that there was no apparent bleeding or cauterization injury after arthroscopy, and reappearance of a soft surface happened. From all the previously mentioned in this prospective study; we would like to compare usage two cutting techniques for anterior disc release they are monopolar electrocautery and radiofrequency ablation system.

**Aim of the study:** The target of this research was to estimate the influences of Coblation in the temporomandibular joint (TMJ) arthroscopy disc release surgeries.

**Patients and Method**

**Patients:** Arthroscopic surgery was done on twelve temporomandibular joints of patients suffering from ID of TMJ. Who had been referred to the department of oral and maxillofacial surgery at Minia University Dental Hospital (MUDH) from May 2017 to January 2019. Selection was based on the clinical examination using the Research Diagnostic Criteria/Temporomandibular joint Derangements systems RDC/TMD of Internal Derangement (ID) anterior disc displacement (ADD) and radiographic by MRI. The patients consisted of three males and nine females mean age 34.5years and they were previously treated by conservative ways but have not been improved, however any patients with history of previous surgical treatment or systemic bone diseases were excluded from the study. Written informed consents after explanation of the nature and the purpose of the study were obtained from them.

**Equipment:** The arthroscopic system includes KARL STRORZ, Germany, 1.9 mm rod lens type, 30° angle, and camera console (LEMEKE vision, Germany)

The Coblation device uses bipolar radiofrequency energy (Stryker SERFAS Energy RF Ablation System).

**Surgical Technique:** All arthroscopic procedures were performed with the patient under general anesthesia by the same arthroscopists. The arthroscopic technique done according to McCain. The lateral anterior channels used for adhesion ablation and anterior release. The arthroscopy lens usually was introduced through the cannula in the posterior recess of the superior joint space, and the Coblation probe introduced through the cannula in the anterior recess.

The Coblation probe was used to release the anterior attachment of the disc and a portion of the lateral pterygoid muscle. This allows the disc to reduce easily and effectively. The incision line was located approximately 2 to 3 mm anterior to the anterior band of the disc, along the entire medial- to-lateral breadth of the anterior recess. The depth is between 2 and 5 mm. bleeding was coagulated by the Coblation tip until muscle fibers can be seen clearly. A blunt probe was introduced through the anterior cannula to release the muscle further and to reposition the disc.

**Figure 1:** Arthroscopic release. A, area insertion for disc release and muscle shadow B. The anterior release was carried out using the arthroscopic coblation. C, The view after arthroscopic coblation
Evaluation: All patients were examined in predefined follow up appointments; at 1, 2 weeks, 1 & 2 months according to RDC/TMD for evaluation of joint function (assisted and unassisted mouth opening) and disability after treatment.

Results

All TMJs disc were reduced correctly by performing anterior release with Coblation and patients were followed up for 2 months. Our results show 83.3% (10/12) had excellent results and 8.3% (1/12) had good results. The success rate was 91.6%. All patients showed increase in mean non-assisted mouth opening (MO) through all periods and assisted mouth opening that denoting increase proper joint function, the mouth opening increased from preoperative (27.54 ± 1.93 mm) to postoperative (37.48 ± 1.2 mm).

Figure 2: Mouth opening preoperatively and during all periods of follow-up.

Discussion

TMDs signs and symptoms are very common and the diagnosis of particular case is not an easy task due to the complex anatomy, biology of TMJ and the complicated pathophysiology of the disorders. Treatment of TMD has always presented a therapeutic challenge to the oral and maxillofacial surgeon; there is a wide spectrum of different interventions which may help in treating TMD. It ranges from simplest method to more extensive and aggressive one. It was a successful use of arthroscopic lysis and lavage for the management of TMDs that subsequently lead to introduction of the technique of ARSCOPY.

Most studies had utilized electrocautery or laser techniques for disc release in cases of anteriorly disc displacement to reduce disc in its proper anatomic position, However Chen et al.[7] were the first one who described a technique of arthroscopic disc release using coblation system but his study not use standardized method for clinical examination or to correlate data. In this study the clinical results of using arthrosopic disc release had been assessed by means of well-designed clinical trials using RDC/TMD; and to find if there is any effect in the success of the technique. Our results revealed statistically significant decrease in pain score at 2-month follow-up postoperatively versus preoperative data (P=0.026), also we found that there was absence of sound which was statistically significant (p=0.025), while for mouth opening there was significant increase at the end of 2 month follow-up but statistically non-significant (p= 0.055).

Our results are consistent with the study of Chen et al and [7] Zhang et al.[17]

Our present study revealed that coblation system has relative advantages over electrocautery in term of being an easier technique and sharp clean cut. these findings are in general agreements with the work made by Chen et al. [7]

Conclusion

We found in this research that the use of the coblation system in arthroscopic TMJ disc release showed good results and we see the need to make a valid randomized controlled trial.

The Influence of Halloysite Nanotube Addition on Some Properties of Room Temperature Vulcanized Maxillofacial Silicone before and after Simulated Aging

Khalid A. Al-Obaidi, Mohammed Moudhaffer M Ali
1Dept. of Prosthodontics, College of Dentistry, University of Baghdad, Baghdad, Iraq

ABSTRACT

Although silicone is the most commonly used material in face and neck prostheses, but there are some drawbacks concerning its mechanical performance and durability. Therefore, this study was carried out to investigate the impact of halloysite nanotube (HNTs) on selected properties of VST-50F silicone before and after simulated weathering. A pilot study was conducted to determine the most suitable weight percentage of HNTs to be incorporated into VST-50F silicone. Accordingly, 1% and 1.5% weight percentage were chosen to be the experimental groups and compared with control. The main study involved the preparation of 240 samples divided equally into two groups; group 1 (before weathering) and group 2 (after weathering). Group 2 samples were subjected to simulated aging for 200 hour. After that, all samples were subjected to five mechanical tests, namely tear strength, tensile strength, elongation percentage, surface roughness and hardness. The research readings were collected and statistically analyzed using ANOVA, post-hoc and paired t-test tests. Additional tests were also performed including Fourier transform infrared spectroscopy (FTIR) and scanning electron microscope (SEM) that test revealed a well dispersion fashion of HNTs within VST-50F silicone, while FTIR didn’t exhibit any chemical reaction between the silicone and HNTs. However, mechanical tests results before aging showed significant rise in all tests readings except for roughness, where the change was non-significant. Meanwhile, the study results after weathering revealed a significant decline in tear strength, tensile strength and elongation percentages, yet roughness didn’t change significantly, but hardness increased remarkably. Reinforcing VST-50F with HNTs improved some of its mechanical properties but didn’t protect it from aging consequences.

Keywords: maxillofacial silicone, halloysite nanotube, fillers, simulated weathering.

Introduction

Maxillofacial anomalies (inherited or acquired) have a negative impact on normal living both physiologically and psychologically (1). The available choices to reconstruct the defective parts include; surgery or prosthesis, the former is desirable and should be performed whenever possible, while prosthesis is considered a substitute to surgery when the latter is contraindicated (2,3).

Regarding maxillofacial prostheses, the scientist utilized different materials in these appliances till the innovation of silicone, where great shift was made in this industry. This is owning to many favorable properties of silicone such as; biocompatibility, durability, ease of manufacturing and chemical stability (4). Nevertheless, Some properties, like tear and tensile, are not optimum and require improvements. Furthermore, noticeable physical and chemical changes might be encountered during silicone aging, where the cumulative effect of sunlight and oxygen (photo-oxidative attack) are considered as major causative factors for deterioration (5).

Consequently, different methods have been carried out to improve silicone, among them was the addition of fillers which would increase the elasticity of the material and improve its properties both physically and
mechanically (6) HNTs was chosen as filler material in this research because of their brilliant properties including; biocompatibility, availability, low cost and ease of processing (7,8). Therefore, the goal of this study is to explore the impact of HNTs on silicone mechanical behavior before and after simulated aging.

**Materials and Method**

Materials used in this research involved VST-50F silicone (Factor II, Inc., USA) and HNTs (Nano shel., USA).

1. **Pilot Study:** different weight percentages (0.5%, 1%, 1.5% and 2%) of HNTs were added to VST-50F and a comparison were conducted regarding tear strength and surface hardness. Consequently 1% and 1.5% weight percentages were selected as they showed the best outcomes.

2. **Specimens Grouping:** Two hundreds forty specimens had been prepared and divided into 2 main groups; group 1 (before weathering) and group 2 (after weathering), with 120 sample for each. These two groups were further subdivided into 3 subgroups; control, 1% HNTs and 1.5% HNTs, and each subgroup contain 40 specimens; 10 for each test(tear, tensile, hardness and roughness), while elongation percentage test was measured concurrently with tensile strength.

3. **Mold Fabrication:** A lase engraving machine had been used to cut acrylic sheets of variable thicknesses (2 - 6 mm), and this cutting was performed according to specifications determined for each test. The mold consist of base, matrix and cover, secured together by bolts and nuts. G-clamps were also used at the margins for additional tightening (Figure 1).

4. **Mixing Procedure:** Mixing followed manufacturers instructions which reveal that; for each 10 parts of base : 1 part of catalyst (by weight) should be added. For control group samples; the base and catalyst were weighed properly using electronic balance and mixed in vacuum mixer(Multivac 3, Germany) at 360 rpm speed under pressure of 10 bar for 5 minute so as to obtain bubble free mix. While for the other experimental groups (1% and 1.5% HNTs) the chosen concentrations of HNTs firstly weighed in the mixing bowel and the base then added in the desired weight, then the base and the HNTs mixed together for 3 minute without air evacuation (to avoid HNTs suctioning) followed by 7 minute of vacuum mixing. After that the catalyst was added and vacuum mixing was repeated for 5 minutes (9).

5. **Sample Preparation and Storage:** Silicone was applied to fill the mold gradually with the aid of wax knife, when the mold became completely filled, the cover was placed carefully and hand pressure was applied at the center of the mold. Then the mold parts secured together using screws and nuts at the corners and tightened by G-clamp at the margins. The prepared sample were stored in a cooling box to keep them within the recommended conditions (temperature of 23 ± 2°C and relative humidity of 50 ± 10%) (10).

6. **Accelerated Artificial Aging of Specimens:** One hundred twenty sample had been placed in accelerated artificial aging tester (model QUV/spray, Q-Lab corp., USA) for 200 hours(Figure 3), where they submitted to alternative periods of darkness, ultraviolet light, high temperature and filtered water (11).

7. **Testing Procedures:**

A. **Tear strength:** The sample design and testing procedure were based on ISO 34-1:2010 (12) specification. The sample has one apex and two tap ends, with thickness of 2 ± 0.2mm. Universal testing machine (Laryee Technology Co., Ltd., China) had been utilized to perform this test. The speed was adjusted at 500mm/min, and the maximum force at rupture was recorded. Tear strength=F/D,where F is the maximum force required for sample breaking in newtons, and D is the median thickness of each sample in millimeter.

B. **Tensile strength and elongation percentages:**

The design of samples and testing procedure were in accordance to ISO 37:2011 (13) specification. Digital caliper was utilized to calculate the cross sectional area of the testing length. These tests had also been performed using universal testing machine, which run at 500mm/min speed. The maximum force and elongation at break were recorded and the tensile strength was calculated using the following formula: Ts=F/W×T, Where F represents the maximum force in Newton, and W is the width of narrow portion of the sample in millimeters, while T refers to the
thickness of narrow portion of the sample in millimeters. Meanwhile, elongation percentage was calculated from the following equation: 

$$\text{E} \% = \frac{(L_b - L_o)}{L_o} \times 100,$$

where $L_b$ is the length after rupturing, while $L_o$ is the original length. 

C. **Shore A hardness:** Sample design and testing procedure were based on **ISO 7619-1:2010** ([14](#)), where the dimensions were dictated to be 25mm×25mm×6mm (width, length and thickness respectively). Shore A durometer (HS, Ezitown, China) was used to take five readings from each sample, with at least 6 mm distance should separate each reading from sample center and from the other readings. The mean of these readings represents hardness value.

D. **Surface Roughness:** The sample were fabricated according to the directions of **ISO 7619-1: 2010** ([1](#)). Prolifrometer of 0.001 μm accuracy (Pocket Surf Mahr, Germany) was used to take three readings from each sample and the mean of them represent the roughness value.

E. **SEM Test:** Two samples were tested, one for the non-reinforced VST-50F and the other for 1.5% HNTs reinforced VST-50F using SEM (Angstrom Advanced Inc, USA).

F. **FTIR Spectroscopy:** This test was conducted for HNTs powder, reinforced and non-reinforced VST-50F silicone before and after weathering using FTIR spectroscope (Bruker, Germany).

G. **Statistical Analysis:** The data had been collected and analyzed by conducting descriptive and statistical tests including ; ANOVA test, post-hoc test and paired t-test. the Significance level set to ($P \leq 0.05$)

### Results

A. **SEM Result:** SEM reveals a well dispersed fashion of HNTs within silicone polymeric matrix (Figure 2).

B. **FTIR Results:** The results show no impact on the spectra range of VST-50F silicone neither by the addition of HNTs nor by the artificial weathering(Figure 3).

C. **Mechanical Tests Results:** The two experimental groups showed higher mean values than control group in all tested properties within group1 (before weathering) and group 2 (after weathering). One way- ANOVA test revealed a highly significant difference among study groups results of all tested properties within group1 and group 2, except for roughness results. Accordingly post-hoc test has been conducted and its results showed significant difference between control and the two experimental groups in all tested properties within group 1 and group 2. Paired t- test was also performed, and its outcomes referred to significant differences between group1 and group 2 in all categories of all tested properties, excepting roughness test which showed a non-significant increase (Tabe 1 and 2).

Discussion

It has been assumed that; none of the commercially available silicone can meet the ideal characteristics (4). Therefore, researches are being established continuously aiming to improve silicone materials either by modifying their formulas or by adding fillers (15).

Tear strength was significantly raised after reinforcement. Such improvement might be owning to well dispersion of HNTs (as shown in SEM), and the physical interaction between HNTs and VST-50F matrix. Physically, nanoparticle have the ability to form three-dimensional meshes inside silicone polymer matrix and trapping some of its chains within such mesh. This interaction is supposed to have a role in prohibiting the movement not only of the trapped polymer chains but also of the other polymer segments. Consequently, the matrix density might be changed leading to higher tear resistance (16,17). However, tear strength was decreased after weathering, and this decline may be attributed to photo-oxidation caused by weathering, accompanied by release of free radicals which in turn react with each other leading to continuous cross-linking. Beside that, they react with oxygen to form what called (peroxyradicals) that make the elastomer brittle and inelastic (18,19).

Regarding tensile strength and elongation percentage, there was also significant increase in their readings after reinforcement. These findings can be explained as follow; when tensile stress applied to reinforced silicone polymer, the polymer chains and the reinforcing fillers would undergo sliding movement over each other, thus the chains would be protected from breakage with the aid of fillers. Additionally, polymer matrix has the ability to dissipate the applied force energy to heat, hence the remaining energy is less than what required to break polymer chains. Reinforcing fillers play a role in the dispersal of such energy (20). Anyhow, the results of these two properties after weathering revealed a significant decline in all categories. This decrease probably due to continual cross-linking that caused by accelerated ultraviolet light which is accompanied by volatile byproducts release, rendering the material inelastic and more susceptible to deformation under lighter force (15).

Hardness result before weathering exhibited highly significant increase in both experimental groups compared with control readings. Such results could be explained as follow; the nano fillers are well dispersed within the polymer (as revealed by SEM test) and capable of forming networks inside polymer, reducing the inter-aggregate space, making the material stiffer and increasing its hardness (20). Moreover, hardness readings further increased in all study groups after weathering. This finding might happened as a result of continual polymerization which is attributed to the ultraviolet light exposure during simulated weathering period. UV light absorption make the polymer network unstable, and the excess energy will be transmuted between the neighboring molecules. This will lead to degradation of these molecules as a result of photo-chemical reactions, leading to increased hardness (22).

Meanwhile, surface roughness test shows a non-significant changes not only between study groups before weathering, but also with their counterparts after weathering. Such results might be due to the small concentrations of HNTs that had been incorporated within VST-50F silicone. Beside that, HNTs are nano-sized and well distributed within polymer matrix (Figure 2B). All the aforementioned facts together make the effect of HNTs on the material surface insignificant, hence surface roughness readings didn’t change significantly as such test concern with outer surface irregularities.

Conclusion

The incorporation of HNTs into VST-50F in 1% and 1.5% weight percentage enhanced tear strength, tensile strength and elongation percentage without significant effect on roughness, while hardness increased but still within the acceptable range. However, such reinforcement didn’t protect the silicone from the consequences of 200 hour of simulated aging.

Effect of Computer Related Ergonomics Intervention on Knowledge and Practice of Primary School Children

Lamiaa Saad Abdallah¹, Nagah Mahmoud Abdou², Afaf Ibrahim Abd Elrehim³

¹Assistant Lecturer, ²Professor, ³Assistant Professor, Community Health Nursing, Faculty of Nursing, Cairo University, Egypt

ABSTRACT

Improper use of computers results in a variety of health disorders. The cumulative effect of this technology-induced, sedentary lifestyle leads to poor posture, pain, repetitive strain injury and dysfunctional movement patterns. Aim: assess the effect of computer ergonomics educational intervention on knowledge and practice of primary school children. Design: Quasi – experimental design. Sample: A total of 100 primary school children were randomly selected. Data were collected using Children Knowledge Assessment Questionnaire, Computer Workstation Assessment Checklist, Children Ergonomics Observational Checklist. Results: This study revealed an increase in knowledge and practice mean scores in immediate and follow up post intervention scores compared to pre intervention mean scores. As well, statistically significant differences were found between total knowledge and total practice scores regarding computer ergonomics in pre, immediate post and follow up the intervention. Conclusion: The educational intervention is effective in improving the children knowledge and practice. Therefore, it is recommended to replicate the research on a large sample and in different settings to achieve more generalization.

Keywords: Ergonomics, Computer use, knowledge and practices, Primary school children.

Introduction

The use of computers in schools is now well established worldwide and strategies to increase the level of use of computers by children are ongoing. However, there continues to be little thought given to ergonomic factors during the setting up of computer workstations in schools or to the subsequent use of the computers by the children. On the other hand, long periods of using a computer can increase chance of developing musculoskeletal problems. Inappropriate posture during computer use can cause muscle and joint pain, overuse injuries of the shoulder, arm, wrist or hand, and eyestrain¹.

The effect of improper ergonomics manifests even before students reach graduation, hence the need for commencing educational and ergonomic interventions from undergraduate years or even earlier². So, building up of school children knowledge and skills regarding ergonomics must be emphasized during these years ³. Proper educational intervention is expected to improve the knowledge and practice of ergonomic principles, which is assumed to reduce the associated health risks ⁴.

Ergonomics is the science that seeks to comfort the work station and all of its physiological aspects to human ⁵. Ergonomics is about fit: the fit between people, the things they do, the objects they use and the environments they work, travel and play in. If good fit is achieved, the stresses on people are reduced. So they are more comfortable, can do things more quickly and easily, make fewer mistakes and get injured less frequently⁶.

Hypotheses:

H1: The posttest-mean knowledge scores of children who were exposed to ergonomics educational intervention will be higher than pretest–mean knowledge scores.

H2: The posttest - mean practice scores of children who were exposed to ergonomics educational intervention will be higher than pretest–mean practice scores.

DOI Number: 10.5958/0976-5506.2019.03101.2
Materials and Method

After the random selection of a three primary governmental school from the available educational governmental sectors in Cairo governrate, one classes from every school was randomly selected from the list of 4th grade classes. The sample size as calculated by power analysis was 100 children. Fourth grade children were selected in particular as preadolescence was an appropriate age for the implementation of educational program to avoid musculoskeletal problems which are more prevalent during adolescence.

Exclusion Criteria: Students with previous surgeries, deformities in the musculoskeletal system or rheumatoid arthritis were excluded.

Data Collection Tools:

I: Children Ergonomics Knowledge Questionnaire: It was used to assess children knowledge regarding computer use ergonomics. For each yes or no question, a correct answer was scored 1 and 0 score for the incorrect one.

II: Computer Workstation Assessment Checklist: It was used to assess computer workstation and related ergonomic risks. The checklist had a total score of 40. A score of 40 indicated the best score as each item fulfilling the standards was given 1 score and if not was given zero.

III: Children Ergonomics Observational Checklist: It was used to assess children practices of ergonomics while using computer in the computer workstation. For each item, children were scored 2 if they adopted proper ergonomics and 1 if they did not.

Content validity was done and tools were tested for internal consistency (Cronbach’s alpha was 0.87).

Procedure: An approval was obtained from Research Ethics Committee at Faculty of Nursing, Cairo University. Official permissions were obtained from the related administrations of schools to conduct the proposed study.

Children were asked to participate in the study and the researcher explained the aim of the study to all students. Also, written consent was obtained from the parents before children were enrolled in the study. Oral consent was obtained from the children to participate in the study.

The study was carried out on four phases: assessment phase, planning, implementation and evaluation phases.

1. Assessment Phase: In this phase, assessment of children ergonomics knowledge was done using tool I. Also, assessment of computer workstation by using tool II. As well, the researcher observed the children in the computer lab using tool III.

2. Planning Phase: The researcher designed the educational intervention. The aim of this educational intervention was to provide children with knowledge and skills of ergonomics principles and to promote behaviors that encourage a healthy musculoskeletal system. The program included knowledge about anatomy and structure of spine; ergonomic science, human body mechanics, solution of obstacles of following ergonomics principles, and stretch exercises for prevention of musculoskeletal health problem.

3. Implementation Phase: The designed intervention was presented in simple Arabic language. The designed intervention was carried out on five sessions, each session was given in the form of teaching class through pre – designed training materials.

Pamphlets, flyers, and a compact disc with a short documentary video was used. Demonstration on the proper ergonomics principles, as well, stretching and strengthening exercises were done. Handouts were given for the children. Feedback was given at the end of each session.

4. Evaluation Phase: Immediate evaluation of the educational program was done using tool I and tool III to assess the achievement of intervention objectives and three months later to ensure stability of knowledge and practice.

Results

Concerning knowledge of children regarding computer use ergonomics table (1) shows that, it was improved in immediate and follow up post tests compared to pre test.

**Table 6: Distribution of pre test scores of computer workstation (N = 3)**

**Discussion**

Regarding children’s knowledge of computer use ergonomics the current study revealed that, the correct responses were increased in immediate and follow up post tests. These results were in harmony with a study done to investigate the awareness and practice of computer ergonomics among students in Ajman and found that, students who were exposed to ergonomics intervention identified the correct viewing distance, used ergonomic key boards and also take frequent breaks when compared to students who were not exposed to ergonomics intervention. These results highlighted the importance of integrating ergonomics educational program in schools as proper educational intervention is expected to improve the knowledge and practice of ergonomic principles, which is assumed to reduce the associated health risks.

Also, the study results were consistent with a study conducted to assess knowledge of computer ergonomics and incidence of musculoskeletal disorders among 120 students in India and indicated that more than half of children considered that an elbow angle of 90 is essential. As well, three quarter of children mentioned use of backrest to support lower back and feet should rest comfortably on the floor or on a footrest. These results may be due to effect of ergonomics educational intervention that enhanced knowledge regarding the proper use of computers, especially when the focus of these interventions has been on overall postural health, environmental ergonomics and body mechanics.

Concerning children’s knowledge about methods of preventing computer ergonomics risk factors the current study showed, improvement in immediate and follow up post tests. These results were supported by the results of a study conducted by Bisht & Bakhshi. Students of their study stating that arm rests, back support and using antiglare screen of computer were very important. Also, distance of arm length from screen is essential. This improvement may be due to ergonomic educational intervention that helped the student remember the ergonomic information presented in the educational intervention and easily answer questions correctly at the first and second assessment.

Regarding body posture ergonomics during computer use, the current study revealed that it was improved in immediate and follow up post tests. Theses results were contradicted with the study conducted to assess computer-related posture and musculoskeletal discomfort in schoolchildren and revealed that no student was found to have an acceptable posture while working at the computer. The majority of student’s postures were inappropriate indicating that further investigation and intervention is required. The positive effect of educational sessions in the current study could have played role in promoting changes in computer use ergonomics and it reflected adherence to the intervention program.

Regarding computer workstation assessment for the three governmental schools and its related ergonomic risks, the study showed that, the three schools didn’t have the acceptable level for computer workstation. This result was consistent with a study conducted to investigate how computers are being used in schools of Mumbai, computer workstations and the posture adopted by students. The study showed mismatch between the students’ dimensions and furniture dimensions in computer labs and computer workstation were inadequate for majority of the students. That result reflected lack of ergonomics consideration while designing computer labs may be due to financial difficulties of the educational facilities at governmental schools.

The current study indicated, highly statistically significant positive correlations between children’s total computer knowledge score and total computer practice scores in pre test and follow up post tests (p =.000 & p =.002 respectively). These results contradicted with a study conducted by Shantakumari et al who found that attendees of ergonomics training workshop didn’t put the principles learned into practice before and after the workshop.
According to learning theories, access to information and knowledge is the starting point in learning process and retention of knowledge thus enhance behavior. According to this logic, improvement in students’ knowledge lead also to improvement in their practices.

**Conclusion**

The ergonomics educational intervention had significant positive effect on children’ knowledge and practices which were evident by statistical increase in their knowledge and practice mean scores in immediate and follow up post intervention compared to pre intervention mean scores. So the research hypotheses were accepted.

**The study recommended the following:**

- Replication of the research on a large probability sample to achieve more generalization.
- Endorse ergonomics educational intervention in the school curriculum.
- Health instructional program that encourage healthful postural habits for school children should be intensified at schools.
- Reinforcement of ergonomics consideration while designing computer workstations at schools tools or equipment used by children.
- Ergonomics intervention in form of students education and computer workstation adjustment may provide solutions to ergonomics risk factor presented in governmental schools.

**Ethical Clearance:** A written approval was obtained from the Research Ethics Committee of the Faculty of Nursing - Cairo University. Written informed consent was obtained from each participant after explaining the nature & purpose of the study. Participants were informed that participation in the study was entirely voluntary, anonymity and confidentiality of the data were assured.

Plasma Leptin and Insulin Resistance Correlation with Obesity in Pre Pubertal Children

Leersia Yusi Ratnawati¹, Bambang Wirjatmadi², Merryana Adriani², Roedi Irawan³

¹Doctoral Student at Public Health Faculty, Airlangga University; Departement of Public Health Nutrition, Public Health Faculty, Jember University, Indonesia; ²Departement of Nutrition School of Public Health, Departement of Pediatric, Faculty of Medicine, Airlangga University, Surabaya, Indonesia

ABSTRACT

Background: Insulin resistance correlates with obesity through a neural mechanism that is represented by an increase in leptin levels.

Objective: The aim of the study was to analyze the correlation between plasma leptin levels and insulin resistance with obesity in pre-pubertal age children.

Method: Observational analytic study with a cross sectional design was used for this research. There are 60 elementary school students aged 6-9 years involved in this study, 30 obese students and 30 students with normal nutritional status. Fasting insulin, fasting blood glucose and HOMA IR index were carried out in Parahita Laboratory at Sidoarjo and leptin at Institute of Tropical Disease Airlangga University. Statistical analysis using independent t-test and pearson correlation with significance value < 0.05. ROC curve was used to determined leptin cut off.

Result: There was correlation between obesity with insulin resistance (BMI(0,000;0,748); Z score BMI for age (0,000;0,738)). There was no correlation between obesity with leptin plasma (BMI(0,175;-0,178); Z score BMI for age (0,147;-0,189). Leptin cut-off against insulin resistance in pre-puberty children was 0.589 ng/ml with a sensitivity value of 0.412 and specificity of 0.581.

Conclusion: There was positive correlation between obesity by BMI and Z score BMI for age with insulin resistance in pre pubertal children.

Keywords: leptin, insulin resistance, obesity, pre pubertal children

Introduction

The incidence of insulin resistance in early age is increasing along with the increasing prevalence of childhood obesity in the world. Insulin resistance is a complication of obesity that is often found in children and adolescents who are obese. (1). Ramualdo et al (2014) evaluated the conditions of insulin resistance in children and adolescents 5-14 years old, 33.2% diagnosed with insulin resistance. (2) Izabel et al (2016) on 7 selected articles, recommending cut-off for HOMA IR 2.5 for both boys and girl. (3)

Obesity correlates with leptin production and high plasma leptin levels. (4) Some studies say that hyperleptinemia or leptin resistance plays an important role in conditions of insulin resistance. In experimental animal studies, leptin also affects the regulation of energy balance and insulin sensitivity. Leptin resistance correlates with the reduction of JAK-STAT signaling, leptin mediators, and induction of Suppressor of Cytokine Signaling-3 (SOCS-3). Imbalance of leptin transport crosses the blood brain barrier, reduces the signal of leptin-mediated JAK-STAT, and induces suppressor of cytokine signaling 3 (SOCS-3). Decreased leptin sensitivity in the brain increases the accumulation of triglycerides in adipose tissue, muscle, liver and...
pancreas resulting in an imbalance of insulin secretion and sensitivity. (5)

Madeira et al (2017) also mentioned in the results of his research that leptin could be one indicator of metabolic syndrome in cardiovascular and cardiovascular disease in pre-pubertal children, where insulin resistance often occurs in the early stages of CVD, with leptin cut-off values > 13.4 ng/dL. (6) At present, several studies in different countries have different conclusions. This study is expected to provide an analysis of the relationship between plasma leptin levels and insulin resistance and obesity in pre-pubertal age children in Indonesia. We focus on pre-pubertal children with obesity as a risk factor for metabolic syndrome in the future.

**Method**

The study involved 60 elementary school children aged 6-9 years who were obese and non obese, and had not entered puberty stage. Sampling was done randomly with regard to the predetermined inclusion criteria. Obese criteria were determined based on BMI/U> +3 SD values and non obese BMI ± mean 2 SD using the WHO 2005 standard. Whereas, puberty criteria were assessed based on Tanner’s scale on a scale of 0 or pre pubertal scale. This research was conducted in 3 Sidoarjo Regency Elementary Schools, Pucang 1 Sidoarjo Elementary School, Pucang 2 Sidoarjo Elementary School and MI Ma’arif NU Pucang Sidoarjo, East Java Province, Indonesia.

**Anthropometry Assessment:** Anthropometry assessment was using WHO Procedure standard. Weight measurement was using digital scale (GEA type eb 9350) to the nearest 0.01 kg, wearing light clothing and without shoes. Height was measured without shoes and hat/head accercories, to the nearest 0.1 cm, by using Microtoice.(GEA).

The results of anthropometric measurements were used to determine obesity by calculating Z score BMI for age. BMI value is obtained by calculating the body weight in Kg squared divided by the value of height in meters. The Z score BMI for age is calculated based on the formula using the WHO 2005 standard.

\[
\frac{\text{BMI} – \text{Median Standard}}{+1SD – \text{Median Standard}}
\]

**Laboratory assessment:** After 8 hours overnight fast, all participants were gotten venous blood sample 5 cc in Parahita Laboratory Sidoarjo, East Java. Insulin resistance was assessed by HOMA index.

\[
\text{HOMA index} = \frac{(\text{fasting insulin (µU/mL)} \times \text{fasting glucose (mg/dL)})}{405}
\]

Fasting insulin assessment was using ECLIA (Electro Chemiluminiscence Immuno Assay) method (µU/mL). Fasting glucose was assessed by Hexokinase (mg/dL). Plasma leptin levels were measured using the ELISA method with a sensitivity value of 1.02 ng/ml, intraassay <8% and interassay and <10%.

All subject and parents signed an informed consent for participation in the study. The study protocol was approved by the local ethics committee of Public Health Faculty, Airlangga University. This work has been carried out in accordance with the code of ethics of the WHO-CIOMS 2016 for experiments involving human.

The data were analyzed by SPSS statistical software. Data was analyzed by using independent t test and Pearson correlation to analyze correlation between variables. For all tests a probability (p) less than 0.05 was considered significant.

**Result**

**Subject Characteristic:** Descriptive description of subject age showed that many obese groups occurred at the age of 7-8 years (76.6%) while the non obese group (normal nutritional status) occurred at a younger age of 6-7 years (73.3%). The sex of the subject was mostly male (80%).

The average value of the obese group BMI showed a very high BMI rate of 26,05; while the non obese group ranged in BMI value of 16,03. The calculation of Z score BMI for age showed that the obese group has an average Z score BMI for age reaching 5,73. The minimum Z score BMI for age makes it clear that all children in the obese group in the obesity category are in accordance with WHO 2005 standards. While the normal group the average Z score BMI of age is 0,25.

**Profil Leptin dan Resistensi Insulin Obese and Non Obese Pre Pubertal Children:** Descriptively the measurement results of the average HOMA index between obese children and non obese showed a significant
difference, with an average value of 2.75 for the obese group and 1.01 for non-obese children. Izabel et al (2016) mentioned in a review of 7 selected articles, recommending a cut off for HOMA IR 2.5 for both boys and girls.\(^{(3)}\)

Fasting blood glucose levels in both the obese and non-obese groups tended to be the same, the average obese fasting blood glucose level was 86.36 ± 6.3 mg/dL, while the non-obese group was 85.27 ± 7.2 mg/dL. Fasting blood glucose levels in the obese and non-obese groups were all in the normal category (< 100 mg/dL).

Obese fasting insulin levels tended to be higher than the non-obese group, the average obese group fasting insulin level was 13 ± 6.29 μU/mL, while the non-obese group was 4.74 ± 2.5 μU/mL. The normal limit of fasting insulin was 2.6 -24.9 μU/mL.

The obese group leptin levels tended to be lower than the non-obese group, on average the obese group leptin levels were 0.795 ± 0.843 ng/ml, while the non-obese group was 1.549 ± 2.447 ng/ml. Normal leptin limit <13.4 ng/dl.\(^{(6)}\)

The insulin resistance condition represented by the HOMA index value in the obese group was higher than the non-obese group was also supported by independent t test results which showed a significant difference between obese and non-obese groups with a value of p = 0.000 (α <0.05) There were significant differences in fasting insulin levels between obese and non-obese groups (p = 0.000), but fasting blood glucose levels between obese and non-obese groups had no significant difference (p = 0.534). These means that between the obese and non-obese groups have different abilities in the insulin response at the same blood glucose level, with a higher HOMA index value in obese group.

p = significant p value (< 0.05); r = coefficient pearson correlation

Obesity in pre-pubertal children has a significant correlation with insulin resistance (IR HOMA). Obesity correlation with insulin resistance is indicated by BMI and z score BMI for age, Pearson correlation test results show a significant good correlation with BMI parameters (0.000; 0.758), Z score BMI for age (0.000; 0.748). BMI that has the highest r value of insulin resistance is 0.748, then the value of r2 is 0.559. This means that the high and low HOMA IR as an indicator of insulin resistance is only 55.9% which can be explained by BMI. So the BMI parameter is the parameter with the highest correlation value in the event of insulin resistance.

Obesity correlations in pre-pubertal age children with leptin showed a non-significant relationship, both with BMI parameters (0.175; -0.178) and Z score BMI for age (0.147; -0.189). The correlation between obesity and leptin showed a negative correlation, the higher the BMI and Z BMI scores for age, the lower the value of leptin.
ROC curve analysis showed leptin cut-off values for insulin resistance in pre-puberty children of 0.589 ng/ml with a sensitivity value of 0.412 and specificity of 0.581. Low values of sensitivity and specificity indicate that the cut-off value cannot be used as a cut off to identify insulin resistance.

Discussion

Accumulation of fat mass during obesity is characterized by hyperplasia and hypertrophy of adipose cells; its correlates with increased angiogenesis, macrophage infiltration, production of extracellular matrix components, endothelial cell activation and production and release of several inflammatory mediators. Disregulation of functions and the production of pro and anti-inflammatory cytokines in obese individuals, will lead to low levels of chronic inflammatory conditions and can increase the correlation of obesity to metabolic and cardiovascular disorders such as insulin resistance, metabolic syndrome and atherosclerosis. (7)

The results showed there was a correlation between obesity and HOMA index as an indicator of insulin resistance. Positive correlation between obesity and insulin resistance showed that the higher the IMT value, the higher the HOMA index. Likewise, the BMI for age z score also shows a positive correlation. BMI average of obese group is higher than non-obese group, also with z score BMI for age. The higher the BMI value and e z score BMI for age indicate the higher the scale of obesity. Higgins and Donahoo (2008) mentioned that several retrospective studies on a large scale showed a correlation between adiposity and insulin resistance and metabolic syndrome, including Martin et al’s study showed BMI at 2-14 years of age having a negative correlation with insulin sensitivity in lean adults at the age of 70 years. Body Mass Index when children become strong predictors of metabolic syndrome events as adults. (2)

Leptin is one of the adipocytokines produced by adipose tissue. Leptin as a mediator of Janus Kinase-Signal Transducer and Activator of Transcription (JAK-STAT) signaling, plays a role in regulating food intake and weight loss by giving signals to the central nervous system to reduce food intake and increase energy expenditure. In muscles, leptin stimulates oxidation of free fatty acids by activating adenosine monophosphatase kinase. Leptin also reduces fat from non-adipose tissue, prevents lipotoxicity, which is possible because of its ability to block stearoyl-coenzyme A desaturase and inhibit the formation of liver triglycerides by activating phosphatidylinositol 3 Kinase (PI3 kinase). (5,6). Decreased leptin sensitivity in the brain increases the accumulation of triglycerides in adipose tissue, muscle, liver and pancreas resulting in an imbalance of insulin secretion and sensitivity.

Wang et al (2010) study in China in adults showed that leptin levels were positively related to IR (insulin resistance), leptin levels increased the risk of prediabetes by OR 2.6, even without obesity. Research in Hispanic overweight shows that leptin levels affect insulin sensitivity. (9). In another study showing the same thing, leptin was positively correlated with insulin resistance in pre pubertal children with regard to gender, age and Z score BMI and leptin could be potential modulators of glucose metabolism and insulin resistance, although in cases of obesity and non-obesity. (9). Madeira et al., 2017 also mentioned in the results of his research that leptin could be one indicator of metabolic syndrome and cardiovascular disease in pre-pubertal children, where insulin resistance often occurs in the early stages of CVD, with leptin cut-off values> 13.4 ng/dl. (6)

Pearson correlation test results showed no correlation between obesity and plasma leptin. Leptin levels in pre-pubertal children in both the obese and non-obese groups have the same average values, even in the obese group, they tend to be lower. Low leptin
levels (reduced leptin receptors) cause hyperphagia and obese conditions. If the energy intake exceeds what is needed, then adipose tissue increases accompanied by increased levels of leptin in the bloodstream. Then, in obese patients there was leptin resistance, so that high levels of leptin do not cause appetite decreasing. Leptin level in pre-pubertal obesity are still low, which allows for hungry stimulation. Increasing hunger stimulation will stimulate hyperplasia adipose cell. The cut off value of leptin against insulin resistance in pre-pubertal children has a low value of sensitivity and specificity, so it is not recommended as a standard for assessing the risk of insulin resistance.

Conclusions

There was a positive correlation between obesity and insulin resistance in pre pubertal children. The higher the IMT value, the higher the IR HOMA index value. Leptin levels in pre-pubertal age tend to be the same between obese and non-obese groups, still normal. Obesity in pre-pubertal children is still in the early stages of obesity, where the condition of insulin resistance is still reversible. Therefore, it is recommended to make efforts to reduce the condition of insulin resistance by regulating diet and increasing physical exercise.

ABSTRACT

Lead (Pb) is one type of heavy metal that has a low melting point, is easily formed, and has active chemical properties. Lead is usually used to coat the metal to prevent rusting. It is highly dangerous for living things as it has carcinogenic properties, can cause mutations, and relatively takes long time to decay and its toxicity does not change for long time period. This study aimed to determine the safe concentration of lead in the water that consumed by people in Tugurejo Village, Tugu Kota Subdistrict, Semarang City, Central Java Province. This study was an observational study with non reactive research using reference dose (RfD) calculation and LOAEL. The sample was 35 people from the Tugurejo Village, Tugu Kota Subdistrict, Semarang City, Central Java Province.

The measurement results show that the concentration of Lead (Pb) is 0.003 mg/L. This concentration is the same as the quality standard of 0.003 mg/L according to Government Regulation No. 82 of 2001 concerning Management of Water Quality and Water Pollution Control. This means that the concentration of lead in river water is still relatively safe. The manual calculation of safe concentration of lead in Tapak river water for drinking water produced a result of 0.00055 mg/L. It is below the maximum Pb limit for drinking water as stated in the Republic of Indonesia Minister of Health Regulation Number 492/MENKES/PER/IV/2010 of 0.01 mg/L. This calculation can be used to predict safe concentrations of toxins in water for the manufacture of safe drinking water for the people of Tugurejo Village, Tugu City, Semarang, Central Java Province. Therefore, the environmental conditions of the Tapak river must be maintained so that the Lead (Pb) levels in the Tapak river water will not increase.

Keywords: Lead (Pb), safe concentration, Tapak river water

Introduction

Lead (Pb) is one type of heavy metal that has a low melting point, is easily formed, and has active chemical properties. Lead is usually used to coat the metal to prevent rusting. It is a bluish gray soft metal and has a +2 oxidation number (Sunarya, 2007).

It is highly dangerous for living things as it has carcinogenic properties, can cause mutations, and relatively takes long time to decay and its toxicity does not change for long time period (Brass, 1981). According to Palar (1994), Pb can pollute air, water, soil,
plants, animals and even humans. Pb can enter the body through food either from plants or animals.³

Lead (Pb) is one of the environmental pollutants. The pollution of the Pb has increased in recent years. The environmental impact has also increased, especially regarding water pollution. The pollution became serious threats to water quality in Indonesia. Most of them came from waste from both industrial and human activities. Basically, the river is one of the water sources commonly used by humans for various activities in their daily life. It has a very important role in human life and all of living things, so that river will affect and be affected by other conditions or components.⁴

Rivers provide many benefits for humans through irrigation, drinking water, agriculture and industry. One of the areas where its river has polluted water by Pb is Java. This is due to the concentration of industry in the area of these rivers. The Tapak River is one of the rivers polluted by Lead (Pb). Geographically, the Tapak River is located in Tugurejo Village, Tugu District, Semarang City, Central Java Province, more precisely on the west side of Semarang City, which is around 12 km from the city center.⁵

Tugu Sub-district is one of the sub-districts in Semarang City. This sub-district is the place where large number of industries situated, from small, medium and large industries. Lead (Pb), the source of pollutants in the Tapak River, comes from residential areas and industrial areas. Most of wastes disposed in the Tapak river are waste from the Tambakaji Industrial Zone and other industries around the Tugu District near the Tapak River.⁵

In terms of water quality requirements, water must comply with the provisions contained in several regulations, one of which is Government Regulation No. 82 of 2001 which stated that Lead content in drinking water should not exceed the standard of 0.03 mg/L.⁶ This is slightly different with other regulation. Regulation of the Head of Drug and Food Control Agency (BPOM) of the Republic of Indonesia Number 23 of 2017 concerning the maximum limit of heavy metal contamination in processed food stated that the maximum limit of Pb for the natural mineral water category and its source is 0.01 mg/kg.⁷ This maximum limit is the same as the limit stated in the Regulation of the Minister of Health of the Republic of Indonesia Number 492/MENKES/PER/IV/2010, which is equal to 0.01 mg/L.⁸

According to the results of the Puspito Raharjo’s study (2018), it was found that lead content was 4.462 mg/L in Tapak river water and 0.623 mg/kg in mangrove oyster meat. A preliminary survey of 20 people in the area found that they consumed 250 gr mangrove oysters per day with a frequency of 2-3 times/week. It also found that the average concentration of lead in river water at each station was 0.03 mg/L. Based on the explanation above, it is necessary to measure the safe concentration of Lead in water for consumption by the people of Tugurejo Village, Tugu City, Semarang, Central Java Province.

Materials and Method

This study aimed to determine the safe concentration of lead in the water that consumed by people in Tugurejo Village, Tugu Kota Subdistrict, Semarang City, Central Java Province. This study was an observational study with non reactive research using safe concentration (c safe) calculation and LOAEL. The sample was 35 people from the Tugurejo Village, precisely in RW 4. The sample of water was taken from 4 different stations in the Tapak River, 2 liters for each station.

This study began by conducting a literature study on the calculation formula of Dose Reference (RfD) and safe concentration (c safe). The variables of this study were Lowest Observed Adverse Effect Level (LOAEL) of Pb dan Reference Dose (RfD). This study used manual quantitative data analysis to determine the safe concentration (c safe) of Pb.

In Saridewi and Tualeka (2017)⁹, it is shown that the calculation of safe (C safe) concentration can be calculated using a formula obtained from William (1985), Davis (1991) and Soemirat (2003) as follows:

\[
C_{safe} = \frac{Rf \times D \times Wb}{\alpha \times R}
\]

Annotation:
C safe: safe concentration (mg/L)
RfD: Reference Dose
Wb body weight
\( \alpha \): % substance absorbed by ingestion

Result

A. Lowest Observed Adverse Effect Level (LOAEL) of Lead: Before determining the safe limits of concentrating chemicals, it is necessary
to determine the Lowest Observed Adverse Effect Level (LOAEL). The process to achieve the safe threshold limit value begins by determine the Lowest dose at which there was an observed toxic or adverse effect (LOAEL)\(^\text{10}\). So the Lowest Observed Adverse Effect Level (LOAEL) value must be known in advance way of literature study by searching the literatur that has been available on the internet, books or other scientific source. However, the literature used must be reliable and there is evidence of scientific studies. Below is Lowest Observed Adverse Effect Level (LOAEL) value based on ATSDR 1990 in Chemical Safety Information from Intergovernmental Organizations, the value of the Lowest Observed Adverse Effect Level (LOAEL) of Lead (Pb) is 3.2 µg/m\(^3\).\(^1\) So that:

\[
\text{LOAEL} = \frac{n \times \text{molecular weight}}{24.45} \times 1000
\]

\[
3.2 \text{ µg/m}^3 = \frac{n \times 207.2}{24.45} \times 1000
\]

\[
n = 0.00038 \text{ mg/kg/day}
\]

Based on the above calculations it was found that the value of Lowest Observed Adverse Effect Level (LOAEL) of Lead (Pb) was 0.00038 mg/kg/day.

**B. Reference Dose (RfD) of Lead (Pb):** Tualeka (2013) states that the Reference Dose (RfD) of a toxin exposure can be calculated using the following formula\(^1\):

\[
\text{RfD} = \frac{\text{LOAEL}}{100}
\]

Using the above formula, the obtained Reference Dose (RfD) for Lead (Pb) was 0.0000038mg/kg.

\[
\text{RfD} = \frac{0.000038}{100} = 0.0000038 \text{ mg/kg}
\]

Based on the above calculations it was found that the value Reference Dose (RfD) of Lead (Pb) was 0.0000038 mg/kg.

**C. Safe concentration (c safe) of Lead (Pb) in Drinking Water:** To determine the safe concentration of Lead in drinking water, the following formula (Tualeka, 2013) was used.

\[
C_{\text{Safe}} = \frac{\text{RfD} \times \text{Wb}}{\alpha \times \text{R}}
\]

Using the above formula and the ingestion absorption percentage of 20% (ATSDR, 2010)\(^3\), the safe concentration of Lead in water in Tapak River was 0.00055 mg/L. The calculation is shown below:

\[
C_{\text{Safe}} = \frac{0.0000038 \times 58}{20% \times 2} = 0.00055 \text{ mg/L}
\]

The result of the calculation above is still below the threshold limit value (TLV) of Pb in drinking water as stated in the Regulation of the Minister of Health of the Republic of Indonesia Number 492/MENKES/PER/IV/2010 of 0.01 mg/L. Thus, this result can be used to predict toxins in water for the manufacture of drinking water for the people of Tugurejo Sub-District, Tugu District, Semarang, Central Java Province. It can also be used as a comparison value for the TLV set by various institutions such as the Ministry of Manpower and Transmigration, the National Standardization Agency, OSHA and so on.

**Discussion**

Measurements of Lead (Pb) concentration in Tapak river water in Tugurejo Village, Tugu District, Semarang City, Central Java Province, were carried out in 4 different stations and 2 liters of samples were taken from each stations.

The measurement results show that the concentration of Lead (Pb) is 0.003 mg/L. This concentration is the same as the quality standard of 0.003 mg/L set by Government Regulation No. 82 of 2001 concerning Management of Water Quality and Water Pollution Control. It means that the concentration of Lead in Tapak river water is still relatively safe.

The manual calculation of safe concentration in the water of the Tapak River, Tugurejo Village produced a figure of 0.00055 mg/L. It is below the threshold limit value of Pb for drinking water as stated in the Regulation of the Minister of Health of the Republic of Indonesia Number 492/MENKES/PER/IV/2010 of 0.01 mg/L. Thus, the calculation can be used to predict toxins in water for the manufacture of drinking water for the people of Tugurejo Village, Tugu City, Semarang, Central Java Province. The calculation of safe concentration of Lead...
(Pb) in drinking water is based on the calculation of the Reference (RfD) and the Lowest Observed Adverse Effect Level (LOAEL). To calculate LOAEL, testing used experimental animals. The calculation result of the Lowest Observed Adverse Effect Level (LOAEL) for Lead (Pb) is 0.00038 mg/kg/day.

Reference Dose (RfD) is obtained from the LOAEL value calculation. The calculation result of the Reference Dose (RfD) was 0.0000038 mg/kg. The safe concentration of Lead (Pb) is obtained from the calculation of the Reference Dose (RfD), the average body weight, Lead (Pb) absorption through ingestion, consumption rate and time. The safe concentration (c safe) result was 0.00055 mg/L. This value is above is still below the threshold limit value (TLV) set in the Regulation of the Minister of Health of the Republic of Indonesia Number 492/MENKES/PER/IV/2010 of 0.01 mg/L. Thus, this concentration value can be used as an additional reference to measure the next safe concentration.

Conclusion

The measurement results of the average concentration of Lead (Pb) in the waters in the Tapak River, Tugurejo Village, Tugu District, Semarang, Central Java Province, was 0.03 mg/L. This value is equal to the quality standard of 0.03 mg/L according to Government Regulation No. 8 of 2001 concerning Management of Water Quality and Water Pollution Control. The result of the manual calculation for safe concentration of Lead in drinking water was equal to 0.00055 mg/L. This is below the TLV set in the Regulation of the Minister of Health of the Republic of Indonesia Number 492/MENKES/PER/IV/2010 of 0.01 mg/L. Therefore, it can be concluded that the water in the Tapak River is still safe to consume.

