In spite of the efforts of the researcher to control the variables that may affect the main experiment and what is required by the scientific secretariat of the department to give a real image when the implementing the program, the researcher created the elements of excitement and thrill in order to achieve the self-interest of participants to ensure the achievement of good results.

Post-tests: After completion of the program, the researcher conducted the tests, taking into account the same conditions in which the tests were conducted in terms of place, time and method of tests as much as possible, where physical and motor tests were carried out over two days according to the dates indicated below.

- Physical qualities test (Monday 4/2018).
- Testing of motor abilities on Tuesday.

The results of pre- and post-tests in Table (2) indicated that there were statistically significant differences between pre- and post-tests and in favor of the post-test in all variables identified in current study. The researcher attributed the reason for this development to the effect of the program prepared and its contribution to raising abilities of students with slow learning by giving them sufficient mobility. The studies confirmed that depriving student of movement will lead to development of physical conditions that limit his mobility compared to ordinary students [5]. Speed rapidly develops in newly-arrived children and the rate of growth stands at approximately (10) years and gradually decreases thereafter. Also, some studies indicated that speed-management requires the efficiency of the nervous system in performing muscle function as it controls functions of the body [6].

In the test of elasticity, the results showed that there were statistically significant differences between pre- and post-tests. These differences showed the extent of influence of vocabulary of the prepared program and its suitability to student’s slow learning abilities. However, availability of the principles of excitement and creation of competition and instilling the spirit of enthusiasm in the students were very influential in overcoming these difficulties. Also, studies indicated that child’s new entry into school constantly needs to increase the purpose of exercises.

Exercise increases flexibility in new-school children and gives a much better result when the child ages in addition to development of the motor flexibility of joints [7].

As for the test (fitness), there were statistically significant differences between results of pre-and post-tests. These moral differences confirmed the impact and contribution of educational program in the development of this trait. The studies indicated that fitness is the character of the child at this stage, and this is what we see in balancing exercises and soft toys as well as tools to help the child earn experience by putting him/her in different situations [8].

The results showed statistically significant differences between results of pre-test and post-tests. These differences were a clear indication of the effect of the program on the development of this function as well as the efficiency of some mental processes consensus that depend on integrity and accuracy of nerve functions and their associations together, because neurotransmitters have to be sent out to more than one place at the time as well as the compatibility of hand-eye and foot-eye compatibility are developing with age. So that, boys perform better than girls throughout childhood [1].

Conclusions

1. The emergence of significant differences between results of pre- and post-tests and in favor of the post-test of physical and motor characteristics.

2. The sports activities of student in general have a great positive relationship with the abilities of student’s mental abilities.

3. The training program had a positive effect on development of research variables through the inclusion of small games and various motor activities contributed to the release of the potential of the student slow learning, because of its impact on the improvement of mental processes.

Ethical Clearance: The research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

The Effect of Learning Exercises Through Flexible Circles on Learning Some of the Composite Skills of Futsal Football for Students

Mazin Hashim Hammood1, Rashad Tarek Yousef1

1Faculty of Physical Education and Sports Sciences, University of Dhi Qar, Iraq

ABSTRACT

Background: Playing fast and quick moving of the ball from the backyard to the front yard drives learners to invest the basic skills effectively together so that they can start an attack larger in number than that of the opposing team which will help them score a goal. Thus, researchers (experts) give great attention to the acquisition and mastering of these basic skills. The objective of this research was to define the effects of learning exercises within the scope of flexible circles on learning of some composite skills of Futsal football for students.

Method: The researcher used the experimental method of equal groups. The fifth grade preparatory students (147 students), in the 2018/2019 academic year, at Mohammad Baqir Al-Sadr School for boys represented the study community. A sample of 30 students was randomly chosen from both classes (B&C). Participants were divided into two groups; one was experimental (15 students from Class B) using the learning exercise with the flexible circles model, while the second (15 student from Class C) was a control group using their teacher’s method (model).

Results: The results indicated that there were statistically significant differences between the pre- and post-tests in favor of the post-tests according to the second hypothesis of the research which was attributed to validity of the learning curriculum of both groups (experimental and control).