However, the effort to maintain the concentration is need to be carried out. Some of them are to always control Lead concentration by regular laboratory check and dissemination to the community around Tugu River not to consume river water. In addition, all communities together with the government must participate in maintaining and supervising all human activities that can increase concentration of heavy metals in river water. This is aimed to conserve the river water, so that it is free of harmful heavy metals and the community can use river water for their daily needs without worrying of the negative effects of using the river water.14

Finding of *Helicobacter Pylori* through Biopsy Trials to Gastro-intestinal Region Infections in Iraq Patients

Mariam Kareem Ali¹, Jaafar Sataar Shia²

¹Medical Microbiology, Department of Microbiology, College of Medicine, Baghdad University, Iraq; ²Pharmacy Ministry of Health, Baghdad, Iraq

**ABSTRACT**

This research work focuses on the determination of the infection rates of *Helicobacter pylori* (*H. pylori*) in Baghdad Iraq. This work was achieved in 2017 from February to December 2017, with 100 samples involved in this research. The average age of patients in this study ranged from 15 to 65 years. Biopsy gastric tissue was collected from one hundred patients suffering symptoms of severe gastrointestinal tract diseases (*GITD*), and all patients were subject to the tests included in the current study and were examined using gastro-endoscopy in the Gastrointestinal-tract and Liver Disease Hospital, and Al-Yarmouk Hospital, Baghdad, Iraq. Direct examination of *H. pylori* from biopsy gastric tissue using the Rapid Urease Test (RUT), samples were cultured and PCR was achieved after that. The outcome data shows that 42% of the samples in study were respond positively to PCR while 32% of them were positively to RUT and 24% were positively to culture. Molecular analysis was used to detect each sample and it was found that the positive percent in males is much higher than females and the (25-45) year’s group has the highest rate in positive cases. According to the type of *GITD* and *H. pylori* diagnostic gene (ureC), showed that 15(41.7%) 18(46.2%), 8(40%), 1(20%) cases of Gastritis, Gastritis & doudenitis, Gastropath ulcer, oesophagas tumor respectively.

**Keywords:** Helicobacter pylori, severe gastro-intestinal tract diseases, Biopsy.

**Introduction**

*Helicobacter pylori* (*H. pylori*) is anaerobic rods and as one of the pathogenic bacterium type Gram negative facultative which reside in mucosa superimposing the epithelium of the gastric antrum. Infection with *H. pylori* was found to activate indications of stomach illnesses. More than three millions of human beings each year died because of the gastric problems and ulcer diseases (¹). Furthermore, *H. pylori* infection used to be consider as a main danger to gastric adenocarcinoma development as well as mucosa which accompanied to lump tissues (MALT). Investigative approaches were alienated interested in offensive and noninvasive classes. Offensive approaches that need endoscopy contain; culture, direct gram stain, campylobacter like creature assessment (CLO), histology, fluorescence in situ hyperdization (FISH) and PCR. Whereas methods that are noninvasive which do not necessitate endoscopy were contain; *H. pylori* stool antigen test (Hp sAg) and serology, urea breath test (UBT) (²).

Biopsy specimens were identified in *H. pylori* lab to detect the presence of gastric bacteria. Diagnosis can be determined with ammonia as well. The antigen test of fecal monoclonal consider of great sensitive, accuracy and specific and can be achieved to all range of ages (³).

PCR can be accomplished fast it laso could be useful in identification of diverse types of pathogenic bacteria as well as epidemiological researches (⁴).

The aim of current work which was achieved in Baghdad city is to study the incidence of *H. pylori* in diverse age groups, the incidence of *H. pylori* throughout the year among patients who suffers from gastrointestinal disorders. Many techniques were used to detect the infection and to evaluate the presence of *H. pylori* infected areas.

**Materials and Method**

This work was carried on in 2017 from February to December 2017. The research was taken a place at Gastroenterology and Hepatology Center at Baghdad governorate, various hospitals and health centers and Special Clinic in Baghdad.
Sample

Biopsy Samples: 100 cases of mixes females and male patients (57 males and 43 females) their ages ranged from 15 to 65 years old, those patients were gathered from special restricted hospitals. All gathered groups were suffers as of GITD and were identified clinically by specialized physicians. All groups of patients filled questioner forms and were asked for their approval to proceed with this research, biopsy from gastric tissues (three from each patient) were gathered from the study groups stomachs. The biopsies were gathered and prepared for molecular and bacteriology study and were send to the lab to examine RUT, GS (Gram Staining) as well as the sensitivity, TSB (Tryptical Soy Broth) was used as medium to protect the biopsy during transportation to the lab.

Statistical Analysis: SPSS was used as a program to compute and analyze the gathered data.

Culture Method: Different media was involved in culture of the H. Pylori like BHI agar (Brain Hear Infusion), HBAP Human Blood Agar Plates) as well as BA (Brucella Agar). Three types of antibiotic were used as supplement. The incubation to all cultures was achieved between three to ten days at regular incubation temperature (37 Celsius), and under nine percent (9%) of carbon dioxide (CO₂) (6). The colonies of bacteria were easily recognized by vision clearly (has a grey colour).

Microscopic Examination: A swab was taken from the stain of the bacteria and inspected by the microscope light. The examination to the samples indicates the presence of spiral and S shape of H. pylori (6).

Biochemical Tests: Subsequently, a samples were taken from the primary growth and a biochemical test was achieved together with (catalase, urease and oxidase). The propagation to single colony was done using blood agar for extra 48 hours (7). The urase was inspected in “HelicotecUT®Plus” test. [15-16], while the oxidase activity was tested by oxidase test strip, the catalase was test by slide drop method using hydrogen peroxide (3%).

Molecular Techniques: DNA was extracted from specimens using buffer solution contain (100 mM NaCl, 10 mM Tris-HCl (pH 8.0) 0.5% SDS) while the bacterial Genomic DNA Extraction was extracted with kit (Geneaid. USA).

Assessments of the DNA Purity: Assessments of the pure DNA and Concentration of DNA extracted of all sample in this study using Nano drop, concentration of Extracted DNA (≥40 ng/μl)and purity between (1.8-2) were enrolled for farther estimations.

Agarose Electrophoresis: DNA extraction was successfully observed from samples by agarose electrophoresis (2%). This DNA was used as a template for RT-PCR assay.

Real Time PCR: The test was achieved according to the protocol of the Korean company that produced the kit (“AccuPrep® 2X Greenstar RT-PCR Master Mix kit, Bioneer. Korea”). All the collected data were listed in Table 1 below.

**Discussion**

Gastroenteritis with (‘‘ H. Pyloyi is the most common infectious disease among humans; an estimated 50% of the infection occurs with humans (9). These bacteria can cause persistent gastritis, peptic ulcer disease, adenocarcinoma and cancer of the lymph nodes associated with gastric mucosa. Individuals living in countries with low socio-economic conditions have high rates of H. pylori acquired at an early age (8).

“The result of this study, showed the rate infection with H. pylori in males (50.88%) higher than in females (30.23 %). This result was agreement with Yemen Bin Mohanna et al (2014) (9). The current study found that infection caused by H. pylori was significantly higher in studied age group. WHO found that the majority of infections occurred in young and middle age groups (25–50 years) more than in other age groups and the factors that predispose the higher colonization rates included poor socioeconomic status and less education in addition to genetic factors. This finding was in agreement with many other studies that showed a similar age incidence of H. pylori, Hamid and Eldaif (2014) (4).

The explanations for the present study is agreement with approved other results studies which were mainly due to socioeconomic status and the sample size of the population studied, type of patients, location of the study as well as the mode of transmission where by spread infection was acquired from person to person or by oral-oral or feco-oral routes. This result indicated that the infection was affected by education level which was reflected in the degree of personal hygiene.

The current study indicates no significant difference between both sexes regarding the incidence of infection with H. pylori, a result which is in agreement with many other studies (10). The RUT results was showed 32 sample from 100 were positive (32%) (Table 4). Rapid urease test depends essentially upon the number of the bacteria in the biopsies (11). More than one biopsy may give a highly significant RUT results. The size of the biopsy itself may be implicated the number of the bacteria within these biopsies. It has been suggested that 104 colony forming unit (CFU) are required to exhibit positive RUT result (12).

It was suggested that uses of RUT for biopsies in the unit theorizing be sensitive enough for the detection of specific urease formation bacteria, however this test might be less effective for detection if the patient taking antibiotics (13).

A positive variation results of H. pylori infection by using RUT in different studies due to the sensitivity of this test, which depends on the type of urea, urea concentration, incubation temperature, biopsy size, buffering, bacterial load and administration of the drug (14). Twenty four cases from 100 samples were positive (24%) for H. pylori culture (Table 3). Previous studies were also showed difficulty and low percentage for H. pylori isolation. Primary isolation of H. pylori is a difficult process for routine laboratories. However, many laboratories have found the primary isolation of H. pylori from gastric biopsies is still problematic. Few percentages attributed to isolate the bacteria H. pylori to the many factors that affect significantly the bacteria, including patient intake of antibiotics or proton pump inhibitors before taking the sample, leading to the small number of bacteria in biopsies (15).

Several factors are implicated in directing the success of H. pylori cultivation. They include the method, time, procedure for tissue processing, composition of culture media, patchy distribution of the organism on the gastric mucosa, contamination of biopsy forceps, and the loss of viability of the organisms during transportation, the presence of oropharyngeal flora may be also responsible for a negative predictive value associated with culture of H. pylori. Real time per ce was widely used to identify H. pylori from gastric biopsy, saliva, stool and archival samples (16). PCR also has been found useful in detecting the organism when normal culture is difficult, as is the case with environmental specimens such as drinking water (17).
The isolated *H. pylori* appeared on petri dish as small colonies convex, transparent, and similar to a drop of water, which is supported by previous studies \(^{(18)}\). Forty two cases from 100 samples were positive (42%) for *H. pylori* PCR technique (Table 3). It depends on the target gene used in the analysis. The first targets recruited were urease *glmM*, formerly named *ureC*. Our results of RT PCR demonstrated wide range of detection rate for UreC gene as well as samples underwent the analysis. The ureC is considered a “housekeeping” gene, which participates directly in cell wall synthesis. It is well-established that the principal ecological niche for *H. pylori* is the gastric mucosa \(^{(19)}\). Other study reported that among patients with gastric ulcer, gastritis, and duodenal ulcer \(^{(20)}\).

**Conclusion**

*H. pylori* was directly detected from biopsy samples of gastritis patients using RT PCR. The study was showed a various relationship between gastropathological cases and (*glmM*) ureC..

Analysis of Maternal Deaths Trends in Bojonegoro, Indonesia

Mariya Ulfah¹, Budi Prasetyo², Lutfi Agus Salim²
¹Master Program of Public Health, ²Department of Public Health, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Maternal Mortality Rate (MMR) could indicate the welfare of a nation. In ASEAN, Indonesia ranks as the highest number of MMR. Furthermore, in Bojonegoro Regency, the MMR ranked 4th in East Java Province after Surabaya, Jember, and Sidoarjo. Indirect causes of maternal deaths consisted of three delays: 1) maternal referral delay; 2) delay in recognizing problems and making decisions; and 3) delay in reaching health facilities and getting services. These three delays are the leading causes of the increase in maternal mortality in Bojonegoro Regency. This study aims to analyze the trends in the number of maternal deaths and predict the occurrence of death in the following year. The data consist of maternal mortality cases for the period 2008-2017, and it analyzed by four trend analysis and compared by the MAPE, MAD, and MSD values for each method. The results show that the two categories use the Quadratic Trend Model precisely. Forecasting results in 2018 are estimated to have decreased maternal mortality by 11.76% from 2017, and in 2019 it is estimated to increase by 33.33%. These results indicate that maternal mortality in Bojonegoro still needs to be anticipated.

Keywords: Bojonegoro, maternal mortality, three delays, trend analysis

Introduction

One statistical tool that can be used to estimate a future event based on past data is the trend. The trend consists of a variable in the periodic series (hours, daily, annual, annual) and tends to go in one direction, namely rising horizontally and decreasing¹. Forecasting is a connection of trend lines over time from the last observation to the time for forecasting made. Several methods can be used to create trends, namely linear trend methods, quadratic trends, and exponential trends². A linear trend is a trend that increases and decreases in value can be predicted up or down linearly. A quadratic trend is a trend in which the value of an independent variable rises or falls linearly, or a parabola occurs when the data is made scatter diagram. The exponential trend is a trend where the value of the dependent variable increases in multiples.

Arsyad³ states that the quantification of forecasting errors required to choose the right forecasting techniques. Some measures of accuracy for selecting forecasting methods use Mean Absolute Deviation (MAD), Mean Square Deviation (MSD), and Mean Absolute Percentage Error (MAPE). The smaller the error values, the more accurate the method (MAPE). The data used in this study are secondary data sourced from the Maternal Perinatal Audit (AMP) report, Bojonegoro District Health Office. The description of the welfare of the Indonesian people can be seen from the indicators of Maternal Mortality Rate (MMR)⁴. In Indonesia, the maternal mortality rate is highest compared to other ASEAN countries⁵. In 2015 the Maternal Mortality Rate decreased compared to 2012 as many as 305 per 100,000 live births of the Intercensal Population Survey⁶. However, it is not significant compared to the Millennium Development Goals (MDGs) target; the maternal mortality rate must be reduced by 102,000 per live birth⁷.

Efforts to reduce maternal mortality are the third indicator of the program (Sustainable Development Goals (SDGs). 2016 is the first year of implementation of the 2015 MDGs development agenda (SDGs). The target set by SDGs reaches a global reduction in MMR of 70
per 100,000 live births by 2030, but this situation is not easy to do where it requires cooperation in various parties with related sectors. The Bojonegoro Regency Maternal Mortality Rate is ranked 4th out of all East Java Provinces after Surabaya, Jember and Sidoarjo can be seen in Figure 1. The Maternal Mortality Rate in Bonegoro has increased in the past two years but still tends to decline below the MDG target will decline if compared to the 2015 MDGs target of 102/100,000 KH (live birth) and SDGs year 2016 which is 40/100,000 KH.

![Figure 1: Maternal Mortality Rate (MMR) of cities in East Java Province in 2016](image1)

The MMR in Bojonegoro Regency in 2015 amounted to 23 people at 128.2 per 100,000 live births (Figure 2). In 2016 there were 23 people 129.23 per 100,000 live births spread across 19 health centers. In 2017 as many as 17 people spread 100.93 per 100,000 live births in 12 health centers. A total of 30 people spread out 30 health centers from 36 health centers in both urban and rural areas. The direct cause of maternal death in 2017 is heart disease, the accompanying cause, preeclampsia, bleeding, and infection (Figure 3).

![Figure 2: Maternal mortality trend in Bojonegoro Regency](image2)
Indirect causes of maternal deaths from the 2017 health service profile are due to three delays; in making maternal referrals, being late to recognize danger signs and making a decision of 8 people as much as 47.05% and being late and getting adequate services in health care facilities in 3 people at 17.64%. This indirect cause is one of the factors that increases the number of maternal deaths in Bojonegoro district, which has increased. Maternal mortality in the Prenatal period was 5.88%, intranatal was 23.58%, and most of the majority occurred in the postnatal period of 70.59%.

Implementing the P4K (Maternity Planning and Complication Prevention Program) is an effort to reduce MMR. Bojonegoro Regency has 430 alert villages which have village P4K that implement 100% P4K are 28 Puskesmas and 8 The Puskesmas with the village and which are still below the target) 376 villages with working groups are active, and 54 Pokja villages are not running, but the maternal mortality rate is still high.

Method

This research was conducted using secondary data on the number of maternal deaths from 2008-2017 for ten years in Bojonegoro Regency for the period of January-December, every year periodic records are carried out every month to one year from 2008-2017. Variable Dependent in this study is the case of maternal death (Y). The collected data was analyzed using the help of a computer program. The stages in the analysis of this study were data exploration, trend analysis stages, and comparing the smallest error values between trend analysis methods by calculating the MAPE, MAD, MSD values.

This trend analysis stage consists of several stages, namely (a) plotting data, using line diagrams to determine the pattern of the number of deaths each month (b). The parameter estimation stage in several trend analysis methods (C) compares the error values between analysis methods by looking MAPE, MAD, MSD values (d) Forecasting/application stage: carried out if the smallest value and error is obtained from the trend analysis method used.

Results

According to Table 1 from Maternal Perinatal Audit data, the number of maternal deaths has fluctuated, but maternal mortality tends to increase.

Table 1: Number of maternal deaths in Bojonegoro Regency in 2008-2017

<table>
<thead>
<tr>
<th>Year</th>

</tbody>
</table>

Trend Analysis: The results of the trend analysis above indicate that the smallest MAPE value model is the Quadratic Trend Model (Table 2). The Trend Equation obtained is:
\( (Y_t) = 10.15 + 4.99t - (0.42t^2) \)

After obtaining the best model and the same form. The equation is used to predict the number of maternal deaths; then Figure 4 show the results of the forecasting.

Figure 4: Results of the 2018 and 2019 forecast

The forecasting results of the number of cases of maternal deaths in 2018 decreased by 11.76%, calculated from 2017 and in 2019 an increase of 33.33% in Bojonegoro Regency.

Discussion

Aligned with the results of the study other than the direct cause of obstetric complications, maternal mortality in Bojonegoro Regency was due to 56.6% of maternal deaths due to three maternal referral delays from 116 cases of mothers referred to the hospital, which supported the increase in the number mother’s death in Bojonegoro. The results were found to be late in recognizing danger signs and making the decision that most of the maternal deaths were 62.1% of events compared to mothers who were not late in referring to the incidence of dead mothers in the amount of 13.8%.

According to the Ministry of Health\(^4\), obstetric complications should be prevented and handled optimally, promptly so that there is no delay in the handling and death of the mother. Delays in the referral process in cases of maternal deaths in Bojonegoro Regency are indirect causes of maternal deaths. The proportion of indirect maternal deaths in Indonesia is 22%\(^{11}\), so prevention before further complications must occur. This study is in line with Biswas et al.\(^13\) that the detection of pregnancy complications by trained professionals and timely referral to a health care facility is useful to save a portion of the baby and the mother’s life. Detecting complications during timely pregnancy and referral is not too late referral will guarantee the safety of the mother and baby.

Every pregnant woman has a life-threatening risk even though her pregnancy is healthy, referral to the hospital is a mother who has an obstetrics case that can cause complications directly from the consequences of her pregnancy because 15% of pregnancies and deliveries will be estimated to experience obstetric complications that result in death.

In cases of maternal death, pregnant women are found, including high-risk pregnancies. Mothers with high-risk pregnancies have a higher risk of infant and maternal death and giving birth with congenital abnormalities and other obstetric complications\(^13\). According to Triana et al.,\(^11\) the Principles for Prevention of maternal deaths are mostly preventable if obstetric complications can be immediately identified and handled, at least three conditions that need to be observed include: 1) Every pregnant woman has a risk of life-threatening obstetric complications because she cannot predict, 2) Access to a risky pregnancy must have adequate access to midwifery services, 3) Maternal mortality occurs mostly during the puerperium or the first 24 hours after delivery. By looking at this statement, the condition of all pregnant women must be adequately monitored, so that there is no delay in recognizing the danger and making decisions to take referral actions.

The local Health Office has made various efforts due to the continuing increase in maternal mortality, starting to mobilize the participation of the community through village alert activities and the implementation of the P4K (Maternity Planning and Complication program) in all Puskesmas districts in Bojonegoro Regency. Throughout Indonesia, by implementing P4K, it is hoped that it can be useful to reduce the incidence of Maternal and Infant Mortality, with the P4K running it will help accelerate village alert functions\(^{10}\). However, in this case, it can be seen from the profile of Bojonegoro District Health Office 430 villages were 100% active standby villages.
and carried out P4K as much as 87.44% carrying out P4K. In the working group activities in P4K through data collection, it is hoped that efforts to improve early detection of complications can be appropriately handled, through integrated ANC, mentoring by pregnant women cadres, delivery planning according to risk factors, all pregnant women with score more than 6 must be sent at PONED (Emergency Neonatal Obstetric Services Basics) or to the Puskesmas.

**Conclusion**

The results of the analysis found that maternal mortality trends increased and even the most in the postnatal period by 70.59% and the forecast results were expected to decline in 2018 calculated from 2017 at 11.76% and in 2019 an increase of 33.33% calculated from 2018. In addition to the direct causes of pregnancy, especially indirect factors, three being late in referral is one of the factors that increases the number of maternal deaths.

ABSTRACT

To overcome these problems, we use the author’s approach to the concept of a statistical relationship (nonlinear, linear) in psychological and sociological research. In addition to the method of studying relationships, we offer a software implemented method for classifying dependencies. The study of nonlinear connections according to the author’s method was tested in various psychological studies representing diverse areas of psychological science: psychology of preschoolers and adolescents, ethnopsychology, psychology of professions, psychology of trust, psychology of stress, theory of personality, psychology of parenthood, psychology of learning, measurement of value relationships of personality others ”, the study of family education as a factor in the formation of the semantic sphere of the child, the dynamics of the motivational and semantic formations of the personality of Dent, the study of dependencies in psychophysiological research, psychological typology of students, political psychology. On the basis of investigation of alcoholism, the problem of lack of linear correlations in the presence of the simplest non-linear connections, which leads to systemic errors at interpretation of results, is discussed. Specific results demonstrating errors of the 1st type, when the linear correlation shows values close to zero, are presented. These connections are simply not taken in consideration, but in fact there is a real strong non-linear connection (maximum, minimum) that changes the picture of the phenomenon under study completely.

Keywords: Alcohol; Alcoholism; Alcohol consumption motives; Psychology.

Introduction

Individual human development is always accompanied by a complex interaction of its genetic program¹,² and various environmental influences³,⁴, often negatively affecting many adaptation processes in the body⁵,⁶. Upcoming changes in the body manifest themselves at different levels of its self-regulation⁷ very often in the form of various dysfunctions⁸,⁹ in the somatic¹⁰ and often in the mental¹¹ spheres. Research in the field of the second group of disorders deals with psychology.

Psychologists always underline a complicated character of their field of investigation – society, psychics, human being, but at that, with very rare exclusions (for example, psychophysiology), they consider in their studies interpretations of connections (dependencies) based on results of the correlation analysis, meaning mechanical approach – the methodology of the late 18th century¹². At that, sciences investigating “simpler” objects for examination (according to statements of those dealing with humanitarian sciences), for example physics, passed in their methodological development both non-classical (the beginning of the 20th century) and post-non-classical (the end of the 20th century) stages of development. To find a way out of this methodological deadlock, it is necessary to accept the fact that psychologists in their examinations, along with linear connections, should also pay attention to the simplest connections that are meaningful and give explanations of many investigated phenomena¹³.

DOI Number: 10.5958/0976-5506.2019.03106.1
Objective
To study the hedonic motives of alcohol use as an object of nonlinear psychology.

Materials and Method
The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11).

To overcome these problems we apply an author’s approach to the concept of statistical connection (nonlinear, linear) in psychological and sociological studies14.

For the analysis of causative relations, data on the following methods were selected:

The study involved 30 people with a diagnosis of alcoholism.

The results obtained are processed with a standard statistical software package.

Results and Discussion
1. Dependence of the parameter “Hedonistic motives for alcohol use (the intention to get pleasure from alcohol)” (X05) on the parameter “Hangover motives for alcohol use (the intention to get rid of physical discomfort)” (X08) in the form of comparative weights of parameter X05 for triads on the scale X08 (Table 1).

Table 1: Dependence of parameter “Hedonistic motives for alcohol use” on parameter “Hangover motives for alcohol use”

<table>
<thead>
<tr>
<th>Triads on scale X08</th>
<th>Comparative weight of parameter X05 for triads</th>
</tr>
</thead>
<tbody>
<tr>
<td>X08-3</td>
<td>+235</td>
</tr>
<tr>
<td>X08-2</td>
<td>-442</td>
</tr>
<tr>
<td>X08-1</td>
<td>+79</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.72 (0.25)
Correlation coefficient = 0.29

Values on the scale “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol) decrease abruptly from +79 to -442 on the comparative weight at the first stage of growth (from low to medium) on the scale “Hangover motives for alcohol use (the intention to get rid of physical discomfort)”. However, the further growth on the scale “Hangover motives for alcohol use” (from medium to high) gives already the opposite effect and the intention to get pleasure from alcohol increases (from -442 to +235) to values significantly exceeding (+235) the original ones (+79).

Thus, the pathological motive “Hangover motives for alcohol use” (the intention to get rid of physical discomfort) provokes in people suffering from alcoholism personal motives “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol). But only a high level of hangover motives for alcohol use promotes the rather high (+235) level of hedonistic motives for alcohol use exceeding the results of the 1st triad of the independent variable (+79). However, it cannot be concluded that the linear connection of these two parameters being implied relative is observed, otherwise their summing up is not purely correct (general motivation for alcohol use). The linear correlation in this case equals to 0.29 (zero threshold at traditional approach equals to 0.36 (p=0.05) and 0.46 (p=0.01), it is not just weak, but is not interesting even within the frame of zero correlation. Thus, the two considered parameters are not equally changeable within the sample frame. It is connected with the fact that for the medium level of the parameter “Hangover motives for alcohol use” the lowest minimal value of the parameter “Hedonistic motives for alcohol use” is observed.

2. Dependence of the parameter “Hedonistic motives for alcohol use (the intention to get pleasure from alcohol)” (X05) on the parameter “Addictive motives for alcohol use (subjective fixation on alcohol, perception of it by a person as a sedative)” (X09) in the form of comparative weights of parameter X05 for triads on the scale X09 (table 2).
Table 2: Dependence of parameter “Hedonistic motives for alcohol use” on parameter “Addictive motives for alcohol use”

<table>
<thead>
<tr>
<th>Triads on scale X09</th>

</tr>
<tr>
<td>X09-1</td>
<td>+92</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.92 (0.28)  
Correlation coefficient = 0.29

Values on the scale “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol) decrease abruptly on the comparative weight from +92 to -597 at the first stage of growth (from low to medium) on the scale “Addictive motives for alcohol use” (subjective fixation on alcohol, perception of it by a person as a sedative). However, the further growth on the scale “Addictive motives for alcohol use” (from medium to high) gives already the opposite effect and the intention to get pleasure from alcohol increases (from -597 to +247) to values significantly exceeding (+247) the original ones (+92).

Thus, the pathological motive “Addictive motives for alcohol use” (subjective fixation on alcohol, perception of it by a person as a sedative) provokes in people suffering from alcoholism personal motives “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol). But only a high level of hangover motives for alcohol use promotes the rather high (+247) level of hedonistic motives for alcohol use exceeding the results of the 1st triad of the independent variable (+92). However, it is not possible to state that the linear connection of these two parameters being implied relative is observed, otherwise their summing up is not purely correct (general motivation for alcohol use), the linear correlation for which equals to 0.29. Thus, the two considered parameters are not equally changeable within the sample frame. It is connected with the fact that for the medium level of the parameter “Addictive motives for alcohol use” the lowest minimal value of the parameter “Hedonistic motives for alcohol use” is observed.

3. Dependence of the parameter “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol)” (X05) on the parameter “General motivation for alcohol use” (X11) in the form of comparative weights of parameter X05 for triads on the scale X11 (table 3).

Table 3: Dependence of parameter “Hedonistic motives for alcohol use” on parameter “General motivation for alcohol use”

<table>
<thead>
<tr>
<th>Triads on scale X11</th>
<th>Comparative weight of parameter X05 for triads</th>
</tr>
</thead>
<tbody>
<tr>
<td>X11-3</td>
<td>+29</td>
</tr>
<tr>
<td>X11-2</td>
<td>-624</td>
</tr>
<tr>
<td>X11-1</td>
<td>+387</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.99 (0.36)  
Correlation coefficient = -0.21

Values on the scale “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol) decrease very abruptly at the first stage of growth (from low to medium) on the scale “General motivation for alcohol use” (from +387 to -624 on the comparative weight). However, the further growth on the scale “General motivation for alcohol use” (from medium to high) gives already the opposite effect and the intention to get pleasure from alcohol increases (from -624 to +29), though to values significantly lower (+29) than the original ones (+387).

Thus, “General motivation for alcohol use” in the context of statistics analogously (dependence with the minimum) influences the parameter “Hedonistic motives for alcohol use” chosen by us as a primary one. However, the dynamics at the expense of other parameters not manifesting apparently as strong simplest nonlinear dependencies, in the general context is negative, when the high level of general motivation for alcohol use promotes significantly lower (+29) level of hedonistic motives for alcohol use, than results of the 1st triad (low level) of the independent variable (+387).

4. Dependence of the parameter “Hedonistic motives for alcohol use (the intention to get pleasure from alcohol)” (X05) on the parameter “The personal growth initiative scale by K. Robitschek” (X12) in the form of comparative weights of parameter X05 for triads on the scale X12 (table 4).
Table 4: Dependence of parameter “Hedonistic motives for alcohol use” on parameter “The personal growth initiative scale”

<table>
<thead>
<tr>
<th>Triads on scale X12</th>
<th>Comparative weight of parameter X05 for triads</th>
</tr>
</thead>
<tbody>
<tr>
<td>X12-3</td>
<td>+88</td>
</tr>
<tr>
<td>X12-2</td>
<td>-397</td>
</tr>
<tr>
<td>X12-1</td>
<td>+223</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.66 (0.23)  
Correlation coefficient = 0.18

Values on the scale “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol) decrease abruptly at the first stage of growth (from low to medium) on “The personal growth initiative scale by K. Robitschek” (from +223 to -397 on the comparative weight). However, the further growth of personal growth initiative (from medium to high) gives already the opposite effect and the intention to get pleasure from alcohol increases (from -397 to +88) to values close to the original ones, but somewhat lower.

The opposite dependence for the considered pair of parameters, i.e. dependence of the parameter “The personal growth initiative scale by K. Robitschek” on the parameter “Hedonistic motives for alcohol use” at comparison of coefficients of connection strength is significantly weaker (0.23 vs. 0.66). It means that the dependence is mostly one-sided. The correlation is also not interesting.

Thus, the process of formation of personal growth initiative in people suffering from alcoholism requires restriction as only medium values on this scale give the positive effect, specifically, minimization of hedonistic motives (the intention to get pleasure from alcohol). At the same time, coming out of the “normal range” (high level) in the process of development of personal growth initiative will more probably give the opposite effect, and the result on the scale “Hedonistic motives for alcohol use” (the intention to get pleasure from alcohol) will move closer to the original one.

**Conclusion**

Five types of dependence considered here clearly demonstrate that models in the study of relation to alcohol obviously do not correspond to linear models. The criteria of zero hypothesis (“significant” correlation), which also is not a sign of strong correlation at all. Besides, it is possible to see obvious one-sidedness of the represented types of dependence; it indicates that the reason and consequence are determined already at the level of quantitative analysis. It means that problems of hedonistic motives for alcohol use do not correspond to linear models at all, and attempts of linear approximation will lead to fundamental errors at study and interpretation of this phenomenon, when with increase of one parameter another one obligatory demonstrates either only increase or decrease.

ABSTRACT

On the basis of investigation of alcoholism, the problem of lack of linear correlations in the presence of the simplest non-linear connections, which leads to systemic errors at interpretation of results, is discussed. Specific results demonstrating errors of the 1st type, when the linear correlation shows values close to zero, are presented. These connections are simply not taken in consideration, but in fact there is a real strong non-linear connection (maximum, minimum) that changes the picture of the phenomenon under study completely. Five types of dependence considered here clearly demonstrate that models of presence and search of life meaningfulness in people suffering from alcoholism obviously do not correspond to linear models. The results on the linear correlation even do not match the criteria of zero hypothesis (“significant” correlation), which also is not a sign of strong correlation at all. Besides, it is possible to see obvious one-sidedness of the represented types of dependences; it indicates that the reason and consequence are determined already at the level of quantitative analysis. It means that problems of life meaning do not correspond to linear models at all, and attempts of linear approximation will lead to fundamental errors at study and interpretation of this phenomenon, when with increase of one parameter another one obligatory demonstrates either only increase or decrease.

Keywords: Alcoholism; Psychology; Psychological process; The meaning of life; The study of the psyche.

Introduction

The functioning of the human body is very complex and well regulated process¹². However, despite the clarity of this regulation in the human body for many reasons you may experience various failures in the form of dysregulation¹⁴ and the formation of pathology⁵⁶. Has repeatedly made attempts to study these disorders from different perspectives⁷⁸. In their development, recognizes great importance to environmental influences⁹ and the characteristics of the response of the organism¹⁰, including in the psychological sphere¹¹. In this regard, studies of disorders of behavior in terms of different changes in

the body are not only doctors, but also psychologists. Psychologists always underline a complicated character of their field of investigation – society, psychics, human being, but at that, with very rare exclusions (for example, psychophysiology), they consider in their studies interpretations of connections (dependencies) based on results of the correlation analysis, meaning mechanical approach – the methodology of the late 18th century¹². At that, sciences investigating “simpler” objects for examination (according to statements of those dealing with humanitarian sciences), for example physics, passed in their methodological development both non-classical (the beginning of the 20th century) and post-non-classical (the end of the 20th century) stages of development. To find a way out of this methodological deadlock, it is necessary to accept the fact that psychologists in their examinations, along with linear connections, should also pay attention to the simplest connections that are meaningful and give explanations of many investigated phenomena¹³.

The aim of the study was to examine aspects of the search for meaning of life in people suffering from alcoholism.

**Materials and Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11).

To overcome these problems we apply an author’s approach to the concept of statistical connection (non-linear, linear) in psychological and sociological studies. In addition to the method of investigation of connections we propose a method of classification of dependencies realized in the form of software14.

For the analysis of causative relations, data on the following methods were selected:

30 people participated in the study, for whom alcoholism is a clinical diagnosis. The obtained results were processed by standard statistical software package.

**Results and Discussion**

1. Dependence of the parameter “The subscale of meaning in life (Search)” (X17) on the parameter “General motivation for alcohol use” (X11) in the form of comparative weights of parameter X17 for triads on the scale X11 (Table 1).

<table>
<thead>
<tr>
<th>Triads on scale X11</th>
<th>Comparative weight of parameter X17 for triads</th>
</tr>
</thead>
<tbody>
<tr>
<td>X11-3</td>
<td>-161</td>
</tr>
<tr>
<td>X11-2</td>
<td>+513</td>
</tr>
<tr>
<td>X11-1</td>
<td>-98</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.77 (0.17)
Correlation coefficient = -0.19

Values on “The scale of meaning in life (Search)” reach maximal values for the average level on the parameter “General motivation for alcohol use” (comparative weight = +513). Thus, the original increase (transition from low to medium level) of general motivation for alcohol use promotes a sharp increase (from -98 to +513) on “The scale of meaning in life (Search)”. However, the further growth of general motivation for alcohol use (from medium to high level) leads already to the opposite effect (from +513 to -161) and the search of life meaning seems to disappear decreasing to values even somewhat lower than the original ones.

Thus, the search of life meaning in people suffering from alcoholism is not possible without moderate (medium level within the frame of their sample) general motivation for alcohol use. However, sudden weakening of general motivation for alcohol use can, more probably, lead to the loss of sense of life meaningfulness (-98), as it also occurs at the high level of general motivation for alcohol use (-161).

It should be also noted that this dependence is a striking example of the one-sided dependence, and the opposite dependence – the dependence of general motivation for alcohol use on the life meaningfulness search – is very weak with the strength of connection coefficient equal to 0.17. Thus, the search of life meaning for this pair of variables is definitely a consequence, and the general motivation for alcohol use is a reason.

Considering separately constituents of general motivation for alcohol use, an analogous dependence was revealed only for one from 9 scales: “Hangover motives for alcohol use”, which within the frame of the method suggested by V.Yu. Zavyalov, are referred to the third group of motives determined as pathological.

2. Dependence of the parameter “The subscale of meaning in life (Search)” (X17) on the parameter “Hangover motives for alcohol use (the intention to get rid of physical discomfort)” (X08) in the form of comparative weights of parameter X17 for triads on the scale X08 (Table 2).
Table 2: Dependence of parameter “The meaning in life search” on parameter “Hangover motives for alcohol use”

<table>
<thead>
<tr>
<th>Triads on scale X08</th>
<th>Comparative weight of parameter X17 for triads</th>
</tr>
</thead>
<tbody>
<tr>
<td>X08-3</td>
<td>-366</td>
</tr>
<tr>
<td>X08-2</td>
<td>+420</td>
</tr>
<tr>
<td>X08-1</td>
<td>-92</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.77 (0.21)  
Correlation coefficient = -0.33

Values on “The scale of meaning in life (Search)” reach maximal values for the average level on the parameter “Hangover motives for alcohol use” (comparative weight = +420). Thus, the original increase (transition from low to medium level) of hangover motives for alcohol use promotes a sharp increase (from -92 to +420) on “The scale of meaning in life (Search)”. However, the further growth of hangover motives (from medium to high level) leads already to the opposite effect (from +420 to -366) and the search of life meaning seems to disappear decreasing to values significantly lower (-366) than the original ones (-92).

Thus, the search of life meaning in people suffering from alcoholism is not possible without moderate (medium level within the frame of their sample) motivation of alcohol use, which is determined as hangover motives for alcohol use, intention to get rid of physical discomfort. At the same time, abrupt alleviation of hangover motives for alcohol use can, more probably, lead to the loss of sense of life meaningfulness (-92), which happens also in case of the high level of hangover motives for alcohol use (-366).

The following three dependences (3-5) described in the article are already of principally different type – these are dependences with the minimum.

3. Dependence of the parameter “Motives for self-injury (alcohol use contrary to everybody and himself/herself)” (X10) on the parameter “The subscale of meaning in life (Search)” (X17) in the form of comparative weights of parameter X10 for triads on the scale X17 (Table 3).

Table 3: Dependence of parameter “Motives for self-injury” on parameter “The meaning in life search”

<table>
<thead>
<tr>
<th>Triads on scale X17</th>
<th>Comparative weight of parameter X10 for triads</th>
</tr>
</thead>
<tbody>
<tr>
<td>X17-3</td>
<td>+119</td>
</tr>
<tr>
<td>X17-2</td>
<td>+184</td>
</tr>
<tr>
<td>X17-1</td>
<td>-491</td>
</tr>
</tbody>
</table>

Strength of connection coefficient = 0.77 (0.35)  
Correlation coefficient = 0.16

Thus, in people suffering from alcoholism the process of search of life meaningfulness gives a positive effect only in the beginning: motives for self-injury (alcohol use contrary to everybody and himself/herself) plummet. Only medium values on the subscale of life meaning search give the positive effect – minimization of motives for self-injury.

4. Dependence of the parameter “The general scale of life meaningfulness” (X18) on the parameter “Submissive motives for alcohol use (reflecting submission under the pressure of other people)” (X03) in the form of comparative weights of parameter X18 for triads on the scale X03 (Fig.1).

Values on the scale “The general scale of life meaningfulness” (the sum of two subscales - “Presence” and “Meaning in life search”) decrease abruptly at the first stage of growth (from low to medium) of the parameter “Submissive motives for alcohol use” (from +270 to -302 on the comparative weight), and they demonstrate submission under the pressure of other people at alcohol use. However, the further growth of submissive motives (from medium to high) gives already the opposite effect and the meaning of life (its presence and search) sharply increases (from -302 to +79) to values, significantly lower than the original ones (+79 vs. +270).
The mean values on the scale “The submissive motivation for alcohol use”, when the influence of other people is not strong enough, cause internal struggle strongly affecting the assessment on the scale of the meaning of life decreasing it to the minimal values. However, when the influence of other people is strong enough, the meaning of life is compensated, but its values are significantly lower for the 1st triad (low level) on the scale “The submissive motivation for alcohol use”.

5. Dependence of the parameter “The general scale of life meaningfulness” (X18) on the parameter “The subscale of meaning in life (Search)” (X17) in the form of comparative weights of parameter X18 for triads on the scale X17(Fig.2).

Values on the scale “The general scale of life meaningfulness” (the sum of two subscales of presence and search of life meaningfulness) surge at the first stage of growth (from low to medium) on the subscale “The meaning in life search” (from -365 to +299 on the comparative weight), as a constituent of the general scale of life meaningfulness. However, the further growth on the subscale “The meaning in life search” (from medium to high) gives, which is quite paradoxical, the opposite effect, and the meaning of life on the general scales sharply decreases (from +299 to -1), but to values, significantly higher than the original ones (-1 vs. -365).

This dependence demonstrates a weak linear connection of two parameters forming the general scale of life meaningfulness: the presence of life meaningfulness and search of life meaning, which is also reflected by the values of correlation coefficient (0.20).

Conclusion

Five types of dependence considered here clearly demonstrate that models of presence and search of life meaningfulness in people suffering from alcoholism obviously do not correspond to linear models\textsuperscript{19,20}. The results on the linear correlation even do not match the criteria of zero hypothesis (“significant” correlation), which also is not a sign of strong correlation at all\textsuperscript{21,22}. Besides, it is possible to see obvious one-sidedness of the represented types of dependences; it indicates that the reason and consequence are determined already at the level of quantitative analysis. It means that problems of life meaning do not correspond to linear models at all, and attempts of linear approximation will lead to fundamental errors at study and interpretation of this phenomenon, when with increase of one parameter another one obligatory demonstrates either only increase or decrease.

ABSTRACT

It is known that the harmonious combination of work and rest, regular physical training, proper nutrition, hardening of the body is very effective in terms of overall recovery and preservation of the health of its cardiovascular system. Prolonged lack of motor activity leads to a persistent deterioration of health and often contributes to the occurrence of heart and vascular diseases. Regular physical activities with elements of sports and health tourism in both groups of young people with dysfunction of the cardiovascular system ensured a stable optimum heart rate and blood pressure. At the same time, their values reached a more preferable level in the experimental group. In addition, against the background of metered physical loads with elements of sports and health tourism, the examinees succeeded in physiologically advantageous increase in the volume of vital capacity of the lungs. This occurred against the background of a very pronounced growth in the examined level of physical fitness. At the same time, the indicators of speed-strength qualities and general endurance have very strongly increased. Thus, sports and health tourism is one of the very effective health technologies for the beginning dysfunctions of the cardiovascular system in adolescence.

Keywords: physical culture, sports and health tourism, motor activity, prevention, cardiovascular diseases, adolescence.

Introduction

The way of life of a modern person starts to differ more and more from the way of life of many generations of our ancestors. In previous times, the movement of a person, the procuring of food and other types of vital activity required a constant pronounced muscular load from a person¹. Now more and more often the lack of active muscular activity is registered due to the lack of daily need for it². This has a pronounced negative effect on the whole organism of a modern person. Moreover, at the current stage of development of modern society, 80-90% of people of working age lack physical activity³. This deficiency has a very negative effect on the adaptive abilities of the cardiovascular and nervous systems⁴.

In economically developed countries, this situation is accompanied by the development of neuro-emotional tension in the majority of the population, which additionally contributes to the increase in the prevalence of diseases of the main life-support systems⁵.

The lack of a sufficient amount of motor activity primarily worsens the condition of the heart and blood
vessels, contributing to the emergence of various dysfunctions of the cardiovascular system already at a young age. The situation is aggravated by the majority of the population living in cities with a progressively deteriorating environment, which leads to a decrease in the natural immunity of a significant mass of the population. It becomes clear that to overcome the current difficult situation, one should actively use the healing potential of the natural environment, which is able to significantly restore human health. It has long been noted that with frequent contacts with the natural environment, it is possible to successfully combine life and work in the city and frequent episodes of active leisure. A very successful solution to this problem is sports and health tourism, which has shown its potential in the prevention of cardiovascular diseases. Its great advantage is the possibility of increasing motor activity without significant financial investments in the presence of bright sports, spiritual and cognitive components.

The pronounced health potential of sports tourism is associated with the “inclusion” of an optimizing effect on the body’s walking, as well as the positive influence of the natural forces of nature. Traditions, excursions, walks, tourist gatherings, competitions, local history and nature conservation activities are traditionally variants of sports and health tourism. Especially successfully it is possible to carry out in conditions of sanatorium stay. At the same time, for all variants of sports and health tourism, physical activity should increase gradually, reaching a peak by the middle of the activity period, taking into account the terrain, weight of equipment and speed of movement. The great health value of tourist recreation is also associated with a powerful positive effect on the body of weather-climatic conditions and landscape. Given the pronounced health potential of sports tourism, it was decided to evaluate its impact on the state of the cardiovascular system in adolescents with signs of dysfunctions developing in it.

The purpose of the study is to evaluate the effectiveness of enhancing physical activity with elements of sports and health tourism in overcoming the dysfunctions of the cardiovascular system in adolescents.

Materials and Method of Research

The study was conducted on the basis of the Russian State Social University (Moscow, Russia). All surveyed were students of this school.

In the experimental group were taken 23 people of adolescence (19.1 ± 1.1 years) with a diagnosis of vegetative-vascular dystonia in a hypertensive type (12 boys and 11 girls) in a medical institution. All of them had burdened heredity for hypertensive illness (one or two parents suffered for at least 5 years at the time of taking young men and women in the study of hypertension). The control group is represented by 21 clinically healthy people of adolescence (19.8 ± 0.9 years, 10 boys and 11 girls) who did not have a hereditary predisposition to any diseases.

Both groups had a similar level of physical fitness, provided by regular attendance of classes in physical culture during their studies at the university.

In the experimental and control groups used the same set of physical activity with elements of sports and health tourism. Within the framework of the tested complex, daily dosed walking was used (its duration gradually increased from 30 minutes to 90 minutes during the month). Also, running was practiced three times a week (duration from 15 minutes to 20 minutes at a free pace). Gradually after 1 month, training was a transition from running on a horizontal plane to running on a surface with an ascending slope of no more than 30°. Once a week after 2 months, until the end of the observations, group sessions were held on sports and health tourism. In winter, it was conducted in the Moscow region in the form of ski trips at a temperature not lower than –18ºС for a distance of at least 10 km. During the absence of snow cover, one-day walking tours through the territory of the Moscow Region with a total length of 12–15 km were carried out. During a skiing or hiking trip, a rest interval was observed every 40-60 minutes on a rugged terrain and every 20-30 minutes on hikes in hilly terrain.

The condition of the individuals who formed the experimental group and the control group was assessed daily. Their examination was carried out according to the methods given below two times - during the taking under observation and at its end. All patients examined measured lung capacity, heart rate, blood pressure level. In both groups of observation, the level of physical fitness was assessed according to the following exercise pattern. Tests for 12-minute run (Cooper test), 20-meter run, a test for flexion and extension of arms in an emphasis on a bench for 10 seconds and a test for throwing a ball weighing 1kg from a sitting position were applied.

Statistical processing of the results obtained in the course of the study was carried out using Student’s t-test.

Research Results and Discussion

Surveyed by both groups in the course of employment by the applied complex of physical loads noted an improvement in overall well-being. At the same time, their fatigue decreased, their headaches stopped bothering, emotional irritability decreased, and sleep returned to normal. The episodes of blood pressure destabilization in the experimental group that ended up by the end of the observation stopped worrying. In addition, in both groups of observation, the incidence of acute respiratory diseases significantly decreased compared with baseline data in the experimental group by 33.6%, and in the control group by 29.8%.

The results of the research are presented in table 1.

</tbody>
</table>

Regular physical exertion with elements of sports and health tourism in both groups of patients examined ensured a stable optimum heart rate for them. During the observation period, this indicator in the control group decreased by 18.5%, in the experimental group by 22.4%. The systolic blood pressure decreased in the control group by 3.5%, in the experimental group by 11.7%. A decrease was also registered for the diastolic blood pressure indicator - by 2.6% and 13.4%, respectively. The achieved results made it possible to consider that as a result of the carried out recreational measures, the signs of vegetative-vascular dystonia in the experimental group were completely stopped by the end of the observation.

Against the background of physical exertion with elements of sports and health tourism, the examined people managed to increase the volume of vital capacity of the lungs - in the control group by 15.9%, in the experimental group by 25.1%. Against this background, the examined showed an increase in the level of physical fitness for all the indicators taken into account. Very significantly increased rates of speed-strength and overall endurance. In the control group, the results in the 20 m sprint improved by 30.3%, the number of flexions and extension of the arms lying flat for 10 seconds increased by 40.8%, the distance of throwing the ball from a sitting position weighing 1 kg increased by 26.1%, Cooper’s test score increased by 41.7 m. At the same time, physical fitness indicators of the examined experimental group improved to a comparable degree and were comparable to those in the control group. Thus, in the experimental group, the reduction of the running time by 20 m was 31.2%; the number of flexions and extensions of the arms in the rest position for 10 seconds increased in this group by 39.2%; the distance of a throw of a ball at these examined increased by 27.6%, and value of an indicator of the test of Cooper increased by 40.7%.

The achieved results testify to the high health potential of the tested exercise pattern with elements of sports and health tourism for people of youthful age, including those with vegetative-vascular dystonia. It can be considered that they successfully stabilize the work of the heart, tone up the vessels against the background of the general growth of the indicator of physical fitness\textsuperscript{18}. The somewhat more preferable values of the recorded indicators in the experimental group for
a number of indicators are largely related to the more conscious approach of these individuals to physical training in order to overcome their dysfunctions in the cardiovascular system\textsuperscript{19,20}. In this regard, the tested scheme of physical activity elements of sports tourism can be considered an effective means of stabilizing the work of the cardiovascular system in adolescents with functional disorders in it.

**Conclusion**

Regular physical activities with elements of sports and health tourism in both groups of young people with dysfunction of the cardiovascular system ensured a stable optimum heart rate and blood pressure. At the same time, their values reached a more preferable level in the experimental group. In addition, against the background of metered physical loads with elements of sports and health tourism, the examinees succeeded in physiologically advantageous increase in the volume of vital capacity of the lungs. This occurred against the background of a very pronounced growth in the examined level of physical fitness. At the same time, the indicators of speed-strength qualities and general endurance have very strongly increased. The results obtained suggest a high recreational potential of the tested scheme of physical exertion with elements of sports and health tourism in respect of people of juvenile age with vegetative-vascular dystonia. Their action is able to stabilize the work of the heart, tone up the blood vessels, improve physical fitness. In this regard, the tested scheme of physical loads elements of sports tourism there is reason to believe an effective means of stabilizing the work of the cardiovascular system in adolescence in the presence of functional disorders in it.

The Effectiveness of Consuming Fruit and Vegetable on Potassium and Blood Pressure in Overweight Youth

Mohammad Jaelani¹, Meirina Dwi Larasati¹, Yuniarti¹, Sunarto¹, Choiroel Anwar¹

¹Lecturer, Ministry of Health Polytechnic Semarang, Indonesia

ABSTRACT

Background: Treatment of hypertension requires a long period so that it can affect patient compliance and cause toxic effects. Therefore an alternative treatment is needed to reduce the dose of the drug in preventing and treating hypertension by utilizing various kinds of nutrients in fruits and vegetables.

Objective: This study aims to determine the effectiveness of consuming five servings of fruits and vegetables to improve potassium and blood pressure levels in overweight teenagers.

Method: This study was an experimental randomized controlled trial with a pretest-posttest control group design. Subjects were an overweight teenager with a total of 17 people for the treatment group and 17 for controls. The intervention was given three servings of fruit and two servings of vegetables a day for two weeks.

Results: Giving 3 servings of fruit and 2 servings of vegetables for 2 weeks showed a significant change in weight loss of 0.79 kg (p<0.01) or 1.12% (p<0.01) and increased blood potassium by 0.34 mmol/L (p<0.01) or 9.37% (p<0.01). Giving fruit and vegetables can reduce systolic blood pressure by 5.62 mmHg and diastolic 3.52 mmHg clinically even though it is not statistically significant (p = 0.36, and p = 0.37).

Conclusion: Giving fruit and vegetables for two weeks can reduce weight, increase blood potassium levels significantly, and reduce blood pressure clinically even though it is not statistically significant.

Keywords: fruits and vegetables, blood potassium, blood pressure, overweight.

Introduction

Treatment of hypertension takes a long time so that it can cause toxic effects such as gastrointestinal disorders, dizziness, coughing, palpitations, and insomnia. Therefore an alternative treatment is needed to reduce drug dosage and prevent hypertension by increasing the intake of fruits and vegetables.

Fruits and vegetables generally contain antioxidants, potassium, omega three fatty acids, and fiber (¹). The recommended antioxidants as antihypertensive are vitamin A (α carotene, β carotene, γ carotene, and crypt xanthine), C, E, Co-enzyme Q10 (CoQ 10), L-arginine, and flavonoids.

WHO recommends increasing consumption of vegetables and fruits at least 400 grams or 5 servings of fruit vegetables per day to help maintain health and potassium from food to reduce blood pressure, avoid cardiovascular disease, stroke and coronary heart disease by 90 mmol/day (3510 mg/day) (²). Addition of a minimum potassium intake of 60 mmol (2340 mg) per day can reduce systolic blood pressure 4.4 mmHg and diastolic 2.5 mmHg in hypertensive subjects (²). Fruits and vegetables that contain potassium and are suitable for people with hypertension include watermelons, avocados, melons, bananas, apples, oranges, bitter melon, squash, pumpkin, cucumber, aloe vera, celery, and shallots and garlic (²).

The majority of the Indonesian population (93.6%) is still in less category. The level of consumption of vegetables and fruit is said to be enough if you consume vegetables and fruit at least five servings every day. Given the importance of fruits and vegetables in maintaining blood pressure, it is essential to conduct this research to determine the effectiveness of consuming five servings
of fruits and vegetables to improve potassium and blood pressure levels in overweight teenagers.

**Method**

This research was conducted from September to October 2018. The location of research for preparation and processing of fruits and vegetables was carried out at the Food Technology Laboratory of the Department of Nutrition, Ministry of Health, Semarang. Blood pressure measurement was carried out by nurses and measuring blood potassium was done in the Health Laboratory.

The research subjects were healthy adult groups of women and men with the following criteria: Index of Body Mass ≥ 23 kg/m², aged ≥ 18-21 years, liked vegetables and fruit and not taking blood pressure-lowering drugs that can affect blood pressure. The sample size of each group of 17 people was added as a reserve of 1 person, so the total sample was 36 people.

This study used a randomized controlled trial using a pre-experimental design “pretest-posttest control group design.” The subjects included in the treatment group will be taken initial measurements which are measured in body weight, potassium, and blood pressure. The next step is to intervene by giving three servings of fruit, which is given in whole form or 2 servings of juice and vegetables given in processed form every day for two weeks. The final step is to measure the change in the subject’s potassium and blood pressure. In the control group, the same initial and final measurements were carried out, but without being treated. The instruments used in this study included: questionnaires, sphygmomanometer, blood potassium measuring instruments, fruit, and vegetable consumption monitoring forms and food scales.

To determine the effectiveness of consumption of 5 servings of fruits and vegetables for weight loss and increase in potassium levels using the independent t-test while to test for systolic and diastolic blood pressure using ANOVA test at α = 0.05.

**Results**

Fruits and vegetables are rich sources of a wide range of beneficial nutrients and non-nutrients including fiber, vitamins (particularly A, B and C), minerals (selenium and potassium), antioxidants (carotenoids and tocopherols) and phytochemicals including flavonoids, glucosinolates, and isothiocyanates. Low fruit and vegetable consumption is not confined to high-income countries but is prevalent across many nations. In a recent study, 77.6% of men and 78.4% of women sampled from 52 low- and middle-income countries reported consuming less than 400 g of fruit and vegetables per day, the minimum recommended by the World Health Organisation (WHO) panel on a diet, nutrition and prevention of chronic disease (8).

Based on the results of the screening by weighing body weight and height for 221 teenagers in one of the universities in Semarang there were 57 people (25.79%) with a Body Mass Index (BMI) ≥ 23 kg/m², while based on blood pressure measurements there were 63 people (28.51%) with blood pressure ≥ 120/80 mmHg. The population that meets the sample criteria is 45 people, while 36 people were taken as research subjects consisting of 18 treatment groups and 18 control groups. The research subjects who followed the research process to the end in the treatment group were 17 people and control group 17 with reasons for being sick and afraid of taking blood samples.

Subjects in this study were the age group of healthy teenagers, two men of male sex and 32 of women and aged between 18 and 20 years. The physical activity of subjects in the treatment group averaged only 1.24 times a week, while in the control group only one time a week. Based on vegetable consumption before treatment in the two groups was almost the same is less than two servings in a day, while after intervention in the group the average consumption of vegetables was 3.12 servings per day, while the control group was 1.29 servings a day. Based on fruit consumption before treatment in the two groups was almost the same, namely less than two servings in a day, while after intervention in the group average vegetable consumption was 3.82 servings per day, while the control group was 1.47 servings a day. The results of the analysis can be seen in table 1.

Based on the results of the mass index measurement, the body shows most of the subjects included in the category of obesity, namely in the treatment group of 42% and the control group 71%. The habit of consuming fruits and vegetables most of the subjects only consumed one portion of vegetables and fruits both in the treatment and control groups. While sports habits there are subjects who never exercise, namely 35% in the treatment group and 30% in the control group.

Table 3 shows that giving three servings of fruit and two servings of vegetables every day for two weeks can significantly reduce body weight, which is 0.79 kg, compared to the control group, up 0.23 kg (p = 0.00). The effect on blood electrolytes only affects blood potassium, which is in the treatment group, up 0.32 mmol/L, compared to the control group, up 0.001 mmol/L (p = 0.01), while the sodium and chlorine changes are not significant (p = 0.93 and p = 0.77). The results of the analysis can be seen in table 3.

Multivariate analysis using ANOVA Test included confounding variables (nutritional status, activity, consumption of vegetables, and fruits). Based on the mean comparison between before and after the intervention, there was a difference in the decrease in systolic and diastolic blood pressure after two weeks of intervention. The effect on systolic blood pressure in the first week of intervention in the treatment group decreased by 2.63 mmHg and in the last week to 5.62 mmHg, while in the control group the first week increased 0.15 mmHg and the last week decreased 0.9 mmHg. The effect on diastolic blood pressure in the first week of intervention in the treatment group decreased by 2.31 mmHg and in the last week to 3.52 mmHg, whereas in the first week the control group decreased 0.03 mmHg and the last week decreased 0.29 mmHg. However, the decrease in blood pressure, both systolic and diastolic was not statistically significant (p = 0.36, and p = 0.37). The decrease in blood pressure is caused by an increase in blood potassium levels in the treatment group of 0.32 mmol/L or an increase of 9.32% from before. The results of previous studies showed that potassium could reduce systolic and diastolic blood pressure, by suppressing renin secretion and smooth muscle relaxation through the production of nitric oxide (6). Increased intake of vegetables and fruit has the potential to change the status of NO (Nitric Oxide) (7). NO function in the body dilates blood vessels to prevent blockages in blood vessels and reduce blood pressure.

Discussion

Giving 3 servings of fruit and 2 servings of vegetables for 2 weeks increased vegetable intake to an average of 3.12 servings a day compared to previously it was only 1.12 servings, as well as fruit intake which increased to 3.82 portions from 1.53 portions previously consumed usually, this amount is in accordance with the recommendation of consuming 3-4 servings of vegetables and 2-3 servings of fruit (4). Increased intake of vegetables and fruit to a decrease in systolic blood pressure of 5.62 mmHg and diastolic 3.52 mmHg after 2 weeks of intervention These results are in line with previous studies that higher fruit and vegetable intake from previous dietary patterns had a beneficial effect on blood pressure control (5), this is because fruits and vegetables can reduce blood pressure and inhibition of ACE-inhibitor enzymes and in the long term You reduce the risk of developing hypertension (4).

Another substance is lycopene, an antioxidant that has an active role in preventing oxidative stress, improving blood vessel function, and preventing cardiovascular disease (8). A study showed supplementation of lycopene could regulate blood pressure, supplementation of lycopene in the form of extract or juice orally at 4.5 mg/day for four weeks, can significantly reduce systolic blood pressure. Vegetables and fruits such as tomatoes contain gamma-aminobutyric acid (GABA), lycopene, beta carotene, and vitamin E, which are antioxidants (deactivate free radicals), lower blood pressure (9).
Increased intake of vegetables and fruit for body weight showed a decrease of 0.79 kg (p = 0.04). Dietary fiber can lose weight with various mechanisms. Vegetables and fruits generally have high fiber content and relatively lower energy. Fiber-rich foods need time to chew and give a feeling of fullness longer. It is also important to note that the effect of dietary fiber consumption on body weight may be related to different intestinal hormones that regulate satiety. In another study with middle-aged female subjects, found an inverse relationship between increased fruit and vegetable intake to the risk of obesity or weight gain. Previous studies show an increase in the intake of fruits and vegetables as much as 100 gr/day can slow weight gain, which is lowering 14 grams in a year. Fruits and vegetables are also sources of antioxidants that can affect leptin hormones in correlation studies show those serum concentrations of vitamins A and E inversely and significantly with leptin.

**Conclusions**

The results of this study can be concluded that the addition of 3 servings of fruit and two servings of vegetables for two weeks in overweight teenagers can reduce systolic and diastolic blood pressure even though it is not statistically significant and can reduce weight and increase blood potassium levels in teenagers overweight.

Prediction of Crime Risk Behavior among Early Adolescences

Mohammad Nasir Bistamam¹, Nor Hafifah Abdullah¹, Nurul Hasyimah Mat Rani¹, Samsiah Mohammad Jais¹, Md Azman Shahadan¹, Pau Kee¹

¹Department of Psychology & Counselling, Sultan Idris Education University

ABSTRACT

Previously, many literatures suggest that low social support (family, peer, school), psychological aspect (low level of resilience, coping skills, empathy, high level of depression and aggression), low level of academic achievement and school involvement activity, and involving in truancy correlate with crime risk behavior. However, only few studies in Malaysia have investigate these constructs simultaneously in a single study involving early adolescence. This study aims to examine which construct in Risky Antecedent (social support and socioeconomic status), Risky Psychology (resilience, coping skill, empathy, depression and aggression) and Marker System (truancy, academic achievement and involvement in school activity) predict involvement in crime risk behavior among early adolescence in Malaysia. Binary logistic regression analysis was conducted involving all variables which were Risky Antecedent, Risky Psychology, Marker System with crime risk behavior in a sample of 1762 early adolescences from six states in Malaysia. Result shows that the most significant factor associated with crime risk behavior were aggression, truancy, involvement in school activity and lastly social support from peer. Finding from this study suggest that intervention targeting early adolescence at risk of crime risk behavior may correlate with greater impact on reduction in crime risk behavior that exclusively targeting the school as the main place to run the prevention program.

Keywords: Social support, socioeconomic status, resilience, coping skills, empathy, depression, aggression, academic achievement, involvement in school activity, truancy, crime risk behavior, adolescent

Introduction

In Malaysia, adolescents make up 28.4 percent of the population of Malaysia [¹]. Adolescence encompass a period of development between the ages of 10 to 19 years old [²]. Adolescence stage is one of the most important developmental periods in which person grows and matures physically, mentally, cognitively, socially and emotionally and risky behaviors restrain adolescents to become responsible adults by threatening their well-being [³]. During the transition from childhood to adulthood, adolescents struggle to make lifestyle choices and establish patterns of behavior that affect both their current and future health [⁴]. Behavior change is based on social cognitive theory and socioecological model of health, which emphasizes a dynamic interaction among cognitive, behavioral, and environmental factor over the life course of individuals, families, and communities contributing to the health of populations [⁵].

Literature Review of Factor Associated with Crime Risk Behavior: There are association between support, SES, psychological aspect, truancy, academic achievement and involvement in school activity with crime risk behavior [⁶-⁸]. However, in Malaysia, knowledge of common antecedents to these behaviors are sometimes limited by studies that often assess construct in Risky Antecedent (social support from family, peer, school and socioeconomic status, SES), Risky Psychology (resilience, coping skill, empathy, depression and aggression) or Marker System (academic achievement, involvement in school activity and truancy) separately in single study [⁹-¹⁶].

A large body of evidence supports an empirical relationship between crime risk behavior with social
support from family [17], social support from peer [18-20], social support from school [20,21] and socioeconomic status [22,23]. In addition to Risky Antecedent, another Risky Psychology that are more likely to influence adolescents getting involved in crime risk behavior are low level of resilience [7,24], coping skills [25,26] and empathy [27,28] and besides, high level of depression [18,29] and aggression [6,12]. This current research suggests that through Marker System, school counsellor can identify adolescent at risk of crime risk behavior. Past research has found that crime risk behavior has significant relationship with low academic achievement [30-32], involvement in school activity [33,34] and high involvement in truancy [14,35].

Research Aim: This study aims to examine which construct in Risky Antecedent (social support and socioeconomic status), Risky Psychology (resilience, coping skill, empathy, depression and aggression) and Marker System (truancy, academic achievement and involvement in school activity) predict involvement in crime risk behavior among early adolescence in Malaysia.

Methodology

1762 secondary school students from standard 1 and 2 (13 and 14 years old) were recruited from 18 school from six different states. Also, the schools came from three different areas (urban, suburban and rural). All construct in this study were measured using self-report measured known as Adolescent’s Crime Risk Instrument (ACRI) [36] that was adopted from Risky Adolescent Instrument [37]. This instrument consists of 89 items in total with 13 constructs and in Malay language.

Face validity analysis have been conducted by appointed 10 experts in the field of measurement and assessment, curriculum, adolescent’s development, psychology, pedagogy, sociology, guidance and counselling. This is to see whether the measures that we use adequately covers all content that it should be. Overall, this measure has face validity. Next, Table 1 shows the internal consistency analysis outcome that is conducted to access the reliability of this measure. The overall Cronbach alpha value is .77 with range between .65 to .90. Ideal Cronbach alpha value according to general rule of thumb are above .70 (good), .80 (better) and .90 (best) [38]. But for the construct that have total number of items below 10, it was normal for them to have low reliability value because Cronbach alpha is quite sensitive to the number of items [39]. So, she suggests that it would be more appropriate if we report the mean inter-item correlation value. Optimal range for mean inter-item correlation value is between .20 to .40 [51]. In this study, mean inter-item correlation for each construct vary between .20 to .38 which shows acceptable values and the average value was .29.

Results

Sample Description: The final analytic sample of this study included 1762 adolescents who had complete answering measure of this study. Overall, there are more than half of the sample was male (n=900, 51.1%). Table 2 shows the mean score for social support from family (x̄ = 4.00), social support from peer (x̄ = 3.85), social support from school (x̄ = 3.67), SES (x̄ = 2.87), resilience (x̄ = 3.74), coping skills (x̄ = 3.67), empathy (x̄ = 3.88), depression (x̄ = 2.85), aggression (x̄ = 2.34), truancy (x̄ = 2.13), academic achievement (x̄ = 2.94), and involvement in school activity (x̄ = 3.75). For crime risk behavior, total number of adolescents involve in crime risk behavior was 1354 (76.8%).

Logistic Regression Analysis: A binary logistic regression was used to model the binary variable of involving in crime risk behavior among early adolescent in Malaysia. The model contained 13 continuous independents variables. The full model containing all predictors to crime risk behavior was statistically significant χ²(13, N = 1762) = 155.63, p < .001, indicating that the model was able to distinguish between respondent’s who involve and did not involve in crime risk behavior. The model as a whole explained between 15% (Cox & Snell R Square) and 22.6% (Nagelkerke R Square) of the variance in crime risk behavior, and correctly classified 78.3% of cases. As shown in Table 3, only four of the independent variables made a unique statistically significant contribution to the models (social support from peer, aggression, truancy and involvement in school activity).

The strongest predictor to crime risk behavior was aggression which shows that early adolescents with increasing one score of aggression, they have 141% (OR = 2.41) chances to engage in crime risk behavior compare to truancy (52%). This means aggression and truancy are risk factor to crime risk behavior. Besides, social support from peer and involvement in school activity are protective factor to crime risk behavior. Increasing one score of social support from peer reduce the chances to involve in crime risk behavior by 37% (OR = .63). While increasing one score of involvement in school activity, reduce the chances to involve in crime risk behavior by 15% (OR = .85).

Discussion, Suggestion And Limitation

Early adolescent who engages in crime risk behavior endure extreme constraints on important resources necessary for healthy adolescents’ development. This study explored three constructs which are Risky Antecedent, Risky Psychology and Marker System that are connected to crime risk behavior. Based on the finding of this study, the following recommendations may be made to school counsellors working with adolescents at schools or other institutions. This study has shown that social support was an important variable in predicting adolescent involvement in crime risk behavior. Practicing school counsellors and psychologists may undertake protective and preventive work to increase the social support that students receive from family, peers and school.

Besides, finding of this study also indicated that social support has a protective effect against the indicators of crime risk behavior. Thus, school counsellors and psychologists working with adolescents may ensure that adolescents have higher perceived social support so that the indicators of crime risk behavior such as aggression is minimized. We focused on Risky Antecedent, Risky Psychology and Marker System as variables that predict adolescents’ crime risk behavior. Future studies may investigate the effects of other predictors on crime risk behavior. Besides, this is cross-sectional study, future study may replicate this study by conducting a longitudinal research.

Ethical Clearance: Ethical procedure of this study was approved by the Educational Planning and Research Division, Ministry of Education Malaysia. Besides, the inform consent was acquired from the participant who agreed to participate in this study.

Conflict of Interest: There is no conflict of interest in this research.

Source of Funding: This study was funded by Ministry of Education Malaysia through the Fundamental Research Grant Scheme (FRGS) with code 2017-0068-106-01 (FRGS/1/2017/SS05/UPSI/02/7).

ABSTRACT

Achieving good results requires the adoption of appropriate methods of training. The problem of the research was the lack of scientific and training methods related to the development of fitness and balance, which have a negative impact on the accuracy of skill performance. Therefore, researchers decided to study the problem through using the effectiveness of exercises as physical - skill in the development of fitness and balance as well as the accuracy of performing both the skills of preparing and receiving the volleyball. The most important conclusions of the research: 1- Psychological differences among the results of pre- and post-tests of the experimental group in all the research variables and in favor of post-tests. 2. Psychological differences among the results of the post-tests of the two experimental groups in all the research variables and in favor of the experimental group.

Keywords: Exercises (physical-skill)-fitness-balance-preparation-reception.

Introduction

For sports excellence and the world-class levels of excellence, trainers shall take this into consideration. The player who has high physical abilities is able to improve his skill and plan level. The physical abilities are the general rule on which the player can move in the court to achieve outstanding performance in all motor skills. This Performance comes only through hard and continuous training on these skills and strengthening them. Therefore, physical abilities are one of the necessary requirements for the volleyball player and any decrease in the level of those qualities will lead to a decrease in the level motor skill which is the essence Performance in the sport. Physical abilities, according to[¹], are “qualities acquired from the ocean. The training or practice is their basis and they can be developed according to the physical, sensory and cognitive ability of the individual. Fitness often called all-or-not trait of motor qualities.” It is necessary to know the characteristics of motor abilities, which are difficult to be enumerated or defined because they include all aspects. [¹] emphasized in terms of the “psychological and physical concept and the mathematical readiness to meet the requirements of sports.” This is the basis for the exercise of sports, which is one of the basic components and is the decisive factor in winning matches, especially when the level of performance between teams and work on finding the means to develop these capabilities for the individual, which is the common denominator for the performance of most of the skills in most sports, and physical preparation is one of the basic and important pillars in sports training. This is what [²] confirmed “It is one of the most important elements of success in preparing for the skills of motor activities as it aims at developing the ability of the sportsman and improving the level of physical abilities to meet the requirements of sports activity, which lead the training status of the...
individual to reach the high levels of activity.” Fitness and balance are some of the motor abilities that fall within the requirements of the game of volleyball; it is characterized by the varied performance and change between offensive and defensive skills during the performance and according to the situation”. Thus, the training methods improve the physical and skill level as well as it has an interesting nature for practitioners as it helps them improve their incentives. The various levels of sports have developed clearly, especially the volleyball which is one of the popular and mass sports. Therefore, the trainer must direct the player to develop his physical abilities for the purpose of achieving the basic goal which is getting a high achievement. During that competition among the countries of the world began to develop modern methods and methods of training. This is what has referred “fitness in volleyball must be in accordance with the requirements of volleyball, then start training in a specialized manner, especially the activity that requires speed, capacity, and fitness so training must adapt to these requirements. Sports training aims at developing physical and skill qualities as well as the delay of the beginning of fatigue due to its positive feedback. Thus, the training curriculum is measured by the need for the use of the methods of regulation and good as well as the use of the sportsman in the activity he used to practice through the physical, skill and functional level. The researchers attributed this to the lack of use of scientific and training methods related to the development of fitness and balance, which have a negative impact on the accuracy of skill performance. Thus, researchers decided to study the problem through the use of the effectiveness of the physical - skill exercises in the development of fitness and balance as well as the accuracy of performing both the skills of preparing and receipting the volleyball. The research aims at:

-preparing the exercises as physical- skill in the development of fitness and balance as well as the accuracy of performing both the skills of preparing and receipting the volleyball. Recognizing the effectiveness of the exercises (physical- skill) in the development of fitness and balance as well as the accuracy of performing both the skills of preparing and receipting the volleyball.

The research methodology: The researchers used the experimental method by using the approach of the equal groups as its appropriate to solve the problem of research. The experimental method is one of the best and most appropriate methods leading to the best results because it deals with the phenomenon and its causes. This is in line with the opinion of [1], “It is an interpretation process of the consequences of a particular situation and verifying its causes because it deals with the facts.”

Research Sample: The research community was determined using the players of the Dhulwiya Sports Club for volleyball players of the sports season 2018/2019. They were 14 players were chosen by the non-random sampling method. The Libero was excluded for not participating in offensive skills, in addition to 3 players for participating in the exploratory experiment. Thus, the sample of the research was 10 players representing both the control and experimental groups as the sample was randomly divided into two equal groups; 5 players represent the control group and 5 players represent the experimental- group so the percentage of the sample is 78.57%.-The researchers have found homogeneity and equivalence in the sample through using T-test in the variables of the research, as shown in the table 1:

**Research Tools:** Arab and foreign sources- A form for recording and dumping data- Weight and Height device- volleyball court- Measurement tape - tests and measurements.

**Tests used in the research:** 1 - Fitness test \(^{(1)}\), Annex 1. 2. Balance test \(^{(2)}\), Annex 2. 3 - Test the accuracy of the skill of preparation \(^{(3)}\), Annex 3. 4 - Test the accuracy of the skill of reception \(^{(4)}\), Annex 4.

**The Exploratory Experiment:** It’s a preliminary experimental study for the purpose of testing the research methods. The exploratory experiment was conducted on a sample of 3 players on 11-12/11/2018 and it was made for finding out what shall be done and testing the most appropriate and the best, so the purpose of the exploratory experiment was:1. Finding out the understanding of the players for the tests. 2. Finding out the time necessary for explaining and applying tests.3. Finding out the validity of the devices used in the tests.

**The field procedures of the research:**

**The Pre-test:** The researchers conducted pre-tests for the research sample on 14-15/11/2018 and test-related conditions, such as the place, the time and the method of carrying out the tests were established for the purpose of achieving the same or similar purposes as possible during the post-tests.

**The training curriculum:** The researchers conducted a number of exercises as physical-skill suggested for the special preparation stage in annex 2. This stage aims at the development of the fitness and balance under consideration, the accuracy of performing both the skills of preparing and receiving the volleyball. The training period is 8 weeks on Sunday, Tuesday, Thursday for each week, it starts from Sunday from 18/11/2018 till 15/1/2019 at Al Dhului Sports Club with 3 training modules per week. The total number of training 24 modules) and the training time is 80-95 minutes at 3:00 O’clock. The experimental group used the suggested training method while the control group used the method followed by the trainer.

**Post-test:** The pre-test for the research tests was conducted on the sample's individuals and in the same manner as the physical test for the research group on 16-17/1/2019.

**Statistical Method:** The statistical spss system was adopted in finding out the results. Percentage- arithmetic mean - standard deviation- law T for matched samples-law T for mismatched samples.

**Presentation, Analysis and Discussion of the Results**

Presentation and analysis of the results of the arithmetic mean, the standard deviation, the calculated and tabular T value in pre-tests for both the control and experimental groups in the variables of the volleyball’s research. Presentation and analysis of the test results of the variables under study related to the volleyball of the control group, as shown in table 2.

Looking at the table no 4, which indicates the arithmetic mean, the standard deviations, the calculated T value in the pre-tests of both the control and experimental groups in the physical and skill variables. In the fitness test of the control-group the arithmetic mean was 5.678 and the standard deviation was 0.444 while the arithmetic mean of the experimental group was 4.770, the standard deviation was 0.478, the calculated T value was 3.118, the error rate was (0.01), below the level of significance was 0.05 and the degree of freedom was 8. This indicates the significant differences between the results of the post-tests for the research sample and in favor of the experimental group.

**Discussion**

Discussing the results of the post-tests for both the control and experimental groups in relation to the variables under research in volleyball. Through what was presented in table 4 of the test results for the control and experimental groups, the table is shown significant differences in post-tests and in favor of the experimental group in the tests of fitness, balance, the accuracy of preparation and volleyball reception in relation to all the variables under research. The researchers attributed the significant differences to the optimal use of the training curriculum, which was applied to the players of the experimental group. This training curriculum adopted in its application to the repetitions and stresses that were developed to match the level of the sample, giving the appropriate break between exercises and practical exercises as well as the privacy of the volleyball game. This was confirmed by Singer Robert N [2] Motor skill is achieved only with an acceptable level of physical capacity “this is consistent with what said as “Exercises aimed at preparing the individual for the activity of the exercise and developing the motor abilities necessary for this activity so as to improve the individual’s performance of the motor and schematic aspects of the activity”. This contributed to the development of players as they include exercises characterized by repetitions and based on a proper scientific basis, in addition, they consistent with the level and the ability of players in terms of concentration on the speed of performance, which has a great role in raising the level of players, either physically or skillfully. This is consistent with
“The standardized and organized training programs in accordance with the scientific basis working on the development of physical and skill level of the players”. As well as the opinion of [6], “The ability to retain a certain position of the body during stability or movement and that the use of adequate time, frequency and stress in exercises with giving rest times adapted to working times will perform the level of performance of players” noted that «The systematic and programmed training and the use of the types of severity prescribed in the training as well as the use of optimum rest between repetitions lead to the development of achievement. The researchers emphasize that the practice of players for more than a repetition help players to achieve excellent performance and accuracy and will be reflected positively during the performance in volleyball and thus get the stability of performance” This is confirmed by [7] noted that “It is a skill that requires a combination of timing, balance, muscular strength, speed of movement and without the right mechanics, all of which is a wasted effort”.

Conclusions

Significant differences between the results of the pre- and post-tests of the experimental group in all the research variables and in favor of the post-tests. Significant differences between the results of the post-tests of the two research’ groups in all the search variables and in favor of the experimental group.

Recommendations

Emphasize the need of the trainers and volleyball players to take care of the physical and skill abilities of the players. The necessity of the volleyball player to perform physical and skill tests on a continuous basis so as to ensure the effectiveness of the training curricula. The need to conduct studies similar to other physical abilities and other age groups in volleyball.

Effectiveness of Health Educational Program on Nurses’ Knowledge Concerning of Developmental Hip Dysplasia at Al-Wasiti Teaching Hospital in Baghdad City

Mohammed H. Burhan¹, Khatam M. Hattab²

¹Pediatric Nursing Department, ²Prof. Pediatric Nursing Department, College of Nursing, University of Baghdad

ABSTRACT

Background: Nurses role is crucial for DDH due to their routine part in the healthcare facilities made them the individuals who are capable of the disease recognition, thus it is important for ongoing constructed health-education programs being made to assure knowledge refreshing. Early detection and standardized care for the child with DDH post operatively or care address the need for more knowledgeable, trained, skilled nurses in the field of orthopedic nursing specifically in DDH topics.

Objective: firstly assessing knowledge of the nurses concerning DDH, secondly constructing a health education program for nurses according to the pre-assessed knowledge, thirdly implementing the program to surge nurses’ knowledge about neonatal developmental hip dysplasia, then Finding-out relationship between nurses’ knowledge about DDH with the demographic status (such as age, gender, marital status, academic achievement, years of employment in nursing field, years of practice at Al-Wasiti teaching hospital, having training sessions in nursing as a general, having training sessions about Developmental Dysplasia of the Hip, and reviewing knowledge resources within nurse’s own area of competence), and finally Evaluating the effectiveness of the program.

Methodology: A quasi-experimental design with case and control groups being tested in three periods pre-test, post-test-1, and post-test-2. The case group participants are tested prior implementing the educational program and in twenty-one days after they are tested post-test-1 (in 6th January, 2019) then after same period the post-test-2 had been done (in 27th March, 2019). The control group participants are provided with the questionnaire to answer in same time intervals as in case group but without enrollment in educational program. The study started in 16th December, 2018 to 27th March, 2019.

Non probability sample (Purposive) of (80) nurses. 10 preliminary study, 10 pilot study, 30 cases, and 30 controls. Working in a variety of departments of Al-Wasiti Teaching Hospital.

Data collection material is done by self-administrated questionnaire form and it was given for nurses to answer after acquiring their agreement in verbal and written consent.

Results: the study outcomes include low in assessment of nurses’ knowledge prior the educational program and became high-assessment after participation in the program. This is not applied on control group in which participants remain within low-assessment for three periods of testing each test is separated with 21 days period without participating in educational program lectures.

Conclusion: Nurses’ knowledge concerning neonatal developmental hip dysplasia was improved by the effect of the educational program intervention for the case-group, concluding that effectiveness of the intended program was high advantageous.

Recommendations: the high advantage effect of the educational program on nurses’ knowledge concerning neonatal DDH in Al-Wasiti teaching hospital, thus recommendation for applying educational programs about this topic for all general or orthopedic hospitals in Iraq.

Introduction

Developmental dysplasia of the hip (DDH) describes a range of hip-joint abnormalities, varying from dysplasia to subluxation to dislocation, usually these abnormalities originate in the womb or in the neonatal period.[1].

The affected structures in hip dysplasia are acetabulum, femoral head or both, making the cup-like acetabulum being shallow and the femoral head ossification being altered or delayed[2].

Well known Risk factors for DDH are intrauterine breech positioning, female babies, estrogen hormone from maternal and fetal origins, first-born infant, and family history.[1]

Swaddling infant in positions of extension and adduction of the hips increases the risk of getting DDH. [2] [3]

Diagnosis of DDH consists of taking health history of DDH patient, physical examination, and radiographic or ultrasonic imaging. [4][5] History taking emphasize on risk factors such as sex, birth ordination, breech presentation, gestational age and family history of DDH.[1]

Treatments for DDH are based according to clinical examination of the hips and radiologic or ultrasonic imaging evaluation that can identify new-born infants whom at risk for DDH, and it includes the surgical and non-surgical treatments that is usually done by abduction braces. [6] The effective treatment of DDH requires multidisciplinary team effort and the parents of the children are also involved.[7]

Importance of the Study: Nurses play an important role for detecting developmental dysplasia of the hip (DDH) in neonates as they perform the routine assessment and care. [2]

The important roles for nurses caring for the children diagnosed with this condition are to council, educate, and prepare the parents to know how to deal and care for the child with DDH. [8] Continuing education is an essential for healthcare providers who are involved in nurturing of neonates to improve knowledge about DDH by providing health education programs [9].

Objectives of the Study

The study aim to:

1. Assess nurses’ knowledge regarding DDH.
2. Construct a health education program for nurses in response to pre-assessed knowledge about DDH.
3. Implement the education program.
4. Find-out relations between the nurses’ knowledge about DDH with the demographic status.
5. Evaluate the effectiveness of the program.

Materials and Method

The study designed as quasi-experiment for case and control groups being tested in three periods pre-test, post-test-1, and post-test-2. The case group participants is tested prior implementing the educational program (16-20 December 2018) then after period they are tested post-test-1(in 13th January, 2019) then after a while the post-test-2 had been conducted (in 27th March, 2019). The control group participants are provided with the questionnaire to answer in same time intervals as in case group but without enrollment in educational program.

The study started in 11th December, 2018 to 27th March, 2019 including prearrangements like preliminary and pilot study. Data collection is done by self-administrated questionnaire form and it was given for nurses to answer after taking their agreement in verbal and written consent.

Setting of the Study: Al-Wasiti teaching hospital in Baghdad city.

The Sample of the Study: A non - probability sample participant were randomly nominated from (80) nurses. 10 enrolled in preliminary study, 10 pilot study, 30 cases, and 30 controls.

Instrument of the Study: A questionnaire was built through the review of literature and studies, it consist of two parts: first one is demographic status of the nurses (as shown in table 3), and the second part is Nurses’ Knowledge regarding developmental dysplasia of the hip that Contain six domains:

1. Basic information related to DDH (5 items)
2. Risk Factors (5 items)
3. Pathophysiology (6 items)
4. Clinical Diagnosis (8 items)
5. Medical and surgical management of DDH (3 items)
6. Nursing Consideration and Management (10 items)

Each item is a question with four multiple choices one of the choice is a correct (scaled 2) and the three others are wrong (scaled 1) scales within SPSS vr.22.

Validity of the Instrument: The study questionnaire and the program reviewed by panel experts views those experts had more than seven years of experience in their field of specialty.

Reliability of the Instrument: A pilot study was conducted on (10) randomly nominated nurses it was done from (11th of December, 2018 to 16th of December, 2018). Questionnaire reliability determination done with Cronbach’s alpha and it is calculated (0.838) which is considered satisfying according to Nunnally (1978) [10].

Statistical Method: Descriptive statistics and inferential.

Results of the Study

**Discussion of the Study Results**

**Part I: Discussion of the demographic status**

**Age:** The majority of case and control group (46.7%) and (43.3%) are of (18-27 age group) respectively. These outputs are approved with [11] their highest percentage of both groups within the age group of 20 – 29 years old.

**Gender:** The majority of participants in case and control (56.7 %) (53.3%) respectively were females. Agreed with [12].

**Marital Status:** The highest percentage of the study sample are married in (63.3%) case group and (66.7%) in control group. This supported by [13] in which (60%) case and (56.7) control group nurses were married.

**Academic achievement:** the high percentage of the case and control groups are nursing school graduates 46.66% and 43.3% respectively. This is accepted with [11] in which majority (50%) secondary-nursing school graduates for both groups.

**Years of experience in nursing field:** The high percentage of both groups are (46.7%) within of (1-5 years) experience in nursing field. This is approved with [14] revealed majority had an experience of 1 – 5 years in the nursing field.

**Years of employment in Al-Wasiti teaching hospital:** the majority1-5 years of employment in the hospital for both case (70.0%) and control (66.7%) groups. Approved[11].

**Training sessions in nursing as a general:** The maximum percentage (73.3%) case and (70.0%) control groups did went for training sessions in general topics of nursing. Those outcomes are agreed with [18] in which majority in case and control groups (84%), (68%) respectively participated in nursing courses.

**Training sessions about DDH:** The most percentage (80%) in both case and control group didn’t participate in training sessions about DDH. This approved with [12] which they stated (70%) of both groups.
Review knowledge resources within nurses’ own area of competence: High percentage of case and control participants (66.7%) (73.3%). respectively were reviewing knowledge resources, the majority of participants review textbooks in both case (70.0%) and control (68.2%) groups. There is no statistical relation of nurses’ knowledge with the reviewing of resources among pre-, post-1, and post-2 tests (p value= 0.577, 0.767, and 0.619) respectively.

Part II:

1. Discussion of the effectiveness of the health educational program on nurses’ knowledge: 1. Among case-group test periods: The knowledge testing of this study reveals low-level before commencing the program and became high-level after the subjects participate in lectures of this study program and underwent the post-test-1 and post-test-2. This lead to conclusion that the program have the effect on nurses’ knowledge. Approved with [15] and [16].

2. Association of nurses knowledge among pre-test, post-test-1, and post-test-2 periods: Shows no statistical relationships. Studies [17], [18], and [19] confirm that there are substantial statistical difference among pre-, post-1, post-2 test periods within the case group, meanwhile, there are no difference among the three periods of the control group.

Part II

Relationship of nurses’ knowledge with the demographic status: There is no statistical significant association among demographic items with knowledge testing, but only with post-test-2 and academic achievement show a relationship. In a study [20] found that there is no significant relation of the age with nurses’ knowledge in pre-test, post1& post-2 within P value <0.05.

Conflict of Interest: The researchers report no conflict of interest.

Source of Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Baghdad.

Relationship of K3 Training and K3 Supervision with Sop Compliance in Building Workers (A Case Study of Surabaya Bridge Infrastructure Project)

Nabylla Sharfina Sekar Nurriwanti¹, Noeroel Widajati¹
¹Departement of Occupational Health and Safety, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia

ABSTRACT

Based on the ILCI theory, the cause of the direct cause in this case work accident, one of which is job factors. In this study, the job factors studied included K3 supervision and K3 training. This study aims to identify K3 supervision and K3 training available in the company to be further linked to SOP compliance on construction workers in Surabaya bridge infrastructure project.

This study is an observational study and was reviewed from the time of data collection, this study is included in a cross sectional study. The sample taken from this study used a system of random sampling using the Slovin formula to obtain 85 respondents. The variables in this study were K3 training and K3 supervision which were then associated with SOP compliance.

The results showed that there was a relationship between K3 training (0.039) and SOP compliance on construction workers and there was a relationship between K3 supervision (0.0030) and SOP compliance on construction workers.

It is recommended to be more routine in carrying out safety morning talk every morning as well as counseling on the importance of implementing SOP compliance. There needs to be an increase in K3 supervision for construction workers in order to work according to the rules set. There needs to be a reward for obedient workers and a punishment for workers who do not comply. In addition, it is also necessary to regulate working hours so that workers can work effectively and efficiently.

Keywords: K3 Training, K3 Supervision, SOP Compliance

Introduction

Work accident is an occurrence that cannot be planned, controlled, which may cause or result in injury to workers, equipment damage, and other losses (¹). According to BPJS data in 2016 showed that at least 30% of work accident cases came from the construction sector. 80% of work accidents are caused by unsafe behavior and 20% are caused by unsafe working conditions (²). In the ILCI theory unsafe behavior is one of the indirect causes and indirect causes originate from the underlying causes, one of which is job factors. Job factors are factors that exist in work that can be one of the occurrences of unsafe actions for workers. In this study the job factors identified were K3 training and K3 supervision. Training is a process to help workers to gain effectiveness in their present or future work through developing habits of mind, skills, knowledge, and a decent attitude. K3 training is a training that is held and directed to equip, improve, and develop the capabilities, productivity, and welfare of the workforce. While K3 supervision is a series of supervisory activities of all actions carried out by employees of labor inspectors or companies for the fulfillment of the implementation of legislation on the object of supervision of the work environment.

Standard Operating Procedure (SOP) is a series of written instructions from a job or activity that exists in a company. In 2010, research carried out in PT. BBS Indonesia showed that violations of SOPs carried out by workers were 27 people who did not comply with the SOP, and in 2011 rose to 65 construction workers who did not comply with the SOP. According to research conducted by Dyanita (2017), it shows that 81.8% of workers in PT. Sri Murni have been obedient to the procedure and 18.2% of workers were still not compliant with the SOP. In this study, the study aims to identify job factors found in PT. X in this case K3 training and K3 supervision can subsequently be used as a basis for developing programs or improving programs in the company thus later workers can adhere to the SOP and avoid the occurrence unsafe behavior. This study examined the relationship of K3 training and K3 supervision with SOP compliance on construction workers in Surabaya bridge infrastructure projects.

Material and Method

This study is a type of analytic research because it analyzed the relationship between two independent and dependent variables. This study is an observational study because the researcher did not give treatment to the subject under study and only did data collection. Judging from the time the research was conducted in a certain time or the same period of time when carrying out the research later workers can be obedient to the SOP and avoid the occurrence of unsafe behavior. This study examined the relationship of K3 training and K3 supervision with SOP compliance on construction workers in Surabaya bridge infrastructure projects.

The population in this study were 100 workers and sampling was done using system random sampling. The method used to determine the number of samples was using the Slovin formula (3),

$$n = \frac{N}{1 + Ne^2}$$

Note:

n = Total sample
N = population
e = fault tolerance limit (0,05)

Thus the calculation obtained is as follows:

$$n = \frac{100}{1 + 100(0.05)^2}$$

n = 80 workers or 80 samples

However, in this study data was collected in 85 samples to avoid data dropping or incomplete.

The variables in this study were K3 training, K3 supervision and SOP compliance. The instruments in this study used a questionnaire. This study used a chi-square test with a confidence level of 95% with a value \( \alpha = 0.05 \).

Findings

Respondents in this study were construction workers at PT. X, which were 85 respondents with the following descriptions:

Based on this research, the distribution of respondents’ data is as follows:

| Table 1: Distribution of Respondents Based on K3 Training and K3 Supervision |
|------------------|---------|----------|----------|
| Variable Category | Frequency| %        |
| K3 Training       |          |          |
| Trained           | 75       | 88.2%    |
| Less Trained      | 10       | 11.8%    |
| Total             | 85       | 100%     |
| K3 Supervision    |          |          |
| Good              | 53       | 62.4%    |
| Fair              | 19       | 22.4%    |
| Bad               | 13       | 15.3%    |
| Total             | 85       | 100%     |

Based on table 1, it is known that the majority of construction workers in PT. X fall into the trained category, namely as many as 75 respondents or with a percentage of 88.2%. Meanwhile, in PT. X in this case the level of supervision is included in the good category according to construction workers with a frequency of 53 people or with a percentage of 62.4%.

From the research that has been done, it is known that respondents who have been obedient to the SOP are as many as 46 workers or with a percentage of 54.1% and respondents who have not adhered to SOP are as many as 39 people with a percentage of 45.9%. This can be seen in table 2.

| Table 2: SOP Compliance Distribution |
|------------------|---------|----------|----------|
| Variable Category | Frequency| %        |
| SOP Compliance    |          |          |
| Obedient          | 46       | 54.1%    |
| Disobedient       | 39       | 45.9%    |
| Total             | 85       | 100%     |
Bivariate analysis produces data relating the relationship between independent variables consisting of K3 training and K3 supervision which are then associated with the dependent variable, namely SOP compliance. The statistical test used was using the chi-square test.

From the results of the chi-square statistical test between K3 training and SOP compliance it was found that the significance of 0.004 means that it is smaller than alpha, namely 0.05 so it can be concluded that there is a relationship between K3 training and SOP compliance. While the test results of the relationship between K3 supervision and SOP compliance obtained a significance result of 0.003 with an alpha of 0.05 thus there is a relationship between K3 supervision and SOP compliance.

Discussion

According to Ekotama (2011) SOP is a system that is structured to facilitate, tidy up, and discipline our work. This system is a sequential process to do work from beginning to end (4). In this study, the working procedure involved is a repetition procedure. Repetition is carried out on rust that occurs in steel and if peeling or wear of paint. The purpose of the repainting activity is that all the steel elements on the bridge can be covered by paint.

In this study it shows that 46 construction workers are compliant with SOP. The results of statistical tests showed that there was a relationship between K3 training and SOP compliance. Training is one form of the Education process, by conducting research learning objectives or Education goals will gain learning experiences that will eventually lead to changes in behavior (5). Research conducted by PT. X is general K3 training conducted before work begins or training carried out when doing safety morning talk. Training conducted once a month or according to company requirements includes training in the use of APD tools, procedures to first aid in accidents and so on. This research is in accordance with the research conducted by Andrea Krisna that there is a relationship between K3 training and safe behavior in construction workers.

K3 supervision is a series of supervisory activities of all actions taken by employees of labor inspectors or originating from the supervision of HSE companies as fulfillment of the implementation of legislation on the object of supervision of the work environment. In this study it was found that the supervision carried out by PT. X had been included in the supervision in a good category thus because the supervision carried out was good, the workers tended to obey the procedure. In this study it was found that there was a relationship between supervision variables and SOP compliance.

This research is in line with the research conducted by Hayati (2004) that there is a relationship between supervision and compliance with the implementation of SOP for welding workers (6). Supervision carried out in the workplace in this study is quite strict, such as giving a warning in the form of seizure of a Driving License or ID card by HSE to workers who are not compliant with the procedure or workers who do not use APD. The importance of supervision carried out by the party most responsible so that supervision can be carried out wisely and can be obeyed by workers.

Conclusion

1. Construction workers in PT. X have been trained on average and have attended K3 training. K3 Supervision for construction workers in the company falls into the category of good supervision.

2. The average construction worker is aware of SOP compliance that must be done. However, in this study, the frequency between obedient and disobedient construction workers is not much different.

3. There is a relationship between K3 training and K3 supervision with SOP compliance on construction workers.

Recommendation

1. Perform safety morning talk every morning to increase the alertness of construction workers while doing work.

2. Increasing K3 Supervision so that construction workers can work in accordance with established rules.

3. Providing rewards to workers who in a certain period of time obey the SOP and the rules set by the company.
Conflict of Interest: All authors have no conflicts of interest to declare

Source of Funding: This is an article “Relationship of Personal factors and job factors with SOP compliance on construction workers (A Case study of PT. X Surabaya infrastructure infrastructure project) of Occupational Health and Safety Departement that was supported by Faculty of Public Health, Airlangga University

Factors Affecting the Occurrence of Stunting in Indonesia

Nailul Izza1,2, Windhu Purnomo1, Mahmudah3
1Student Master of Public Health at Airlangga University Surabaya, Indonesia; 2Research Center for Humanities and Health Management, Ministry of Health, Indonesia; 3Deparment of Biostatistics, Faculty of Public Health, Airlangga University Surabaya, Indonesia

ABSTRACT

Stunting is an indicator of children’s welfare and a reflection of social inequality. The stunting prevalence in Indonesia ranks fifth in the world, in 2018 it is still above the national target of 30.8%. The scope of the causes of stunting is wide ranging from toddlers themselves, households to the community. This study aims to determine the factors that influence the occurrence of stunting in Indonesia. This research is a non-reactive study because it only carries out secondary data collection obtained from the 2017 Nutritional Status Monitoring (PSG) and Socio-Economic Survey (Susenas) research data. The analysis shows that the factors that influence stunting are household factors that have access to proper sanitation (p value = 0.037). Exclusive ASI variable, toddler weighing > 4 times, energy adequacy, protein sufficiency and poverty did not affect stunting. The factors that influence stunting are the percentage of households that have access to proper sanitation, but are only able to explain 37.2% for stunting. The cause of multifactor stunting, the need to involve other causes such as infection, cases of diarrhea in this analysis that can arise due to low access to proper sanitation.

Keywords: stunting; toddler; sanitation.

Introduction

Childhood stunting is an indicator of children’s welfare and a reflection of social inequality.(1) Stunting is a condition of failure to thrive in children under five (infants under five years old) due to chronic malnutrition so children are too short for their age. Malnutrition occurs since the baby is in the womb and in the early days after the baby is born but the stunting condition only appears after the baby is 2 years old.(2) Toddlers are short (stunted) and very short (severely stunted) are toddlers with body length (PB/U) or height (TB/U) according to their age compared to WHO-MGRS standard of less than -2 SD.(3,4)

The prevalence of stunting in Indonesia ranks fifth in the world,(5) in addition, the prevalence of stunting is still above the national target (<30%), which in 2013 was 37.2 percent and for 2018 it was 30.8% in addition, the prevalence of stunting is still above the national target (<30%), which in 2013 was 37.2% and for 2018 it was 30.8%.6) Based on data from the 2014 Global Nutrition Report that Indonesia is included in 17 countries experiencing a double burden of nutritional problems and as many as 159 million stunting children worldwide 9 million of them from Indonesia.7) The data from the research shows that Indonesia is a country that still has public health problems, in accordance with a statement from WHO to set limits on nutrition problems of no more than 20%,7) Regions with low stunting prevalence (<30%) based on 2018 Riskesdas data is in Bali, while the highest prevalence is in the East Nusa Tenggara Region.6)

The cause of stunting according to a modified concept of UNICEF’s “Logical framework of the Nutritional Problems” 2013 happens because it is multifactorial, which is the direct, indirect and main problem.8,9,10) Direct causes of stunting include breastfeeding factors which are considered very important in addition to supplementary feeding.1) According to the National
Team for the Acceleration of Poverty Reduction that 60% of children aged 0-6 months do not get breast milk exclusively.\(^{(5,11)}\) The results of Anisa’s research that low protein nutrient intake has a chance of stunting 5.775 times compared to toddlers in Kalibaru Sub-district whose protein intake is sufficient.\(^{(12)}\)

Parenting factors are an indirect cause of stunting. One form of parenting is to weigh the toddler’s weight regularly (weigh more than 4 times) to be able to monitor growth.\(^{(13)}\) Stunting is often not recognized in a community where short stature is so common that it is considered normal. Visual identification is quite difficult and the lack of regular assessment of linear growth in primary health care services contributes to stunting.\(^{(13)}\)

The availability of proper sanitation is one of the environmental factors needed to nurture mothers and children because it can be an indirect cause of stunting.\(^{(8,10)}\) Poor sanitation facilities can increase the incidence of infectious diseases because the energy for growth is diverted to resistance to infection so that nutrients cannot be absorbed properly and inhibit growth.\(^{(13)}\) The lack of fulfillment of nutrient intake in the family itself is also due to lack of food availability in households that are affected by low family income.

The scope of the causes of stunting is wide ranging from toddlers themselves, households to the community. Based on the description of the background, this study aims to determine the factors that influence the occurrence of stunting in Indonesia.

### Method

This research data uses secondary data obtained from research data “Nutritional Status Monitoring (PSG)” in 2017 by the Directorate of Community Nutrition of the Ministry of Health of the Republic of Indonesia\(^{(4)}\) and the Central Bureau of Statistics through 2017 socio-economic survey (Susenas).\(^{(14,15)}\) The unit of analysis of this study is the provinces in Indonesia, which number 34 provinces.

Data were analyzed using the multiple linear regression method enter. The multiple linear regression function to determine the effect of independent variables on the dependent variable, besides that it can model the state of the variable that is affected and the variables that influence it. The equation for multiple linear regression models is:

\[
Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \ldots + \beta_kX_k
\]

**Description:** \(Y = \) independent variable; \(X = \) independent variable (bound) \((i = 1, 2, 3, \ldots, k); \beta_0 = \) intercept; \(\beta_1 = \) regression coefficient \((i = 1, 2, 3, \ldots, k).\)

### Results

Bali Province is the province with the lowest stunting prevalence of 19.1%, while East Nusa Tenggara Province is the province with the highest stunting prevalence of 40.3%.

![Figure 1: Stunting prevalence by province in Indonesia, 2017\(^{(4)}\)](image)

Table 1 shows the percentage of poverty is the variable with the lowest average value, while the variable with the highest average value is the variable weighing under five more than 4 times (X2).

</tbody>
</table>

The results of multiple linear regression analysis in table 2 show that only significant value of sanitation access variables (X6), while exclusive breastfeeding variables, toddler weighing> 4 times, energy adequacy, protein adequacy, and poverty did not affect stunting. As for the T test the regression equation was obtained, namely:

\[ Y = 38,760 - 0,208 \text{ access to proper sanitation} \]

The value of households that have access to proper sanitation of 0,208 means that if a household that has access to proper sanitation increases by 1 point, then the prevalence of stunting will decrease by 0,208.

Discussion

Provinces that have a stunting prevalence below the national prevalence rate (29,6%) are only one-third of the provinces in Indonesia in 2017. The number of provinces with stunting prevalence is still above the national level making the region included in the category.
of experiencing chronic acute health problems. Based on the category of community nutrition problems by WHO in 1997 stated that a region is said to experience acute acute nutritional problems if the prevalence of under-fives is short 20 percent or more and the prevalence of under-fives is thin 5 percent or more. \(^{(4)}\) WHO set limits on nutritional problems no more than 20\%, \(^{(7,8)}\)

The lowest stunting prevalence was in Bali Province (19,10\%) while the highest province was the prevalence of stunting in NTT Province (40,30\%), the magnitude of the gap that occurred indicated an unequal imbalance and development. \(^{(16)}\) Handling the problem of stunting seems very slow, globally the percentage of children who are stunted has decreased only 0.6\% per year since 1990. WHO proposes a global target of decreasing the incidence of stunting in children under 40 percent by 2025, but predicted only 25-36 countries who are able to meet these targets. \(^{(17)}\)

The results of multiple linear regression analysis indicate that the factors that influence stunting are household factors that have access to proper sanitation (\(p = 0.037\)) with the equation model:

\[
Y = 38,760 - 0,208 \text{ access to proper sanitation}
\]

Exclusive ASI variable, toddler weighing \(> 4\) times, energy adequacy, protein adequacy and poverty level did not affect the occurrence of stunting in Indonesia. The percentage of households that have access to proper sanitation increases by 1 point, then the prevalence of stunting will decrease by 0,208. This is reinforced by the results of the analysis of \(R^2\) value of 0.372, which means the percentage of households that have access to proper sanitation is only able to explain the magnitude of variation in stunting by only 37.2\%, while the remaining 62.8\% is explained by other variables not included in the equation variable studied.

The results of this study are not in line with the research conducted in the Kalibaru Sub-district of Depok that the low intake of protein nutrients has the opportunity to stunting 5,775 times compared to toddlers with sufficient protein intake. \(^{(12)}\) The results of research conducted by Aridiyah et al (2015) in the Patrang and Mangli Jember Community Health Center work areas that in rural areas protein and calcium adequacy are associated with stunting, but not in urban areas. \(^{(18)}\) Research conducted by Setiawan, et al (2018) said that the low level of energy intake had an effect on the occurrence of stunting (\(p = 0.001\)). \(^{(19)}\)

The results of the research conducted by Setiawan, et al (2018) that exclusive breastfeeding status did not affect stunting (\(p = 0.464\)). \(^{(19)}\) However, it is different from the results of Aridiyah’s research (2015) that exclusive breastfeeding is related to the incidence of stunting in infants in both rural and urban areas (\(p\) value <0.05). \(^{(18)}\)

Based on the WHO concept that lack of available water and sanitation infrastructure is one of the factors causing stunting at the community level. \(^{(15)}\) Lack of access to clean water and sanitation. Data obtained in the field shows that 1 in 5 households in Indonesia still defecate in open spaces, and 1 in 3 households do not yet have access to clean drinking water. \(^{(5,11)}\) One form of activity that can contribute to stunting reduction through Specific Nutrition Interventions is providing and ensuring access to clean water and access to sanitation.

Olaf Muller (2005) reported that the condition of environmental sanitation in developing countries was in a bad category. \(^{(20)}\) Poor sanitation conditions increase the incidence of infectious diseases, leading to a high prevalence of malnutrition. Households with the ability to be able to access proper sanitation will certainly be able to minimize the attacks of various diseases such as ARI, diarrhea and other infectious diseases. The results of the research conducted by Mustikaningrum A, et.al (2016) showed that the incidence of diarrhea was a determinant of the incidence of stunting, in which infants with diarrhea were at a risk of 2,14 times stunting compared to those without diarrhea. \(^{(21)}\) The average prevalence of diarrhea increases with increasing disparity in the prevalence of stunting (\(p = 0,000\)). \(^{(22)}\)

The factors that cause stunting are very complex, therefore the intervention efforts undertaken also involve various sectors, both the health sector and the non-health sector. Stunting is caused by multi-dimensional factors and is not only caused by malnutrition factors experienced by pregnant women and children under five. Results of discussions conducted by Aryastami (2017) efforts to reduce nutrition problems must be handled cross-sectorally in all lines, strengthening the system so that the 1000 First Days of Life (HPK) become part of the culture and social life in the community. \(^{(7)}\)
The results of the literature review conducted by Mitra that the reduction in stunting was focused on Scaling Up Nutrition (SUN) or the national nutrition awareness movement carried out on the first 1000 days of life.\(^{(17)}\) The principle of the Scaling Up Nutrition movement is that everyone has the right to good food and nutrition. The results of the research conducted by Kusudaryati, et.al (2017) said that the adequacy of Zn had a significant effect on changes in the Z score of TB/U \((p = 0.042)\), so that the presence of sufficient Zn intake would help deal with the occurrence of stunting.\(^{(23)}\)

**Conclusion**

Factors that can influence stunting are households that have access to proper sanitation. Whereas, exclusive breastfeeding variable, toddler weighing > 4 times, energy sufficiency, protein sufficiency, insignificant poverty. The percentage of households that have access to proper sanitation is only able to explain 37.2 percent for stunting. So the causes of stunting are 62.8 percent of which are caused by many other factors.

**Suggestion**

The cause of multifactor stunting, the need to involve other causes such as infection, cases of diarrhea in the analysis that can arise due to low access to proper sanitation.

A Study of Job Burnout among Faculty Teacher at Kirkuk University

Nashwan Nadhim Hasan¹, Faisal Younus Sameen², Fakher Abobaker Ahmed Gli³, and Kasim Sakran Abass⁴

¹Department of Fundamental Nursing, ²Department of Adult Nursing, ³Department of Community Nursing, College of Nursing, ⁴Department of Pharmacology and Toxicology, College of Pharmacy, University of Kirkuk, Kirkuk, Iraq

ABSTRACT

Burnout and stress at work area have undesirable effect on individual and the organization. Among human service workers the teachers have the highest levels of burnout. The main objective of this study was to identify presence of burnout among Kirkuk university teachers and relationship with the sample sociodemographic characteristics.

However, quantitative study (Descriptive design) implemented on Kirkuk university teachers, during the period from (10 Jun 2017 up to 1 May 2019). The results show Kirkuk university teachers experienced moderate level on subscales of burnout. Lecturer assistant had higher intensity in emotional exhaustion and depersonalization subscales while professors more lack of personal accomplishment. In conclusion, generally the teachers at Kirkuk University had a moderate level of burnout. Furthermore, when making policies concerning the welfare of teachers, the management should listen to teachers' opinions and involve them in the policy-making process.

Keywords: Job, Burnout, Teacher, Kirkuk, University

Introduction

Freudenberger was first who used term “Burnout” in 1974(1). Burnout defined as “that what started out as important, meaningful, and challenging work becomes unpleasant, unfulfilling, and meaningless”(2). Burnout and stress at work area have undesirable effect on individual and the organization(3). Among human service workers the teachers have the highest levels of burnout(4). Educator burnout has presented itself as an emerging problem in the mental health field over the past 50 years (5). Generally known that burnout has three essential subscales. The first subscale is emotional exhaustion (EE), includes loss of energy and physical debilitation. Cynicism or depersonalization (DP) are the second subscale which is includes loss of idealism and a negative view towards clients. third subscale is known as lack of professional efficacy or lack of personal accomplishment (PA), which includes a negative view toward oneself, inability to adapt and low self-esteem(6). More than 41% of teachers leave the profession within five years of starting, and teacher attrition has risen significantly over the last two decades(7). Almost 66% of the teachers leaving the occupation for careers elsewhere(8).

Methodology

Quantitative study (Descriptive design) implemented on Kirkuk university teachers, during the period from (10 Jun 2017 up to 21 October 2018). To identify presence burnout among Kirkuk university teachers and relationship with the sample sociodemographic characteristics. A probability sampling (Cluster type) used to select 204 teachers from 10 different Kirkuk university colleges.
Consisted of two parts: part one was developed by investigators “Socio-demographic characteristics” consist from the (teachers College, Marital Status, Gender, age, Academic qualifications, Teaching Experience, Educational background, Teaching workload, and have chronic disease). Second part of the questionnaire consist of 22 items divided into three subscales first and second subscales Masluch Burnout Inventory, Educator Edition(MBI-ES) instrument scoring identified according to dimensions, for Emotional Exhaustion (EE) and Depersonalization (DP) high scores indicate a high Burnout level while in Personal Accomplishment (PA) indicate low level of Burnout. The instrument was translated into Arabic language and used for data collected through self-report method. Participants respond on a seven-point frequency rating scale, ranging from “never” (0) to “every day” (6). The sensitivity value was 0.875. The data were entered and analysed through the Statistical Package for Social Sciences (SPSS) version 25.

|               | >56 yrs.                        | 4(4.3)   | 20.5(10.7)   | 8.2(8.0)     | 36.2(11.4)   |
Table 3 shows highly significant and significant relationship between teachers College and EE and PA subscales subsequently. Teaching workload had highly significant relationship in comparing with PA subscale finally Having a chronic disease significant relationship in comparing with EE subscale.

**Discussion**

This study shows in Figure 1 teachers of the College of law had best response to participate in the study they responded by 12 teachers while, only 5 teachers responded from college of Education for Human Science.

Table 2 shows that mean of Kirkuk University teachers a moderate level according to burnout subscales. The finding coincide with study among female teachers in Malaysia by Mukundan and Ahour (2011) (11). Current study finding also congruent with the Luk, et al. (2010) finding regarding to the EE and PA subscales and incongruent with DP subscale(12). University administration must provide appropriate mechanisms to diagnose the stressors that causing strain in university instructors (13) and it is important to provide the basic psychological needs for teachers (14) and linked with better autonomous motivation, job satisfaction, work related well-being and organizational adherence(15).

From Table 2 noted that 42.4% of teachers suffers from high level of EE burnout. Regarding DP subscale 45.7% of teachers had low level of burnout and 47.8% of sample complaining from low level of lack on Personal Accomplishment. Above findings indicates that teachers at Kirkuk University complaining from first subscale which is emotional exhaustion. Emotional Exhaustion burnout among teachers influenced by many factors and the most important factor in predicting emotional exhaustion among teachers is disruptive behaviour(16). Iraq has entered several wars over the past decades and the wars have had a negative effect on health in general in addition to the abuses that have been recorded against human rights(17).
The Iraqi community need an urgent education and provision effective mental health care(18).

Table 3 illustrate sociodemographic characteristics of the sample in addition to the relationship with burnout subscales. First variable shows the distribution of teacher according to the college and which had a highly significant relationship with EE subscale and significant DP subscale at p value .002 and .021 respectively. on the other hand, non-significant relationship teacher college with PA subscale. Concerning to the highly significant relationship between teacher’s college and emotional exhaustion subscale. Nursing college teachers had highest mean by 34.5 of burnout while, Agriculture and Medicine teachers had lowest mean subsequently by 16.6 and 16.9. There is little literature about this relationship. Ling Qin et al. (19), find highly significant relationship between burnout and speciality. While study of Al-Mehasi and Al-Sumaili (2016) (20) more precisely found that burnout had significant relationship with teachers speciality. These results provide the administrators with useful information in developing policies to overcome or at least decrease teacher’s burnout.

About teacher’s marital Status most of responded were Married and non-significant relationship between teacher’s burnout and marital status. This result like the findings of (12, 21, 22).

Fourth variable in the Table 3 illustrate the age groups of participants the mean of age was 40.23 ± 8.09. The relationship between age and burnout subscales outcome display that non-significant differences. These result same with findings Coulter and Abney (2009) (25).

Fifth variable of Table 3 shows that Lecturer account about half of teachers also illustrate non-significant relationship between teacher’s academic qualification and burnout subscales. In comparing with previous results Li (2015) found non-significant relationship between first and third subscales of burnout with academic qualification. while, adversely second subscale highly significant relationship between academic qualification and DP subscale(23). Lackritz found non-significant burnout relationship with teachers rank (Assistant Professor, Associate Professor and Professor) while significant relationship with teachers Status (Tenured, Probationary and Lecturer) (30). Jackson et al. (1993) (31) they found significant relationship between teachers academic qualification and burnout. Non-significant relationship between teachers in current study may be due to instability of security in addition to environment of working are same for all teachers and most of teachers not acquiring social support from university or society.

Table 3 reveals non-significant between teaching Experience relationship with burnout subscales. In related to the earlier finding Luk (12) found non-significant relationship between both DP and PA sub-scales with teaching Experience. On the other hand, Luk results indicated significant relationship with EE subscale. Contrarily Li (2015) study outcome demonstrate teaching experience had non-significant relationship with first subscale while, teaching experience had a significant relationship with second and third subscales(23).

Table 3 indicate significant relationship between teaching workload with PA subscale. While non-significant relationship with other two subscales. Skaalvik in (2009) (2011) found that Time pressure positively correlated with EE sub-scale but not with the other sub-scales(32, 33). Lou and Chen (2016) used one-sample t-test to found significant relationship between subscale workload categories 11 - 20 hours/week and Over 21 with both of EE and DP subscales. On the other hand, significant relationship between PA subscale at two categories of workload <10 hours/week and 11 - 20 hours/week. Whereas, significant relationship between workload > 21 hours and personal accomplishment subscale (26).

**Conclusion**

Generally the teachers at Kirkuk University had a moderate level of burnout. When making policies concerning the welfare of teachers, the management should listen to teachers’ opinions and involve them in the policy-making process.

IL-18 -607 Gene Polymorphisms in Iraqi Obese Patients

Nawal Mohammed Utba

Department of Biology, College of Science, University of Baghdad, Al-Jaderia, Baghdad, Iraq

ABSTRACT

Obesity is a serious medical illness where excess body fat has stored to the amount that it might have a negative impact on health. In general, people are regarded as obese when their body mass index is more than 30 kg/m$^2$. A total of 100 Iraqi subjects from Wasit province were included in this study, 50 of them had normal weight with BMI less than 25 kg/cm$^2$ and 50 obese with BMI more than 30 kg/cm$^2$. The polymorphisms were analyzed using single specific primer-polymerase chain reaction at the position -607 C/A (rs1946518). The genotype frequencies of normal weight group were in agreement with the Hardy-Weinberg equilibrium. While the genotype frequencies of obese group revealed significant variation ($P> 0.05$). In conclusion, IL-18-607 A alleles, CC, and CA genotypes showed positive association with the obesity in Iraqi Arab population or protection against it.

Keywords: obesity, overweight, IL18 gene polymorphism, BMI, Iraq.

Introduction

Globally, obesity is one of leading avoidable causes of death; significantly, its rates are increased in both adults and children. People are commonly regarded as obese when their body mass index (BMI) exceeds 30 kg/m$^2$. Obesity have a negative effect on health and increases the likelihood of various diseases, particularly heart disease, type 1 diabetes, obstructive sleep apnea, certain types of cancer, osteoarthritis, and depression. In 2014, 600 million adults (13%) and 42 million children under the age of five were obese and obesity is more common in women than men. The prevalence of obesity can vary greatly by gender, race/ethnicity, and socioeconomic status. In 2016, the rate of obesity prevalence in Iraqi adult is 30.4%. Xu et al. indicated that the adipose tissue, in addition to energy storage, harboring inflammatory cells which are thought to maintain inflammation and damage adipocyte function. Such consequences might be occurred through cytokines produced in significant amounts from adipocytes, in addition to inflammatory cells employed into adipose tissue. Numerous proinflammatory cytokines (e.g. IL-1 family) have been designated to be raised in overweight and obese individuals. IL-18, as one of IL-1 family, plays a regulatory role through the induction of IFN-γ that applies alterations in a variable range of cell types and is linked with the pathogenesis of many inflammatory diseases such as obesity. The present work aimed to explore possible association of IL-18-607 polymorphisms in the development of obesity in Iraqi subjects from Wasit province.

Materials and Method

Study Subjects: A total of 100 Iraqi subjects from Wasit province were included in this study, 50 of them had normal weight with BMI less than 25 kg/cm$^2$ and 50 obese with BMI more than 30 kg/cm$^2$. All enrolled subjects were non-smokers and with no proof of cancer and free of any metabolic disorders other than obesity. All participants gave informed consent before enrolling in the research, which was approved by the Biology Department, College of Science, Baghdad University ethics committee in accordance with the Helsinki Declaration.

Lipid Profile Analysis: Sera were collected from all subject groups. Lipid profile test were evaluated by using semi-automatic biochemistry analyzer BTS-350.
(Biosystems/Spain) according to the manufacturer’s instructions.

**DNA Extraction:** DNA extracted from studied subjects blood sample by using the Wizard® Genomic DNA Purification Kit (Promega/USA) and the purification was done according to kit instructions.

**Detection of IL18 - 607 C/A Genotypes:** The polymorphisms were analyzed using polymerase chain reaction-single specific primer, at the position -607 C/A (rs1946518) in the promoter of *IL18* gene with minor modifications.

Reactions were carried out in a Bio-Rad PCR thermal cycler (T100/USA). PCR reaction was performed in Accupower® PCR PreMix tube with a final volume of 20µl consisting of 5 µl of 10-25ng DNA template, 1 µl of each of the reverse primer and sequence-specific forward primers (10 pmol/µl), and 12µl of nuclease-free water.

An IL-18-607 common reverse primer 5'-TAACCTCATTCAGGACTTCC-3' and two sequence-specific forward primers 5'-GTTGCAGAAAGTGTAAAAATTATTAC-3' and 5'-GTTGCAGAAAGTGTAAAAATTATTAA-3' were used in order to detect an amplification product of 196 bp. Reaction conditions consisted of initial denaturation at 94°C for 2 min followed by 7 cycles of denaturation at 94°C for 20 sec., annealing at 64°C for 40sec. and extension 72°C at 40 sec., then 25 cycles of denaturation at 94°C for 20 sec., annealing at 57°C for 40 sec. and extension at 72°C at 40sec. Lastly final extension at 72°C at 5 min. PCR products were visualized by 2% agarose gel electrophoresis stained by ethidium bromide.

**Statistical Analysis:** All statistical analysis was performed using statistical package for social science program version 17 for Windows (SPSS INC., Chicago IL, USA). Results were expressed as mean ± SD. Comparisons between two groups were performed using T-test for categorical data. P value of <0.05 were considered to indicate statistical significance.

Genotypes of *IL18*-607 were presented as frequencies percentage, and significant differences between their distributions in subject groups were assessed by two-tailed Fisher’s exact probability (P). Also, odds ratio (OR), etiological fraction (EF) and preventive fraction (PF) were calculated to define the association between a genotype with the disease. These estimations were calculated by using the WINPEPI computer programs for epidemiologists. The latest version of the WINPEPI package (including the programs and their manuals) is available free online at http://www.brixtonhealth.com.

Allele frequencies of *IL18*-607 genes were estimated by direct gene counting methods, however, compatibility to Hardy-Weinberg equilibrium (H-WE) was calculated using H-W calculator for two alleles, which is available free online at http://www.had2know.com/academics/hardy-weinbergequilibrium-calculator-3-alleles.html. Significant differences between the expected and observed frequencies are assessed by Pearson’s Chi-square test.

**Results and Discussion**

**Demographic characteristics of the subject groups:**

The clinical characteristics of the subject according to their BMI and lipid profile test are listed in Table 1. For best separation among phenotypes, the participants were divided into two BMI groups: normal weight (BMI >25 kg/m²) and obese (BMI ≥30 kg/m²).

**Table 1: Demographic characteristics of the subject groups**

HDL: high-density lipoprotein, LDL: low-density lipoprotein, VLDL: Very low-density lipoprotein, NS: non-significant, S: significant difference P < 0.001.
In the present study, there were significantly increased level of cholesterol, Triglyceride, and LDL in the serum of obese group than normal weight group and significantly decreased level of HDL in obese than normal weight. While VLDL showed insignificant increased in obese than normal weight group.

This Finding agreed with many previous studies around the world. In Poland, obesity and overweight are accompanied by unfavorable blood lipid patterns. Mean total cholesterol and triglyceride concentrations were higher in obese persons in comparison to normal weight subjects. HDL cholesterol concentration was lower in obese subjects as compared to normal individuals. The mean concentrations of LDL cholesterol showed insignificant variation. In India, obesity is associated with increased serum lipid profile levels except HDL-Cholesterol. And in Pakistan, all the parameters of lipid profile except serum HDL level showed significant increase in obese persons while HDL level was significantly decreased. Aljaffar [10] found that the adult obese has relatively larger changes in serum lipids at any given level of obesity in Karbala/Iraq. Furthermore, he observed a significant increase in levels of serum cholesterol; LDL and a significant decrease HDL level in obese woman and men.

The greater increase in BMI the greater the abnormalities in lipid levels. Approximately 60-70% of patients who are obese are dyslipidemic while 50-60% of patients who are overweight are dyslipidemic. The increased risk for cardiovascular disease in patients with obesity is partially accounted for by this dyslipidemia.

**Frequency of genotypes and allele in subject groups:**
The genotype and allele frequencies for IL-18 -607 polymorphisms are summarized in Table 2. The genotype frequencies of normal weight group were in agreement with the H-WE. While the genotypes frequencies of obese group showed a significant variation (P > 0.05). This variation was observed due to differences between the observed and expected frequencies of CC, CA and AA genotypes.

**Table 2: Observed and expected numbers and frequencies percentage and H-WE of IL-18 -607 genotypes and alleles in subject groups**

The results of present study were in agreement with Lin-Kim et al., results in normal weight Korean population but not in obese, as they found that the IL-18 607 genotype frequencies were in agreement with the H-WE in normal weight and obese group. Also, the results of this study did not agree with Fatima et al. who reported that in South Asian population, the IL-18 -607 genotype distributions was compatible with H-WE in total study subjects and in subgroups (Normal Weight, Overweight and Obese). The deviation from H-WE are observed in different populations (ethnicities) because the factors that influence the equilibrium are ethnicity–based.

Comparing between subject groups, IL-18 607 CC and CA genotypes showed significantly variations; CC genotypes significantly increased in obese (56 vs. 18%; P > 0.001), with OR value of 5.8 and the EF of such difference was 0.46. While IL-18 -607 CA genotype was insignificantly decreased in obese (16 vs. 64%; P > 0.01), with OR value of 0.26 and the PF of such difference was 0.47. However, in terms of allele frequencies, the C alleles were significantly increased (72 vs. 50%, P > 0.01) in obese than normal weight groups, while allele A was significantly decreased (28 vs. 50%, P > 0.01) in obese compared to normal weight individuals, as shown in table-3.

OR= odds ratio; 95%CI = 95% confidence interval.

The results indicated that IL-18-607 C (OR= 0.44, P=0.002) and A (OR=0.3, P=0.002) alleles and CC (OR= 5.8, P= 0.001) and CA (OR= 0.25, P=0.003) genotypes showed positive association with the obesity in Iraqi Arab population or protection against it, and the recorded OR, EF and PF values are in favor of such conclusion. This result was conflicting with Lin-Kim et al. 12 results demonstrated insignificant differences in the genotype distribution and allele frequency among Koreans (overweight and obese subjects) and controls (normal weight). While Fatima et al. 13 reported that the percentage of IL-18 -607 A/A genotype was higher in overweight and obese vs. normal weight subjects (P < 0.001), which is also not coincide with the results of this study.

Obesity is marked by low-grade chronic inflammation. On the other hand, IL-18 has various functions in chronic inflammation and autoimmune disorders. Moreover, it has been proposed as an adipogenic cytokine, which is implicated in excess adiposity12. IL-18 is considered as an imperative regulator of both innate and acquired immune responses besides its role in functional cytokine network being an essential player in the homeostasis of the immune response; consequently, any alteration may result in an abnormal immune response. Furthermore, diverse pathological and infectious disorders may lead to an alteration in the cytokine network, and later confuse the pathological events. Henceforth, studies concentrated on genes regulating the cytokine expression; particularly, on gene polymorphisms that may affect the expression levels and thus the whole immune response15.

BMI and lipid profile distribution according to IL-18 607 genotypes: BMI and lipid profile test in obese and normal weight groups distributed by IL-18 607 genotypes are shown in Table 3. There are insignificant variations between IL-18 -607 genotypes in both obese and normal weight groups for cholesterol, triglyceride, LDL and VLDL serum levels. Whereas BMI and HDL showed significant variations between CC, CA and AA genotypes of normal weight group (the higher BMI was observed in CC genotype followed by AA then CA genotypes, however, the higher serum levels of HDL was in CA genotypes followed by AA then CC genotypes). BMI and HDL serum level was insignificant differences between obese group genotypes.

Different letters denoted to significant variations, SD denotes to standard deviation, NS denotes to non-significant.

Lin-Kim et al. 12 analyzed the polymorphism of the genotype distributions and they found that IL-18 −607C/A associated with an increase in BMI in obese women in the Korean population. However, Fatima et al. 13 reported that subjects with AA genotype had a higher BMI, in south Asian population and they did not find any difference in the lipid profile between the three subgroups. Nevertheless, we did not find significant difference in the BMI and lipid profile test between three genotypes in subject groups except BMI and HDL in normal weight had a significant difference between them.

The mechanism how the IL-18 gene polymorphism may affect obesity is associated with IL-18 synthesis, secretion, and activity. Definitely, an elevated circulating IL-18 concentration has been found in obese and insulin resistant people.16,17 Furthermore, serum IL-18 was increased in obese women has been declined when body weight was lost.18

Conclusion

According to the results of this study, IL-18-607 C, A alleles and CC, CA genotypes showed positive association with the obesity in Iraqi Arab population or protection against it. BMI or lipid profile test showed insignificant variations between IL-18 −607 genotypes in obese.

Correlation between Pain and Cone Beam CT Sialographic Finding in Chronic Inflammatory and Non-Inflammatory Conditions

Nermien Ali Mohamed Fathy¹, Maha Eshak Amer²

¹Assistant Lecture, ²Head, Oral and Maxillofacial Radiology Department, Faculty of Dentistry, Minia University

ABSTRACT

Objective: The aim of this study to evaluate the radiographic finding of CBCT sialography in patients suffering from pain in chronic inflammatory and non-inflammatory lesions of salivary gland.

Patients and Method: Twenty patients of both sexes and varying ages were selected complaining from pain in chronic inflammatory and non-inflammatory salivary gland lesions diagnosed by patient history, clinical examination and were undergone CBCT sialography scanning. Then all images were analyzed and scored, the radiographs had been evaluated by three radiologists independently of each other and the findings were correlated to pain as a clinical symptom.

Results: There was statistically significant difference between the presence of pain and the visualization of the main duct, while there is no statistically significant difference between all cases experienced different degree of pain and all parenchymal finding.

Conclusion: CBCT sialography can detect salivary glands with secondary inflammatory changes, moreover, the presence of pain as clinical symptoms is important in the evaluation of non-tumor lesions of salivary glands, it has no correlation with CBCT sialographic finding

Keywords: pain, sialography, cone beam CT

Introduction

Salivary glands diseases are many but they are broadly categorized into inflammatory conditions, non-inflammatory conditions, and space occupying masses. (¹) Symptoms of salivary gland disorders are limited in number and generally nonspecific as Patients usually complain of swelling, pain, xerostomia, foul taste, and sometimes sialorrhea (excessive salivation). (², ³)

The common clinical indications of salivary gland imaging are pain and swelling which are important in the diagnosis of salivary gland disorders. A comprehensive history and physical examination are the first order for evaluation of salivary gland disorders and there are specific points must be examined such as the onset and duration of symptoms, their frequency, the presence of swelling and pain, and the characteristics of salivary secretion. (⁴)

A complete history and focused physical examination are crucial in evaluation of patients with obstructive/inflammatory salivary gland disorders. Key points should include the acute onset or long persistence of gland swelling, associated fever or pain, drug exposures, history of malignancy and chronic illnesses such as rheumatologic diseases or sicca syndrome. (⁵)

Swelling and pain were classified into the 4 categories of normal, swelling, pain, and both swelling and pain. (⁶)

Sialography is a functional examination of the parotid and submandibular salivary glands that was first performed in 1902. It maps the delicate ductal structures
of the salivary glands following the introduction of an iodinated contrast agent through the orifice of the gland duct. The gland is then imaged with ionizing radiation (plain film, CT, fluoroscopy or cone beam CT) (7), the procedure is indicated to assess the extent and severity of the resultant changes to the gland (8).

Hence, this study aimed to correlate between clinical symptoms (pain) and radiographic finding of CBCT sialography.

Patients and Method

Twenty patients (Adults over 18 years of age) were selected into this prospective clinical study over a two-year time period from June, 2016 to July 2018, from the outpatient clinics of Minia University Dental Hospital. This study was approved by the (Research Ethics Committee) (REC) under number 172 in 27/6/2016, Faculty of Dentistry, Minia University before starting the research and all the entire patients had signed a standardized informed consent laid down by REC explaining the nature and the procedures of the study protocol, only those who agreed to sign the consent were included in this study.

Inclusion criteria in this study were patients having signs and symptoms related to a salivary gland disease, based on the presence of symptoms of pain of the parotid or submandibular salivary gland, while exclusion criteria were the presence of acute stages of inflammation affecting the salivary glands, known or suspected allergy to iodinated contrast agents, or an immediately anticipated thyroid function test had been excluded and neoplastic condition of salivary glands.

Detailed history taking and clinical examination of the patients were performed thorough extra- and intra-oral examinations were performed to determine the presence of a swelling, and pain.

Sialography was performed by probing and cannulation of ducts for affected salivary gland and, followed by injection of approximately 1.5-1.7 mL Urografin contrast media until the patient felt fullness. The gland of interest was imaged by CBCT examination was performed using Scanora® 3D with Auto- SwitchTM (Soredex, Helsinki, Finland) with 85 kVp, 15 mA, and a field of view (FOV) of 4 cm for the submandibular gland and 5 cm for the parotid gland. On Demand 3DTM software (Cybermed Inc., Seoul, Korea) was used to manipulate the CBCT images in multiplanar slices as well as three dimensional images to examine the lesions.

Three radiologists evaluated the images separately and scores were given for the interpretation of the images according to the following scoring systems.

A scoring system was performed to evaluate the visualization of the duct:

Not visualized: 0, Visualization: 1.

The width and contour of Duct system: (main duct, and intra glandular branches): Normal: 0, Narrow with or without irregularity: 1 Dilated with or without irregularity: 2 and, Destroyed: 3.

The sialectasis: based on the accepted criteria proposed by Rubin and Holt According to the size of contrast material collections in the gland: Stage-0: Nosialectasis., Stage-I: Punctate; <1 mm in diameter., Stage-II: Globular; 1–2 mm in diameter.

Stage-III: Cavitary; >2 mm in diameter. Stage-IV: Destructive; severe irregular dilatation of the main duct and destruction of the parenchyma with pooling of contrast medium giving a bizarre pattern.

Retention of contrast, absent 0, and Present 1.

The above mentioned scoring system for evaluation was used by each radiologist to assess the interpretation separately.

Data was analyzed using IBM SPSS statistics version 24. Numerical data were expressed as mean and standard deviation. Qualitative data were expressed as frequency and percentage. Chi-square test (Kruskal Wallis test) was used to examine the relation between qualitative variables. Intraclass correlation coefficient test “Cronbach’s alpha” was used to test the inter-rater reliability. p-value < 0.05 was considered significant.

Results

Twenty 20 patients in this study 8 cases (40%) were male while the remaining 12 cases (60%) were females. The ages of the patients ranged between 20 to 60 years with a mean age of 40 years, (4 cases, 20%) were healthy with non-contributory medical histories. 10 subjects (50%) reported rheumatoid. Two subjects
had received previous anti-hypertensive treatment. In total, 17 parotid glands and 3 submandibular glands were examined. Referral to clinic for sialography was primarily from oral and maxillofacial radiology, all subjects were symptomatic, and most subjects (80%) reported pain. 14 subjects (80%) reported dull pain and 4 subjects (20.0%) reported sharp pain. 1 another subject (5%) reported “discomfort”.

In an attempt to correlate the radiographic findings detected by CBCT sialography concerning the duct with pain, results are shown in table (1).

This table shows that there is no statistically significant difference between all cases experienced different degree of pain and all ductal finding except the visualization of the main duct and all cases with mild pain had dilated duct while narrow or dilated duct was detected in 37% of the cases of moderate pain and this relation was not statistically significant moreover, cases with different degree of pain the CBCT sialography can detect any number of strictures that was located in the main duct.

In an attempt to correlate the radiographic findings detected by CBCT sialography concerning the parenchyma with pain, results are shown in table (2).

This table shows that there is no statistically significant difference between all cases experienced different degree of pain and all parenchymal finding. However, the presence of different pattern of sialectasia had been detected in 50% of cases with moderate pain, acinar dilatation more than 2/3 with or without severe dilatation of the entire glandular area was differentiated in 25% of cases with moderate pain, in addition the retention of contrast was found in 75% of cases with moderate pain.

The inter observer agreement was very good regarding to CBCT sialographic finding, results are shown in table (3).

** Highly significant

This table shows that there was strong agreement due to very high similarity between raters

Discussion

In this study the cases were diagnosed as non-tumor salivary gland diseases and were suffered from pain as the most common symptom.

Oscar 2010(9) who revealed that modern sialography is not time-consuming, and the refinement of intravenous catheters has made the procedure painless and easy to perform, the contraindications for the procedure include when the duct is blocked by sialolithiasis or the presence of an internal stricture, in both situations, duct dilatation with probes and sialography is not possible.

However, this result in dis agree with a study performed by Weber in 1992(10) stated that the cannulation of the duct cannot always be achieved even in the absence of duct abnormality, also the orifices of
the submandibular ducts were difficult to identify, and cannulation may be impossible.

In this study, all patients experienced no pain during infusion of the contrast material, and only 5% of the cases reported discomfort and slightly unpleasant, and this result was in disagree with Kalk et al 2001 (11) who reported on the morbidity of the procedure as most of their patients included in their study reported discomfort, and slightly unpleasant.

This study didn’t not report any iatrogenic conditions.

There was very strong inter observer agreement in visualization of the normal gland structures and in identifying abnormal findings for CBCT images as the three observers were all certified specialists in oral and maxillofacial radiology with extensive training in sialography and advanced imaging interpretation as CBCT sialography highly sensitive for depicting changes in the delicate ductal anatomy because of its relatively high spatial resolution.

Few reports have been published about correlation between clinical symptoms and the degree of inflammation in major salivary glands, this study studied the correlation between common clinical symptoms (pain) and sialographic diagnostic images finding.

In this study all cases experienced mild and moderate pain had statistically significant relation with the visualization of the main duct as all cases with mild pain had dilated duct and this result was in harmony with UGGA et al in 2017 (5) who reported that Patients presented with pain of the concerned salivary gland diseases, their CT finding showed dilated duct from sialolithiasis or stenosis and enlarged intra- or extra- glandular lymph nodes may also be seen but this is non-specific and can occur in other conditions such as malignancy.

In this study there was not statistically significant difference between the severity of the pain and the ductal finding regards to { the presence of abnormality of main duct, intra glandular duct and the number of strictures } as well as all parenchymal radiographic finding as most of cases with moderate pain and severe pain showed normal intra-glandular duct without stricture and most cases with severe pain had no sialectasia, this was may be explained by Acharya et al 2018 (12) who concluded that pain usually occurred due to burning sensation of the oral mucosa.

**Conclusion**

Although the presence of pain as clinical symptoms is important in the evaluation of non-tumor lesions of salivary glands, it has no correlation with CBCT sialography finding.

**Case (1):** 52 y old female patient had rheumatoid arthritis and suffered from pain and xerostomia

![Fig. 1: Reformatted lateral oblique view of coronal cut show degeneration of the branches of the ductal system due to intra glandular degeneration](image1)

(2): Reformatted coronal view show well defined mass degeneration of the parotid gland cause destruction of the ductal system.
Ethical Clearance: This study was approved by the (Research Ethics Committee) (REC) under number 172 in 27/6/2016, Faculty of Dentistry, Minia University before starting the research and all the entire patients had signed a standardized informed consent laid down by REC explaining the nature and the procedures of the study protocol, only those who agreed to sign the consent were included in this study.

Factors Associated with Knowledge, Attitude and Behavior of Condom Use among Women Living with HIV AIDS

Nessy Anggun Primasari1, Nursalam Nursalam2, Ferry Efendi3

1Magister Student, 2Professor, 3Lecturer, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Introduction: The transmission of HIV is likely in women lacking information related to the transmission of a husband’s unwillingness to use a condom when having sex. The focus of this study is to understand the knowledge, attitude and behavior in condom use as a way to prevent the transmission of HIV.

Method: This research used cross-sectional research. The population in this study was 60 married housewives aged between 17 and 49 years. Samples were taken by purposive sampling according to inclusion and exclusion criteria. Data were analyzed by using correlation and logistic regression with a significance level of p <0.05.

Results: The results showed their knowledge, attitude, and behavior regarding the use of a condom. The focus of this study is to understand the knowledge, attitude and behavior in condom use as a way to prevent the transmission of HIV; for knowledge r = 0.280; attitude r = 1.000 and behavior r = 0.420. Women living with HIV/AIDS (WLHA) who had good knowledge, attitude, and behavior, impacted on condom use as a prevention effort against HIV/AIDS.

Discussion and Conclusion: From this study, we can conclude that the knowledge, attitude, and behavior had an impact of the use of condoms in women as a precaution against transmission of HIV/AIDS.

Keywords: condom, HIV/AIDS, transmission, women

Introduction

Current developments in the initially high-risk groups of Human Immunodeficiency Virus (HIV) are those with certain sexual behaviors: homosexual groups; heterosexual groups multiple partners; sex workers; and those who use unsterilized needles, such as injecting drug users. Today, HIV & AIDS also infect women, wives or housewives loyal to their husbands or spouses. Thus, the exposure is no longer only in groups that had been stigmatized, or considered “worthy of a bad stamp”, but has also extended to the most vulnerable groups, women and infants [1]. The number of women with AIDS continues to increase globally, especially in those of reproductive age [2]. Findings from a preliminary study of data from the Semi-Public Health Center from 2007 until 2011 show a high prevalence of housewives who suffers from HIV/AIDS. Among the most common attempts to reduce HIV/AIDS prevalence are 100% condom use programs, not having multiple partners during sex, and primary prevention efforts to respond to the high risk of sexual transmission [3]. Unprotected heterosexual transactional sex is one of the major drivers of the HIV epidemic in Indonesia. Indonesia’s efforts have focused on increasing AIDS awareness and access to male condoms among sub-populations at high risk of sexually transmitted HIV infection, such as female sex workers (FSWs) [4]. However, condom use in Indonesia is considered less significant when compared with the large population and the spread of HIV/AIDS [5].

Condom use is a part of global HIV prevention, including Indonesia, and began in Uganda at the end the 80s with slogans such as Abstain, Be Faithful, Condom (ABC) [6]. So, it can be concluded that HIV/AIDS is

something that can harm women, especially [7]. Factors that influence behavior include personal experience and culture while others that are considered important include mass media, institutions such as educational institutions and religious institutions, and emotional factors in the individual [8]. However, until now, factor analysis affecting the behavior of condom use in HIV/AIDS prevention efforts for housewives living in a former prostitution area still cannot be explained. From the results of this study, it can be concluded that knowledge, attitudes and behavior impact on the use of a condom in women as an effort to prevent HIV/AIDS.

**Material and Method**

This research used descriptive-analytic research design with a cross-sectional design, that is research which emphasizes time measurement data observation of independent and dependent variables only once at one time. In this type, independent and dependent variables are assessed simultaneously, so there is no follow-up [9]. The population in this study was 103 married housewives aged between 17 and 49. Samples were taken by purposive sampling according to the inclusion and exclusion criteria of 60 samples. Data were analyzed by using correlation and regression logistic with significance level alpha <0.05.

**Results**

All of the respondents were housewives living in a former prostitution area, semi-district, Surabaya. Overall, of the 60 females most respondents in the age criteria were in the range 35-39 years (31.66%) (Table 1).

**Table 1: Characteristic demographic of the respondents**

Table 1 shows the characteristic of WLHA in a former-prostitution area in Surabaya. Most of PWHLA were aged 35-39 years with educational level on non-academic. Their husbands mostly worked in the private sector and duration of marital status was more than 20 years.

The result of logistic regression test of the effects of the factors in the use of condoms among housewives with HIV/AIDS are significantly correlated. Knowledge of a housewife is better compared to other factors.

**Discussions**

Based on the results of the study, it shows that respondents, especially women, have good knowledge. Knowledge in increased from the point of view of the attitudes and behavior of women as a precaution against early transmission of HIV/AIDS.

According to Notoadmojo, the factor that influences knowledge is education. Education affects the learning process, the higher a person’s education, the easier the person is to receive information [10]. The more information that comes in, the more the knowledge gained about health. Knowledge is closely related to education whereby it is expected that someone with a higher education will be more knowledgeable. It should be emphasized, however, that a person with a low level of education does not mean an absolute low knowledge. The economic status of a person will also establish the availability of the facility necessary for a particular
activity, so that this socioeconomic status will affect one’s knowledge. Based on the theory of adaptation, the level of knowledge can at least encourage having a good attitude and behavior as well \cite{10}. Given the knowledge about HIV/AIDS, there is an attitude of awareness and intention to use condoms.

Among the respondents with less knowledge, they can be influenced by education because the average respondent had a high school education level. According to Notoadmojo, someone with low education can also have good knowledge due to experience, age and number of members in the family \cite{10}. Age affects the ability to capture information and the mindset of a person \cite{12}. So, increased age will also increase the ability to capture and the mindset, so that the knowledge gained is better. At middle age, more active individuals will be more active in using time to read. New things are learned by reading. Of the majority of knowledgeable respondents, this had less impact on attitudes. It is viewed from the education taken by the respondents, who were mostly educated to high school graduates. This knowledge of the respondents about the use of condoms as an effort to prevent HIV/AIDS is still lacking; this can be seen when researchers asked respondents whether the use of condoms is good and true because there is still no extension from doctors and nurses Puskesmas Semi and healthcare in ex-prostitution areas on the use of condoms for housewives as an effort to prevent HIV/AIDS.

Good knowledge also obtained results with a good indicator. A factor affecting knowledge is education, which, in turn, affects the learning process, the higher a person’s education, the easier the person is to receive information. So, the more information that is received, the more the knowledge gained about health. It is found that housewives have some understanding about the use of condoms because of the health cadres. The majority of respondents were aged between 35-39 years. This age affects the experience of knowledge about condoms. However, respondents with good knowledge also had a bad behavior.

Based on tabulation of analysis with Spearman’s Rho (r) test shows that there is a correlation between attitude and behavior of condom use as a prevention effort of HIV/AIDS in housewives with value (p) = 0.001 and correlation coefficient (r) = 0.420, which means having a relationship with a moderate correlation power. Azwar (2012) argues that most positive attitudes experience good behavior. In this study, there was more emphasis on the formation of attitudes in the form of personal experience, while we know that, to be the basis for the formation of attitudes, personal experience must leave a strong impression. Therefore, attitudes will be more easily formed when personal experience occurs in situations involving emotional factors. In such situations, appreciation of the experience will be more profound and longer lasting. An attitude is not automatically manifested in an action (overt behavior). For the realization of the attitude to be a real difference, it requires supporting factors or a condition that allows, among others, facilities. In addition to facilities, it also needs a support factor (support) from another party \cite{10}.

That is, the absence of any experience with a psychological object tends to form a negative attitude towards the object \cite{13}. Alport (1954) states that attitude is a readiness or willingness to act and not an exercise of a particular motive \cite{12}. In other words, the function of attitude is not yet an action (open reaction) or activity, but is predisposing to behavior (action), or a closed reaction.

Based on the results of the study, it showed that most respondents have poor behavior in the use of condoms when housewives have intercourse with their husbands, while there is a small part of good behavior of housewives in the use of condoms during sexual intercourse with their husbands.

One of the most potent factors for influencing the behavior of a person is the socioeconomic and structural factors. Socioeconomic and structural factors are the level of welfare, level of education and access to health services \cite{4}.

In this research, attitude of housewives can influence behavior in condom usage because their mother’s attitude is awkward in talking about and using condoms during sexual intercourse with their husbands. It was seen during research that there were housewives in the group discussion where the mother asked how it feels to wear condoms during sexual intercourse because the housewife and her husband never use condoms during sexual intercourse and rarely discuss about condoms. Then there was one housewife, who was one of the group discussion organizers, who spoke about her experience using condoms when having sex with her husband that it feels different when not using condoms, but to prevent
the spread of HIV/AIDS from husband to wife it would be nice if condoms were used. Based on current research, researchers can conclude that there is still a lack of knowledge among women, especially housewives, about condoms. This affects the lack of condom use behavior. Monitoring programs and evaluation of the HIV/AIDS program by the health office Surabaya have not been performed intensively, especially as related to health cadres’ cross-cutting cooperation, community-based organizations, non-government organizations, community leaders and mass media.

**Conclusion**

Knowledge, attitude, and behavior to prevent transmission of HIV/AIDS is an important factor in giving purpose and understanding to women living chiefly in the former location of prostitution. This means the need for considerably more information in providing information is maintained, which can at least reduce the rate of the transmission of HIV/AIDS through sexual intercourse. Recommendations of the research are more emphasis on health workers educating and directly involving women in advanced knowledge and well altering their behavior, which may be fostered more positively via regular meetings of leaders and public discussion. Counseling on sustainable health and women’s empowerment in matters of knowledge can bring improvement in increased better behavior in the use of condoms to prevent HIV/AIDS.

The Role of Support Systems on Self-Acceptance in Chronic Kidney Disease Patients Undergoing Hemodialysis in Malang

Ni Luh Putu Suardini Yudhawati¹, Lilik Supriati², Titin Andri Wihastuti²

¹Master of Nursing Program Student, ²Lecturer, Faculty of Medicine, Universitas Brawijaya, Malang, Indonesia

ABSTRACT

Chronic Kidney Disease (CKD) is a non-communicable disease that is progressive and irreversible for a long time. CKD patients who need hemodialysis (HD) which must be done for life by CKD patients to improve the quality of life. Self-acceptance is one of the essential aspects of CKD patients, which is a trigger factor for adaptive coping strategies to the effects of HD; the support system influences this. This study aims to know the relationship between the support system and self-acceptance of CKD patients undergoing HD. This quantitative research was conducted using observational design with a cross-sectional approach. The sample used was 114 patients with the stratified random sampling method according to the duration of HD. Measurements were made using a questionnaire to measure self-acceptance, family support, and social support. The results were analyzed using a logistic regression test using a confidence level of 95%. The results of the majority of patients experienced negative self-acceptance (52.6%), excellent family support (55.3%), and sufficient social support (5.6%). Results show there was a relationship between family support and social support for self-acceptance of HD patients and the most influential factor for self-acceptance of hemodialysis patients was family support. The results of this study can improve mental health nursing services in the HD unit in overcoming psychological problems experienced by improving the support system for patients.

Keyword: Support system, Self-acceptance, CKD, hemodialysis.

Introduction

Chronic Kidney Disease (CKD) is characterized as a non-communicable disease and is progressive and irreversible, which experienced for a long time. This condition is due to the degradation of the Glomerular Filtration Rate (GFR) less than 60 mL/min/1.73m² for three months¹. The prevalence of CKD continues to increase globally, estimated around every 1 in 10 individuals experience CKD and has become the 18th leading cause of death in 2010. In Indonesia, CKD is a disease that ranks second in the most significant financing of national health insurance after heart disease². So that CKD is a health problem throughout the world with increasing prevalence, poor prognosis, and high treatment funding.

Patients with CKD need hemodialysis (HD) therapy to maintain their lives. HD is a replacement therapy for kidney function with a dialysis machine, where there is an artificial semi-permeable membrane that functions to filter blood. According to Ignatavicius and Workman (2013), the HD process aims to remove excess fluid and urea or waste nitrogen in the blood and maintain electrolyte homeostasis in the body of CKD patients³. Practically, patients undergoing HD in the hospital only get biological treatment and not focused on psychological aspects. This therapy must be done for life by CKD patients and has side effects on the physical and mental sufferers⁴. Psychological disorders that are often experienced by patients with CKD with HD include depression (15-69%), fatigue (60-97%)⁵, severe anxiety (23.68%)⁶, and insomnia (54%)⁷. Patients with HD must have kind self-acceptance to be able to adapt to the effects of HD so that they can maintain their quality of life⁸.
Self-acceptance is one of the critical aspects in patients with CKD, which is a trigger factor for an adaptive coping strategy\(^9\). Patients with HD therapy undergo lifelong therapy and are prone to prolonged stress. Self-acceptance in CKD patients varies according to their experience and coping ability. Low self-acceptance causes non-compliance in carrying out treatment and is unable to deal with problems due to the impact of the disease\(^{10}\). There is internal and external factors influence self-acceptance in patients. One of the influencing external factors is the support system, which consists of family support and social support. Such support plays a vital role in increasing the ability to accept and adapt to all changes that occur in CKD patients so that it will improve the quality of life. This study aims to know the correlation of the support system to self-acceptance of CKD patients undergoing HD.

**Method**

This quantitative study was conducted using an observational design with a cross-sectional approach to finding the relationship between self-acceptance and the factors studied. This study conducted on CKD patients undergoing HD at the dr. Soepraoen Army Hospital Malang. The number of samples was 114 people and determined by the stratified random sampling method, which was adjusted using the duration of hemodialysis. Data collection uses a questionnaire adapted from the Unconditional Self-acceptance Questionnaire (USAQ), Social Support Survey Instrument (SSSI), and The Social Support Inventory (SSI). This study was approved to be carried out by the Health Research Ethics Commission of the Faculty of Medicine, Universitas Brawijaya Malang. The multivariate analysis used was logistic regression to determine the influence of family support and social support simultaneously on self-acceptance. The hypothesis rejected if the value is sig. > α (0.05). Data analysis results presented in the table of characteristics of samples, bivariates analysis, and multivariates analysis.

**Result**

1. **Characteristics of the Study Sample:** Specific data will be broken down by age, gender, marital status, formal education, duration of HD, frequency of HD every week, and the caring family. These results described in table 1.

</table>

Based on table 1 found that most of the samples had ages 46-55 years was 37 people (32.5%), the male was 61 people (53.5%), married was 94 people (82.5%), and had elementary school education was 47 people (41.2%). In the process of
HD therapy, the majority of the sample performed HD two times/week as many as 92 people (80.7%) and treated by the spouse of patients (husband/wife) was 65 people (57.0%).

Based on table 2., most of the sample felt proper family support of 63 people (55.3%) and sufficient social support experienced by 60 samples (52.6%).

2. Analysis of each factor toward self-acceptance

Based on table 3., Family support and social support have a significant relationship to self-acceptance (Sig. <0.05) with a weak correlation. Based on the results, both variables fulfilling the criteria were included in the logistic regression test (Sig. <0.25).

3. Analysis of factors that influence simultaneous toward self-acceptance:

Based on table 4. both factors of family support and social support simultaneously have a close relationship to self-acceptance in CKD patients. The results showed that patients with CKD with a reduced level of family support 11 times more at risk of experiencing negative self-acceptance. Whereas if you feel sufficient, family support will experience four times more risk of experiencing negative self-acceptance. On the factor of social support, if patients think poor social support experience four times more risk of experiencing negative self-acceptance and whereas patients with sufficient social support will be twice as likely to experience negative self-acceptance. When compared, the most related factor is the factor of family support for self-acceptance in CKD patients with HD therapy.

Discussion

1. Family support and self-acceptance of CKD patients with HD: The results show that most of the samples have excellent family support. While the majority of samples have good family support experienced by patients who have HD therapy for 1-2 years. The findings in this study are different from the research conducted by Sari (2016) in HD patients at the dr. Soeproaen Amry Hospital Malang found that the majority of patients with HD therapy received adequate family support(10). When compared, this study is different because of measurements at different times. And it can be interpreted, family support felt by samples in this study, increases with increasing duration of HD.

In this study, the majority of treating families were spouses (husband/wife) from CKD patients.
undergoing HD. Family care is one form of support. Family support indicated as the most critical support. Family members play a vital role in improving self-care behavior and facilitating patient adjustments to disease. Pair support can be a source of strength, while support from the environment is additional support in HD patients\(^{(11)}\).

The type of support most felt by patients at the research site is informational support. The result showed that patients at the research site receive perceived support in the form of giving advice and essential information needed by patients to improve their health status. This finding is in line with the research conducted by Sukriswati (2016) that informational support enhances the quality of life of patients CKD with HD\(^{(12)}\). While patients who do not receive information support, respondents perceive their quality of life to be less evident that more than those of good quality of life. If it is related to the age of the respondent, stereotypes of elderly who have slowed thinking processes, are forgetful, confused, so the information provided by the family does not have enough influence on the respondent\(^{(13)}\). Family support is a support system that comes from the family members, in providing information to family members with health issues including receiving information relating to their illness, namely to eliminate anxiety due to uncertainty also the patient’s ability to use technology resources effectively.

There is a significant relationship between family support and self-acceptance in patients with CKD undergoing HD. The results of the study conducted by Sari (2016) found that there was a significant relationship between family support and self-acceptance in patients with CKD who is undergoing HD with a weak correlation\(^{(10)}\). Whereas the research conducted by Anggraeni, Sarwono, and Sunarmi (2017), the results showed that there was a correlation between family support and level of depression in patients undergoing HD therapy with a negative correlation value \(^{(14)}\). Support from the family is an essential thing for patients with CKD to experience HD because it can further motivate patients to undergo HD. Patients will feel that there is still someone who gives attention, affection, or someone who cares about him even though he is sick. According to Bomar’s theory (2006), family support is a form of serving behavior carried out by the family, both in the way of emotional support (attention, affection, empathy), appreciation support (respect, feedback), information support (advice, advice, information) or in the form of instrumental support (assistance in energy, funds, and time)\(^{(15)}\). A family is a place for individual growth and development\(^{(14)}\).

2. Social support and self-acceptance of CKD patients with HD: The results showed that the majority of samples had sufficient social support and samples who had adequate social support experienced by samples who had HD therapy for 1-2 years. The findings in this study are different from the research conducted by Purnama (2016) found that patients with HD experienced high social support\(^{(16)}\). In this study, social support is the support felt by patients and comes from friends, neighbors, community, or health worker, which distinguishes them from family support.

This study indicates that there is a significant relationship between social support and self-acceptance in patients with CKD undergoing HD. Research shows that social support is significantly associated with self-acceptance in patients with CKD. The higher social support felt by patients with CKD, the better their self-acceptance will be, or the lower the perceived social support, the worse their acceptance will be.

The study conducted by Gao, Zhou, Guo, and Zhao (2016), found that social support was directly related to distress symptoms, and symptoms of distress mediated the relationship between monthly income, active coping style, passive coping style, social support, and expectations\(^{(17)}\). Whereas the research conducted by Karadag, Ugur, Mert, and Erunal (2019), states that there is a significant and robust relationship found between the scale of social support and the average score of resilience in patients with HD\(^{(18)}\). Patients felt the highest comfort of their friends and personal assistance, apart from family support.

Every individual need support in living patient’s life. Support obtained from anyone who advises making a patient with CKD able to accept reality. This type of social support includes
emotional support, appreciation, and material or instrumental. The explanation strengthened Sari’s opinion (2002), who argued that one of the factors that influenced self-acceptance was social support\(^{10}\). Someone who gets help from the environment and social will make the person feel more accepted by his background. The social environment treatment of a person shapes the behavior of that person. A person who gets treatment from a supportive social context will be able to accept himself better\(^{16}\).

Social support will reduce risk factors for chronic diseases, including smoking, inactivity, and changes and maintenance of health behaviors. Increasing social support will reduce stress so that there is an increase in the immune response in the body so that health status will increase. People who access more social support can better manage their stress and experience better health outcomes. Besides, a reduction in social support increases the likelihood of death\(^{19}\).

**Conclusion**

The results show that there is a relationship between the support system, which consists of family support and social support for self-acceptance in CKD patients with HD. When both factors are measured simultaneously, family support has more influence on self-acceptance compared to social assistance.

Self-acceptance has a vital role in the condition and psychological readiness of patients during HD, and hemodialysis nurses play an essential role in increasing self-acceptance of CKD patients undergoing HD. This study can be used as a reference in mental health nursing services in overcoming psychological problems experienced by improving the support system for patients.

ABSTRACT

The notion of mentoring can be understood as a one-to-one relationship between a mentor and a mentee. Aim; investigate the effect of training program on unit managers’ mentoring knowledge and skills. Research design; Quasi experimental design was utilized. The study sample; composed of all head nurses (n= 27) who were actually in the active workforce during the time of data collection. Was carried out after explanation of the aim of the study, an official administrative approval was obtained, all unit staff were observed for mentoring skills by observational checklist; pre, immediate and follow up the program. Every participant was observed three times at different time’s period at different days. Knowledge assessment questionnaire was concerned with the assessment of the participants’ knowledge regarding to mentoring, negotiation and counseling. Results; this study showed that there was positive correlation between unit managers’ mentoring skills and knowledge in pre, immediate post and follow up the program implementation. Conclusion: based on these findings the training program is effective in improving the unit managers’ mentoring knowledge and skills which were evident by statistical increase in their knowledge and skills mean scores in post program scores compared to pre program mean scores. So the research hypotheses were accepted. Therefore, it is recommended that replication of the research on a large probability sample is recommended to achieve more generalization.

Keywords: Mentoring, unit managers’ knowledge and skills

Introduction

Mentoring is the most powerful method by which future can be shaped, through most positive change in the life, attitudes, and behavior of the mentee. A mentor is someone who can patiently assist with someone’s growth and development in a given area. This assistance can come in the form of guidance, teaching, counseling to one individual, imparting of wisdom and experience”. Additionally, mentoring is a contributing factor to quality practice environments and also, has fostered healthy relationships among staff and professional development opportunities¹.

Mentors play the role of counselor in relation to mentoring when counsel, listen, provide emotional support, act as sounding boards, and help mentees to take responsibility for their own actions. In essence the counselor’s interactions with the mentee are a powerful tool in the helping relationship².

Unit manager might use negotiation with respect to mentoring to interact with subordinates and supervisors, whether implementing a program, approving a budget or adjusting patient care standards. The mentor has to possess effective negotiation skills such as an interpersonal and communication skills which used together to bring a desired result³. This study conducted to investigate the effect of training program on unit managers’ mentoring knowledge and skills in a selected university hospital, Egypt.

Hypotheses:

H1: After implementing the mentoring program the unit managers’ knowledge posttest score will be higher than the pretest.
H2: After implementing the mentoring program the unit managers’ skills score will be higher than pre intervention.

**Materials and Method**

The study sample composed of all available unit managers (n=27) who were actually in the active workforce during the time of data collection and met the inclusion criteria were selected for the study from a selected university hospital in Cairo, Egypt.

**Inclusion Criteria:** Baccalaureate nursing degree and a minimum of one year as head nurse.

**Data Collection Tools:** Tools of data collection were developed by the investigator based on literature review; Mentoring skills observational checklist was used to assess the unit managers’ skills regarding to ‘negotiation and counseling skills’ and Mentoring knowledge assessment questionnaire were used through the program phases to assess levels of participants’ knowledge.

**Tool Validity and Reliability:** Tool validity was assured and was also tested for internal consistency by test-retest reliability. Cronbach’s alpha was 0.91.

**Procedure:** Procedure was carried out after explanation of the aim of the study an official administrative approval was obtained from the General Director of Cairo university Hospitals to collect the study data. The participants’ skills was assessed by the investigator using the observation checklist at three time period at different days and Mentoring knowledge assessment questionnaire was used three times during the study. Which are: pre, immediate, and after three months of the program implementation. After obtaining the ethical consent from the participants.

**Results**

Table (1) shows that the majority of the study sample (70.4%) was nursing bachelor degree. The highest percent of age (59.3%) was from 30 to less than 40. Regarding years of experience the highest percent was (44.4%) was from 15 to less than 20.

Discussion

Regarding to mean scores and difference between the unit managers’ mentoring skills as displayed in table (2), shows that there was significant statistical difference between unit managers’ negotiation and counseling skills in pre, immediate post and follow up the program implementation.

According to Farouk and Hassan's conducted a study on “Effect of Education Program about Negotiation Skills for Head Nurses on Their Time Management”, this study revealed that there were highly statistical significant improvements in the head nurses’ negotiation skills after intervention both post and follow up program. And also there was statistically significant difference among program phases.
Kocoglu, Duygulu, Abaan and Akin\textsuperscript{5} conducted study entitled “Problem Solving Training for First Line Nurse Managers”. They concluded that statistically significant improvements were observed in providing counseling and guidance by independent and qualified nurse managers would also positively impact the development of these skills and behaviors.

Regarding to mean scores and difference between the unit managers’ mentoring knowledge, the immediate post and follow up the program mean score of each knowledge dimension were significantly higher than the pre program mean score.

The result of present study was in agreement with Abdullah\textsuperscript{6} conducted study on Mentoring as a Knowledge Translation Intervention to Inform Clinical Practice” they revealed that there were positive effects on knowledge. Levin, Fineout-Overholt, Melnyk, Barnes and Vetter\textsuperscript{7} concluded that there were improvements in knowledge level.

Rhay-Hung, Ching-Yuan, Wen-Chen, Li-Yu, Syr-En and Mei-Ying\textsuperscript{8} conducted a study on “Exploring the impact of mentoring functions on job satisfaction and organizational commitment of new staff nurses” they concluded that improve the mentors’ knowledge and skills, help in resolving task-related problems, and further promote their overall growth.

Regarding to Correlation between unit managers’ mentoring skills & knowledge in pre, immediate post and follow up the program as displayed in table (4), the immediate post and follow up knowledge was positively correlated with immediate post and follow up practice program.

This result is consistent with the study of Sutevski\textsuperscript{9} about managerial skills concluded that head nurses’ performance is based on knowledge that can be learned. Training programs are effective only to the extent that the skills and behaviors learned and practiced during instruction are actually transferred to the workplace\textsuperscript{10}. Farouk and Hassan\textsuperscript{4} and Cascio\textsuperscript{11} concluded that, there was a positive correlation between head nurses’ knowledge and skill.

The results of the current study indicated that near of all of unit managers’ mentoring skills were satisfactory in immediate post and follow up the program implementation in compared to the majority of unit managers’ mentoring skills were unsatisfactory in pre program implementation. This might be due to unit managers’ motivation to apply new competencies resulting in increased the confidence in their capabilities. These findings support the study hypotheses which was the training program has significant impact on unit managers’ skills. So the study hypothesis is accepted.

**Conclusion**

The mentoring training program had significant impact on the unit managers’ knowledge and skills which were evident by statistical increase in their knowledge and skills mean scores in post program scores compared to pre program mean scores. So the research hypotheses were accepted.

**The study recommended the following:**

- Replication of the research on a large probability sample is recommended to achieve more generalization.
- Nursing curriculum should emphasis the interpersonal skills required for a mentor role.
- The organization should implement formal and informal mentoring to enhance nursing satisfaction and increase retention.
- Researches are needed to determine the value of mentoring in quality improvement training.
- Availability and supporting the mentoring culture.

**Ethical Clearance:** A written approval was obtained from the ethics and research committee of the Faculty of Nursing - Cairo University. Written informed consent was obtained from each participants after explaining the nature & purpose of the study. Participants were informed that participation in the study was entirely voluntary, anonymity and confidentiality of the data were assured.

**Source of Funding:** Self-funding.

**Conflict of Interest:** The authors declare that there is no conflict of interest.

Samban/Tutulak and Immunization: The Sick Concept of Dayak Tribes in the Context of Modern Life

Oedojo Soedirham¹, Ida Hastutiningsih²

¹Department of Health Promotion and Behavioral Sciences, Public Health Faculty, Universitas Airlangga, Surabaya, Indonesia; ²District Health Office, Tabalong District, South Kalimantan, Indonesia

ABSTRACT

Immunization is one of the intervention in health that is widely regarded as the most successful and cost effective intervention. Contrary to that achievement, more than 19 million children in the world still have not received complete basic immunization and current immunization coverage of the world shows no improvement. This fact also happened in the Balangan district where the several Dayak tribes settle.

However, based on the preliminary study the Dayak tribes have traditional illnesses’ prevention i.e. the use of the samban/tutulak for their children. Hence, the aim of this paper is to explore and discuss the concept of samban/tutulak and immunization and the sick concept of Dayak tribes in the context of modern life.

This article is based on the result of ethnographic qualitative research conducted in April to October 2018. Data collected through in-depth interview with 41 informants and participatory observation.

In general the purpose of immunization and the use of samban/tutulak is the same which is to protect children from diseases and make children stay healthy. Both immunization and the samban/tutulak are intended to develop immunity for the children. Immunization develops immunity artificially whereas the use of samban/tutulak develops the immunity naturally.

The use samban/tutulak in protecting the health of children in Dayak is the consequences of the sick concept believed by the Dayak tribe.

Keywords: tutulak, samban, Dayak tribe, immunity, sick concept

Introduction

Immunization is one of the interventions in health that is widely regarded as the most successful and most cost effective interventions (1)(2)(3)(4)(5)(6)(7). However, according to the WHO in 2015 more than 19 million children in the world still have not received complete basic immunization and current immunization coverage of the world shows no improvement (8).

In Indonesia, immunization coverage only shows a slight increase, so that by WHO Indonesia is categorized as a stagnant country and is considered not showing the expected growth in efforts to increase coverage of basic immunization (9). This situation also happened in South Kalimantan Province, with the lowest coverage is in Balangan District, which is 25.5% in the Basic Health Research in 2007 and 20% in the Basic Health Research in 2013 (10)(11).

Based on several in-depth interviews conducted during the preliminary study, it is likely that one of the causes of the low coverage in the Dayak community is due to the people belief in the cause of the illness itself. The cause of the illness that is believed by the community as stated by the informants are as follows:

1. Diseases caused by real or natural causes such as heat, cold, rain, tiredness.
2. Diseases caused by unreal causes such as ancestral spirits, breaking taboos and witchcraft and other supernatural causes.

The difference in the concept of illness that they believe in the concept of western medicine ill causes to never mention germs as the cause of an illness. This belief then affects their prevention efforts that they believe may protect against the disease. One of the efforts is the use a kind of amulet namely samban/tutulak to protect the children from diseases.

Hence, the aim of this paper is to explore and discuss the concept of samban/tutulak and immunization and the sick concept of the Dayak tribes in the context of modern life.

**Materials and Method**

This paper is based on the result of an ethnography study. Data for this research was collected through in-depth interviews and observation with total 41 informants i.e. 9 of baliins the traditional healers, 15 of the Dayak traditional leaders and other group members and 17 of the mothers of 12 - 35 old age children, conducted from April to October 2018. All the material was recorded as field note, and some were tape recorded and video recorded.

**Results**

**Overview of Research Sites, Population and Demographic:** The research location was at Dayak tribe in the Balangan District in the northern part of South Kalimantan Province that stretches at coordinates 2°01'37” to 2°35’58” South Latitude and 114°50’24” up to 115°50’24” East Longitude.

There are 4 sub tribes namely Dayak Uren, Dayak Deyah, Dayak Pitap and Dayak Halong with total population 12,996 settled on 18 villages in sub district of Tebing Tinggi and Halong.

Most of the Dayak tribe still plant rice, supplemented by the sale of the product of planted rubber tapping, vegetables or other field and forest products and some educated citizens working in coal companies and become civil servants. But even though they have other permanent jobs, they still have to go to the field and planting rice because of the obligation to participate in their annual harvest ritual.

**Use of Samban/tutulak:** Tutulak (figure 1) in the form of bracelets used by Dayak Deyah and Dayak Halong while samban (figure 2) shaped necklace used by Dayak Uren and Dayak Pitap.

Immunization is required for all children, whereas the samban/tutulak is only required for children “requested” by Nining Baharata, the Almighty ancestor spirit. According to balian, the sign of child allegedly asked to use samban/tutulak, among others, is born with a umbilical cord around the neck, often crying or weeping, easy to sick or litter, sprue continuously and the baby does not gain weight. To ascertain whether the marks of a child are really signs given by Nining Baharata to ask children to use samban/tutulak then performed ritual batamung by balian.

**The Process on Wearing the Samban/tutulak Ceremony:** Preparation for ritual to use samban/tutulak will be performed by all villages’ members. Cakes made mostly of glutinous rice will be prepared as offerings to the ancestors. All guests will be openly accepted even if they are not from the same customary units or even non-Dayak people.
In this ritual, *balian* will recite the spell called *bamamang* and dance called *batandik* accompanied by drum rhythm from 7 pm to 9 am the next day. In this ritual, the spirits believed to have disturbed the health of a baby or child will be transferred to wooden puppets called *impatu*. Then the ritual is continued by putting the *samban*/*tutulak* to the child.

After the ritual completed, parents and children must go through a period of abstinence that make them not allowed to leave the house, forbidden to receive guests and forbidden to defecate. This 24-hour period is believed to be the time span needed to sharpen the power of the *samban*/*tutulak* to protect the child from future illness and also because the spirits that is called on the ritual is still roaming around the house and is feared to be able again interfere with newly given *samban*/*tutulak* children because they do not have the optimum power yet.

To reinforce the ability of *samban*/*tutulak* in protecting child from disease, every year at the harvest ritual, the baby or child wearing *samban*/*tutulak* together with their parents will be given spell again by *balian* and *samban*/*tutulak* will be smeared oil.

The duration of the use of *samban*/*tutulak* ranged from 3 to 8 years and in that period the health of the child becomes the *balian’s* responsibility. If in the span of time the child gets sick, it becomes the responsibility of the *balian* to perform the necessary healing rituals.

**Discussion**

**The History of Vaccine:** Immunization in the western biomedical concept firstly known when Edward Jenner is creating the first vaccine, which was taken from a cowpox to protect the human form smallpox (12) but actually this concept was initially created long before it.

Documented in the timeline of vaccination created by The College of Physicians of Philadelphia that ritual inoculation in China and India had been started since 1500 AC. In the late of 1600 AC, Emperor K’ang Hsi, who has been recovered from smallpox in his childhood, conducted inoculation of his children by blowing the milled smallpox scabs into the nostrils. He conducted this ritual because he noticed that everybody that he has known to be recovered from smallpox not infected by this disease twice.

In 1545, when smallpox epidemic stroke India that cause around 8,000 child deaths, the *brahmins*, the traditional healer, also observed the same concept, the basic concept of immune development which is hardly ever a person infected with the same illness twice (14). The *brahmins* done a ritual called buy the disease by making a healthy person infected with smallpox through a dry smallpox scab taken, at that time bought, from smallpox patients who have recovered, through scratches made on the skin. Most people who carry out this ritual will fall ill, but then recover and be protected from infection in the future.

**Understanding Immunization:** Immunization by WHO is defined as “the process whereby a person is made an immune or resistant to an infectious disease, typically by the administration of a vaccine” which can be interpreted as a process in which individuals are immunized or resistant to infectious diseases usually by using a vaccine\(^9\). Vaccines help the formation of immunity by mimicking an infection even though this artificial infection is relatively unlikely to cause a serious illness as a naturally occurring infection. However, this artificial infection can make our immune system produce T-lymphocytes and antibodies and provide our body with a memory of how to fight the infection if in the future the body is attacked by infection from the disease. Some vaccines do require more than one dose to be effective and some require boost or boost to raise the level of immunity\(^15\).

In natural infections when the body is attacked by a germ it takes several days before forming the body resistance system to defeat the infection that often the disease becomes severe and must be hospitalized and even deadly.

**Value Concept of Samban/tutulak for Dayak Tribe in Balangan District:** As mentioned earlier, the use of *samban*/*tutulak* is one of the efforts believed by the Dayak people to protect infants/children from diseases caused by the disorder of spirits supra natural power. What kind of illness is caused by a supernatural disorder and not because of physical illness is not generally known and it is the duty of a *balian* to communicate it with the ancestor to determine it through a *batanung* ritual.

Besides being believed to be a form of disease prevention, the use of *tutulak/samban* also symbolizes their faith in the command and their respect for their
ancestors. These rituals will also keep the social coherent in the community and the kinship between members in one tribe with the other or even an outsider because in the ritual usually run by the whole village even relatives or guests from other villages will come. And since the costs incurred to perform each ritual relatively large, it is possible that this ritual is also a prestige for the family doing it.

In addition, using samban/tutulak can also cause a sense of security because as long as children use samban/tutulak then balian who has paired samban/tutulak will be responsible for performing a healing ritual if the child gets sick.

Samban/tutulak and Immunization: In order to fulfill their health need, every community develop a health system, which is consist of prevention and healing activities. A part of this system is the etiology of illness or the cause of illness. The cause of illness will determine the choice activities that their chosen for the prevention and healing.

In general, the purpose of immunization and the use of samban/tutulak are to protect children from disease and make children stay healthy. Specifically immunization aims to protect children from immunized preventable diseases such as tuberculosis, diphtheria, pertussis, hepatitis B, Haemophilus influenza B, Polio and Measles whereas the use of samban/tutulak aims to protect children from disruptive spirits they are causing children sick.

The key concept of immunization is protection against the possibility of disease. This vaccine can be repeated several times with a certain time interval called a booster. This procedure is intended to maintain immune levels against the intended diseases. This concept is actually the same as the concept of samban/tutulak traditionally given by a balian. Even the concept of “booster” is also known by updating or changing samban/tutulak with a new one.

The concept of immunization is actually the development of experience about the occurrence of cowpox disease events where Jenner observed that those who had suffered cowpox turned out to be relatively more immune to not inflict the disease anymore. So cowpox events are like stimulation of antibodies. While in the event of a samban/tutulak giving waiting for the child to be sick, it is actually in the body of the child, there is an antibody. So samban/tutulak is a booster with the hope that the child will not contract a similar disease. But in vaccination programs basically the healthy child is told to be sick by giving a vaccine which is a seed of a disease that has died or is weakened with the hope of antibodies without harmful side effects.

Since ancient times humans have always studied the environment in which they live. They understand that if humans always treat the environment well then the environment will provide comfort act for humans. As illustrated by the quotation of Hippocrates (c. 460–377 B.C.) was familiar with the importance of cultural–environmental interactions more than 2,000 years ago.

On Airs, Waters, and Places

Whoever wishes to investigate medicine properly, should proceed thus: in the first place to consider the seasons of the year, and what effects each of them produces (for they are not at all alike, but differ much from themselves in regard to their changes). Then the winds, the hot and the cold, especially such as are common to all countries, and then such as are peculiar to each locality. We must also consider the qualities of the waters, for as they differ from one another in taste and weight, so also do they differ much in their qualities.

—Hippocrates (c. 400 B.C.)

The study of these interactions, which are important to disease etiology, health promotion, and health service provision alike, continues to this day as medical geography. As old diseases, almost forgotten, are reemerging amidst new risks; as the majority of the world’s population becomes urban and moves toward stabilization of numbers; as biotechnology transforms medicine, agriculture, and our understanding of the nature of life; and as climate change, air and water pollution, metastasizing consumption, and parasitic inequalities transform the ecology of disease—so the ancient study about how people, their cultures and societies in different environments, create and spread disease, promote health, and provide care for the ill has never been more relevant.

It is important to understand the interactive processes of cultural and environmental change, as well as the importance of distance and location. By doing this,
medical geography can not only advance knowledge, but
be useful for analysis and have applied outcomes (16).

The Dayak Tribes are no different. They believe that
disease is due to the act of supernatural power including
evil spirits

Conclusions

This research reveals the phenomenon of belief
about the disease causation and its protection using
samban/tutulak which in concept is actually similar
to the concept of immunization in western medicine.
Immunization develops immunity artificially whereas
the use of artificially develops the immunity naturally.

Both of them has a role in shaping children’s health
in the Dayak tribe in the Balangan district.

Conflict of Interest: There is no conflict of interest for

ABSTRACT

The planning family acts to help the family to plan the pregnant and natal they want. The target of research: to knowing the factors related to the contraception use plan in women of reproductive age. Method Research: Sample of The Indonesia Demographic and Health Survey (IDHS) 2017 includes 1,970 census blocks covering urban and rural areas. The implementation of the IDHS uses 3 types of questionnaires. Results: the planned use of contraception in women of reproductive age is mostly in rural areas and in women of reproductive age with elementary-high school education. Most women of reproductive age know more about modern contraception. Plans for use of contraception in women of reproductive age in married women. Conclusions: residence, education, knowledge of the types of contraceptive methods and marital status are related to contraception use plans in women of reproductive age.

Keyword: The Choice of Method, Contraception Use Plan, Women of Reproductive Age

Introduction

Indonesia is one of the developing countries with various types of problems. The main problem in Indonesia is the field of a population where population growth is still high. Such a condition of the population has made it difficult for businesses to improve and equalities people’s welfare. The higher the population growth, the more effort is made to maintain people’s welfare. Therefore the Government continues to strive to reduce the rate of growth with the Family Planning Program. Based on the results of the population census in 2010 it was found that Indonesia’s population had reached 237.2 million, with a growth rate of around 3.1% a year and a birth rate of 2.6 per woman. Indonesia’s population is increasing every day, even though the government continues to strive to reach 2.1 children per woman. However, there are still many people who have large numbers of children[1].

Family planning is the act of helping couples to avoid unwanted pregnancies, getting a very desirable birth, arranging intervals between pregnancies, controlling the time of birth in relation to the age of husband and wife and determining the number of children in the family[2]. Family planning service that aims to achieve quality families through the arrangement of the number of families in a planned manner, so expects acceptance of acceptors in the use of contraception is expected to remain a family planning acceptors.

Contraception use has increased in many parts of the world, especially in Asia, America Latin and lowest in Sub-Saharan Africa. Globally, modern contraception users have increased not significantly from 54% in 1990 to 57.4% in 2014. Regionally, the proportion of couples of reproductive age 15-49 years reporting the use of modern contraceptive methods has increased at least in the past 6 years. In Africa, from 23.6% to 27.6%, in Asia, it has increased from 60.9% to 61.6%, while America Latin and the Caribbean up slightly from 66.7% to 67.0%. An estimated 225 million women in developing countries want to delay or stop fertility but do not use any contraceptive method for the following reasons: limited choice of contraceptive methods and experience of side effects. Unmet needs for contraception are still too high. Injustice is driven by population growth[3].
Indonesia will face three mega demographic trends ahead of 2030. First, Indonesia’s large population will continue to increase despite the low Population Growth Rate, in line with the rapid flow of urbanization. Second, demographic advantages have occurred since the late 1980s and will peak in 2030 resulting in a demographic bonus, before the percentage of the working age population declines. Finally, Indonesia will experience a shift in the situation from permanent population mobility to non-permanent population mobility. These three demographic trends will have a large influence on Indonesia’s ability to achieve sustainable development goals (SDGs) by 2030⁶.

It is estimated that Indonesia’s population in 2017 will reach 255.5 million. This condition causes Indonesia to occupy the fourth position with the highest population in the world and the first position in Southeast Asia. Indonesia’s population will increase and reach 296.4 million by 2030. In other words, there will be an additional 40.9 million Indonesians between 2015 and 2030. This additional population is greater than the total population of Malaysia and Brunei only 31 million in 2015⁷.

The family planning program promoted by the government has become very important as control of the population explosion. Data from the National Population and Family Planning Agency in 2013 received 8,500,247 PUS (fertile age couples) who were new family planning participants, with details of injectable contraceptive users 4,128,115 participants (48.56%), pills 2,261,480 participants (26.60%), implants 784,215 participants (9.23%), condoms 517,638 participants (6.09%), uterine contraception 658,632 participants (7.75%), MOW (male surgery method) 21,374 participants (0.25%), from the above data we can see injection contraception method is the most used method⁶.

Many women have difficulty in choosing the type of contraception. This is caused not only by the limited methods available but also because of the mother’s ignorance about the requirements and safety of the contraceptive method⁶. In addition, many factors have resulted in not all fertile couples joining the family planning program. According to Hartanto (2003), there are other factors that influence family planning acceptors in choosing contraception, namely age, number of children, education, and knowledge⁷. Whereas according to Glasier and Gebbie (2005), periodic visits to clinics, the role of officers, the frequency of action needed, partner cooperation, privacy, frequency of sexual relations, future fertility plans, and costs are factors that influence a person in choosing contraception⁸.

In accordance with Green (1980) theory in Notoatmodjo (2003) that health behaviour including the selection of contraceptives is influenced by three factors namely predisposing factors (Knowledge, attitudes, Education, family economy), supporting factors (availability of medical devices, sources of information) and driving factors (family and community leaders support). The study analyzed predisposing factors related to contraceptive plans in women of childbearing age. The predisposing factor consists of knowledge about family planning, values, community culture about family planning, perceptions, attitudes, education level, type of work⁹.

Material and Method

We used data from the Indonesia Demographic and Health Survey (IDHS) 2017. The IDHS is a five-year periodic survey used to collect information from ever-married women aged 15-49 years and ever-married men 15-54 years about demographic and health status. Three types of questionnaires used were the Household, Women’s, and Men’s Questionnaire. The Women’s questionnaire included questions about women’s demographic characteristics, their reproductive history, pregnancy, postnatal care, as well as immunization and nutrition. The IDHS sample includes 1,970 census blocks covering urban and rural areas. Respondents of women of childbearing age aged 15-49 were 59,100, 24,625 respondents were unmarried young men aged 15-24 years, and 14,193 married men aged 15-54 years. The IDHS sample frame uses the Master Census Block Sample from the 2017 Population Census data in this study.

Findings

Based on the results of the cross tabulation (Appendix 1), it can be seen that contraceptive plans that tend to be chosen by women of reproductive age who live in rural and urban areas are injections every three months with a p-value of 0.000. However, this injection method is mostly chosen by women of reproductive age who live in rural areas compared to urban areas. In addition,
women of reproductive age with elementary-high school level tend to plan to use injectable contraception three months with a p-value of 0.000.

In urban areas, more information media are available than in rural areas, so in urban areas access to information, family planning services related to contraception are easier. In addition, cultural inequality and literacy rates can also influence contraceptive use. This might be one reason women of reproductive age tend to use contraception. Plans for contraceptive use can also be affected by the availability of health facilities. Regions with high availability of facilities will tend to use contraception, whereas if regions with low availability of health facilities, contraceptive use will be low[10].

Education has a relationship with contraceptive use plans. Research conducted in Kenya shows that the status of higher education increases the probability of contraceptive use two to four times[11]. The higher a person’s education, the higher the use of contraception[12]. Someone who has higher education will be more exposed to information, so they tend to choose modern contraception[12,13]. Someone who is often exposed to information will know more and understand the types of contraception and their side effects so that they can consider the contraception that will be used. Education affects someone to choose injection contraception every three months[14]. Someone with low knowledge is less informed about contraception. Whereas a person with higher education gets more information about contraception so they prefer three-month injection contraception[19]. Education not only improves his status but is also important for achieving reproductive health needs. Thus, someone with a higher education level three times more likely to use contraception compared to people with low levels of education[16].

Knowledge of contraceptive methods is generally known to women of reproductive age. Knowledge of contraceptive methods can affect the contraceptive use plan. Low knowledge will have an impact on low contraceptive use. A person will accept using contraception if the knowledge of contraception is deep and adequate regarding the side effects of its use[17]. The use of effective contraceptive methods will be chosen in the future. Knowledge of contraceptive methods is also important for planning children’s distance and preventing unwanted events[18].

Marital status is the main predictor in the research conducted in Ghana[10]. Married women will have higher contraceptive use[17]. Married women will consider contraceptive methods to be used with their husband[13]. It is inversely proportional to the research conducted in Ghana, that unmarried teenagers have a four-fold chance of using contraception[10].

**Conclusion**

Housing, education, knowledge of the types of contraceptive methods and marital status are related to the planned use of contraception in women of childbearing age.

**Conflicts of Interest:** None declared.

**Source of Funding:** This work has been fully supported by the National Family Planning Coordinating Board

**Ethical Clearance:** Ethics approval was received from The Demographic and Health Surveys (DHS). DHS Program has collected, analyzed, and disseminated accurate and representative data on population, health, HIV, and nutrition through more than 400 surveys in over 90 countries.

Effect of the Procedure of the Sweet Lupine Powder as an Alternative to the Camel Meat on the Quality and Sensory Characteristics of the Manufactured Burgers

Qays Satwan Abass Abdullah¹, Kasim Sakran Abass²

¹Department of Horticulture & Gardening Engineering, College of Agriculture, ²Department of Pharmacology and Toxicology, College of Pharmacy, University of Kirkuk, Iraq

ABSTRACT

The experiment included five factors (100% camel meat, 0% sweet lupine powder) (T1), (95% camel meat, 5% sweet lupine powder) (T2), (90% camel meat, 10% sweet lupine powder), (T3), (85% camel meat, 15% sweet lupine powder) (T4), (80% camel meat, 20% sweet lupine powder) (T5). The results showed high protein, fiber and carbohydrate concentrations (T2, T3, T4, T5) compared to the standard treatment (T1), while the ash ratio increased in all treatments except the second treatment (T2) compared to standard treatment (T1), although the moisture and fat ratio of the treatments decreased (T2, T3, T4, T5) compared to standard treatment (T1). The results showed high pH value and water retention for the coefficients (T2, T3, T4, T5) compared to the standard treatment (T1). The value of free fatty acids and the loss of (T2, T3, T4, T5) compared to standard treatment (T1). The percentage of change in the post-cooking characteristics of the Barker tablets decreased the percentage of change in weight, change in thickness and change in diameter of the transactions (T2, T3, T4, T5) compared to the standard transaction (T1), while the price value of transactions (T2, T3, T4, T5) compared to (T1). The results of the sensory evaluation of the studied traits showed a general assessment of Juicer (7.2), The coolness (7.2), Flavor (7.7), Color (7.6), Textures(7.7) And general acceptance (7.9), from (9) degrees indicating that the manufactured product obtained a good rate of all sensory characteristics studied.

Keywords: Sweet Lupine, camel, meat, Burgers

Introduction

The trade in the manufacture of processed meat products, half cooked and ready, the manufacture of Barker. The Iraqi Standard No. 1580¹ states that the components of meat crackers include fresh meat, chilled or frozen meat. Many studies have confirmed that camel meat is like chicken meat with low fat content, high energy, high protein and calcium. It turns into glucose. Plant proteins have been partially used in the manufacture of various types of meat products, The cost of using vegetable protein is much lower than the cost of animal protein with low fat and cholesterol. (upinus albus) as a source of protein content in the thermos seeds is high and sometimes higher than those found in Bean For soy, ranging from 24 to 48% in different species, with a high content of essential amino acids that meet the nutritional requirements of humans except lysine, cysteine and methionine. White lupine seeds followed by blue and yellow lupine are more suitable for Production of high protein concentrates for use in food processing and in human and animal nutrition. Several studies manufacture of varicose tablets from various animal meat and the production of beef crackers with the replacement of vegetable proteins Or erase,¹ the effect of adding the rehydrated and lipid residue powder on the specific and sensory characteristics of the beef burger cooked in different ways mentioned the possibility of making the Barker of old chicken meat, substituting beef, and adding soybean protein to the Barker process.
Materials and Method

1. Meat: Use local camel meat it was purchased after refrigeration to separate the meat from the bone sliced into small pieces and kept at a temperature of -18 °C.

2. White thermos (upinus albus): thermos seeds are processed and grinded to a 75 - inch size and kept in frozen until use.

3. Garlic: garlic was use after peeling, sprayed a good horseradish to be ready to used (1%).

4. Spices: A mixture of spices, containing (black pepper, coriander, cumin, desserts, nutmeg) use by 1%.

5. Salt: Use Nacl by (1%) of the weight of the product.

6. Treatment:
   - T1 100% camel meat 0% sweet lupine seed powder
   - T2 95% camel meat 5% sweet lupine seed powder
   - T3 90% camel meat 10% sweet lupine seed powder
   - T4 85% camel meat 15% sweet lupine seed powder
   - T5 80% camel meat 20% sweet lupine seed powder

After calculating the required quantities of camel meat, the meat pieces were separated, homogenization and mixed with the prescribed proportions of sweet thermos powder and added spices, garlic and salt. The manufacturing process was done with discs of the meat breaker and refrigerator at a temperature of 4 °C for 24 hours.

Determination of some chemical and physiological characteristics

A. Moisture, fat, ash and protein were evaluate.

B. The proportion of carbohydrates was calculated^{7,8}

C. The price value was estimated by multiplying the percentage of protein and carbohydrates x 4, and multiplying the percentage of fat by x 9.

D. pH Determination by the PH meter^{9}.

E. Water resistance was estimated^{10}.

F. Changes in weight, thickness and diameter^{11,12}.

G. Determination of free fatty acid (FFA): Determination of free fatty acid ratio based on the method mentioned^{13}.

The sensory evaluation was conducted by evaluating a questionnaire by the researchers based on the method proposed by^{14}

Results and Discussion

Table (1) shows chemical composition, The high humidity in treatment (T1) followed by (T5, T4, T3, T2), respectively, may be due to higher humidity of the control treatment than other treatments. The percentage of replacement of plant variant increased when the moisture content was less than^{15}. The percentage of moisture increased by increasing the concentration of plant variant (the remaining powder and soy protein) in the processed turkey burger, the results are consistent with both^{16,17}. If reduced humidity of the transactions of the manufactured Barker with increasing the replacement of animal proteins with plant proteins. The higher the protein content of the treatment (T5) followed by the treatment (T1, T2, T3 and T4) respectively, the reason for the high protein ratio of the treatments compared to the control treatment is the result of increasing the ratio of the replacement of animal proteins with plant proteins.^{18} observed low protein content in processed meat products with an increase in the percentage of plant additives, including bran, salmon and flour, indicate high fat in (T1) followed by (T5, T4, T3, T2), respectively. The results are consistent with what reached^{16,17}. Table (1) also shows the high rate of ash in (T5) followed by (T1, T2, T3, T4), respectively. The reason for the higher ash ratio of the treatments compared to T may be due to the increase in the ratio of total solids with increased replacement of the sweet thermos powder, results are consistent with^{16}. The results were also consistent with^{17}. The high proportion of fiber in the treatment (T5) followed by treatment (T1, T2, T3, T4) respectively. The increase in the fiber ratio of treatments compared to the T1 is due to the increase in the ratio of fiber in the sweet lupine powder, the results are consistent with what reached^{16}, as they observed. Increase in percentage of fiber in the processed Barker transactions with increasing the addition of different percentages of legume proteins (chickpea). Table (1) shows the high proportion of carbohydrates in the treatment (T5) followed by treatment (T1, T2, T3, T4) respectively.

Table (2) shows some physical properties of the plant. The pH value of the treatment (T5) and the treatment (T1, T2, T3, T4), respectively. The reason for the higher pH value of the coefficients compared to the control treatment may be due to the increase in the replacement ratio of the sweet granules of thermosetrate powder with results similar to the increase in PH values at16 when adding 20% of the moisturized soybean protein to the cooked meat burger. The effect of base reaction of plant proteins, resulted in a decrease total acidity of transgenic treatments in plant proteins21,22, As well as solubility of plant proteins and spread in water and formation of basic solutions contribute to increase value of PH as this result corresponds23. Table (3) shows high value of free fatty acids in (T1) followed (T5, T4, T3, T2), respectively, as23 found. The lack of free fatty acids (FFA) make product less susceptible to analytical tattoos17. Table (3) indicate a high water retention ratio (WHC) in (T5) followed by (T1, T2, T3, T4), respectively, due to the high water retention ratio (WHC) of treatments relative to the pH T1, which results in a high (WHC)24. From table (3) the high proportion of recipe loss charity (T1) followed by (T5, T4, T3, T2) respectively.

From table (3) The reduction in the weight for (T5) was observed, followed by (T1, T2, T3, T4), respectively, the reason is the ability of proteins in the plant sources used in the manufacture of the Barker tablets to maintain water and fat during cooking and the increase in the value of the hydrogen, which increases the retention of moisture and decreases the loss during cooking, has already been pointed out and reduce the weight loss ratio by adding some plant proteins. Table 4 shows the low rate of change in the diameter of the tablets in the treatment (T5) followed by the treatments (T1, T2, T3, T4), respectively, the cause of this increase and loss in the vector of treatment (T1) may be due to the occurrence of protein synthesis and the accumulation of meat tissue. The more the replacement of animal bronze with protein production of chicken meat powder added to soy protein by (20%), the percentage of loss in diameter was (20%). The results from Table (4) show the low change in the thickness of the VAR in the treatment (T5) followed by the treatment (T1, T2, T3, T4) respectively. The results are consistent with16. The value of the transaction price (T5) and the treatment (T1, T2, T3, T4), respectively, may be due to the higher price values of the transactions compared to T1 because the sweet lupine powder contains Carbohydrate content may reach more than 45% because 1 gram carbohydrate yields 4 calories. The results are consistent with16.

Conclusion

From the results possibility of replacing the sweet thermos powder with different mixing ratios, which contributes to improving the qualitative and sensory characteristics of the camel burger, while preserving the nutritional value, as well as producing a healthy, economical and cost effective food product.

Climate Factors Improve Accuracy of Time Series Model for Dengue Hemorrhagic Fever Forecasting in Pasuruan Regency, Indonesia

Qurrotul Aini Meta Puspita Sari1,2, Hari Basuki Notobroto3, Mahmudah3
1Student Master of Public Health at Airlangga University Surabaya, Indonesia; 2Research Center for Humanities and Health Management, Ministry of Health, Indonesia; 3Departments of Biostatistics, Faculty of Public Health, Airlangga University Surabaya Indonesia

ABSTRACT

A large number of dengue cases in Indonesia must be followed by vector control, and efforts to terminate the chain of disease transmission with promotive and preventive activity. Pasuruan Regency is one of the regions in East Java, Indonesia that has a large number of dengue cases and exists monthly throughout the year. Accurate forecasting of Dengue Hemorrhagic Fever (DHF) cases before the outbreak in Pasuruan, can help public health practitioners to prioritize public health activities. This study aims to obtain a time series forecasting model for the number of dengue cases with the addition of climate factor predictors as rainfall, air humidity, air temperature and duration of irradiation. Secondary data of DHF and climate factor in 2015-2017 were analyzed by ARIMA and Multi Input Transfer Function. Forecast model was evaluated by actual data in 2018. The Result showed that he addition of the climate predictor factor as rainfall, air humidity and air temperature in Multi Input Transfer Function model succeeded in increasing forecasting accuracy compared to the ARIMA (1,1,1). RMSE Transfer Function model decrease by 9.19%. DHF was significantly affected by DHF in the previous month, rainfall in the previous 1 and 2 months, air humidity 3 and 4 months before and the air temperature 1 and 2 months before and interaction of random effects of rainfall, humidity and air temperature with DHF one month earlier.

Keywords: DHF, Forecasting, ARIMA, Transfer Function, Climate

Introduction

Dengue Hemorrhagic Fever (DHF) has spread across the world in more than 100 countries in WHO’s African, Eastern Mediterranean, South-East Asia and Western Pacific regions; the Americas, South-East Asia and Western Pacific regions are the most seriously affected. Indonesia is a South-East Asia categorical country that ranks first in the highest case of DHF from 1990-2015.1) According to WHO, the incidence of dengue fever worldwide has increased significantly in the past few decades. Even the actual number of DHF cases is greater because it is often not reported and many cases of misclassification. An estimated around 390 million dengue infections per year (95% CI 284–528 million), of which 96 million (95% CI 67–136 million) manifest clinically (with the severity of the disease).2) A large number of dengue cases in Indonesia especially in East Java Province which is the second highest number of cases must be followed by vector control, and efforts to terminate the chain of disease transmission with promotive and preventive activity.3) Pasuruan Regency is one of the regions in East Java that has a large number of dengue cases and exists monthly throughout the year.

DHF is a disease that is widely spread in tropical and sub-tropical regions. The study of the relationship of climate change with DHF in several countries, namely Thailand, Taiwan, India, China, Singapore, Australia, including Indonesia states that global climate change can have an influence on the transmission season, the area of dengue disease spread and increased risk associated

with its emergence in the region Asia-Pacific.\(^{4,5,6}\)

Dengue is widespread throughout the tropics, with risk factors influenced by local spatial variations of rainfall, temperature, relative humidity, degree of urbanization and quality of vector control services in urban areas.\(^{1}\)

Accurate forecasting of Dengue Hemorrhagic Fever (DHF) cases before the outbreak in Pasuruan regency, can help public health practitioners to prioritize public health activities. One forecasting model is time series data modeling. Time series is a series of observations taken sequentially based on time at the same interval. Univariate time series can be done with an autoregressive (AR) approach or combined with moving average (MA) as ARIMA.\(^7\) The transfer function model is the development of the Box-Jenkins method whose model consists of two or several variables, but each variable has a specific ARIMA model. The transfer function model is a model that illustrates that the future forecast of a time series (output series or \(y_t\)) is based on past values of the time series itself and is based on one or more other time series (input series or \(x_{ht}\)) related to the output of the series.\(^{7,8}\) This study aims to obtain time series analysis for DHF forecasting models using the ARIMA and the multi-input transfer function with the addition of climate variables.

**Material and Method**

This study used secondary data. DHF case’s data were from the East Java Provincial Health Office, and climate data as monthly rainfall from Meteorology and Climatology Station Karang Ploso Malang while air humidity, air temperature, and duration of radiation were taken from Center for Sugar Research and Development, Pasuruan. The population of this study included monthly DHF cases which were recorded in the East Java Provincial Health Office. While the sample of this study were monthly dengue cases of in 2013-2018. DHF data in 2013-2017 were used for developing models that would evaluate using DHF data in 2018. ARIMA and Transfer Function Analysis were carried out using SAS on Demand for Academic data processing application. Model accuracy based on Root Mean Score Error (RMSE) value.

**Autoregressive Integrated Moving Average (ARIMA)** included autoregressive (p), differencing (d) and moving average (q), written with notation ARIMA (p,d,q);\(^{7,8}\)

\[\phi_p(B)(1-B)^d z_t = \theta_q(B) a_t\]

with \(\theta_q = \text{constant} \)

\[\phi_p(B) = (1 - \phi_1 B - \ldots - \phi_p B^p)\]

\[\theta_q(B) a_t = (1 - \theta_1 B - \ldots - \theta_q B^q)\]

\[\phi_p(B) = \text{AR component coefficient order } p\]

\[\theta_q(B) = \text{MA component coefficient order } q\]

\((1 - B)^d = \text{differencing order } d\)

\(a_t = \text{white noise residual with mean = 0}\)

The Transfer Function model is formed through the Cross-Correlation Function (CCF) so that it can be used to predict a variable based on information from other variables. There are two types of transfer functions namely, single input and multi input. The general form of the transfer function model for multi-input is as follows: \(^{8}\)

\[y_t = \sum_{h=1}^{H} \frac{\omega_s(B)B^h x_{ht}}{\delta_r(B)} + \frac{\theta_q(B)}{\phi_p(B)} a_t\]

with,

\(y_t = \text{stationer output series}\)

\(x_{ht} = \text{stationer input series variable-}h\)

\(\omega_s(B) = \text{operator with order } s, \text{ which represents the number of past observations } x_{ht} \text{ variables that have an effect on } y_t \text{ for } h \text{ variable,}\)

\(\delta_r(B) = \text{operator with order } r, \text{ which represents the number of observations of the past series of outputs that affect the } y \text{ for the } h \text{-variable.}\)

\(\theta_q(B) = \text{moving average operator order-}q \text{ error series}\)

\(\phi_p(B) = \text{autoregressive operator order-}p \text{ error series}\)

\(a_t = \text{white noise residual of error series}\)

The accuracy of Model based on Root mean square error (RMSE) with formula:

\[\text{RMSE} = \sqrt{\frac{1}{M} \sum_{i=1}^{M} (Z_{n+i} - \hat{Z}_n(i))^2}\]

with \(M\) was the number of predictions made, was actual data and was forecast data.\(^{8}\)
Result and Discussion

Table 1 showed that there were cases of DHF in every month from 2013 to 2018 with an average of more than 30 cases per month.

Data stationarity was the main requirement in conducting time series data analysis. This indicated by constant in mean and variance over time. Figure 1 showed that DHF cases were not stationary in the mean and variance and Box cox value (lambda) not include 1 in its Confident Interval (CI).

Furthermore, the transformation of natural logarithms (ln) and differencing 1 was done to produced stationary data with lambda values to 2.00 (95% CI 0.97-2.72). The ADF tests proved existence of root units in time series data. The p-value ADF for post-transformation and differencing 1 of DHF data is 0.001. This means that the DHF data was stationary.

Figure 1: Time series and Box cox plot of monthly DHF

Figure 2: ACF and PACF plot of stationary DHF post-transformation and differencing 1
Based on the ACF and PACF plot (Figure 2) the ARIMA model formed was ARIMA (1,1,1) with moving average parameter (θ) estimate $0.9862$ (p-value $<0.0001$) and autoregressive parameter ($Φ_1$) estimate $0.7985$ (p-value $<0.0001$). The parameters estimation significant at the 0.05 level, so they could be used in the model. The next step was diagnostic checking to check suitability of the model. The residual autocorrelation’s p-value was greater than 0.05 and normality test is based on the Kolmogorov Smirnov test value 0.0826 (p-value $>0.1500$), which meet the assumptions of white noise and normal distribution and feasible for forecasting.

Time series data of rainfall, air humidity, air temperature, and duration of radiation used as input variables on transfer function model and had non stationer mean and variance. Differencing 1 was done to produced stationary data. Univariate time series model for climate factors was ARIMA (7,1,0) for rainfall, ARIMA (0,1,1) for air humidity, ARIMA (1,1,1) for air temperature and ARIMA ([4,6],1,0) for duration of radiation. The climate ARIMA model used to estimate the parameters and did pre-whitening on the input and output series. The ARIMA model formed for input data had a significant parameter. This model was used to pre-whitening the series of input and output series (dengue cases) in Pasuruan Regency that have been stationary. Cross-correlation between input and output variables (DHF) which has an ARIMA (1,1,1) model shown in Figure 3.

![Cross Correlation Function plot between output variable (DHF) and input variable (climate factor)](image)

The impulse response weight for rainfall input data was $b=1$, $s=0$, and $r=0$, air humidity data was $b=3$, $s=0$, and $r=0$, air temperature data was $b=1$, $s=0$, and $r=0$, while radiation data $b=0$, $s=0$, and $r=0$.

### Table 2: Parameter estimation of Multi Input Transfer Function Model

<td>0.0018</td>
<td>3.47</td>
<td>0.0011</td>
<td>0</td>
<td>Rainfall ($x$)</td>
<td>1</td>
</tr>
</tbody>
</table>
The estimation results (Table 2) showed that only duration of radiation variable had p-value more than 0.05 or not significant. Transfer function multi input model results showed that DHF data in Pasuruan Regency was influenced by the number of previous DHF and several climate factors namely rainfall, air humidity, and air temperature. Diagnostic checking on this model result that there was no autocorrelation on white noise of residual testing and had a normal distribution with the Kolmogorov Smirnov Test value of 0.0810 (p-value >0.1500). This means that the modeling residuals had met the assumptions of white noise and fit use.

Forecasting was carried out for January-December 2018 with both model ARIMA and Multi Input Transfer Function (Figure 4). Forecast results trend showed that from January to June these two models have almost the same pattern. But then in the Multi Input Transfer Function model forecast decreased in June to July, this may be due to the influenced of climate factors that changed. These forecast values were compared with actual data and calculated the RMSE value of each model formed. RMSE of ARIMA (1,1,1) model was 0.6312 greater then Multi Input Transfer Function model (0.5732).

| $\omega_2$ | 0.0322 | 2.65 | 0.0108 | 0 | Humidity ($x_1$) | 0 |
| $\omega_3$ | 0.0899 | 3.00 | 0.0042 | 0 | Temperature ($x_2$) | 1 |
| $\omega_4$ | 0.0430 | 0.97 | 0.3349 | 0 | Duration of radiation ($x_3$) | 0 |

Table 2: Coefficients and p-values for DHF forecasting model

Figure 4: Actual and forecast data of DHF for January-December 2018

Based on the RMSE value, the Multi Input Transfer Function model was better in predicting the number of DHF cases, with equation as $y_t = 0.8768y_{t-1} + 0.0018x_{1,t-1} + 0.0016x_{1,t-2} + 0.0322x_{2,t-3} + 0.0282x_{2,t-4} + 0.0899x_{3,t-1} + 0.0788x_{3,t-2} + at – 0.9788a_{t-1}$ and $y_t$ was ln transformed. The number of dengue cases in Pasuruan regency was affected by DHF one month before, rainfall 1 and 2 months before, air humidity 3 and 4 months before and air temperature 1 and 2 months earlier. The interaction of the random influence of rainfall, humidity and air temperature with DHF one month earlier also determined the future period. Research with other transfer functions in forecasting DHF also resulted in significant rainfall and humidity variables in the previous month.\(^{(9,10)}\)

Addition of climatic factors succeeded in increasing forecasting accuracy by 9.19%. Rainfall conditions affected Aedes aegypti life cycle, mainly related to increasing breeding sites. Rainfall was already proven to be related to the number of DHF cases.\(^{(11,12)}\) Relative air humidity was more than 60%, so that it could support the growth of Aedes aegypti mosquitoes. Aedes aegypti could live for up to three months. Experiments at a temperature of 20°C and relative humidity 55% decreased mosquito life to 50 days. Air humidity less than 60% would cause it to be shorter. The longer the lifespan of Aedes aegypti mosquitoes, the greater the potential for breeding and possibly to be a vector. In addition, this was related to the possibility of insufficient time to transfer the dengue virus from the stomach to the salivary glands so that the viral breeding cycle is broken in the body of the mosquito which takes 8-12 days.\(^{(1,13,14)}\)

Figure 4: Actual and forecast data of DHF for January-December 2018

Temperatures that are quite high caused the life cycle of mosquitoes to be shorter as well as shortening the incubation period of the dengue virus. The air temperature in Pasuruan was sufficient for mosquito growth. Female mosquitoes respond to increased temperatures by reducing egg production, and laying time. At 25°C and 80% relative humidity, female mosquitoes survived twice longer and produced 40% more eggs than those stored at 35°C and 80% relative humidity.\(^{(15)}\) Other study proved that rainfall variables had a positive effect on the incidence of DHF if the intensity of rainfall starts from 1500 mm to 3670 mm in 1 year. Air temperature has a large effect on changes in the incidence of DHF at temperatures between 22°C to 27°C, while humidity has a positive effect on changes in the incidence of DHF when humidity is in the interval of 82% to 87%. DHF events are responsive when changes in temperature and humidity occur.\(^{(16,17,18)}\)
Conclusion

Time series model could be used to forecast DHF cases in Pasuruan Regency, East Java Province, Indonesia. ARIMA (1,1,1) was a model that formed from univariate time series. The addition of the climate predictor factor as rainfall, air humidity and air temperature in Multi Input Transfer Function model succeeded in increasing forecasting accuracy compared to the ARIMA (1,1,1). RMSE on Transfer Function model decrease by 9.19%. DHF was significantly affected by DHF in the previous month, rainfall in the previous 1 and 2 months, air humidity 3 and 4 months before and the air temperature 1 and 2 months before and interaction of random effects of rainfall, humidity and air temperature with DHF one month earlier.

ABSTRACT

The aims of the study are determine some immunological aspects namely total IgE, specific IgE, eosinophil count, IFN-γ, IL-10 and CCL-17 in serum of atopic patients and apparently healthy control to determine their relationship to atopic diseases. The age group of 21-40 years seems to be the most affect group with atopic diseases (P = 0.0001) and asthmatic and allergic rhinitis patients are at this age group also (P =0.005, P =0.001 respectively). There is a major differences (P < 0.001) in level of total IgE between allergic subjects and controls and among three atopic patients groups (P < 0.001) but Specific IgE is significantly higher in asthmatics than allergic rhinitis and atopic dermatitis patients (P < 0.05). Inhalation of outdoor allergens is significantly affected asthmatic patients and allergic rhinitis patients (P < 0.01). Controversially, indoor allergens are significantly affecting atopic dermatitis (P < 0.01). The mean of IFN-γ serum level in asthma patients was lower than IFN-γ serum level of the control group and atopic dermatitis patients (P < 0.05). The allergic rhinitis patients mean of serum level of IL-10 was significantly low as compared to the mean of the serum level of IL-10 control group (P= 0.020). All of three groups of atopic patients are significantly have high level of CCL-17 compare to mean of serum level of control group (P < 0.01).

Keywords: asthma, allergic rhinitis, atopic dermatitis, cytokines.

Introduction

Allergy is the immune system reaction to substances that are not familiar to it, this case may cause various symptoms that can appear on the skin, in the sinuses, in the respiratory airways and in the digestive system, sensitivity and severity of allergic reactions vary from person to person can range from mild to even anaphylaxis (1). Allergens are precise substances (protein in nature) in the atmosphere that are transmitted to the human body by breathing that induce IgE responses in humans, and divided into indoor and outdoor allergens (2).

Mast-cells and eosinophils are activated (in the effectors phase of these responses) to rapidly release mediators that cause vasodilation, elevation in the permeability of blood vessels and bronchial and muscle contraction. Rapid immediate reactions occur in minutes of antigen challenge in a previously sensitized individual (3). Asthma can be defined as chronic-disease in respiratory tracts due to the lower-airways, with a several cells that have an important key role in it, due to risk of respiratory system diseases especially asthma, on other hand diabetic patients and asthma also contribute in risk of allergy diseases, these factors contribute in weakening of immune response to corticosteroids therapy (5,6).

Rhinitis is an inflammation of the mucus membrane of the nose in upper respiratory tract, there is a tight connection between AR and asthma, due to “one airway, one disease” concept (7). The encounter and contact between masts cell of dermal tissues and specific-IgE-receptors induce the secretion and making of a rapid series of inflammatory mediators, eosinophils are also contribute pertinent to skin-tissues damage, after their activation and recruitment onto the skin (8).

The aims of this study are determined some immunological aspects namely total IgE, specific IgE, eosinophil count, serum level of IFN-γ, IL-10 and CCL-17 with patients of atopic disease and apparently healthy control to determine their relationship to atopic diseases.

Methodology

Study Groups: A total of 75 diagnosed atopic patients, as 25 blood samples from atopic asthma, 25 blood samples from allergic rhinitis, 25 blood samples from atopic dermatitis patients, were integrated in this research, and
25 blood samples that were collected from apparently normal people and were considered as controls.

**Serological Tests:** Total serum IgE was determined by Immunoenzymetric Assay by the uses of the total IgE ELISA kit (Euroimmum/Germany). Allergen specific IgE was determined in serum of total subjects was estimated by using Polycheck Allergy kit (Biocheck GmbH, Munster, Germany). The levels of IFN-γ and of IL-10 in serum were estimated by using serum level of serum level of IFN-γ and serum level of IL-10 kits (Diaclone/France) and the serum level of CCL-17 were estimated by CCL-17 kit (Biosource/USA).

**Eosinophil Count:** Eosinophil count determined from complete blood count that was performed (to all study groups) by Beckman Coulter analyser instrument.

**Statistical Analysis:** SPSS program (version 20) was used to elucidate the differences in parameters. ANOVA, chi-square and Duncan tests were used to compare between means of parameters of patients and apparently healthy control.

**Results**

Among all studied groups, the age groups were separated into three groups, first one was less than 21 years (childhood and beneath youth), the second group was between 21-40 years (adulthood) and the third group was over 41 years. In control group the frequency of subjects was 24 %, 52% and 24% in the first, second and third group respectively. In asthmatic patients, it was 16 %, 64 % and 20 % in the three groups respectively. The frequency of patients in three groups of allergic rhinitis was 12%, 56 %, and 32 % respectively. In atopic dermatitis, the frequency of patients was 32 %, 40% and 28% in the first, second and group respectively. The distribution of age groups displayed in table 1.

**Discussion**

The middle age group (21-40 years) is the age at which the asthma and allergic rhinitis are occurred, but not atopic dermatitis, which affect all age group. The current results in agreement with Brakhas et al., (9) who concluded that allergic patients with any age have significant increased level of total IgE compared to healthy controls and explained the immunity responses towards allergens that mediates by IgE antibodies specifically to the allergen, after IgE bindings, mast cells and basophils were activated, opening a series of molecular and cellular actions which leads to the clinical manifestation of allergic diseases.

Indoor allergens are significantly affecting atopic dermatitis as compared with asthmatic patients and allergic rhinitis patients. The current results agreed with Smoldovskaya et al., (10) who concluded that outdoor allergens (pollen) are the most prevalent than indoor
allergens, specific IgE response to most pollen allergens is associated strongly with asthmatics and allergic rhinitis patients than atopic dermatitis.

The high eosinophil count was seen in patients of atopic subjects than in apparently healthy control but asthmatics have eosinophil counts higher than allergic rhinitis and the last have eosinophil counts higher than atopic dermatitis. Allergen irritation of the airways can produce blood eosinophilia within hours (11), in allergic rhinitis, the recruitment of eosinophils to the nasal mucosa and lumen is driven by Th2 cytokines after the exposure to aeroallergens. Th2 cells are significant for producing key cytokines that includes IL13, IL5, and IL4. These cytokines have a great importance for antibody class switching, rule of local and systemic IgE synthesis, enrolment of inflammatory cells, and survival of eosinophils and also, concluded that eosinophil counts over 80 cells/ml were suggested the atopic aetiology towards the patients that shows symptoms of rhinitis (12).

In patients with asthma a clear changes in the epithelium airway’s, which includes a disruptions of the epithelial cell tight junctions, and impair producing of IFN-β IFN-α, that supports the epithelial damage and increases the susceptibility to viral infections (13), reducing the producing of IFN-γ by T-cells of asthmatic patients which correlated to the disease severity. Also, secretion of exogenous IFN-γ prevents the airway eosinophilia and hyper-responsiveness after allergen exposure (14).

Since Th1/Th2 imbalance can cause disorders in immune response, this reflects the lowest levels of IFN-γ; in asthmatic patients; which produced by Th1 due to increase levels of eosinophil count (Table 3-6) which recruited in response to IL-5 and IL-13 produced by Th2, and increased levels of IgE (Table 3) which produced by B-cell in response to IL-4 that produced by Th2, like this imbalance may contribute to disease severity (15).

The key function played by the suppressor cytokines (IL-10) and transforms the growing of factor-β (TGF-β) that produces in functional Treg cells during creation of immunity tolerance to allergens, is very important in allergy. Both, Treg and Breg cells have a unique role in repression of IgE and initiation of IgG4 isotype allergen-specific antibodies mainly mediated by IL-10 (16). In healthy subjects, allergen-specific Tr1 cells are the dominant T-cell type and many researches clarified that these cells are capable to inhibit allergic immune responses to different allergenic sources such as birch pollen or, house dust mite, or related food allergens.

Activation of naïve T cells and their differentiation into Th2 cells are marked by the appearance of CCR4 receptors (CCL17 receptors) and other receptors, these receptors enable Th2 to move down the concentration gradient in response to CCL17 and other chemokines (1) due to increase in Th2 cells subsets and this, in turn, explains the increased levels of their cytokines. In the current study, serum CCL-17 levels were increased in all atopic groups. The current results agreed with Hijnen et al., (17) who concluded that serum TARC levels are specifically elevated in patients characterized with atopic dermatitis were significantly higher than those in allergic respiratory diseases compare to control. Chemokine regulates infiltration and specific migration of lymphocytes and recruitment of inflammatory cells into tissues (18).

As a conclusion, atopic disease can be diagnosed at any age, at both genders. A significant increase of serum IgE levels, eosinophilia, and serum levels of CCL-17 in atopic patients compared to control. Inhalation of outdoor allergens is significantly affected asthmatic patients and allergic rhinitis patients. Controversially, indoor allergens are significantly affecting atopic dermatitis. There is significant decrease in levels of serum IFN-γ in asthmatic patients, and slightly decreases in allergic rhinitis patients and no difference in serum levels of IL-10 in the three atopic groups.

Visual Capabilities According to RehaCom Cognitive System as a Healthy Significance to Determine the Performance in Tennis

Rasul Hameed Mezher¹, Prof. HishamHindawiHoweidi¹
¹College of Physical Education and Sports Sciences, University of Al-Qadisiya. Iraq, Al-Qadisiya

ABSTRACT

The research focused on several main aspects. The focus was paid to the visual capability measurement of the research sample and its relation to the performance level of the straightforward strike in tennis. Some visual capabilities were measured through the RehaCom Cognitive System. The researchers have prepared a test to measure the performance level of the straightforward strike in tennis as well as deducing the contribution ratios of the visual capabilities and building a predictive equation for the performance level through visual capabilities.

The statistical results that were collected, analyzed and discussed showed that there is a significant correlation between some of the visual capabilities in the skills performance of the straightforward strike in tennis and the highest percentages of the contribution of the visual capabilities in the skill performance were obtained and the predictive equation was based on the skill level.

Keywords: Visual Capabilities, Skill

Introduction

At the present time, tennis has attracted the attention of most of people, which led to its spread throughout the world because of its aesthetic performance and the arts of play. Visual capabilities play an active role in tennis because of the much stimulation exposed to the player such as the speed of the body and tracking the ball. In addition, recognition of all the stimulations to which the player is exposed by the eye and then transferred them to the brain, interpreted and giving appropriate reactions to get the best results.

Research Objectives

1. To identify the relationship between the most important visual capabilities on the one hand and its relationship to the performance of the straightforward strike in tennis on the other hand.
2. To identify the percentage of the contribution of the most important visual capabilities specified for the performance of straightforward strike in tennis.
3. To measure the level of skill performance and build predictive equation.

Research Procedures: The researchers adopted the descriptive methodology by using the method of correlative relationships for its convenience with the nature of the research. The researchers chose the sample from the research society in the simple random way represented by students of the third stage of the College of Physical Education and Sports Sciences – Al-Qadissiya University for the academic year 2018-2019, of (150) students and (30) students were selected as a sample to search.

Test of the Visual Capabilities: The researchers tested the students according to RehaCom Cognitive System in order to conclude to the statistical results of the visual capabilities. Such tests are available in the laboratories of the College of Physical Education and Sports Sciences - Al-Qadissiya University. RehaCom Cognitive System is known as a comprehensive system for containing examination and diagnostic units as well as training programs of high accuracy and objectivity far from bias and intervention. Its programs are described by

DOI Number: 10.5958/0976-5506.2019.03126.7
adaptively, as well as the possibility to create motivation and willingness to train independently and under self-control, as well as many other features. The examination units provide results compared to a standard healthy sample of the same sex and age. It is worth mentioning that the system consists of (9) examination units. The visual capabilities included (validity accuracy, selectivity, visual reflex rate of the right eye, visual reflex rate of the left eye, parallel of the visual eye scan, and sequential research of the visual scan).

This table shows a comparison between the arithmetic means and hypothesis means to determine the sample levels in each of these variables. The table indicates that (the validity accuracy) when comparing its arithmetic mean to its hypothesis means, which is a benchmark for the comparison within the sample itself. When it is showed that it is insignificant at the significance level of (0.173) indicating that the sample of the research has an average level. The researcher attributed the reason to the slow reaction time of the research sample led to this level\(^1\). In addition, the validity accuracy and good concentration would lead to the use of mental abilities to fulfilling the achievement and having good performance\(^2\). Further, since the validity accuracy is medium, it is reflected in its ability to see goals in a timely and accurate\(^3\).

As for the selectivity variable, which is one of the variables, the higher the value, the more positive it was. Selectivity variable was indicated thru the data analysis and the comparison of the arithmetic means and hypothesis means. The research sample showed a significant level at the significance level of (0.000) and for the arithmetic mean, indicating that the sample has a high level of Selectivity\(^4\). The researcher attributed the reason to the reaction time to peripheral stimuli was at an appropriate level\(^5\).

As for the variable of the eye reaction time (right and left), which is one of the variables that depend on the measurement unit of time, which indicates the less time, the more positive of the examinee performance. Therefore, it is noted that there are significant differences at the significance level of (0.118) and (0.474) respectively. Since the arithmetic mean is higher than the hypothesis mean, it is indicated that the sample has an average level. The researcher attributed the reason behind the sample’s having an average level at the time of the visual reaction to the fact that the sample did not receive exercises or trainings on the visual reaction time, which led the sample to enjoying an average level of reaction time\(^6\). The reaction time depends on the visual and neurological systems and the sensory stimuli of the distances, colors, sizes and angles of vision in the completion of the duty and the extraction of a suitable response and rapid and stimulate nerve centers responsible for movement\(^7\).

The visual scan variable is indicated by the value of (T) for the parallel research and the value of (T) for the sequential research. Further, since it is one of the variables that depend on the measurement unit of the degree, which indicates the higher the score, the more positive of the examinee performance. Such indicates
when comparing the arithmetic mean of parallel research with the hypothesis mean, it is noted that there are no significant differences at the level of significance (0.857). It is indicated that the research sample has an average level of parallel research. When comparing the arithmetic mean of the sequential research with the hypothesis mean, it is found that it has a significance level at (0.000) and for the favor of the hypothesis mean, indicating that the sample has an average level of sequential research. It is also referring that the research sample has an average level of visual scanning by comparing the arithmetic mean of parallel and sequential research [8]. The researcher attributed the reason for the average achievement in the visual scan to the lack of visual perception and the many stimuli that the examinee receives where he looks for the targeted stimulus. The stimuli are increased with the progress of the (10) test stages [9]. The color of the stimuli changes between each stage, resulting in the loss of focus and attention on the target stimulus, thus affecting the performance result [10]. In addition, the visual scan depends on the role of nervous system in tracking the movements or the ball as it moves [11].

<td>Significant</td>
</tr>
</tbody>
</table>

This table shows the level of skill performance by comparing the arithmetic mean with the hypothesis mean, which is a benchmark for the comparison within the same sample, it was found to be significant because the calculated (T) value is greater than the (T) value at the significance level of (0.000). It has been indicated that the research sample has an average or above average level. The researcher attributes the reason for that to the fact that the skill of a front-end strike is one of the front-hitting skills, one of the basic and easy-to-play skills in tennis, familiar and widespread in tennis [12], but at the same time upon which learning most other skills [13] are built. The researcher points out that students focus on the accuracy in more than the other aspects so that he tries as much as possible to use the physical and biomechanical variables so that the strike is correct and at the required level.

Determination of the performance levels of the straightforward strike in tennis: The results of the skill performance were statistically analyzed and the sample was divided into five levels. The results showed that the arithmetic mean of the research sample of (30) students was (75.43) with a standard deviation of (9.61) and a percentage (40%). This indicates the occurrence of the research sample at the above average level.

Figure 1: Diagram for the sample levels in skill performance
Results of the contribution of visual capabilities and biomechanical variables in skill performance and predictive equation

The researcher has used the regression model to achieve the goal of prediction. For the large number of independent variables by which the dependent variable can be predicted (the skill performance), the researcher used the multiple regression on steps. For this purpose, the adjusted contribution ratio was obtained (the third column of the multiple correlation tables) [14]. The researcher also used the stepwise method in the regression equation. These multiple correlations were tested by using the F-law, where the value of the value is detected using the significance level. As for the predictive equation, the value of the constant and regression slope parameters and the value of (T), which reflects the difference in the inclination values from zero, were extracted.

</tbody>
</table>

This table shows that the value of (F) was significant for both variables, indicating their ability and validity to predict the dependent variable by the level of significance that shows the probability of chance at (0.000). This table shows the significance of regression slope by the (T) value as a function at the level of significance (0.000), (0.036), indicating the high probability of predicting skill performance through the two variables above. The sequential search variable in the visual scanning was the first in the correlation of the visual capabilities under study because it makes sense to be the highest correlation because it performs a high degree and control of skill performance [15]. It is obvious to the mobile targets depends on the search or visual survey and different from the fixed goals, this is shown in the variable accuracy of the installation, as the fixed goals depend on attention and focus at a specific point, depending on the fixed focus system focused on a fixed target center, i.e. selection of stimuli that is in the center of the sight. The visual search depends on the central and peripheral validity accuracy [16], indicating that the visual scan depends on the accuracy of the installation so that it is a form that is the most highly correlated with the skill performance and capable of predicting the dependent variable.

Conclusions and Recommendations

The validity accuracy and the visual scanning is the proportion of the contribution of the correlation with the performance of the skilled tennis players in general and for the straightforward strike in tennis in particular. We can also predict the skill level of the players through the above variables to compensate for the values of the two variables equation prediction.

The researchers recommend the trainers and teachers to develop the visual capabilities of tennis players through training for the visual capabilities and strengthen the trainee, which is reflected positively in the performance of skilled players.

Change Commitment and Change Efficacy of Public Health Center in Indonesia in Implementing Efforts to Improve the Quality of Health Services

Ratna Dwi Wulandari1,2, S. Supriyanto2, M. Bagus Qomaruddin3, Nyoman Anita Damayanti2, Agung Dwi Laksono4

1The Doctoral Program of Public Health, 2Department of Health Policy and Administration, 3Department of Health Promotion, Faculty of Public Health, Universitas Airlangga; 4National Institute of Health Research and Development, Indonesian Ministry of Health

ABSTRACT

The successful implementation of efforts to improve the quality of health services is influenced by many variables, both organizational and individual variables. The two main variables that are widely discussed when studying the level of organizational readiness to change are commitment to change and efficacy to change. This research was conducted to analyze change commitment and change the efficacy of Public Health Centers (PHC) in Indonesia in implementing efforts to improve the quality of health services. A cross-sectional survey was conducted on health workers in 40 PHCs in Surabaya, to measure change commitment, change efficacy, and efforts to improve the quality of health services that have been implemented. The rank Spearman correlation test is done to prove the relationship between these variables. The results showed that the implementation of efforts to improve the quality of health services was not significantly related to change commitment, but there was a significant relationship with change efficacy. Therefore, so that the implementation of efforts to improve the quality of health services can run well, it is necessary to carry out various activities to improve the capabilities and skills of the staff of PHCs to have an impact on increasing efficacy.

Keywords: Change commitment, change efficacy, health service quality, readiness to change

Introduction

Organizational change is not a new domain in the study of organizational behavior. Various studies have been conducted by researchers from various countries to examine aspects of organizational change, including research in India1, Canada2, and Indonesia3. Various studies have found that organizational change processes are influenced by many variables, both organizational and individual level variables. Some of the individual variables examined in the study included commitment, self-efficacy, and change readiness. Weiner4 found that organizational readiness to change is a key factor that will determine the success of implementing change. Therefore, research on organizational readiness to change will always be an interesting area of study, because, for all organizations that want to grow, organizational change is an event that cannot be avoided.

For primary health care organizations in Indonesia, in the last 4 years, there has been a huge wave of change. Since the implementation of the National Health Insurance policy in 2014, all Public Health Centers (PHC) in Indonesia must carry out a new management order in which it emphasizes the importance of the quality of health services, through the accreditation mechanism. The quality standards written in the accreditation guidelines stipulate that quality audits both internal and external are obligations that must be routinely carried out. This rule has succeeded in overhauling various habits and patterns of program governance from conventional ways to being more professional and accountable. International
surveys conducted in 2002 and 2010, prove that health care accreditation is often used for quality improvement or as a means for health reform.

But unfortunately not all health workers at the PHC are ready to change. In a preliminary survey conducted at one of the PHC in Surabaya, there was still 4.9% of staff who did not support the accreditation process, and 9.8% of staff felt indifferent. The attitude of these officers will certainly influence the readiness of the PHC to change.

In accordance with the concept presented by Weiner that commitment and efficacy are indicators of change readiness, measurement of commitment and efficacy is important to diagnose the level of readiness to change in an organization. Therefore, this research was conducted with the aim of analyzing the readiness of PHCs in Indonesia in implementing efforts to improve service quality, through measuring commitment and efficacy.

**Method**

The study was conducted at a PHC in the city of Surabaya. Surabaya is the capital of the East Java province, and is the second largest city, after Jakarta. The number of PHCs involved in this study was 40, which were selected by simple random sampling from 63 PHCs in Surabaya. The variables measured in this study are a commitment to change and efficacy to change as independent variables and the implementation of efforts to improve service quality as dependent variables. Each variable was measured using a questionnaire with closed-ended answers, with 4 rating scales, 1: poor, 2: near poor, 3: fair, 4: excellent. Data were collected through surveys with cross-sectional design.

Commitment to change is defined as a strong will or mindset that binds individuals to behave in a certain way needed for successful implementation of change. While change efficacy describes shared beliefs of organizational members that they have the capability to manage and carry out a series of actions in implementing change.

The measurement of change commitment in this study refers to article by Visagie and Steyn which state that the change commitment indicator consists of: (1) Willing to make extra efforts to ensure the organization succeeds in implementing changes; (2) Willing to carry out relational functions, share information with other parties during the change; (3) Willing to act beyond the normative demands to help the organization function. Whereas the measurement of change efficacy refers to the article by Bandura which states that there are several things that describe efficacy, including the belief in one’s ability to diagnose the demands of the task, design and evaluate alternative actions, set goals, motivate themselves, manage stress, and attenuate disturbing thoughts. Implementation of efforts to improve service quality is measured by using measurement indicators developed based on several standard assessment points in the accreditation guidebook issued by the Indonesia Ministry of Health.

The data collected from the survey results are processed in stages, first a descriptive analysis is performed to get a description of the conditions in each measured variable, and the second bi-variate analysis with the Rank Spearman correlation test to draw conclusions about the relationship between change commitment and change efficacy with the implementation of efforts to improve service quality.

**Findings**

The descriptive analysis indicate variations in measurement results, as shown in table 1. Change commitment obtained the highest score compared to the other two variables. With the score of mode 4.00 and a mean 3.143, it shows that the commitment of the PHC staff to change is in fair condition. The result of change efficacy measurement is only a slight difference, which is the mean 3.083, meaning that the level of confidence of the PHC staff to be able to implement the changes has been fair, but the mode score obtained is only 2.97. This illustrates that there are still many PHCs staffs that are a little less confident in their ability to implement the efforts to improve service quality. Meanwhile, the results of the efforts to improve service quality results in the lowest score, that is modes 2.18 and mean 2.446, meaning that the PHCs has not been able to implement service quality standards properly.

</table>

To examine whether there is a relationship between change commitment, change efficacy and the implementation of efforts to improve service quality, the Rank Spearman correlation test is conducted, with results as can be seen in table 2. The test results between change commitment and the implementation of efforts to improve service quality obtained a correlation coefficient of 0.207 and sig. (2-tailed) 0.200. This means that the strength of the relationship between change commitment and the implementation of efforts to improve service quality is very weak, so the relationship is said to be insignificant.

While for the change efficacy obtained different results. The strength of the relationship between change efficacy and the implementation of efforts to improve service quality is 0.347 and sig. (2-tailed) 0.028. This means that change efficacy is related to the implementation of efforts to improve service quality with sufficient relationship strength so that the relationship between the two is significant. According to these results, it can be concluded that what is more necessary for the success of the implementation of efforts to improve service quality in this study is change efficacy.

Both change commitment and change efficacy, describe the psychological conditions possessed by members of the organization, or often referred to as the shared team property. High organizational readiness to change will be obtained if shared property teams are dominated by members of the organization who have high commitment and efficacy of change so that they will be encouraged to initiate change, exert greater effort, show greater persistence, and display more cooperative behavior.

The findings of this study indicate that the implementation of efforts to improve service quality at the PHC in Surabaya is still in a sufficient category.
Based on the results of statistical tests, it was obtained information that the factors that contributed to the less optimal implementation of efforts to improve service quality were the change efficacy. Although change commitment is good, but change efficacy still tends to be low, this has resulted in health service quality standards as required in the accreditation guidelines cannot be implemented optimally.

As has been widely known, the implementation of health service accreditation has been recognized internationally as a process used to assess and improve the quality of services\textsuperscript{11}. Indonesian government regulations that require every health service organization to be accredited, can be seen as a factor causing changes in PHCs. The impact of accreditation on health service organizations can be manifested in three types of changes, that is: 1) changes in the area of management, organization and culture; 2) changes in professional practice and clinical procedures; and 3) changes in health service outcomes\textsuperscript{12}. Assessment standards in accreditation require health service organizations to apply rigid quality standards, in accordance with those set out in the accreditation handbook. The implementation of PHC accreditation in Indonesia forced the PHC to radically improve management practices. If not prepared properly, the process of improving quality through this accreditation will fail.

To avoid these failures, both change commitment and change efficacy are needed together. As an attitude, commitment is often defined as (1) a strong desire to remain a member of a particular organization; (2) willingness to mobilize high-level efforts on behalf of the organization; and (3) confidence, trust and acceptance of the values and objectives of the organization\textsuperscript{13}. Hakim\textsuperscript{14} in his article also stated that the willingness of employees to contribute energy in achieving organizational goals was significantly affected by a commitment to the organization. The greater the energy contributed, the better the change effort will be carried out. Meanwhile, efficacy describes the beliefs of organizational members in carrying out their efforts to achieve goals. Goddard and Salloum\textsuperscript{13} argue that the level of group effectiveness in resolving challenges depends heavily on the collective efficacy they have. Positive beliefs will positively influence the normative environment of the working group and will stimulate the emergence of creativity, endurance, and commitment to achieving performance goals.

If in an organization that is experiencing a phase of change, one of the commitments or efficacy is in a weak condition, it will weaken the level of readiness to change. As the results in this study, change commitment is actually already in a good condition, but because change efficacy still tends to be weak, it results in less effective implementation of efforts to improve service quality in PHCs. Klein and Sorra\textsuperscript{16} define the effectiveness of implementation as the consistency and quality of efforts by members of the organization of new ideas, programs, processes, practices or technologies. Referring to the opinion of Klein and Sorra, it can be interpreted that the PHCs in Surabaya have not consistently made efforts to improve the quality of health services. Consistency in implementing service quality standards requires a long-term and sustainable effort. Some previous research found that consistency often appears as a weakness of the accreditation process. For example, a time series study conducted by Devkaran and O’Farrell\textsuperscript{17} found that although accreditation was carried out with the aim of improving the performance of quality health care organizations, this increase was not able to be maintained during the 3-year accreditation cycle. To ensure that efforts are made to improve quality over the long term, it is important that the commitment is accompanied by strong efficacy.

Commitment is indeed to make PHC staff have a strong intention to carry out health services according to the quality standards that should be, but if this is not supported by the belief that they can implement quality standards properly, what will happen is a decrease in staff motivation at work. Of course, this will ultimately have an impact on decreasing the PHC’s performance.

Therefore, the recommendations that can be given based on the results of this study are the need for increase self-efficacy for PHC officers through a series of capacity building activities and training related to the implementation effort to improve health service quality. The improvement of the capabilities of the PHC staff is needed as a way to maintain and foster staff commitment in implementing quality standards on an ongoing basis.

Conclusion

To establish health service organizations to be ready to change, change commitment and change efficacy is needed. The correlation test results show the relationship between change commitment and the implementation of
efforts to improve service quality is not significant, but
between change efficacy and the implementation of efforts
to improve service quality, significant results are obtained.
The existence of high commitment makes PHC staff willing
to devote greater energy to the successful implementation
of better quality improvement for health services. But
commitment without high efficacy will cause obstacles in
implementing high-quality standards properly.

Ethical Approval and Consent to Participate: This
study has an ethical clearance that was approved by the
national ethics committee (ethic number: 500-KEPK).
Informed consent was used during data collection, which
was considered aspects of data collection procedures,
voluntary, and confidentiality.

Conflict of Interest: The authors declare no conflict of
interest, financial or otherwise.

ABSTRACT

Outbreak Response Immunization (ORI) is an activity carried out in an effort to overcome diphtheria outbreaks. Post Immunization Follow-up Events (KIPI) are medical events related to immunization. Diphtheria is an acute upper respiratory tract disease that is highly contagious but can be prevented by administering the DPT vaccine. The purpose of this study is to describe the profile of diphtheria cases in the East Java province. The design of this study used a descriptive research design with a case report design. Data obtained based on case reports of KIPI diphtheria ORI reported by KIPI surveillance officers from 38 regencies of East Java in 2018. Based on subjects who experienced KIPI cases as many as 2007 cases, the most age who experienced KIPI after being given diphtheria immunization was Age <5 year (59.2%) with female sex (52.6%). While the symptoms most often experienced after DPT immunization were heat (45.2%), fever and swelling injection location (17.7%), swelling (8.9%), dizziness (5.5%) and mutation and fever (5.2%). The need for coordination between health workers is still needed so that they can take appropriate action if the baby or toddler experiences a KIPI reaction.

Keywords: immunization, outbreaks, and diphtheria

Introduction

In the era of globalization, immunization is an effort to prevent an infectious disease that is the most perfect and has an impact on improving public health. Therefore, the need for vaccines is increasing along with the world’s desire to prevent various diseases that can cause disability and death. Diphtheria is an acute disease caused by corynebacterium diphtheria which is transmitted through direct contact or droplets from patients\(^1\). DPT immunization is an attempt to administer diphtheria toxoid from coughing, sneezing, vomiting, through cutlery with patient, pertussis vaccine and tetanus toxoid which aims to cause active immunity to diphtheria, pertussis, and tetanus at the same time\(^2\). Increasing the scope of immunization provision will increase vaccine use as well as related events after immunization\(^3\).

Diphtheria is one of the types of infectious diseases that can cause an outbreak. Indonesia is one of the countries with the largest cases of diphtheria in the world\(^4\). So if one case of probable diphtheria is found or a confirmed case is an extraordinary event\(^5\). In the last three years diphtheria cases experienced a significant increase in 2015 as many as 529 cases, in 2016 as many as 591 cases, and in 2017 as many as 622 cases\(^6\).\(^7\).

Adverse Events Following Immunization (AEFI) or Post-Immunization Follow-up Events (KIPI) are those related to immunization or relating to vaccines given or happened by chance\(^8\). According Sari \textit{et.al} (2018) when dealing with events related to immunization, please note that these events are related to vaccines given or happened incidentally. The purpose of KIPI monitoring is to monitor the events that occur due to immunization, it is necessary to report recording of all reactions that arise after giving immunization. The KIPI reaction can be monitored through a good surveillance system to obtain a safety profile of vaccine use in the field. To find out the magnitude of KIPI problems in Indonesia, KIPI reporting and recording is needed and coordination.
between decision makers and implementing officers in the field, in order to determine the attitude in overcoming the KIPI that occurs.

**Material and Method**

This research was a descriptive study with a case report method. The time for data collection began at the time of the first round of diphtheria ORI implementation in February, the second round of July and the third round in November 2018. The population in this study was all infants or toddlers who got in the East Java Provincial Health Office in 2018. Samples at this study was data on infants or toddlers who experience KIPI diphtheria ORI reported from 38 regencies reported by KIPI surveillance officers. Sampling uses a simple random sampling technique based on data from a case report of KIPI diphtheria ORI reported by surveillance officers in 38 in East Java province 2018.

Based on Table 3 shows that after DPT immunization, the most KIPI reactions from respondents with KIPI Diphtheria ORI patients were fever in 908 cases (45.2%), fever and swelling 356 cases (17.7%), swelling 179 cases (110) and vomiting and diarrhea 105 (5.5%).

Discussion

Based on the results of the KIPI surveillance officer report that occurred in infants and children after DPT immunization was fever. If a toddler or child has a fever after immunization, then a toddler or child is stated to experience a KIPI reaction in the form of a general reaction that occurs after immunization(9). In Table 3, the most common symptoms of KIPI are fever of 45.2%, then symptoms of fever accompanied by swelling at the injection site 17.7%. Ranuh et.al (2014) stated that, KIPI reactions often occur in infants after DPT immunization. Children who after being given DPT immunization experience a KIPI reaction in the form of fever, this can occur as a result of the preparation of a vaccine that is not in accordance with the procedures and methods of injection in infants that are not appropriate. Therefore, health workers must really understand and apply the theory of how to prepare vaccines, how to inject the right ones to babies so as to suppress the occurrence of KIPI reactions.

Some studies say that children will experience KIPI after DPT immunization. The results of the KIPI surveillance report data analysis were supported by Sari’s research (2018) that the symptoms of KIPI that appeared most after receiving KIPI immunization were fever of 82.9%. The most common symptoms are fever, swelling in the location of injection and redness at the injection site(10). In addition, research conducted by Sari (2018) that symptoms that occur after immunization is related to vaccine induction, which is generally predictable before immunization is given because vaccine adverse reactions and clinically are usually mild, and these intersection reactions have been well identified and are listed in the vaccine usage instructions.

The results of research conducted by Sari (2018) found that it was interesting that one child could experience 4 symptoms at a time, but the symptoms of KIPI on DPT experienced by children were mild KIPI with local symptoms and general symptoms. Mild KIPI is an event or symptom that is commonly experienced by post-immunization infants so that the incident is prevalent because the care can still be done by the baby’s parents. The most common symptoms of local KIPI are swelling at the injection site and symptoms of KIPI, the most common of which is fever.

Conclusion

Based on the analysis of report data 2018 on KIPI diphtheria ORI in children who were immunized against DPT, 45.2% had a fever. This happens because fever is a normal reaction that occurs in people who have just received DPT immunization. However, it should be noted from parents, especially mothers, to understand the situation, so parents do not stop giving DPT immunization.

Evaluation *Eruca Sativa* Aqueous and Alcoholic Extract on *Fusarium Oxysporum* Growth

Saba Hadi¹, Sundus Hameed¹, Shahad Ali¹, Isam Hussain T. Al-Karkhi²

¹Biology Department, College of Science, Mustansiriyah University; ²Former Ass. Prof., University of Baghdad

ABSTRACT

The current study was done to evaluate the effect arugula extracts on the growth of *Fusarium oxysporum* mushrooms, which included extraction of active ingredients in the plant, and effect of these extracts on inhibition of *Fusarium oxysporum* fungus. The results of the study showed the efficacy of alcoholic and aquatic plant extracts on fungus growth, and the results showed that the alcoholic extract has a significant effect in inhibition the growth of fungus, it was noted that the developing colony diameter decreases in the higher the concentration of aquatic and alcoholic extract of plant to the lowest diameter 0.75 mm when the concentration 100% of the extract compared to the control treatment of 3.4 mm. The statistical analysis of the results indicates that there were differences in the bioactivity in comparing between the alcoholic extract and water extract according to the concentrations. It was found that bioactivity of the extract increases with the increasing of the concentration and the 100% of alchololic extract shows the higher bioactivity in comparing with other concentrations and in comparing with water extract.

**Keywords:** *Eruca Sativa, Fusarium oxysporum, Growth, Evaluation*

Introduction

The origin of the word *Eruca sativa* rocket can be attributed to the sharp taste caused by leaves on the tongue and has a variety of labels and most often called the vegetable table (Salad rocket) (¹). The plant is described as having a length of 30-60 cm. Its leaves are simple or fragmentary to the feathers of the shape, the upper leaves have equal edges. Flowers are light purple or yellow, and bloom in March to July seeds oval shape (², ³).

The rocket plant uses many medicinal uses for the treatment of dermatitis, localized burns, poor digestion, hair loss and reduced blood sugar for people with diabetes, which works to slow absorption of sugar in the intestines and sexual anchors (⁴).

It has a very large proportion of nutrients for the weight of its leaves, as well as being very rich in food compared to the very small quantity that gives it calories, as it contains many important vitamins for the body, such as vitamins A, C and K, as well as Minerals, including calcium, magnesium and potassium, Sodium, and in this sense, it is a good choice for those who want to lose weight. Research and studies have indicated that drinking watercress leaves and eating sour seeds, such as mustard, as well as eating leafy leaves, has many different benefits. (⁵).

Rocket has certain benefits because of the food it contains, it helps to reduce the risk of cancer, increase bone health, improve the health of eyesight and skin, as well as it raises the performance of the brain and immune system. The most common causes of vascular wilt disease, mainly affects annual vegetables, Fusarium longer fungus. Agricultural crops, plants grown for their flowers, ornamental plants, perennials and herbs, and mediated by several specialized forms of each family known as Forma-specials and genetically different, which has so far identified 75 patterns (⁶-⁸).

The fungus grows through on the plant bark of the root towards the vascular vessels, and is placed in the wooden vessels of the plant, which leads to wall clogging.

or rupture. In both cases, the fungus stops. The arrival of water and nutrients into leaves branches dry and wilt occurs \(^9,\ 10\). This will cause economic losses to crops and the advantage of the mushroom ability to produce many of the toxins such as Fusaric Acid, Vomitoxin and Deoxynivalenol, since no studies have been conducted on the effect of the watercress leaves extract on the growth of the plant, F.oxysporum fungi. In this study we looked at the selection of different concentrations of water and alcohol extract of the watercress plant on the growth of Foxy Sporum fungus laboratory \(^11,\ 12\).

**Material and Method**

**Plant Combination:** The plant sample was collected from the popular markets in the Dora area in Baghdad. The plant was washed with running water to remove the dust and soil from the surface if rge plant then it was left to dry at room temperature, taking into account continuous rounding to prevent rot, then the powder was kept in dry packs.

**Preparation of plant extract**

**Hot Water Extract:** For the purpose of preparing the hot water extract, the following method was followed \(^13\):

Weight 10 grams of the vegetable powder and put it in a 250 ml flask, add 100 ml of boiling distilled water, and place it in the shaking incubator for 30 minutes at a temperature of 70 °C, then use sterilized gauze as a filter and place it in the centrifuge at 2500 rpm for 10 minutes.

**Cold Alcoholic Extract:** In this extraction method ethyl alcohol was used with a 70% concentration instead of distilled water. The extract should be kept in dark environment and the flask was coated with aluminum foil \(^13,\ 14\).

**Fusarium Isolates:** The F.oxysporum isolates were obtained from the Faculty of Agriculture, the final extract obtained after the centrifugation process was 100% stock solution and three concentrations were prepared from the stock solution: 75, 50, 25% and, then sterilized with autoclaving at 121°C.

**Phytochemical Screening:** Phytochemical screening by chemical tests \(^15\).

**Antioxidant Capacity:** Different concentration (1 mg to 5 mg) of the samples were added to (5 ml) of 0.004% DPPH solution in methanol and kept for 30 min at RT (Room Temperature). The absorbance was taken against a blank at 517 nm using a spectrophotometer. Scavenging of DPPH free radical with a reduction in absorbance of the sample was taken as a measure of their antioxidant activity \(^7\). Ascorbic acid was used as positive control. IC which represented the concentration of sample that caused 50% neutralization of DPPH radicals was calculated from the graph plotting between percentage inhibition and concentration

\[
I_\% = \frac{(A_{\text{Control}} - A_{\text{Sample}})}{(A_{\text{Control}} - A_{\text{Blank}})} \times 100
\]

**Preparation of sample for GC-MS:** 0.5 g of methanolic-ethanolic extract (F3) was dissolved 95% methanol, the extract was filtered through micro filter 0.45 μm, and then 2 μl of this solution was employed for GC/MS screening 19-21.

**GC-MS screening:** GC-MS screening was carried out on a Shimadzu GCMS-QP2010Ultra system comprising a gas chromatograph interfaced to a mass spectrometer (GC-MS) instrument employing the following conditions: column Elite-1 fused silica capillary column (30×0.25 mm ID×1EM df, composed of 100% Dimethyl poly siloxane), helium (99.999%) was used
as carrier gas at a Flow Control Mode :Pressure:100.0 kPa, Total Flow :17.6 mL/min, Column Flow :1.33 mL/min, Linear Velocity :43.0 cm/sec, Purge Flow :3.0 mL/min, Split Ratio :10.0, injector temperature 220°C; ion-source temperature 200 °C. The oven temperature was programmed from 100 °C (isothermal for 2 min), with an increase of 10 °C/min, to 200 °C, then 5 °C/min to 220 °C, ending with a 9 min isothermal at 220 °C. Mass spectra were taken at 70 eV, then the time required for sample chromatography was 20 minutes (9).

Effect of water and alcoholic extract on Fusarium oxysporum: In this experiment we used 9 flasks of 100 ml and add 3.9 g of nutrient medium Potato Dextrose Agar (PDA) and add 75 ml, and completed to 100 ml and well enough to ensure thawing of the medium before it was introduced into sterilization.

Comparative treatment (1) PDA only—
1. Treatment comparison (2) PDA + 25 ml ethanol alcohol concentration (70%).
2. Alcoholic extract (100%) take 75 ml PDA + 25 ml of the extract
3. Alcoholic extract 75% take 75 ml PDA + 25 ml of alcohol extract
4. alcoholic extract (50%) take 75 PDA ml+ 25 ml of alcoholic extract
5. alcoholic extract (25%) 75 ml PDA + 25 ml of alcoholic extract 25%
6. water extract (100%) take75 ml PDA + 25 ml of water extract
7. Aqueous extract (75%) 75 ml of PDA + 25 ml of water extract
8. Aqueous extract (50%) take 75 ml PDA + 25 ml of water extract
9. Aqueous extract (25%) take 75 ml of PDA + 25 ml of water extract

The media was sterilized by autoclave at 121 °C and pressure 1 bar after sterilization. Left the food medium in the laboratory and before its fixation, the alcoholic and water extracts were added at 100, 75, 50 and 25% concentrations for each flask separately. Was represented by the PDA alone. After inserting the extract with 25 ml to the PDA medium, stir well to ensure that the extract is distributed to the medium. Then, the sterile Petri dishes are placed 9 cm in diameter and left until the center is hardened. A small piece of F.oxysporum has been added to each dish.

The small pieces of the fungus were placed upside down until the fungal growth touched the surface of the medium. The dishes were incubated in the incubator at 25 °C and the result was taken after five days of incubation. The percentage of growth inhibition was calculated by calculating the average of two perpendicular diameter of each colony, Mushrooms by

The following equation:

\[
\%\text{inhibition} = \frac{\text{Comparative treatment in colony diameter} - \text{Colony treatment diameter}}{\text{Comparative treatment in colony diameter}} \times 100\%
\]

The results were statistically analyzed and their averages were measured according to the Duncan Multidimensional Test

Results and Discussion

Table (1) represent the detection of effective chemical compounds for plant extracts. The table shows the active compounds in the leaves of the rocketplant, which is attributed to the medical or physiological effect of the plant, and has great medicinal significance.

Eruca sativa, dried leaves and its extract revealed the presence of medicinal active constituents. In the GC-MS analysis, 81 bioactive photochemical compounds were identified in the methanolic-ethanolic extract of Eruca sativa. The major ten compounds have been identified for the first times in sample of Eruca sativa dried leaves were illustrated in the Figure 2 that represents the GC-MS Spectrum, while Figure 3 represent the comparison between the extract and ascorbic acid (which are approximately the same).

Table 1 shows the chemical component of the abstract. (These components were specified from GC-MS Spectrum).
Figure 2: GC-MS Chromatogram of *Eruca sativa* dried leaves.

The results of Table (2) indicate that the highest mean value of the diameter of the colony in comparison between alcohol treatment and water treatment where there are no significant differences between them and the colony diameter 3.75 and 3.4 respectively, followed by treatment of water and alcohol extract at the concentration 25% diameter was 2.8 for both water extract and alcohol extract. The mean diameter value of 50% alcohol extract and 50% of water extract the diameter reached 2.1 and 2.5 respectively which indicates no significant differences between them. In 75% concentration, the diameter of the plant was 2.1 for water extract and the alcohol extract was 1.6 which indicates a significant difference. Finally, the 100% concentration shows 0.2 in alcoholic extract while the mean value in water extract was 2, this maximum effect is due to the fact that the most of active compounds present in the alcohol extract and can’t extracted with water, especially alkaloids compounds and most of organic compounds which have activity against microbes and considered as antimicrobial compounds \(^{14-16}\).

The inhibition percent in of alcoholic extract with concentration of 100%, 75%, 50% and 25% were 75.1, 54.9, 41.4 and 21.9 respectively, while, and for the same sequence of concentrations for water extract were 45.9, 41.4, 32.4 and 23.4 respectively, this results indicate that alcohol extract has much more activity against microbes than water extract and this bioactivity of alcoholic extract increase with concentration increases, and as it is clear from Table 3 below, the P-Value of alcoholic extract is 0.01 while there is no significant differences in the demineralized water (DM) extract.

ABSTRACT

A variety of single-engine driven files and kinematics have been introduced to improve the clinical performance of NiTi rotary files. The purpose of this in vitro study was to measure and compare the incidence of dentinal defects after root canal preparation with different single file systems.

Keywords: Root canal preparations, Root canal instrumentation, Tooth cracks

Introduction

During and after chemomechanical root canal preparation with rotary instruments that aimed to remove infected soft and hard tissue through the enlarged root canal; [1] the root canal wall can be harmed with the development of dentinal defects in the form of dentinal cracks or craze line which serves as localized sites of increased stress. [2]

Through the application of repeated tension via occlusal forces or when further clinical procedures are required such as post placement, these dentinal defects may have the potential to develop into vertical root fracture (VRF)[3,4, 5].

Most shaping systems are categorized as to whether the file has active or passive cutting edges, a fixed or variable taper along its active portion, or a more traditional or unique cross-sectional design [6]. In addition to that whether the file has benefited from heat treatment that improves flexibility and the resistance to cyclic fatigue [7]. Also described whether it has a centered or offset mass of rotation, works with a rotary or reciprocation, whether the clockwise (CW) and counter clockwise (CCW) angles are equal or unequal [8,9,10]. A single file technique in conjunction with a novel reciprocating movement of unequal bidirectional angles that complete a full forward rotation of 360 degrees after four 90-degree cutting cycles of reciprocation can start and fully complete the preparation of a canal to a perfect shape [11].

It operates at 350 rpm speed in 170ºCCW and 50ºCW direction and completes 360º, torque 5 Ncm in 3 cycles, also it has parallelogram cross-section with two cutting edges at apical end [12].

F 6 Sky Taper (Komet Brasseler GmbH and Co., Lemgo, Germany) is a NiTi system that performs root canal treatment with continuous clockwise rotation, speed 300 rpm and torque 2.2 Ncm. It is available in five different sizes (20, 25, 30, 35 and 40) with a constant taper of 0.06 with S-shape section [13].

When using this instrument alone. It performs root canal preparation with continuous rotation at speed 800 rpm and torque 1 Ncm [14].

AF Blue R3 (Shanghai Fanta Dental Materials Co., Ltd) is a rotary AF- R wire- 3- files- system suitable for curved canals, it performs root canal preparation with a reciprocating motion. It operates at 300 rpm speed, torque 2.6 Ncm in 150ºCCW and 30 º CW direction with 06 taper design and improved file flexibility while still retaining the cutting efficiency [15].

Root sectioning at different levels and inspection through a digital stereomicroscope allows direct inspection of dentinal defects on the root surface and provides information regarding the extension pattern and direction of cracks [16, 17].

To the best of our knowledge, little information has been found regarding the incidence of dentinal defects
resulting from the use of AF Blue R3, and F6 Sky Taper systems. Thus, the purpose of this study was to measure and compare the incidence of dentinal root defects after root canal shaping with four automated file systems: Wave One Gold, AF Blue R3, F6 Sky Taper and XP-Endo Shaper. The null hypothesis was that there would be no significant difference in dentinal defects amongst the studied groups.

Materials and Method

Seventy-five freshly extracted human mandibular premolars with approximately similar bucco-lingual and mesio-distal. The teeth were disinfected in a 0.1% thymol solution at room temperature for 24 h and were kept in purified filtered water until they were used [19]. Savannah, GA USA) under copious water coolant approximately 17mm from the apex to the facial CEJ [20]. The patency of the canal was ensured before and after instrumentation [21]. All the roots were imbedded in its simulated socket in impression materials [22].

Seventy-five root samples were randomly divided into five groups.

**Group I:** Specimens were instrumented by Wave One Gold (25\(\times\)0.07), length 25mm in a reciprocating movement.

**Group II:** Specimens were instrumented by AF Blue R3 (25\(\times\)0.06), length 25 mm in a reciprocating movement using endodontic micromotor (speed: 300rpm and torque: 2.6 Ncm).

**Group III:** Specimens were instrumented by F6 Sky Taper (25\(\times\)0.06), length 25 mm in a rotation movement at WL with gentle in-and out- motion using endodontic micromotor (speed: 300rpm, torque: 2.2 Ncm).

**Group IV:** Specimens were instrumented by XP-Endo Shaper (30\(\times\)0.04), length 25 mm in a rotation movement at WL with gentle in-and out- motion using endodontic micromotor (speed: 800 rpm, torque: 1 Ncm).

**Group V:** Specimens without instrumentation (control group).

The glide path was performed using size #15 K-file (DentsplyMaillefer) up to the working length. A total amount 12 ml of 1% NaOCl was used per canal [23, 24].

A final flush of 5 ml of distilled water was administered to the prepared specimens to remove the remnant debris and irrigating solutions inside each canal. All root canals were dried with a sterile paper points to ensure that a complete instrumentation was achieved [25]. All the root samples were sectioned perpendicularly to the long axis in 3, 6, and 9 mm slices from the root apex [26, 27] using diamond disc (0.1 mm) under water cooling to avoid heating and to minimize smearing [28].

“Defect” was defined if any craze lines, microcracks, or fractures were present in root dentin or extending to outer root surface [18].

Results

The distribution of incidence of dental defects by the experimental groups at each level (apical, middle, and coronal) is shown in Table (1).

Discussion

During the root canal instrumentation using engine driven instruments, high stress concentration in the wall of the root canal system is applied. This may increase the risk of dentinal damage predisposing the tooth to vertical root fracture [29].

Dentinal defects and then root cracking are a complex procedure because it is affected by many factors such as the design feature of the file used and its kinematics in addition to the alloy from which the instrument was manufactured. Since the primary aim of chemomechanical root canal preparation is to decrease the bacterial load and prepare the root canal for
obturation, at the same time; the preservation of tooth structure and increase its resistance to fracture that lead to a long-term survival rate to the tooth \[30\]. The length of the canal and lower overall stresses, also to facilitate comparison of the results with several previous studies in which similar teeth had been used \[27,31\].

Adorno et al., found that apical cracks occurred in 50% of mandibular premolars after root canal preparation \[32\].

The teeth samples were selected from young adult patients because aging result in changes in the dentinal microstructure which in turn change the mechanical behavior of dentin resulting in average reduction of its strength predisposing it to crack growth and dentinal defects \[33\], \[34\]. Unlike the use of SEM that requires section treatment which may change the actual status of the tissue \[35\].

Although high resolution micro CT scans method is conservative and non-destructive, it is a complex procedure that lasts for an hour or more, this may increase dehydration of the samples resulting in spontaneous cracks in dentin \[36\].

The control group after sectioning was not shows any dentinal defects. This finding comes in line with several studies \[4,18\].

The largest number of dentinal defects promoted by Wave One Gold instruments may be related to its high level of flexibility due to the heat treatment of NiTi alloy and its parallelogram-shaped cross section \[37\]. During root canal preparation \[40\], which agrees with previous reports \[16,18\]. However; reciprocating movement could prevent the continuous rotary force and constant torque that are applied to the walls of the canal \[41\].

The occurrence of dentinal defects is independent on the kind of the instrument used. The experimental groups varied in their design, cross section, tip design and taper but similar only in size (#25) of the tip, therefore; the null hypothesis of the present study has been partially accepted.

**Conclusions**

Within the scope of this \textit{in vitro} study, it can be concluded that Wave One Gold system generated the significantly higher incidence of dentinal defects in mandibular premolars compare to the other tested file systems. While XP-EndoShaper system generates the lowest incident of defects in the rotating file systems compare to F6 SkyTaper file systems. The highest incidence was at the apical level in all of the tested groups. Additional researches may be required to assess these instruments on crack propagation and the fracture resistance of the root canal treated teeth.

Predictive Value of Spectral Waveform Indices; Intimal Medial Thickness and Lumen Diameter of Carotid Artery in Iraqi Diabetic and Hypertensive Patients

Samar I. Essa¹, Ahmed Abduljabar Al-Sabbagh²

¹Department of Physics, College of Science, University of Baghdad, Baghdad, Iraq; ²National Diabetes Center (NDC), AL-Mustansiriyah University, Baghdad, Iraq

ABSTRACT

Background: Diabetes and hypertension are related to cardiovascular risk factors and are possible to detect development of atherosclerosis in cardiovascular system, were can predict their effect and measurement by ultrasound and Doppler study. These risk factors included increased intima-media thickness, resistive index (RI) and pulsatility index (PI) of the right common carotid arteries.

Method: We studied 20 patients with diabetes and hypertension, and 20 patients with diabetes only, were examine right carotid arteries for these two groups. In this sample we studied the Lumen diameter of the Rt. carotid arteries, Intima – media thickness (IMT), peak systolic velocity, end diastolic velocity, and Pulsatility index, Resistance index were measured.

Results: Showed that the change differences in Intima – media thickness and Lumen diameter between patients with diabetes and hypertension than diabetes only were (-18.29%), (-11.26%) respectively with significant (p value <0.05). On the other hand the change difference in peak systolic velocity was (21.25%) for diabetes and hypertension, and diabetes only, with significant p value <0.05. The end diastolic velocity is higher value at DM group than diabetic and hypertensive group with significant p value. The change difference between Pulsatility and Resistance Index for both patients group were (-18.18%), (-16.12) respectively, with significant (p value <0.05).

Conclusion: Spectral waveform indices of Rt. Internal carotid artery including Peak systolic velocity (PSV); End-diastolic velocity (EDV), Resistive index (RI) and Pulsatility index (PI) are profound predictive value of atherosclerosis, cardiovascular disease and ischemic changes in Diabetic and hypertensive Iraqi patients beside the intima –media thickness increment and lumen diameter change effect of common carotid artery.

Keywords: Resistance index, blood flow velocity, atherosclerosis, diabetic and hypertension, pulsatility index (PI).

Introduction

Intima-media thickness of carotid artery is associated with cardiovascular complications and thus is considered an indicator of atherosclerosis, were can easily measured by high-frequency B-mode ultrasonography, which is a noninvasive, safe, and inexpensive ¹.

Diabetes, and hypertension are the most potent cause of decrease in artery compliance, that is lead to structural changes within the arterial wall thickness. These changes include elastic component decrement; increased fragmentation; increased concentration of collagen; reduction of endothelial nitric oxide values; and increased smooth muscle ²,³.

Flow velocity (end diastolic velocity and peak systolic velocity) obtained by Doppler sonography. End diastolic velocity is a predictive value of intracranial resistance, low end diastolic velocity is associated with an increased risk of stroke or ischemia ⁴.
Resistive index (RI) is considered an important risk factor for both atherosclerotic and cardiovascular disease. Many studies show that resistive index is related to the vascular resistance and vascular compliance. Vascular compliance defines change in volume of vessel with change in pressure.

Pulsatility index is a popular parameter for characterizing the arterial waveform at Doppler ultrasound, and this parameter is related to resistive index, which has also been shown to relate to vascular resistance. Both RI and PI show changes in the carotid artery blood flow velocity and waveforms.

The aim of the present study was to determine the effect of diabetes and hypertension effect on carotid hemodynamics such as waveform parameters (RI and PI) and blood flow velocity relative to diabetes only.

### Patients and Method

From October 2017 to May 2018, a total of 40 patients were studied. The study included 20 patients with type 2 diabetes and hypertension (12 females and 8 males, the age ranged 41-68 years, mean age 56.6 ± 6.42) and 20 patients with type 2 diabetes mellitus only (9 males and 11 females, the age ranged from 40-67 years, mean age 54.75 ± 8.077). The study was conducted in compliance to the medical ethics rules and all participants have given their consent. The study was performed in National Diabetic Center/AL-Mustansyirah University. The following laboratory parameters obtained for known diabetic and know hypertensive patients were: fasting glucose, cholesterol, Triglycaide(TG), and HbA1C. Ultrasound examination was performed by the use of a linear-array 6-9 MHz probe of (FUT-LD 386-9A) Fukuda Denshi (UF-750XT). Patient was examined to lie in a supine position and aid of a pillow inserted just below the shoulder and neck to enable the common carotid and internal arteries to be visible for examination. Diameter of the common carotid artery was measured by placing the probe on the neck at the level of the Isthmus of the thyroid.

Peak systolic velocity (PSV) was measured by duplex sonography. It is a widely accepted and reliable diagnostic method for assessing internal carotid artery (ICA) stenosis. PSV measurements from the common carotid artery and the internal carotid artery in order to have a record of the examination. These are obtained using spectral Doppler from the upper common carotid artery 2-3 cm below the bifurcation; the internal carotid artery from 1 to 2 cm above the bulb, or as high as possible, in order to allow normal bulbar turbulence to settle.

Resistance index (RI), pulsatility (PI) were measured and recorded.

### Statistical Analysis

Results were expressed as mean values with standard deviations and the difference as percentage. The comparison between the values for both groups was tested by paired student’s t-test and p value < 0.05 was considered as the level of significance.

### Results

Table 1: shows the change difference between right common carotid (CCA) and internal carotid artery (ICA) in patients with diabetes and hypertension group, and diabetes group only.

**Discussion**

Ultrasonography is use to detect changes in carotid arteries, many studies show that the increase in IMT thickness give marker for the development of atherosclerosis and cardiovascular diseases. Increased IMT and reduced distensibility related to hypertension and diabetes mellitus. The results of the present study show that the increase in both of lumen diameter and IMT of carotid arteries in (DM+H) patients correlated with reduce compliance and distensibility of arterial wall, that lead to carotid artery become stiffer. Arterial stiffness can be caused by two distinct mechanisms: structural and a dynamic mechanism. The structural changes result from increase of collagen, arterial calcification an increased amount of glycation of both elastin and collagen, resulting in degenerative changes and interadventitial enlargement. The dynamic mechanism is represented by the tone of smooth muscle cells, also in the arterial media. This tone is dependent on vasoactive substances released from the endothelium.

The RI is called (impedance index) which is related to local vascular resistance and vascular compliance, that can be easily determined by Doppler sonography using Pourcelot’s formula, the peak systolic velocity and minimum end diastolic velocity are linked to the increases of resistive index with decreasing diastolic flow fraction. These findings that increase RI is associated with atherosclerosis and cardiovascular risk factors.

Arterial stiffness is due to atherosclerotic changes have also been shown to be associated with reduced blood flow velocity (PSV and EDV), in (DM+HT) patients which is reflected by an increase in the RI and diameter is associated with an increased risk of stroke and ischemia.

The pulsatility index (PI), which is calculated from (systolic velocity-diastolic velocity)/mean velocity, it measured by Doppler ultrasonography. Higher resistance beds have low diastolic flow, a peaked waveform, lead to higher PI.

The PI is a reflection of the vascular resistance distal to the examined artery; Higher PI may not only imply a higher severity of small vessel disease but also contribute to further vascular injury and progression of atherosclerosis in cerebral vasculature. Therefore the pathologies of small intracranial perforating arteries may affect the PI of the proximal artery (internal carotid arteries, immediately after bulb or distal) so, may be better than IMT for predicting cerebral infarction or ischemia. Thus, a high of resistive index and pulsatility index is associated with difference in velocity between systolic and diastolic phases, this difference in flow velocities reflects downstream resistance, which depend on the degree of arterial stiffness.

Third Delay for Maternal Deaths in Maternity Hospitals in Baghdad

Sara Dhia Salman, Lamia Dhia Al Deen

1M.BCh.B, Iraqi Ministry of Health (MOH), Iraq, Baghdad; 2MBCBMScph, Prof. Community Medicine, Al Mustansiriyah Medical College, Iraq, Baghda

ABSTRACT

Background: Among multiple other factors that cause preventable maternal deaths, the most significant one has been the ‘third delay’ or the delay in gaining access to quality care. If this third delay is reduced, or in other words, the health care service quality of existing facilities is improved, the avoidable maternal mortality would be significantly reduced.

Objectives: To determine the causes of maternal deaths, and recognize the substandard care factors, being the potential determinants of the third delays in maternal deaths.

Method: This is a descriptive retrospective study that utilized information from public datasets belonging to the Iraqi Ministry of Health (MOH), Baghdad Health Directorates, for a period of five years (from 1st January 2014 to the end of December 2018). Maternal death was classified according to the three delays model, but the research is focused on Type III delays. Therefore the analysis was provided only for the deaths that occurred within the health facilities.

Results: A total of 318 maternal deaths were reported during the study period. Maternal Mortality Ratio (MMR) showed an increasing pattern from 24.23/100000 live birth in 2014 to 30.04/100000 live birth in 2018. The mean age of pregnant women died was (30.1 ± 7.4 years) and the mean gravida number was (3.8 ± 2.3). Three quarters (74.5%) of the cases were caused by direct medical reasons while (21.4%) were having indirect medical reasons. Type III delay was the most common delay, and was identified in 71.4% of cases, and was mostly resulted from equipment shortage, limited availability of drugs and other supplies; delay in proper management; and also the incompetence of the care providers in the health care facilities.

Keywords: Maternal deaths, third delay, Baghdad.

Introduction

From the 10th Revision of the International Classification of Diseases i.e., ICD-10, the definition of maternal death is reported as “The death of a woman while pregnant or within 42 days of the end of pregnancy, irrespective of the duration and site of the pregnancy, from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes” [1]. Maternal Mortality Ratio (MMR) as monitored by the Millennium Development Goals (MDGs) has declined worldwide from 385 in 1990 to 216 deaths per 100 000 live births in 2015 [2].

The WHO has reported the scenario of MMR for Iraq during 1990-2015. Statistically, 50 deaths were recorded in 2015 that were 107 per 100 000 live birth in 1990. Thus, annually 3.1% decline rate has been achieved, which is quite lower than the 5.5% annual decline necessary to achieve the MDG 5a [3]. Thaddeus and Maine (1994) had developed a three-delay model, having implication towards determining the scenarios of appropriate obstetric emergencies. This framework categorizes the delays in quality care delivery into three types. The first one refers to the delayed decision-making process of seeking care in case of complications.

Corresponding Author:

Email: sara88diaa@gmail.com
It is then followed by the delay in reaching the medical facility (Type II), and the subsequent delay in gaining access to the appropriate care at the health care facility (Type III) [3].

The efficacy of a health care facility in responding to the delivery of appropriate care in obstetric emergencies is affirmed to be affected by multiple factors. These factors have been grouped into six categories; equipment and drugs, human resources, infrastructure of the facility, policy and guidelines, and certain aspects related to patients and also referrals (4).

Method

This is a descriptive retrospective study that utilized information from public datasets belonging to the Iraqi Ministry of Health (MOH), and Baghdad Health Directorates, for a period of five years (from 1st January 2014 to the end of December 2018). Maternal death cases where collected when they met criteria defined by WHO [1]. The death registers were thoroughly reviewed to evaluate the recorded death summaries, and as such identify the substandard care factors being the potential determinants of the third delay in maternal deaths. A structured questionnaire was designed for the purpose of the study depending on “maternal mortality inquiry form” which was already used by maternal deaths committee of Iraqi Ministry of Health.

The questionnaire included information regarding maternal age, parity, gestational age, the status of booking, arrival timing, death timing, the reason of death, and also the existence of below standard aspects of care. Maternal death was then classified according to the three delays model [3]. There could have been more than one delays with each maternal death, but the current research has targeted the type III delay. Accordingly, only the death cases have been analyzed that reportedly occurred at the facilities. Meanwhile, the identified aspects that were below standard with respect to the expected care quality were also noted, assuming to be the contributing factors of the third delay. The below standard care refers to the level of care quality that is lower than the standards of care to be given to such patients within this scenario. Once the data was collected, SPSS-25 was used as the statistical tool of analysis. The analysis was carried out in terms of frequency, percentage, central tendency (mean), and range and standard deviation as the measures of dispersion.

Results

During the study period, there were reportedly 318 cases of maternal death. MMR showed an increasing pattern from 24.23 to 30.04 per 100000 live birth from 2014 to 2018 (Table 1).

The mean age of pregnant women died was (30.1 ± 7.4) years, about one fourth (24.5%) of them were 35-39 years, whereas the lowest percentage (9.4%) were among 15-19 yrs as shown in Table 2.

The results of the study revealed that 44% of deceased were in their (second-fourth) pregnancy, and 20% of pregnant women were primigravida. (Table 3)

Table (4a and b) highlight the leading direct and indirect contributors to maternal deaths, though the cause of death was mentioned in 298 cases of maternal deaths. As such, for 13 cases (4.1%) out of 318 cases, the study could not determine the cause of maternal death. Three quarters (74.5%) of the cases were directly caused by medical reasons while (21.4%) were having indirect medical reasons. Post-partum hemorrhage (34.2%) was identified as the most reported direct cause of maternal deaths, followed by sudden death due to thromboembolism (20.3%), and also maternal hypertensive disorders (18.6%).

Cardiac was among the mostly reported indirect cause of these deaths, which accounted for (54.4%) of the total indirect deaths.

Table (5) showed the types of delays reported in the maternal deaths. Almost 71.4% of cases reported Type-III delays to be the cause of maternal deaths. Type 1 delays were reported in 15.7% of cases while type 2 delays were reported in only 1.0% of all deceased women.

Table (6) showed the reasons for type III delay, where wrong assessment and management were identified in (39.6%) of cases. Shortage of equipment, drugs, and supplies was identified in (32.6%), including the unavailability of blood, inadequate Intensive Care Units, and limited availability of drugs. In addition, (30%) of cases reported that the health care providers were typically unskilled or incompetent with respect to the nature of the cases, while poor follow-up of the patient was detected in 29.5% of cases.

*The Same woman experienced more than one substandard care at a health facility, therefore the total exceeds 227
Discussion

In Iraq, the national MMR in 2015 was 35.08/100,000 live births\(^5\). This figure is very high, in comparison with, 4 in Kuwait, 6 in the United Arab Emirates, 12 in Saudi Arabia, 16 in Turkey, and 25 in Iran, but near to Egypt 33, and less than 58 in Jordan \(^2\). Analyzing the findings of the study, it is interpreted that the MMR for Baghdad has increased from 24.23/100,000 live births in 2014 to 30.04/100,000 live births in 2018. In this regard, it can be asserted that maternal age has been the most significant factor that contributes to maternal mortality. Being older turns out to potentially increase the risks of death in pregnant women. This can be interpreted that old-age women are more likely to have symptoms of an underlying undiagnosed cardiovascular diseases, which typically make these women in adaptive towards the usual psychological aspects of pregnancy \(^6\).

The current study affirmed that women over 35 years of age (35.5%) were the most to suffer maternal death. It signifies that there is a need for providing high-quality care to such old-aged women having comorbidities, both before, during, and after pregnancy. Aside from the age factor, a significant relationship between parity (number of pregnancies) and maternal death has also been identified. In other words, the greater is the number of pregnancy, the more likely are the women to suffer maternal death. A study reported maternal deaths to be 1:400 for the women being first time pregnant, 1:200 for the women being second time pregnant, and 1:100 for women being pregnant for the fourth time \(^9\). As such, the findings of the current study are consistent with an existing study on Iraq, affirming the increased rate of maternal death among multigravida \(^7\).

A vast majority of maternal deaths in this study were found to be due to direct obstetrical causes. Similar findings have also been established by other existing studies \(^8\-\)\(^10\). Postpartum hemorrhage was the most common direct cause (34.2%) identified in the present work. Most of these cases were due to inappropriate diagnosis or delayed onset of management caused by delayed referral from peripheral or private hospitals, delay in replacing blood and blood products, also most of these women were anemic and not managed properly during the antenatal period. Same results were reported in other studies in Iraq and neighboring countries. \(^{5,7,11,12,13}\).

In accordance with the systemic analysis of WHO, almost 28% i.e., more than a quarter of reported maternal deaths during 2003-2009 were caused by indirect reasons. Thus, these indirect causes have become to be the second most significant reasons for maternal death (the leading cause is Hemorrhage) \(^14\). More specifically, these indirect causes are counted as the key contributors of most of the maternal deaths in the high-income countries \(^15\). The current study has established cardiac disorders among pregnant women as the most significant indirect cause of maternal mortality in Baghdad. It is in line with the scenario of an increased occurrence of Congenital Heart Disease (CHD) among women in their age. Alongside, the women with chronic medical diseases are already at risk for cardiac complications. These findings are consistent with the previous studies \(^{5-6}\).

It can be asserted that the outcomes of delays have always been poorer, regardless of the delay type. Still, Type III delays are affirmed to be typically stressing the below standard service delivery at healthcare facilities. Which may be due to poorly functioning health systems, limited or no availability of required equipment and drugs, incompetent staff, inaccurate diagnoses, wrong or delayed treatment, inappropriate monitoring, and also delayed referrals \(^3\-\)\(^17\). The findings of this study represent that the death cases involved all three delay types, but type III was the most reported cause among the deceased women (71.4%). It highlights the scenario of care delivery at the majority of the facilities i.e., the facilities are ineffective in dealing with serious obstetric emergencies due to typically lacking in resources and competence.

A similar review of maternal deaths in relation to facilities was carried out in Malawi, which reported the presence of type III delays in 96.8% cases, mainly including delayed treatment, delayed admission, lack of drugs, and lastly the incompetent staff \(^18\). Likewise, a similar inquiry was carried out in South Africa, which revealed that the clinical settings suffered delayed referrals, exploitation of standard protocols, and inability towards a responsive monitoring system \(^19\). The current study revealed that unavailability of essential drugs, equipment and supplies happened in 32.6% of the cases, delayed treatment was recorded for 26.9% of cases of maternal deaths, inadequate referral system, and several referrals were carried out from lower to higher level facilities in 11% of the deceased women, and a total of 9.3% cases suffered the delayed treatments and then deaths due to the unavailability of doctor.
It is critical that the presence of professionally competent healthcare providers is ensured in a well-functioning system of care, which is resourceful both in human and financial domains and offers quick and easy access to essential equipment and drugs. In addition, the staff must be given frequent skill-based training to ascertain the delivery of quality care as expected for obstetric emergencies (like birth attendance, neonatal care, and other emergencies).

Conclusion

Third delay was present in most of the cases. It is concluded that effective care delivery in obstetric emergencies greatly relies on the capability of a healthcare provider in identifying the existence of an abnormal condition that would immediately demand determining the level of severity and the correspondingly needed intervention plan.

Implementation of Food Safety for the Soft Drink Industry in Indonesia

Sayyidatul Munawaroh¹, Dumilah Ayuningtyas²
¹Postgraduate Faculty of Public Health, ²Department of Health Policy and Administration, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

ABSTRACT

Background: The awareness of food safety and the responsibility to meet the standards in the food industry is still lacking. As a logical consequence, the authorities implement the HACCP (Hazard Analysis Critical Control Point) system as a strategy for fostering and supervising food safety in the food and beverage industry. This study aimed to assess the implementation of food safety in the soft drinks industry.

Method: The database used in this systematic review was Ebsco/Annuler/Pubmed/Google Scholar/ScienceDirect/Willey Online Library. The search for Scopus-indexed literature about food safety keywords including Implementation, Food safety, Food security, Industry, and Soft drinks. The total number of literature found was 18,829 and then data extracts were obtained to get the number of articles 184 and finally a total of articles 7 that carried out the analysis to obtain the thematic phenomena of the description of implementation. The criteria for systematic literature review was using Prisma method. This study also compares the implementation of food safety in Indonesia with other relevant countries such as Pakistan and India.

Result: This study revealed that the awareness of the soft drink companies in meeting the requirements for production permits was low. The licensing system for beverage industry in Indonesia uses HACCP (Hazard Analysis Critical Control Point), as recommended by the Codex Alimentarius Commission (CAC) WHO/FAO as the basis for developing the quality management system in ASEAN countries. The level of security and the constraints of this system has been recognized internationally. The application of the HACCP system in the soft drink industry in Indonesia only fulfilled 8 of the 12 procedures of the HACCP system.

Conclusion: Implementation of the HACCP process in the soft drink industry in Indonesia is not in accordance with the actual HACCP procedure. The application of the principle of food safety in the soft drink industry in Indonesia only includes 8 steps, while the correct HACCP procedure consists of 12 steps.

Keywords: Implementation, food safety, food security, Industry, Soft drink

Introduction

Fundamental needs of every human being include clothing, food, and housing. Nowadays, the demand for basic needs is continuously increasing and becoming more diverse as people find it difficult to distinguish the primary needs and secondary needs. Basically, humans have basic needs that must be met in order to survive, including water, food, security, and love⁴

The development of public consumption is reflected by the development of the beverage industry which began in 2016, where the number of soft drink industries reached 335 business units with a production capacity of 4.7 tons per year. This industry is not only dominated by large companies but also small and medium industries (IKM). Small and medium industries (IKM) contribute 40% to the overall IKM sector GDP. The increasing development and demand of the beverage industry affect the requirement or standard of food security, which is also increasing. This makes food security issues to be crucial for the industry and food business⁵⁶
Food security in Indonesia is identified from 4 aspects, namely affordability (related to how to simplify the supply chains), availability (maintenance of supply), quality and safety (quality and safety of nutritional standards and supervision), and natural resources and resilience (related to the area and food production). Food security in Indonesia scored 55.2% in 2018.

Industry awareness of food security and responsibility in fulfilling standards is still lacking. As a result, the strategy for fostering and supervising food safety in the food industry is carried out through the application of the Hazard Analysis Critical HACCP system. The HACCP system is believed to be the best system since it is more effective, safe, and has been recognized internationally (2)(3)(4).

Commonly, food distributors do not fully understand the Good Distribution Practice (GDP). Examination of food product distribution facilities in terms of sanitation, buildings, and facilities used, and distributed products found that 41.60 to 44.29% of food distribution facilities did not meet the requirements. In addition, the lack of knowledge and concern of consumers about food security is reflected in the small number of consumers who demand producers to produce safe and quality food products; (5)(6)(7).

Method

This research implemented systematic review using secondary data. The criteria for determining the articles were based on the Prisma method which consists of 5 stages of literature review. The first stage was the identification of articles based on inclusion and exclusion criteria. The inclusion categories for selected articles were 2009 – 2019 publication time, using qualitative method, listed on open access journal, focus on the food industry, and has the output on the implementation of food security and the process of controlling food security. The exclusion categories are articles that have been published for more than 10 years and carried out in developed countries.

As for the search of secondary data, initial exploration was obtained in six publishers; Ebsco, Annuler, Pubmed, Google Scholar, Science Direct, and Willey Online Library. The second stage was the screening by using specific keywords; Implementation, food security, food security, industry, and soft drinks. The total of literature found based on those keywords was 18,829 articles, thus the data extraction was needed using specific keywords and location. Furthermore, the data was extracted using inclusion criteria, and 65 articles were obtained. Meanwhile, 30 articles were eliminated since they did not comply with the inclusion criteria.

The third stage was accessibility, of 65 articles that have been extracted (and 30 articles are eliminated), 35 articles were selected based on the titles and abstracts. These 35 articles were then extracted again by considering the inclusion category; published in 2009-2019, using qualitative methods, and is open acess. After that, the literature data was extracted again until 7 articles were determined to be reviewed. This is the included stage, which is the last stage in the method.

Based on the inclusion and exclusion criteria, 7 articles were found suitable to illustrate the importance of food security in the soft drink industry in Indonesia, and to describe the implementation of food security. Those 7 articles were then selected for further study. We also compared the application of the HACCP system in other developing countries that have the same conditions in terms of food security procedures. Countries chosen for comparison were Pakistan and India. Both were selected based on predetermined inclusion and exclusion criteria. In addition, Pakistan and India have the same implementation of food security as Indonesia. These are the articles:

1. “Quality control of raw materials for carbonated beverage products on line 8 of PT Coca-Cola Armatil Indonesia Central Java” by Julius. Accessed from Ebsco. Participants were asked about the application of food security with the HACCP system.

2. “Analysis of Application of Hazard analysis & critical control points (HACCP) in your drinking water UMS” by M. Noor. Accessed from Google Scholar. Participants were asked about methods of controlling food security and the process of controlling food security.

3. “Sensory Test of Liquid Milk and Sweetened Condensed Milk at PT Frisian Flag Indonesia” by Linda. Accessed from Willey Online Library. Participants were asked about the production mechanism.

4. “Increased Competitiveness of Instant Functional Drinks (Celup and Apple Juice), as a Typical
Results

The application of the HACCP principle follows the concept prepared by the world food agencies (FAO and WHO), as well as by the National Advisory Committee on Microbiological Criteria for Foods (NACMCF) which consists of 12 steps and 7 principles. The following are the steps for implementing HACCP in industry: (5)(8)(9)(10)(11)

a. Assemble the HACCP Team: Formed based on 3-6 special members.

b. Describe the product: The stage of applying the HACCP system concept which includes product name, product specifications, packaging size, presentation method, durability, product distribution, packaging properties, type, and packaging label

c. Identify the intended/expected use: How to use soft drink products by consumers and how producers serve consumers

d. Construct a flow diagram: Process diagram explains the flow of the manufacturing process from production to finishing

e. Perform an on-site confirmation: At this stage, the HACCP team matches the diagrams that have been made to ensure that the process applied is in accordance with the procedure.

f. Conduct a hazard analysis: A step where control can be applied and the danger of security can be eliminated, or reduced to the acceptable limits.

g. Determine Critical Control Points (CCPs): Control points can be seen from the process stage, hazard, correction measures and critical limits.

h. Monitoring: According to Codex in the book “Food International” (2012), monitoring is the act of carrying out a series of observations or planned parameter measurements to ensure control of the process according to the procedure.

The implementation of HACCP for food security in Indonesia has been carried out by every industry player. The implementation of these stages has no obstacles. (12)(13)(10)

The stages included 8 steps, where the findings are the same as the implementation of HACCP in Pakistan. The application of HACCP in Pakistan is more emphasized in the food production process. The biggest producer barriers are access to mileage, transportation costs, and infrastructure which are also included in one of the sizes of building for industrial companies. 8% of household producers in Pakistan have a very low level of food security which has an effect on their income insecurity. (13)(12)(8)

The findings of this study are in line with research conducted in India about the factors that affect household food security, the results obtained that the small-scale home industry food security has a significant relationship with building size in home industry companies, distance to the place of production, costs transportation, competition between producers, and the risk of rising food prices. Another obstacle in home industry companies in India is that most rural areas still have limited internet and cellular services so online bookings cannot be made. As for the current era of globalization, almost most human activities are supported by technology (8)(3)

Based on studies conducted in Pakistan and India, it can be stated that food security is more emphasized in the production process, and has different techniques and obstacles. This is in line with the conditions in Indonesia
that the application of HACCP is still emphasized in the production process.\(^{3(9)(14)}\)

**Discussion**

Initially, security guarantees in the food processing sector depended on the application of Good Manufacturing Practices (GMP) or Guidelines for Good Processed Food Production. In RI Government Regulation No. 28 of 2004 concerning Food Safety. HACCP is a procedure for identifying, evaluating and controlling the hazards found in foodstuffs as well as indirect risks derived from food (Hulebak and Schlosser, 2002; Mortimer et al., 2004). HACCP is designed as an effort to prevent risk and at the same time as an alternative to food safety assurance that focuses on testing end-food products (Ropkins and Beck, 2000). HACCP as a food safety guarantee system is not easy to implement in the food industry. Every food company that wants to implement must develop its own HACCP plan in accordance with their respective conditions and situations.\(^{9(15)}\)

In Indonesia, HACCP has experienced rapid development since 1990, where this system was later adopted in the Indonesian standardization system in 1998 to become SNI 01-4852-1998, adopted from CAC/RCP 1-1969, Rev. 3 (1997) -Recommended International Code of Practice-General Principles of Food Hygiene. Technically, the National Standardization Agency (BSN) in Indonesia gives authority to certain agencies or institutions to issue HACCP certificates.\(^{(11)(13)}\)

In theory, HACCP steps include the establishment of a HACCP team, the preparation of a product description, identification of usage plans, arrangement of process flow diagrams, verification of flow diagrams in fields, Hazard analysis, detection of critical control points (CCPs), the set of critical limits, establishment of supervision system, Establishment of corrective actions, and verification procedures. However, HACCP implemented by the soft drink companies include describing the product, Identifying the intended/expected use, Construct a flow diagram, On-site confirmation of the flow diagram, Conduct a hazard analysis, Determine Critical Control Points (CCPs) and Monitoring.\(^{(12)(16)}\)

The result demonstrated that there is a difference between the theory and the practice. The HACCP mechanism applied by the soft drink industries have 5 differences with the HACCP procedures in its theory. These differences include corrective action designed to identify the potential health hazards, and enforce the appropriate strategies to prevent health.\(^{(12)(13)}\)

In the table there are 5 stages that are not carried out by the industry, namely forming the HACCP team, establishing Critical Limit, establishing corrective actions, establishing verification procedures and establishing documentation. The 5 stages that did not do so did not explain the reasons why they did not do this step.\(^{(15)(13)(11)}\)

Basically, the application and development of HACCP systems in industry is only 7 which is the main principle and that has been done by the industry and the other 5 stages are the stages of the process flow diagram called process flow verification verification so that the first 5 steps to build the HACCP, 5 these steps are steps that are not carried out by the industries mentioned above. So if put together into 12 steps to build an effective HACCP system and this 12-step concept is the HACCP concept according to CAC where 7 main principles of HACCP are included.\(^{(11)(13)}\)

**Conclusions**

This result of this study demonstrated that the implementation of the HACCP process in the soft drink industry in Indonesia is not in accordance with the actual HACCP procedure. The application of the principle of food safety in the soft drink industry in Indonesia only includes 8 steps, while the correct HACCP procedure consists of 12 steps. HACCP must play an active role in raising awareness of the industry that the HACCP procedure must be implemented properly and thoroughly to ensure food products are safe before being traded to the public.

ABSTRACT

The purpose of this study was to investigate the change of oral hygiene and attitude in oral health education for multicultural families. To investigate changes in knowledge and attitudes before and after the training, a structured questionnaire was conducted by self-filling method. O’Leary index was used after coloring with all teeth and measure the quantity of plaque of supragingival. The oral health education was conducted mainly on oral knowledge, and demonstration practice training was conducted mainly on oral hygiene products. In addition, in-depth interviews were provided about the necessity of oral health education for multicultural women. Most of the subjects were interested in general health as well as oral health. The attitudes of the subjects were 1.50 ± 1.73 before the training and 2.20 ± 2.12 after the training so that the change of attitude after the training was positive. There were significant differences in attitude according to oral health education (p<0.05). The oral hygiene management ability test of the subjects showed 25.97 ± 19.77 before training and 10.38 ± 5.33 after training. There was significant difference in oral hygiene management ability index according to education (p<0.05). However, there was so significant difference in tooth brushing and knowledge after training.

Keywords: health knowledge, behavior, oral health education, multi-cultural family

Introduction

Recently, the Korean society is rapidly becoming a ‘multicultural society’ as the multicultural families are increasing due to the increase of foreign workers, North Korean defectors, and international marriages. Petersen P.E., et al. reported that immigrants, minority racial and ethnic groups, and poor indigenous peoples have poor oral health status⁵.

The dental caries occurrence patterns are as follows. First, the distribution of disease does not appear equally in all people, and there is a specific group of dental caries activity. The distribution of disease has a distribution that is biased toward on side distribution rather than a normal distribution⁶. Second, it does not occur equally in all teeth in the dentition, but in specific teeth⁷. In other words, there is a dentition in which dental caries develops in one of the teeth, and the results of epidemiological studies are different in children in Africa and Asia⁸.

In one study, the oral status of Alaskan native children was reported to be higher than that of native immigrants, and the rural children⁹, and the social environment factors such as race, economic power, and educational environment to prepare for the occurrence of caries⁹. As multicultural families grow, attention to oral health is also needed to improve their lives. However, it was difficult to obtain knowledge and information about oral health because of lack of education.

The purpose of this study is to understand the importance of oral health education in multicultural families by examining whether knowledge, attitude and oral hygiene status are changing when oral health education is conducted.
Material and Method

**Subjects and Period:** From June to July, 2017, randomly biased sampling method was conducted on multicultural women living in Busan area. A self-entry questionnaire was administered to the subjects who were explained the purpose of the study and had voluntary consent, and 20 subject were selected as the final subjects except for the unfair responses.

**Research Method:** The subjects were instructed to use proper tooth brushing methods and oral appliances (dental floss, toothbrush and tongue cleaner) and provided three times of training through lecture, demonstration and practice. Lecture training was conducted mainly on oral knowledge, and demonstration practice training was conducted mainly on oral hygiene products. To investigate the change of the number of brushing, knowledge and attitude change, before and after the training, we surveyed structured questionnaire by self-entry method and examine changes of brushing frequency, oral hygiene knowledge and attitude by proceeding to 1st and 3rd rounds. To quantify the amount of bacterial membranes in the tooth surface, O’Leary index was used after coloring with all the teeth and measure the changes on the progress of the education. In addition, in-depth interviews were conducted about the necessity of oral health education for multicultural women.

**Statistical Analysis:** Statistical analyses were performed with the Statistical Package for the Social Sciences (SPSS), version 24 (IBM SPSS Statistics for Windows, Armonk, NY, USA). To examine the frequency, percentages were calculated and evaluated by using the analytical technique that is based on the general characteristics of the subjects, subjective perception and interest in the health and oral health of the subjects, periodic health and oral examination, and awareness of oral health education needs. A t-test was conducted to examine the changes in the number of teeth brushing, knowledge, attitude score, and O’Leary index before and after oral health education. The level of significance was set at \( p < 0.05 \).

**Findings:** Total subjects were 20 people in which 17 subjects (85.0%) were under 30 years of age and 3 subjects (15.0%) were over 31 years of age. The nationality is as follows: 7 (35.0%) from Vietnam, 4(20.0%) from Cambodia, 2 (10.0%) from Philippines, 1 (5.0%) from Uzbekistan, and 4 (20.0%) were not responded their nationality (Table 1).

</table>

The need for oral hygiene education was as follows: 1 (5.0%) for ‘Never need’, 1 (5.0%) for ‘Not need’ before the education, but these answers has changed to 0 (0.0%) after the education. The answer for ‘Very need’ was 5 (25.0%) before the education but it increased to 8 (40.0%) after the education. The oral hygiene education was conducted by lecture and there were 10 (50.0%) subjects but 4 (20.0%) after the education. Whereas 1:1 education
(personal education) was 7 (35.0%) before the education but 14 (70.0%) after the education. For oral hygiene education location before the education was as follows: 4 (20.0%) for community health center and 15 (75.0%) for multicultural family support centers. However, the answer for multicultural family support centers increased to 19 (95.0%) after the education. The appropriate oral hygiene education time for less than an hour was 16 (80.0%) but 17 (85.0%) after the education. The average number of oral hygiene education courses was 5 (25.0%) for 1-2 times per week, 5 (25.0%) for once a month, and 6 (30.0%) for twice a month before education, but 3 (15.0%) for 1-2 times per week, 9 (45.0%) for once a month, and 4 (20.0%) for twice a month after the education (Table 4).

Metz et al. reported that oral health behaviors of parents affected the knowledge, attitude and behavior of their children’s oral health(6), and in multicultural family mothers, dental treatment was delayed until the subjective symptoms become severe(7,8), the prevalence of dental caries in immigrant groups and economically difficult children is high(9), and the incidence and appearance of dental caries vary according to race, country and region(10).

In addition, the parents’ social class and income level were inversely related to the children’s cariogenic experience(11), the oral health consciousness of the mother has a great influence on the development and maintenance of the dental caries of the child(12). In the present study, the method of conducting oral hygiene education desired was a lecture before and after the education, 1:1 individual education was desired more, and the desired oral hygiene education place was the multicultural family support center. And the number of appropriate oral hygiene education was about once a month.

In multicultural families, the socio-demographic characteristics and oral health belief of each country are also necessary for understanding oral hygiene education and its improvement programs. The questionnaires and researches that considered these cultural differences were rare in Korea as well as overseas, and mainly the qualitative research by interview was made(13-15).
The opinions of women in multicultural families about the necessity of oral hygiene education through in-depth interviews were applied without knowing what oral hygiene education was about before the education, but there were many opinions that they had confidence after oral health education. Other comments suggested that it was difficult and time-consuming to decide the education time which could be matched together, and the role to get educated on oral hygiene was important because they can educate their children directly.

Teaching about brushing and its knowledge seems to be hardly effective at a certain level with only three rounds of education. The lecture-based knowledge part was not effective due to the linguistic problems. However, education seems to be needed because it led to a positive change in attitude and oral hygiene management ability index by conducting oral hygiene product education and demonstration.

Conclusion

The purpose of this study was to compare the change of knowledge, attitude and oral hygiene status in oral hygiene education for multicultural women. The before- and after-education changes increased the number of people who needed oral hygiene education and method of oral hygiene education process preferred the 1:1 personally study rather than lecture style. It was suggested that number of oral hygiene education programs should be from twice a month to once a month. There was no significant difference in tooth brushing and knowledge change after the education. However there was a positive difference in attitude and oral hygiene management ability index.

The Effectiveness of the Use of Propolis toward the Number of Polymorphonucleas Cells in Mice Wounds

Shaerly Horax¹, Harun Achmad¹, Nurmala Dewi²
¹Department of Pedodontic, Faculty of Dentistry, Hasanuddin University, Makassar South Sulawesi, Indonesia; ²Student of Dentistry Faculty, Hasanuddin University

ABSTRACT

Background: Propolis is a honey bee product with a very complex chemical composition, made by gummy and balsamic materials collected by bees from sprouts, flower buds, trees and other vegetal-tissue resinous trees. Propolis is useful as an antibacterial, antifungal and anti-inflammatory. During inflammation, polymorphonuclear migration to the wound area increases and propolis acts to suppress the amount of polymorphonuclear in the wound.

Objective: To know the effectiveness of propolis to decrease the migration of polymorphonuclear neutrophil cells to the wound in mice.

Method: Experimental research with post-test only design with group control design. Propolis taken from the forest then made an extract with a concentration of 80% and then the mice were inserted with a wound depth of 2 mm and a wound length of 15 mm. Cut wounds of mice smeared with 80% propolis extract twice a day and then sacrificed 3 mice for check-up on days 1, 3, 5, and 7. Then histology was examined. Statistical analysis was performed by Mann Whitney test.

Results: There were significant differences between treatment groups and control groups.

Conclusion: Propolis extract with 80% concentration has an influence on suppressing the amount of polymorphonuclear migration to the inflammatory area.

Keywords: Propolis, Inflammation, Polymorphonuclear.

Introduction

The incidence of injuries is increasing due to the increasingly complex activities carried out in everyday life. In carrying out activities, we often experience accidents that result in injuries. Both minor injuries and severe injuries. Wounds are damage or loss of body tissue due to a factor that interferes with the body’s protection system. These factors include trauma, temperature changes, chemicals, explosions, electric shock, or animal bites.¹ The body has a physiological response to wounds, namely the process of wound healing. The wound healing process consists of various complex processes to restore network integrity. During this process blood clots, acute and chronic inflammatory responses, neovascularization, cell proliferation to apoptosis occur. This process is mediated by various cells, cytokines, matrices, and growth factors. Disregulation of the process can cause complications or abnormalities of the wound, hypethrophic and keloid wounds. Healing skin wounds without outside help runs naturally, but sometimes special treatment is needed to help the process.¹

Tissue healing is an adaptive biological response that makes repair of damaged tissue. The initial stage of healing is represented by an acute inflammatory reaction, wherein inflammatory cells migrate to damaged tissue and phagocyte debris, in this phase occurs interrupted blood vessels in the wound will be stopped by the occurrence of vasoconstriction reactions to restore blood flow and inflammation to remove tissue damaged and prevents bacterial infections. In the later stages, endothelial cells are fibroblasts and multiply and produce scars. The occurrence of an inflammatory process with incomplete healing has been a concern for hundreds of years. Various kinds of natural products have been used as anti-inflammatory and healing agents, with propolis being an extraordinary choice.¹

Propolis is a resinous substance with various colors and consistency. Propolis is a honey bee product with a
very complex chemical composition, made by gummy and balsamic materials collected by bees from sprouts, flower buds, trees and other vegetal-tissue resinous trees.²

Polymorphonuclear neutrophils (PMN) and macrophages will migrate to areas that have inflammation. Both types of cells function to eat and clean infected tissue or from toxic agents. The process of inflammation of the initial cellular phase is the phase where there is the first cell that is chemically attracted to the inflammatory area, namely polymorphonuclear neutrophil cells (PMN). Polymorphonuclear neutrophils (PMN) are mature cells that can attack and damage bacteria and viruses even in blood circulation. In an inflammatory process, neutrophils are responsible for cleaning tissue from infectious or toxic agents, that it can be used as a reference in assessing inflammation. Neutrophilia (PMN) is caused by inflammation products that enter the bloodstream which are then transported to the bone marrow and work on the bone marrow capillaries and in stored neutrophils to move these neutrophils quickly into the blood circulation causing an increase in the number of neutrophils in inflamed tissue.³

Method

The type of research used is an experimental (true experiment) laboratory with post test only with control group design research.

Propolis used is propolis from Trigona Spp bee, which is widely found in South Sulawesi’s North Luwu Regency. What is applied to the wound is mice twice a day.

The mice used were Mus Musculus ages 2-3 months and weighing 20-30 gr. The next one will be wound with a length of 15 mm and a depth of 2 mm(fullthicknesswound).

Neutrophils Polymorphonuclear was seen on a microscope by counting the number of polymorphonuclear neutrophils on a tissue preparation.

The number of samples were 24, and was divided into 8 groups. And each group consisted of 3 mice. Then the results of the calculation of the number of Neutrophil PMN in the two groups, namely the control group and the treatment group, will be analyzed by the statistical parametric method, Mann Whitney.

</table>

Based on the table above, it can be seen that the average value of the number of polymorphonuclear in the control group on the first day is 40 which is higher than the average value of the number of polymorphonuclear treatment groups in the first day, which is 17.33333. on the 3rd day the average value of the polymorphonuclear control group was 54.33333 while the treatment group was lower at 27.66677 where this was the highest number of each group. on the 5th day the average number of polymorphonuclear in the control group was 23 higher than the average number of polymorphonuclear treatment groups on the first day ie 16,66667 and on day 7 also showed a higher number of polymorphonuclear in the control group ie 18 compared the treatment group was 15.66667.

From the above data it can be visualized the number of polymorphonuclear in the graph below:

Figure 1: Graph of average polymorphonuclear quantities
Based on the above graph it can be seen that polymorphonuclear began to appear on the first day and then increased on the third day and then decreased on the fifth day and the seventh day. And the average number of polymorphonuclear in the group given propolis extract was lower than the group not given propolis.

**Observation of polymorphonuclear cells (PMN):**

1. **First day (Control)**

2. **First day (treatment)**

3. **Seventh day (Treatment)**

**Discussion**

From the research conducted, the results obtained that the administration of propolis in the wound of mice caused a reduction in migration of polymorphonuclear cells. Polymorphonuclear activity arises since the onset of injury. Inflammation occurs due to mediation by cytokines, chemokines, growth factors, and effects on receptors. When the inflammatory process passes through the first hour then a number of neutrophils will invade the inflammatory area and mature cells are formed that function to kill bacteria and increase the number of neutrophils which is four times the normal number of neutrophils (normal = 4000 – 5000).4,5,6

At the time of inflammation, changes occur in the area around the affected tissue, namely increased heat (heat), redness (rubor), swelling (tumor), and loss of function (laesa function).7

Then the incisions made on mice were given propolis extract for healing and some were left alone without giving anything and allowing physiological changes to occur. Incisions given by propolis extract showed that the amount of polymorphonuclear cell migration was lower than the incision which was left alone without propolis and was allowed to undergo physiological changes.

This caused a reduction in the number of polymorphonuclear cell migration, which was due to the presence of Caffeic Acid Phenetyl Ester (CAPE) which is a derivative of other flavonoid compounds with anti-inflammatory ability because it inhibits the release of arachidonates by cell membranes, causing inflammatory mediators to be formed.2

According to other literature, research carried out both in vivo and in vitro shows the biological and pharmacological activities of flavonoids are very diverse, namely as anti-inflammatory, anti-microbial to fight bacteria, anti-fungal, and anti-viral.8,9,10 Other contents found in propolis are vitamin B1, vitamin B2, vitamin B6, niconitic acid, pantothenic acid, and riboflavin.2,8,12

Anti-inflammatory compounds contained quercetin, pinostrobin, kaempferol, galangin, pinocembrin, pinobaksin as well as several types of compounds from other phenolic groups, namely cinnamic acid, cinnamic alcohol, vanilin, benzyl alkhol, benzoic acid, caffeic as well asferulic acid which causes a decrease in polymorphonuclear neutrophil (PMN) activity. Flavonoids will suppress the formation of prostaglandins which function to increase vascular permeability in the inflammation process.2,11,13

Provision of propolis causes wound healing because the content contained in propolis can reduce the amount
of immigration of polymorphonuclear neutrophil cells so that there is no accumulation of polymorphonuclear neutrophil cells and can accelerate healing compared to wounds not given propolis.

**Conclusion**

The conclusion of this study is that there are significant differences between the number of PMN in the treatment group and the control group.

At the beginning of the inflammatory process, polymorphonuclear neutrophils (PMN) begin to invade the inflammatory area and form mature cells.

The increase in the number of polymorphonuclear neutrophils (PMN) is four to five times, from 4000 to 5000 to 15000 to 25000 polymorphonuclear cells (PMN).

The life span of polymorphonuclear cells (PMN) is 1 to 4 days and greatly increases on the 3rd day and starts apoptosis on the 4th day.

Topical administration of propolis extract can reduce the number of polymorphonuclear neutrophil cell migration (PMN).

Hazardous Effects of Lead (Pb) on Hematological and Biochemical Parameters in Awassi Sheep Grazing in the Najaf Center

Shatha Atta Abeed¹, Ali Hussein Aldujaily², Nadia Abdul Hadee Abdul Ameer¹
¹Al-Forat Al-Awsat Technical University, Iraq; ²Veterinary College, Kufa University, Iraq

ABSTRACT

This study was aimed to compare between lead blood levels and its hazardous effects on hematological and biochemical parameters in Awassi sheep grazed on pastures located in Najaf center and sheep grazed in desert of Al-Najaf province-Iraq. The results showed that the lower blood lead levels in sheep grazed on desert with values enclosed in generally within the normal limits, while, higher blood lead levels were shown in sheep grazed on pasture located in the city center of Al-Najaf, with average values significantly higher than the maximum limits. On the other hand, there are a significant decrease (p<0.05) in hematological parameters (Red blood cells (RBCs), hemoglobin (Hb), packed cell volume (PCV), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), and mean corpuscular hemoglobin concentration (MCHC), also, a significant increase (p<0.05) in biochemical parameters (alanine aminotransferase (ALT), aspartate aminotransferase (AST), sorbitol dehydrogenase (SDH), blood urea nitrogen (BUN) and creatinine) but decrease in total protein (TP) in sheep grazed on pasture located in the city center compared with sheep grazing in desert Al-Najaf. Thus, the current study showed that elevated mean blood lead level above the acceptable limit of (0.1 ppm) in all Sheep living in the city Centre, suggesting that iron deficiency anemia may amplify the effect of lead contamination in the environment.

Keywords: Awassi sheep, Hematological parameters, Serum biochemistry, Lead (Pb).

Introduction

Lead (Pb) is found ubiquitously in the environment¹ and even though lead is a non-essential metal, its presence in the body at any level could be considered as contaminated², therefore, it has well-known hazardous effects on human and animal health as it accumulates in the body via the food chain³. Excessive blood lead level could affect hematopoiesis and bone formation as well as the nervous and cardiovascular systems, renal insufficiency, impaired cognitive function, abdominal pain, and peripheral neuropathy in the general population⁴.⁵. However, high levels of lead exposure, anemia may occur due to the interference with heme synthesis and also to red cell destruction⁷. Also, it can seriously affect the hematopoietic, renal, reproductive, nervous, and hepatic tissues to produce metabolic interactions with enzyme systems⁸. Moreover, in ruminants, the acidic environment of the fore-stomach enhances its absorption and thus makes it as extremely toxic. Among domestic animals, sheep exhibit more chances of ingestion of Pb due to grazing of herbage very close to the ground surface therefore, it has been found to excrete more Pb compared to other animals⁹.

The aim of this study was to evaluate the magnitude of lead exposure in sheep living in Najaf city and sheep living in the desert, also, explain the relationship between blood lead levels, hematological and biochemical parameters level in sheep. In Najaf, there are no available data in this context, so this research work has been carried out to study the alterations of blood parameters in sheep.

Materials and Method

This study was carried out on a total of 90 sheep living in Al-Najaf city grouped as follows: group 1 (40 sheep)
living in city center, group 2 (50 sheep) living in the desert during the period from September 2018 to February 2019, both aged 7-12 months in Najaf governorate.

A venous blood sample (10mL) was taken from the jugular vein for hematological parameters screening. Blood samples from each sheep divided into two tubes. The first tube (3 mL in EDTA tube) used for estimation of hematological parameters; PCV was measured by using micro hematocrit centrifuge according to\textsuperscript{10}, the hemoglobin was determined by drabkins reagent and measured by spectrophotometer\textsuperscript{11}. RBCs counts were measured by using hemocytometer (12). The MCV, MCH and MCHC were calculated according to the following formulas; MCV=PCV/RBC × 10\textsuperscript{fl}, MCH = Hb/RBC×10pg and MCHC = Hb/PCV × 100g/dl\textsuperscript{12}.

The second blood sample (7 mL) was collected into plain tube used for obtaining serum. Blood samples in plain tubes were centrifuged at 3000 rpm for 15 minutes, after which serum was harvested according to standard methods\textsuperscript{12}. Biochemical analysis included the measurements of serum total proteins (TP); aspartate aminotransferase (AST), alanine aminotransferase (ALT), sorbitol dehydrogenase (SDH), Creatinine and blood urea nitrogen (BUN). Serum biochemical variables were measured using UV spectrophotometer. The third tube (3ml in EDTA tube) used for estimation of lead by using Flame Atomic Absorption Spectrophotometer (AAS).

Data were analyzed using SPSS version 21. The least significant differences test (LSD) were used to determine differences among groups. Data were subjected to analysis of variance statistically using one-way ANOVA.

Results

The result of serum lead concentration illustrates in table (1). The serum of Awassi sheep live in the city show significant increase in lead concentration (p<0.05) when compared with sheep live in the desert

Discussion

The results of this study indicated that concentration of lead in sheep blood living in desert close from the normal references of lead obtained by (13, 14). Also, the sheep living in city center that have more lead concentration were close from Pb level of sheep blood in Pakistan obtained by13,15 in Turkey. Therefore, our results showed that sheep living in Najaf city exposed to high lead levels in their environment through vehicles exhaust (leaded petrol) and lead used in various industries (lead-acid batteries and paints) are the main cause of the widespread existence of lead in the environment16,17, where their mean blood lead level twice as high as the limit value of 0.01 ppm16. Moreover, effects of lead (Pb) on blood parameters in table (2). The significant decrease(p<0.05) in levels of RBCs, Hb, PCV, MCV, MCH, and MCHC are observed in the Awassi sheep live in the city center resulting in microcytic hypochromic anemia this agreement with18,19,20.

High levels of lead exposure, anemia may occur due to the interference with heme synthesis and also to red cell destruction. The mitochondrial enzyme ferrochelatase is the enzyme in the heme biosynthetic pathway inhibited by lead. Ferrochelatase catalyzes the transfer of iron from ferritin into protoporphyrin to form heme. Inhibition of this enzyme results an increase of the substrates erythrocyte porphyrin (EP), and zinc protoporphyrin (ZPP)5,6.

In table 3 there is a significant increase in ALT, AST and SDH, which may be due to increased cellular basal metabolic rate, irritability and the destructive changes of liver and skeletal muscle cells21. Sorbitol dehydrogenase (SDH) is an enzyme most specific for ruminant predominantly found in the liver and its elevation in serum is an accurate indicator of hepatic injury, also, Mild increases in SDH can also occur by obstructive GI lesions, endotoxemia, and anoxia from shock, acute anemia22,23. Similar results were attained by24,25.

Also, a significant decrease in total protein, this decrease in total protein values may be a result of damage of liver responsible for protein biosynthesis in the body as well as renal tissue damage. Similar results were recorded as a result of exposure to different doses of lead in sheep26.

Moreover, this study revealed a significant increase in both urea and creatinine were used to check kidney function indicating renal deficiency in sheep living in city center compared with sheep in desert areas this agreement with27,28,29.

Conclusion

The results of this study showed that sheep living in Najaf city are suffering from a high risk of environmental lead exposure indicated by the elevated mean blood lead level above the acceptable limit of (0.01 ppm). This study suggested that the use of leaded petrol has served a continuous source of lead accumulation in sheep which may pose serious health hazards for the consumers. This is the first study, which correlates the concentration of a heavy metal (Pb) in a natural environment and its cumulative effect on the liver, kidney and blood parameters in sheep grazing in the city center.

ABSTRACT

Introduction: Breast cancer is the most common cancer that threatens life of women all over the world, in Iraq breast cancer has become the second leading cause of death among women after cardiovascular diseases, with a cancer-related mortality rate of 23%. The objectives of the study is to find out the reproductive risk factors of breast cancer in the pre-menopausal and post-menopausal women.

Patients and Method: A case-control study was conducted in Erbil Breast Center, and Erbil Teaching Hospital in Erbil city-Kurdistan- Iraq, between the 1st of September 2016 and the 30th of April 2018. Cases were breast cancer patients who had visited Erbil Breast Center. Controls were women who have visited the surgical consultation unit in Erbil Teaching Hospital for surgical problems other than breast.

Results: Out of 136 breast cancer patients, 91 (66.91%) were pre-menopausal, 44 (32.35%) were post-menopausal, and one case (0.74%) underwent hysterectomy at 42 years old. Out of the 150 non breast cancer women; 110 (73%) were premenopausal women and 33 (22%) were postmenopausal, and 7 (5%) women underwent hysterectomy. Early menarche was a risk factor for breast cancer in pre-menopausal women only, while post-menopausal women having < 3 children were at increased risk for breast cancer.

Conclusions: Reproductive risk factors association with breast cancer are more important for post-menopausal breast cancer than for pre-menopausal breast cancer.

Keywords: Breast cancer, women, malignancy, Erbil.

Introduction

Breast cancer is the most common cancer that threatens life of women all over the world, there were over 2 million new cases all over the world in 2018.

In Iraq it is the most common cancer; 5141 new cases of breast cancer registered in 2018 comprising 36.7% of all women cancers and 20.3% of all cancers in both sexes.

In Kurdistan Region of Iraq (KRG), breast cancer is the most common female cancer; in Erbil (the capital city of KRG) the incidence of breast cancer was 37.95 per 100,000 women in 2016.

The age standardised breast cancer incidence varies across different populations ranging from 18 per 100,000 in South Africa to 88 per 100,000 women in Western Europe; as the menstrual and reproductive factors are the most important risk factors for breast cancer, therefore the differences in these two factors may mainly attribute to this variation. As hormonal factors play significant role in causing breast cancer and there is a marked variation in the level of these hormones throughout the life of a women starting with menarche then pregnancy and lactation and start of menopause, therefore pre-menopausal women might not have the same hormonal risk factors as do the post-menopausal women. Many studies have tried to address this question and have found variable results.

The objective of the study is to find out the reproductive risk factors of breast cancer in the pre-menopausal and post-menopausal women.
Patients and Method

A prospective case-control study was conducted in Erbil Breast Center, and Erbil Teaching Hospital in Erbil city-Kurdistan Region of Iraq, between the 1st of September 2016 and the 30th of April 2018. Cases were women visiting Erbil Breast Center who have been diagnosed as breast cancer. Controls were women visiting the surgical consultation clinic of Erbil Teaching Hospital for surgical problems other than breast problems.

After obtaining verbal consent from the women, both the cases and the controls were asked about their basic demographic characteristics, menstrual and reproductive history were taken in detail by direct interview and any missing data was obtained by phone contact. Physical examination and radiological investigations were done for both women groups and the women with breast masses underwent core biopsy by a radiologist using 14 G needle and the specimens were examined by the same histopathologist in the lab of Erbil Maternity Teaching Hospital. 142 women with breast masses suspicious for breast cancer were enrolled in the study, they have been sent for core biopsy and histopathological examination, 135 of them proved to have cancer by the mentioned test, seven women had not completed their investigations and they were excluded from the study, while 170 women enrolled in the study as the control group, only 151 women continued with the study, one of these 151 women had a breast mass proved to be cancer by histopathological examination and included in the breast cancer group.

The data were analyzed using the Statistical Package for Social Sciences (SPSS, version 22), Chi-square test was used to compare the proportions of the two groups, and the p-value ≤ 0.05 was regarded as statistically significant.

Results

The total number of the sample was 286 women, 136 were cases of breast cancer, and 150 women had no breast cancer (control group). The highest proportion of the sample (34.3%) aged less than 40 years, and 33.9% aged 40-49 years. No significant (p = 0.122) difference in the age distribution of the sample was detected between cases and controls as presented in Table 1.

*Out of 33 women of the control group, who were married, one of them had no live birth.
** Out of 44 women with breast cancer, 8 had no live births.

Discussion

This study showed that early menarche increased the risk of breast cancer in pre-menopausal women; this finding is consistent with two other studies, on the other hand it is inconsistent with other studies; Antoniou et al concluded that early menarche increases risk only in post-menopausal women. A number of studies reported that early menarche increase breast cancer risk in both pre-menopausal and post-menopausal women, while in a Malaysian study no association found between age at menarche and breast cancer risk. A review of 26 articles concluded that older age at menarche decrease breast cancer risk in both pre and post-menopausal women; for every year older menarche age, decreased the risk of breast cancer by 9% and 4% in pre-menopausal post-menopausal women respectively.
The current study showed that marital status has no association with the risk of breast cancer, which is consistent with two local studies done in Iraq; Sulaimaniyah, Kurdistan Region of Iraq, and Baghdad, same results were obtained in a study done in southern Iran, however a study done in Qatar showed that single women has more risk for breast cancer.

This study has found that, post-menopausal nulliparous women were at increased risk for developing breast cancer which is consistent with another study, a study done in UK showed increased risk for both pre and postmenopausal women, however, another study has reported increased risk for only pre-menopausal women. At the same time, women with three or more live births get more protection against breast cancer in their postmenopausal age, which is consistent with another two local studies done in Kurdistan Region of Iraq, and a study done in France. Some studies have found that increasing parity decreased risk in both pre and post-menopausal women. A review article concluded that each full term pregnancy reduces breast cancer risk by 3% for pre-menopause and 12% for post-menopausal women. The protective effect of parity against breast cancer can be explained by the process of differentiation of the mammary epithelium during pregnancy and subsequent lactation, thus the mammary epithelium is protected from the estrogen because of the cessation of menstrual cycle along the period of pregnancy and subsequent lactation.

In this study, women having their first live birth (FLB) at age younger than 35 years did not get decrease risk of breast cancer development neither in pre-menopausal nor in their post-menopausal age, this finding is inconsistent with many previous studies which found that younger age at FLB decreased breast cancer risk in both pre and post-menopausal women. However, some studies found that a higher age at first live birth is a risk factor only for postmenopausal women. In a cohort study, the relative risk of breast cancer for age at FLB >30 years was 1.63 for pre-menopausal women and 1.35 for post-menopausal women. A study done by Russo et al found that women who gave birth to a child before 24 years of age exhibit a decrease in their lifetime risk of developing breast cancer, and moreover additional pregnancies increase the protective effect. These findings may be explained by the fact that, the younger age at first pregnancy (and live birth and lactation) the earlier the process of the mammary epithelial cells differentiation, and more capability of metabolizing carcinogens and more efficient DNA damage repair, in addition to the earlier protective effect of pregnancy and lactation against estrogen exposure as long as the menstrual cycle ceases during these periods.

This study showed that late menopause was not a risk factor for post-menopausal women. This finding is consistent with three local studies (Kurdistan Region of Iraq); two studies done in Erbil, and a study done in Sulaimaniya, a meta-analysis including 117 epidemiological studies performed by a Collaborative Group on Hormonal Factors in Breast Cancer concluded that for every year older at menopause the risk for developing breast cancer increases by 1.029.

We found that breastfeeding was protective against breast cancer only for post-menopausal women, which is consistent with a western study. Two local studies in Erbil showed no protective effect of breastfeeding against breast cancer, while two regional studies showed that breastfeeding is generally protective against breast cancer and the more the duration of breastfeeding, the more the protective effect. Some western studies have shown that breastfeeding is protective against pre-menopausal breast cancer. A collaborative re-analysis of 47 studies showed that breastfeeding was protective for both pre-menopausal and post-menopausal women.

Conclusion

In the postmenopausal women, the factors that associated with breast cancer were less number of live births, lower rates of breast feeding. In the pre-menopausal women, early menarche was the only factor that was associated with breast cancer.

Limitations: Small number of breast cancer cases because we only included women with breast problems visiting Erbil Breast Center which is the only governmental center receiving women with breast problems, while women who visit private clinics are not included because of difficulty in obtaining information from private clinics and hospitals.

Conflicts of Interest: There author not conflict of interest in this study.

ABSTRACT

Background: The Child Behavior Checklist/1,5-5 is a widely utilize to assess emotional and behavioral problems (EBP) in children aged 1,5-5 years in USA and Europe. Although, CBCL/1,5-5 have been used on ASD and normal children in many societies. However, the CBCL/1,5-5 in Indonesian version has not been proven to assess EBP in Indonesian ASD children.

Aim: The aim of this study was to examine the effectiveness of CBCL/1,5-5 to screen of EBP in Indonesian children with ASD.

Method: This study used a Cross-Sectional design. One hundred and eighteen mothers of ASD and Typical Development children (TD) were registered in this study. Statistical analysis was performed using A Chi-Square and Independent T-Test.

Results: Six of seven CBCL/1,5-5 scales were significantly higher in children with ASD compared to TD (except anxious). Total problems, internalizing, and externalizing scores were significantly higher in ASD than those with TD children in Indonesia.

Conclusions: The CBCL/1,5-5 is suitable tool to detect problem of emotional and behavioral in Indonesian ASD children

Keywords: Problems of Emotional and Behavioral, Children with ASD, Child Behavior Checklist/CBCL 1,5-5.

Introduction

Globally, autistic disorders accounted for more than 58 per 100,000 population and others ASDs accounted for 53 per 100,000,1 16.8 per 1.000 in children aged 8 years.2 Prevalence of childhood autism was 11.6 - 18.75 per 10.000 in Northern European Region (IUK, Iceland, Denmark, and Sweden), 11.6 per 10.000 in Western Pacific region (Japan, China), and South East Asia.3

Children with ASD present high rate of emotional (internalizing) and behavioral (externalizing) problems.4,5,6 Young children with ASD commonly exhibit the following EBP: including internalizing (emotionally reactive, anxious, somatic complaints, and withdrawn) and externalizing (attention problems and aggressive behavior).7,8,9 Preschool children with ASD have been found to exhibit EBP frequently,10,11,12 A previous study shown that 72-86% of children with high-functioning ASD had at least one problem of emotional and behavioral in Singapore.13 Internalizing was also reported higher in ASD Children with Developmental Regression.14

Previous studies reported that the CBCL/1,5-5 (items had positive correlations with total score and had high internal consistency.7,15,16 The CBCL/1,5-5 is a widely used tool to assess EBP in children aged 1,5-5 years in USA and Europe.17 The CBCL scales were developed through factor analysis of data from normal children populations.18,19,20 Internal consistency of the CBCL scale in Indonesian version, measuring

DOI Number: 10.5958/0976-5506.2019.03138.3
internalizing and externalizing problems in normal samples were 0.89, 0.89, and 0.84, respectively.\textsuperscript{21} In ASD sample at 24 countries, alpha coefficient scales of CBCL/1.5-5 ranged from 0.63 to 0.89, internalizing, externalizing, and total problems score were 0.80, 0.90, 0.93, respectively.\textsuperscript{22} Although, CBCL/1,5-5 have been used on ASD and normal children in many societies. However, the CBCL/1,5-5 in the Indonesian version has not been proven to assess EBP in Indonesian ASD children. The purpose of this study was to investigate effectiveness of CBCL/1,5-5 to detect EBP in Indonesian children with ASD.

**Material and Method**

**Design and Sample:** This study used a cross-sectional design. The participants of this study were mothers of children with ASD and TD aged 1,5–6 years. Children with ASD were recruited from a special school in Yogyakarta and Surabaya, whereas TD children were recruited from kindergartens in the same area. ASD diagnoses were made by pediatric neurologists refer to DSM IV TR.\textsuperscript{23}

**Instruments:** The CBCL/1,5-5 was used in this study. The CBCL/1,5-5 consists of 100 items (7 scales, such as emotionally reactive, anxious, somatic complaints, withdrawn, sleep problems, attention problems, and aggressive behavior).\textsuperscript{17} Emotional reactive, anxious, somatic complaints, and withdraw belong in the internalizing category. Whereas, externalizing consists of attention problems and aggressive behavior. The CBCL/1,5-5 contains 3 pages and instructs parents to score each of the emotional/behavioral problem items by circling a 0 = not true of the child, 1 = somewhat or sometimes, and 2 = very true or often true. The questionnaire was translated from American English into Indonesian and then re-translated by another linguist back into American English. Finally, after ensuring the validity and reliability of the Indonesian version of CBCL/1,5-5, the questionnaire was given to parents of 130 Indonesian children. Ninety-six of the 100 items of CBCL have significant positive correlation with total problems score (ranged of items correlation, 0.22 to 0.69; \( p < 0.01 \)). Four items of CBCL/1,5-5 did not have significant positive correlation with total problems score (upset by new people or situations, doesn’t want to sleep alone, nightmares, and physically attack people). However, those four items maintained significant positive correlation with CBCL scales. Internal consistency of CBCL scales ranged from 0.55 to 0.90. Cronbach alpha scores of total problems score, internalizing, and externalizing were 0.95, 0.92, and 0.90, respectively.

**Data Collection:** This study was conducted in Yogyakarta and Surabaya Province from July to December 2014. After the permission from parents was approved the questionnaires were distributed.

**Data Analysis:** Independent T-Test was used to compare CBCL scales, both internalizing and externalizing between children with ASD and TD.

**Finding**

**Participants’ Background:** One hundred and eighteen mothers of children with ASD and TD aged 1–6 years old were enrolled in this study. The Chi-square analysis showed a significant differences male/female ratio in the sample. There were a significant different of participants’ religion (Table 1).

**CBCL items in ASD and TD Children:** Five of 9 items on emotionally reactive were significantly higher on ASD than TD children. The mean of items of disturbed by any change in routine, panic for no good reason, rapid shifts between sadness and excitement, sudden changes in mood or feelings, and whining were significantly higher on children with ASD than those TD children. Among anxious scale, items of clings to adults or too dependent, look unhappy, and nervous were significantly higher in children with ASD than those TD (\( p < 0.01, 0.05, 0.05 \), respectively). There were three items of somatic complaint significantly higher in children with ASD than TD (can’t stand having things out of place, constipated, and stomachaches or cramps without medical cause). Seven of eight items on withdrawn scale were significantly higher on children with ASD than TD (avoids looking others in the eye, doesn’t answer when people talk to children, refuse to play active games, seems unresponsive to affection, shows little affection toward people, shows little interest in things around children, doesn’t get involved with others). However, only one item on sleep problems scale was significant different among children with ASD and TD (resists going to bed at night, \( 0.54 \pm 0.62 \text{ vs } 0.12 \pm 0.33, p < 0.01 \)). All items on attention problems scale were significantly higher on children with ASD than TD. Three ten of nine ten items in scale of aggressive behavior were significantly higher on children with ASD than TD.
There were 4 items of aggressive behavior (Can’t stand waiting, Demands must be met immediately, Stubborn, and Uncooperative), 3 items of attention problems (can’t concentrate, can’t sit, Poorly coordinated), and 3 items of withdrawn scales (doesn’t answer when people talk, avoid looking others in the eye, shows little interest) with the ten highest scores in children with ASD.

**CBCL scales among emotional (Internalizing) and behavior (Externalizing) Problems:** Table 2 shows there were six of seven scales were significantly higher in children with ASD than those TD. Emotional (internalizing), behavioral (externalizing) problems, and total problems score were significantly higher on children with ASD than TD.

*P<0.05; **P<0.01. CBCL, Children Behavior Checklist; ASD, Autistic Spectrum Disorder; TD, Typically Developing
Discussions

We found the total problem score of CBCL was significantly higher in children with ASD than TD (64.97 ± 24.60 vs 33.56 ± 21.23; \( p = 0.00 \)). A previous study reported the same finding that children with ASD score significantly higher in the total problems score of CBCL/1,5-5 compared than TD children in Italy, and in Korea.\(^7,8,9\) The finding showed that emotional (internalizing) and behavioral (externalizing) problems were significantly higher in children with ASD than TD. This finding was consistent with a previous study that reported the EBP were significantly higher in children with ASD than TD.\(^9,10\) The previous study reported that there were 29.6% of externalizing problems and 27.2% of internalizing problems in young children with ASD.\(^24\) The similar studies also reported the internalizing and externalizing were higher in preschool with ASD than TD in Italy, in New York, and in Korea.\(^7,8,16\)

We also found that six of seven scales were significantly higher in children with ASD than TD (except anxious). Similarly, a previous study in New York reported that children with ASD score significantly higher in the same 6 scale of CBCL (except anxious). Moreover, a previous study found that all of CBCL scales were significantly higher in preschool children with ASD than TD (emotionally reactive, anxious somatic complaints, withdrawn, sleep problems, attention problems, and aggressive behavior; \( p < 0.01 \)).\(^9\) Rescorla \textit{et al}., (2012) reported the mean of CBCL scales across 15 countries were almost the same with the present study (the range of mean of CBCL scales, the present study = 2.34 ± 2.23 to 8.42 ± 5.27; Rescorla \textit{et al}., = 0.8 ± 0.6 to 6.9 ± 2.4).\(^20\) Our study revealed that the highest of mean score of CBCL scales were aggressive behavior, withdrawn, and attention problems. This result is similar with a previous study on USA children with ASD (age, 1.5-5.8 years), which reported that the CBCL scales with the highest percentage of clinically significant scores were withdrawn, attention problems, and aggressive behavior.\(^11,24\)

We found the ten highest items scored in children with ASD, and three items (aggressive behavior), one item (attention problems), and one item (withdrawn); also the ten highest in TD children (aggressive behavior: can’t stand waiting, demands must be met immediately and stubborn; attention problems: can’t sit still; and withdrawn: doesn’t answer when people talk to him/her). Ivanova \textit{et al}. (2010) evaluated the EBP in children in 23 countries.\(^18\) They found that the ten highest score of CBCL items ranged from 0.76 ± 0.06 (Emotionally reactive: sudden changes in mood or feelings) to 0.70 ± 0.08 (withdrawn: shows little affection toward people). Compared with previous studies in 24 countries, there were 5 items that were the same in the ten highest with the present study in TD children (can’t stand waiting, demands must be met immediately, quickly shifts from one activity to another, doesn’t want to sleep alone, and can’t sit still). Two items in the ten highest score were the same with the previous study in 24 countries.\(^22\)

Finally, we found the total problems score of CBCL, internalizing, and externalizing were not significantly different among boys and girls with ASD and TD. Several previous studies evaluated the differences of total problems score, internalizing, and externalizing among boys and girls. The results showed that the total problems score of CBCL/1,5-5, internalizing, and externalizing were not significantly different among boys and girls in Denmark\(^19\) and in Kosovo.\(^25\) Previous studies were reported that there was no significant different of emotional problem and hyperactivity of children with ASD based on gender.\(^26-27\) Studies in the Muslim population (Pakistan, and Turkey) reported no significant different in total problems of CBCL, externalizing\(^28\) and internalizing among boys and girls preschool aged.\(^23,28\)

Several limitations in this study should be mentioned. The number of children studied was limited. The studied area was also limited to the Java Island. In addition socio-economical situations of parents were not measured in this study.

Conclusion

The CBCL/1,5-5 is suitable tool for detection of EBP in Indonesian children aged 1,5-6 years with ASD.

Acknowledgments

We were grateful to Professor Thomas Achenbach who gave us permission to translate the CBCL 1,5-5 into Indonesian version and utilized the CBCL/1,5-5.

The Effect of Health Promotion Based on the Health Promotion Model with a Peer Group Approach Regarding the Utilization of Maternal and Child Health Handbook

Sri Utami1, Rekawati Susilaningrum1, Nursalam2
1Polytechnic of Health, Ministry of Health, Republic of Indonesia; 2Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Background: The reduction of maternal and child mortality in Indonesia is one of the government’s goals in the health sector. The use of maternal and child health books by mothers is still not optimal. The purpose of this study was to analyze the relationship between the functions of the maternal and children’s health book which included recording, education and communication with the maternal knowledge of maternal and children’s health.

Method: This study was quasi-experimental (pre-post-test control group design) with a sample of 50 respondents over both the control and treatment groups. The sampling technique used was simple random sampling. The instruments used were Individual Characteristics and Experiences and Specific Behavior Cognitions and Effects. The analysis used was regression analysis.

Results: There was a difference between before and after receiving a health promotion model-based health promotion with a result of p < 0.05 for all of the indicators in the treatment group. In the control group, there was no difference.

Conclusion: Health promotion model-based health promotion seeks to improve the perceptions of the benefits, perceived barriers, self-efficacy and attitudes toward any action plans that can improve maternal behavior in MCHHB utilization.

Keywords: health belief model, peer group, maternal and child health handbook.

Introduction

Maternal and child health improvement is one of Millennium Development Goals (MDGs) goals. Infants mortality in Indonesia is still a problem although showed a significant decreased recently. In 2017, infant mortality rate in Indonesia was 21 per 1,000 birth1. There were 9 provinces in Indonesia which contribute to 75% of maternal and child mortality in Indonesia2 and Easy Java is the highest province contributing to maternal and child mortality in Indonesia.

MCHHB utilization have a lot benefit such as improving immunization coverage10, improving maternal knowledge on exclusive breastfeeding11, Government have made various effort to reduce maternal and child mortality such as Suami siaga (male engagement in maternal health) program3, village engagement in maternal health program4, strengthening the health system of universal health coverage and health services5,6 and providing maternal and child health handbook (MCHHB) continuum7. This handbook was given to pregnant women during their first antenatal care visit in health care services. Previous study showed that the use of MCHH by pregnant women can increase antenatal care visits and improve communication between mothers and health care providers8,9. Although this MCHHB distribution to all pregnant women is mandatory, MCHHB utilization and ownership is still limited.
increasing ANC information, and improving proper nutrition during pregnancy and child health care. MCCHB utilization were correlated with wealth and education level, number of children, age of child, communication with health personnel. A preliminary study conducted in Public Health Center in East Java found that all pregnant woman who visited to Public Health Center for antenatal care had an MCHHB, but the MCHHB utilization is lacking. Mothers were not utilize MCHHB because of various reasons including have no time, lack of understanding, and mistaken assumption that the MCHHB was a notebook for the health personnel. MCHHB utilization coverage still below the Minimum Service Standards target.

Previous study found there was a significant positive relationship between commitment and maternal behavior. Commitment is a desire to do certain health behaviors, including the identification of strategies to be able to do so well. To build a commitment, it is necessary to provide health education or information through a method to increase one’s level of commitment. The purpose of this study was to analyze the effect of health promotion based on the health promotion model with a peer group approach regarding the utilization of maternal and child health handbook

Method

The design used in the study was a quasi-experiment study (pre-post-test control group design). The research subjects in this study were pregnant women and mothers who had children who were under five years old who came to the health center in Surabaya. The inclusion criteria for respondents are 1) had an MCHHB and 2) able to read and write. The sampling used in this study was simple random sampling. The sample size in this study totaled 50 people for the treatment group and 50 for the control group.

Data on pregnant women in health care centers were collected. Prospective respondents who met the inclusion criteria were visited at home to be given an explanation of the study then asked to sign informed consent. The intervention was carried out in the form of providing health education that contained the benefits of the MCHHB book, followed by peer support on how they used and utilized MCHHB. Peer support also provides a solution to the difficulties experienced by mothers in utilizing MCHHB. On the first day in the form of health education about the use of MCHHB for 60 minutes. the second day, small groups were formed, each of which consisted of 5 people, the discussion continued with a discussion about the difficulties facing mothers in utilizing MCHHB books and discussions to provide solutions to each other.

Individual characteristics and experiences include prior related behavior and personal, biological, psychological and socio-cultural factors. The characteristic questionnaire was created by the researchers by adopting and developing from existing questionnaires. Specific cognitions affect behavior were measured which consist of perceived benefits of action questionnaire which consist of MCHHB ownership, perceived Benefits for mothers, perceived Benefits for the family, perceived Benefits for health services, and perceived Administrative benefits; perceived barriers question which consist of time and mothers understanding about MCHHB benefit and self efficacy question which consist of Level of difficulty, situations and Strength.

The commitment plan of action questionnaire was made by the researchers by adopting pender health promotion model combined with the MCHHB. The questionnaire was developed and modified by the researchers in accordance with the scope of the utilization of the MCH handbook.

Descriptive analysis and Mann Whitney test was used to determine differences between the groups, and Wilcoxon test was used to determine the effect within group with p-value of α=0.05.

Results

The majority of respondents were in the age range of 21-25 years old. The majority education level was a secondary level of education with the majority working as housewives. Most mothers had one child, and the majority of respondents had become Indonesian National Health Insurance System participants (Table 1).

**Discussion**

HPM-based health promotion affects the level of commitment to the action plan which consists of the indicators of resilience, independence, goal setting, self-desire and the desire to succeed in the plan for action. Commitment in relation to HPM is defined as the intention to carry out certain health behaviors, including the identification of strategies to be able to do well. Previous research stated that the HPM has a significant effect on the commitment of the public health center nurses and commitment has an influence on the duties of the nurses. Strong commitment is influenced by the high perceived benefits as one of the measures to achieve this vision will require proximity access and improving the quality of health services in the community. Health cottage village (Ponkesdes). The more that the mothers have perceptions of obstacles when fulfilling child nutrition according to nutritional adequacy standards, the more that their commitment will be increasingly weak when it comes to carrying out the actions.

There is a significant positive relationship between behavioral specific cognition and affect with the maternal commitment to the prevention of under-nutrition in children under five. Individuals are committed to carrying out behaviors where they have thought of useful or beneficial personal values. HPM-based health promotion affects the behavior of mothers when utilizing the MCHB. Perceived benefits directly affect the behavior of mothers in relation to fulfilling the nutrition of pre-school children. The perception of the benefits that can increase will affect the behavior of the mother when it comes to carrying out such an action. Positive perceptions relate to the implementation of increasing behavior.

A high level of confidence or self-efficacy will bring in more positive values to the individual, which will appear in their behavior. Parents 'beliefs in managing asthma in children will improve their parents’ abilities and related sub-scales. Behavior changes or adopting new behaviors is related to various processes, knowledge, attitudes and actions. In this study, there was an effect of HPM-based health promotion on the maternal behavior of MCHHB utilization in the intervention group. Attitude toward a given behavior together with belief will form the intention to behave in a certain way. In the theory, it states that behavior is influenced by intention. Someone will do an action when looking at and believing that the action is both positive and useful for themselves and others.

The results of the study showed that after being given a health promotion, there were significant improvements in the maternal behavior through their commitment to the plan of action. Commitment in HPM is defined as intention/the intention to carry out certain health behaviors, including the identification of strategies to be able to do well.

Based on the aforementioned, the mother needs to be informed about the importance of utilizing the MCH handbook in order to maintain her own health and to prepare her children as a qualified future generation. A person will commit and engage in a behavior that promotes health when seeing other people as an example, modeling the behavior and expecting the behavior to occur or be implemented while providing assistance and support to enable the behavior to be carried out. In an effort to improve the behavior of mothers in the use of MCH books, it is necessary to create a high commitment in the mother in order for them to be motivated and to have the strong intention to optimally utilize the MCH books. This motivation or intention will emerge if the mother has a good perception of the benefits of the action, a high self-efficacy perception, a good attitude about the positive action plans and a good perception of
the barriers. This can be generated through the HPM-based health promotion.

The role of peer support can influence the commitment of mothers to use MCHHB. Therefore, health care centers need to consider making a forum that contains pregnant women and mothers with children under five to give each other support and information to one another.

**Conclusion**

To increase success in relation to utilizing the MCH handbook, it is necessary to increase the mother’s commitment to the plan of action. Improved maternal behavior can be measured through an increase in knowledge, attitudes and actions. Health workers need to increase the level of understanding and commitment regarding the use of MCH books by pregnant women and by mothers who have children under the age of five. Further research is needed on the relationship of the other variables in HPM with the behavior of the mothers in the use of MCH books.

The Risk of Protein Deficiency and Breast’s Milk Complimentary on the Event of Stunting Children

Sunarto¹, Enik Sulistyowati¹, Choiroel Anwar¹, Ali Rosidi²

¹Lecturers in Ministry of Health Polytechnic, Semarang, Indonesia; ²Lecturer in Unimus Semarang, Indonesia

ABSTRACT

Background: One of the severe threats to efforts to improve health, especially on the quality of future generations is stunting. This study aimed to determine the risk factors for lack of protein intake and the provision of breast milk complementary food for the incidence of stunting in children aged 12-24 months.

Method: This study uses the design of case-control. The study sample was toddlers aged 12-24 months Semarang with 60 cases and 60 controls. Data collected includes sample and respondent identity, protein intake, and complementary feeding of breast milk. The test used is Mc Nemar with α = 0.05.

Results: The test results showed as many as 15.9% of toddlers suffered from stunting. Lack of risky protein intake is significant for the incidence of stunting of children aged 12-24 months.

Conclusion: Toddlers who have sufficient protein intake probably has less five times the risk of suffering from stunting.

Keywords: Protein intake, Nutrition, Complimentary Breast Milk, Stunting

Introduction

The growth process experienced by toddlers is a cumulative result since the toddler was born. The condition of proper and healthy nutrition in toddlers (aged under five years) is an essential foundation for their health in the future. Conditions that have the potential to disrupt the fulfillment of nutrients, especially energy and protein in children, will cause problems with growth disorders (¹).

Stunting or short toddlers are toddlers with chronic nutritional problems, who have nutritional status based on length or height according to the age of a toddler when compared to the standard WHO-MGRS (Multicentre Growth Reference Study) in 2005, have a Z-score of less than -2SD and if the z-score of less than -3 is categorized as a very short toddler (¹). Stunting starts when the fetus is still in the womb, and only appears when the child is two years old. Stunting problems is a new issue that adversely affects nutritional problems in Indonesia because it affects the physical and functional aspects of the child’s body as well as the increase in child morbidity, even the stunting event has become the spotlight of the World Health Organization (WHO) to be completed soon (²).

One in three Indonesian children experience stunting and even the number is increasing from year to year. Stunting is a short or concise body condition. Stunting occurs due to malnutrition and recurrent disease for a long time since the fetus until the first two years of the life of a child (²). To improve the nutritional status of the community, attention must be paid to the health sector from the outset or under five. It is essential to make timely prevention efforts so that the growth of the brain of children up to the age of 5 years can run well, to avoid loss generation. Stunting is a serious threat to efforts to improve health, especially for the quality of future generations.

Method

The study design used a design case-control that is research to see the relationship between exposure and
effects by comparing case groups and controls. Control was taken with gender matching. The sampling technique used is simple random sampling. The population in this study was all toddlers aged 12-24 months in the working area of the Bangetayu Health Center in the City of Semarang.

Sample size calculation is by the formula:

\[
n_{\text{case}} = \frac{(M + 1)[Z_{1-\alpha} (1 + \varphi) + 1Z_{1-\beta} \sqrt{\varphi}]}{2Mk(\varphi + 1)\pi p(1 - \pi p)}
\]

\[
(1 + 1)\left[\frac{1.96(1+3.5)+2(0.84)\sqrt{3.5}}{3.5 - 1}\right]
\]

\[
2(1)(0.28)(3.5 + 1)0.57(1-0.57)
\]

\[
2\times \frac{8.82 + 1.79}{2.5}
\]

\[
0.6176
\]

\[
2\times \frac{10.61}{2.5}
\]

\[
0.6176
\]

\[
2\times 18.03
\]

\[
0.6176
\]

\[
36.06
\]

\[
0.6176
\]

\[
n_{\text{case}} = 58.3845 \sim 59
\]

Description:

\[
n_{\text{case}} = \text{large sample case}
\]

\[
Z_{1-\alpha} = \text{standard normal distribution value (table Z)}
\]

\[
at \alpha = 0.05
\]

\[
Z_{1-\beta} = \text{standard normal distribution value (table Z)}
\]

\[
at \beta = 0.2
\]

\[
k = 1/[1 + (\varphi + 1) \pi p] = 0.28
\]

\[
\varphi = \text{OR} = 3.5 \ (\text{Widiyawati, 2013})
\]

\[
M = \text{Matching (control case)}
\]

\[
\pi p = \text{p (exposure)} = 0.57
\]

Based on the above calculations in this study used a sample of 60 toddlers 12-24 months for each case and control group. With a ratio of 1: 1, the number of samples (cases and controls) obtained was 120 toddlers 12-24 months with matching sexes.

To get a case of 59 stunting toddlers aged 12-24 months from the study population, there were 431 toddlers aged 12-24 months, an extensive calculation of cases that needed to be screened was needed. Then the screening calculation was carried out as follows:

\[
N = \frac{\text{sample size}}{\text{incidence prevalence in the population}}
\]

\[
N = 59
\]

\[
N = \frac{60}{20.42%}
\]

\[
N = 294
\]

Results

Work is often associated with the role of a mother who has additional work outside of household work to increase family income (3). The mother’s work data is obtained from the toddler’s identity form, then grouped into five categories: non-work, employees, entrepreneurs, farmers/fishermen/laborers, and other jobs. Distribution of frequency of respondents based on working mother can be seen in table 4.

Table 1: Distribution of under-five mothers according to the type of work in the working area of the Bangetayu health center in Semarang

</table>

Based on Table 1. It can be seen that the respondents are divided into five types of work, case groups 75% of mothers of a toddler do not work while in the control group only 71.7% of mothers of the toddler are not working. This shows that there were more cases group respondents who did not work compared to the control group.
The sample used in this study is toddlers aged 12-24 months in the Bangetayu Community Health Center in Semarang. Frequency distribution of sample characteristics can be seen in table 5.

The average age of the sample in the case group was 19 months, while in the control group, the average age was 18 months. The average nutritional status of the sample in this study, according to body height/age indicators in the case group had a Z-score of -2.6, while in the control group had a Z-score of -0.47. Characteristics of protein intake in this study sample, in the case group, had an average value of 23.6 grams of protein intake, while in the control group had an average protein intake value of 28.6 grams. The characteristics of complementary feeding of breast milk complimentary food in this study sample, in the case group, had an average score of 70.3, while in the control group had an average value of 66.3. Based on the results of body height/age nutritional status screening conducted on 314 toddlers aged 12-24 months in the working area of the Bangetayu Community Health Center in the City of Semarang, it was found that 15.9% of the toddler had low nutritional status and 4.8% of children were concise.

Discussion

Stunting is a high index state bodies according to age below minus two standard deviations based on WHO standards. Stunting is a long-term manifestation of the factor of consumption of low-quality diets, recurrent infectious diseases, and the environment (4). The purpose of this study was to determine the factors associated with the incidence of stunting in children aged 24-59 months. This type of research is an observational analytic study with a cross-sectional design. A total of 74 samples were selected by simple random sampling. The study was conducted from March to April 2018. Data collection was done by measuring height, interviewing, and filling out questionnaires. Bivariate analysis using Chi-square test and multivariate using multiple logistic regression test. The results showed that the proportion of Stunting was 26.9 percent, and the average was 73.1 percent. Chi-square test results showed a significant relationship between the level of energy intake, history of duration of infectious disease, birth weight, maternal education level, and family income level with the incidence of Stunting. Mother’s education level has the most dominant relationship with the incidence of Stunting. This research suggests that governments, health agencies, and related parties collaborate in implementing policies to reduce the risk of Stunting. The community is advised to get quality education, provide balanced nutritional intake, and improve children’s health.

1. Relationship between Stunting Protein and Toddlers: Provision of protein to toddlers needs to be considered according to their needs because if excess can damage the kidneys, lack of protein is also not good for the health of toddlers’ growth. Protein needs are not only for physical growth but also crucial for brain cell growth. Given that brain cells will stop growing at the age of 3-4 years, then toddlers need to be monitored so that brain cell growth can be optimal (5). Protein adequacy in toddlers aged 1-3 years, both male and female are 26 grams per day.

From the results of research conducted on 120 samples of toddlers to show the relationship between protein intake and the incidence of Stunting, the following data were obtained.

Table 3: Distribution of Toddlers by Protein Intake and Nutritional Status in Bangetayu Health Center in 2017

Based on the table, it can be seen that in the case group, 50% were included in the category of less protein intake, whereas in the control group only 16.7% were included in the category of less
Protein intake. The difference in proportion after statistical tests using McNemar produces p = 0.00. This number gives a meaning that there is a significant relationship between protein intake to the incidence of stunting of children aged 12-24 months in the Bangetayu Health Center Working Area. Lack of pure protein at a severe stage causes quartz corps in children under five years. Protein deficiency is usually accompanied by a lack of energy, which causes a condition called marasmus (8). Protein has many functions, including forming new body tissues during the period of growth and development of the body, repairing and replacing body tissues, repairing and replacing worn, damaged, or dead tissue. Children who experience growth barriers are caused by a lack of adequate food intake and recurrent infectious diseases and increased metabolic needs of decreased fiber appetite, thus increasing malnutrition in children. This situation makes it increasingly difficult to overcome growth disorders that ultimately have the chance of stunting (7).

From the analysis results also obtained Odd Ratio (OR) = 5, which means that toddlers who have protein intake have less than five times greater risk of stunting than toddlers who have proper protein intake.

Protein intake is a substantial factor in the incidence of stunting because it directly affects the body. This happens because stunting is one form of malnutrition which is characterized by indicators of height according to age (6). One of the causes of malnutrition itself is a lack of protein intake. Protein has many functions, including forming new body tissues during the growth and development of the body. In children who lack protein intake, there will be a growth disorder that ends in the incidence of stunting. Stunting children are caused by a lack of intake, especially energy and protein, which results in abnormalities in the form of short or concise bodies, even though gene factors in cells show the ability to grow normally (8).

The results of this study are in line with the research conducted by before, entitled the Influence of maternal education on child immunization and stunting in Kenya. Based on the results of statistical tests, it is known that there is a significant relationship between the level of protein adequacy and stunting in infants. It was also explained that the less the level of protein sufficiency, the higher the child’s risk of being short (9).

2. Relationship between Providing Complementary Breast milk with Stunting Events: Along with the growth of toddlers, nutritional needs will also increase. Slowly decreasing milk production makes toddlers need additional sources of nutrients. Provision of complementary food for breast milk as a compliment and preparation for developing toddlers (10). From the results of research conducted on 120 samples of toddlers to show the relationship of the provision of complementary food with the occurrence of stunting, as stated in table 4.

Table 4: Distribution of Toddlers according to Breast Feeding Complementary Food with Stunting Events in Bangetayu Health Center

Based on the table, it can be seen that in the case group, 70% were included in the poor category of complementary feeding, whereas in the control group, 53.3% were included in the type of supplementary feeding.

The difference in proportions was carried out statistical tests using McNemar produced p = 0.11, and this number gives the meaning that there is a non-significant relationship between complementary feeding of complimentary breastfeeding and the incidence of Stunting in infants. In complimentary breastfeeding, it is necessary to pay attention to the timeliness of administration, frequency, type, amount of food ingredients, and how to make them. The provision of baby food is not right, one of which is feeding too early or too late. If the complimentary breastfeeding is too early given while in the baby’s intestine has not been able to absorb these foods often the baby has constipation so that the health of the baby is disturbed can cause other diseases and thus its growth will be disrupted (12).
From the tabulation table, it can be found that OR = 1.9, which means that toddler with the provision of complimentary breastfeeding foods are at risk 1.9 times more likely to experience stunting.

This research is in line with the opinion of the Department of Health which states that growth disorders at the beginning of a baby’s life are due to malnutrition since the baby, the supply of complimentary breastfeeding is not nutritionally appropriate to the baby’s needs or the pattern of giving according to age and lack of proper care (11).

**Conclusion**

There is a significant relationship between the level of energy intake, the average duration of illness, birth weight, maternal education level, and family income level with the incidence of stunting in children aged 12-24 months in the work area of Bangetayu Health Center Semarang City. Levels of protein intake, the mean frequency of illness, exclusive breastfeeding status, completeness of primary immunization status, level of maternal knowledge about nutrition, and the number of household members did not show a significant relationship with the incidence of Stunting.

Effect of Using Coriander Seed Powder on *in Vivo* Digestion Coefficient, Total Volatile Fatty Acid and Some Blood Parameters on Awassi Lambs

Sundus F. M., A. S. Rejab, A. Same, Z. Raid

**ABSTRACT**

Sixteen, lambs weighing 25 kg average initial weight and 4 to 5 months age, were divided into two groups (6 lambs each), to study the effect of two levels (0 and 6g/h/d) of coriander seed powder to support the digestive coefficient, rumen fermentation and some blood parameters. The experiment utilized one diet with concentrate: roughage ratios 70:30 on a dry basis, including a control group (0) and groups received a basal ration 6g/h/d, *coriander sativum* respectively. The result appeared significantly increased the digestion of dry and organic matter and total protein 67.17, 68.18 and 71.50 respectively, as well decreases ammonia-N and increases acetic proportion in rumen fermentation. On the other hand, no significant differences were noticed in serum total protein, albumin, globulin, glucose and essential oils effects on rumen microbial population, amount of volatile fatty acids. Recent studies have tended to regulate ratio by using plants and medicinal herbs as feed substitutes to avoid a few side effects of antibiotics and other dietary categories and their effect on animal health and performance.

**Keywords:** coriander seed powder, digestion coefficient Herbs, volatile fatty acid, blood parameters, Awassi lambs

**Introduction**

Recently the use of herbal medicines, have been considered as an alternative for therapeutic usage. The major active compounds of medicinal plants (essential oils, saponins flavonoids, tannins and polyphenols) have been mainly tested as concentrated extracts to examine their antimicrobial activity1 to decrease rumen methane emissions2. Coriander (*C. sativum* L.) belonging to the family Umbelliferae/Apiaceae is an aromatic, herbaceous annual plant antibacterial, antifungal and antioxidant activities *C. sativum* is useful in food preparation (as a flavouring agent and adjuvant) and preservation. This coriander seed essential oils was also found to improve blood glucose control and it held promise for use as an ant hyperglycemic agent3. The essential oil content ranged from 1.87 to 2.33% (v/w). The presence of 40 components of the coriander oil was determined, out of which 9 were unidentified. The main components of the coriander seed oil were as follows: linalool, camphor, a-pinene, geraniol, and γ-terpinene). Coriander fruit contains about 0.2%–1.5% of volatile oil and 13%–20% of fat oil4. However, it has been recorded that some cultivars contain up to 2.6% of volatile oil5. As has been reported by6. The researchers fed ruminants by adding some substances to improve the environment of animal and performance such as yeast7. Currently; the medicinal plants have been used to avoid harming their use and are considered safe. This is why coriander seed powder has been used in the current experiment. The objective of this study was to investigate the effects of various levels of coriander seed powder on the digestible coefficient, rumen fermentation, and some blood parameters.

**Materials and Method**

Sixteen, lambs weighing 25 kg average initial weight and 4 to 5 months age, were divided into two groups...
(6 lambs each), to study the effect of two levels (0 and 6g/h/d) of coriander sativum to support the digestive coefficient, rumen fermentation and some blood. The experiment utilized one diet with concentrate: roughage ratio 70:30 on a dry basis. Table 1. Shows the nutritional composition of coriander seed powder.

1. Digestibility Trail: Digestibility trail was conducted to determine the digestibility coefficients of total diets. The sixth week was assigned for this trail using half of the lambs (three lambs per each treatment). The offered quantities of diets and those remained were accurately recorded to estimate daily intake during the 7 days-collection period. Feces excreted by each lamb were weighed and about 10% were subsample daily and stored at -20°C. Feces were collected by using special handmade digestion sacs, which suited for each lamb, and ensured separation of urine without preventing to their movement inside the individual pens8. At the end of the collection period, Samples of diets and feces were thoroughly mixed and one sample of each was obtained and stored in deep-freezing for the subsequent chemical analysis a according to9.