Conclusion: It was concluded that learning exercises prepared by the researcher had increased the efficiency of learners and the skillful and planetary side of the Futsal football.

Keywords: learning, exercises, flexible Circles, Futsal, composite skills.

Introduction

Teachers of physical education have long been interested in how to reach the highest levels of learning activities and sports games for their students. Therefore, there have been many attempts to find educational alternatives to the kinetic skills as represented in different educational ways and methods based on active role and actual participation in all stages of the class in a way that suits students’ capabilities and potentials. Among these methods is the style of flexible groups, which makes student focuses on learning process and provides him with educational alternatives to choose the most appropriate for him(1).

Futsal football is one of these sports games. It is a multi and diverse skill game besides its relation with the psychological, cognitive, physical, mental and procedural skills which led researchers to pay attention to those skills to acquire and master them effectively.

The researcher noted that most teachers follow the traditional methods when teaching the skills of Futsal football. It is to be noted that these old methods depend on the repetition of these skills one by one not collectively together with assigning little value to teaching how to practice this game. Thus, the researcher studied this real problem through the use of learning exercises according to the flexible circles and linking the learning of basic
skills to plans of playing directly and knowing the extent of their contributions in teaching of some of the complex skills. Thus, we have taught students the procedural and planetary performance in a simplified manner at the same time \[2\]. Therefore, the objective of current study was to identify the effect of learning exercises according to the flexible circles in learning some of the complex skills of Futsal football for students.

Research hypotheses

1. There are significant statistical differences between the pre- and post-tests of the control and experimental groups in learning some of the composite skills in the Futsal football in favor of the post-test.

2. There are significant statistical differences in the post-tests between the control and experimental groups in the learning of some of the composite skills of the Futsal football and in favor of the experimental group.

Method

The researcher used the experimental method of the two equal groups (control and experimental) for being suitable for the research problem.

Research Community and Sample: The research community was represented by the fifth grade preparatory students at Mohammad Baqir Al-Sadr School for Boys in the 2018/2019 academic year. The total number of students was (147) representing four classes (A, B, C and D). Thirty students from the classes (B & C) were chosen randomly to be the sample of the research. Thus, the percentage of the sample of the research was (20.40%), divided by lotto into two groups; experimental group, 15 students using learning exercises according to flexible circles, and control group, 15 student using the teacher’s method.

Sample Homogeneity: The researcher used the torsion coefficient to find homogeneity in the variables of the search as shown in Tables (1 and 2).

Table 1: Homogeneity of control group members in terms of age, height and mass

All values of the torsion coefficient were (1+) indicating homogeneity of the members of the sample in term of the abovementioned variables.

Samples equivalence: The researcher made the equivalence to ensure a single starting line in the work of both groups (experimental and control) so used the \(t\)-test for independent samples to extract the parity.

Methods of data collection and the devices used in the study

- Arabic and Foreign references- school records, extraction of students’ age for the nearest month.
- Forms of questionnaires for the selection of technical tests.
- Scientific observation tests and measurement.

Identification of complex attacking skills: After having reviewed sources, references and scientific studies, identification and selection of complex skills suitable for Futsal ball players were accomplished.

Determination of tests used in the research: The researcher presented a set of tests concerning complex attacking skills in a questionnaire form to a group of experts to identify the appropriate test.

Complex Skills Tests\(^{[3]}\): Receiving from the movement then running and then targeting. The tools used in the test were Futsal balls, Stopwatch, Measuring tape, Stakes and Small goals.

Test Method: The student stood 3m away behind the starting line, and when he hears the whistle, he quickly sets out to take the ball being passed to him by the teacher from a movement in a half circle of 1m radius, then runs with the ball as quickly as possible in a straight line for 10 meters then shoots towards the goal which is 10m away from the place of targeting, from within the drawn rectangle of 2m width, and 1m length, with his preferred foot, the student must repeat his attempt three times.

The method of scoring: The performance time of each targeting attempt was calculated from the moment the ball received until it crosses the goal line.

Accuracy of the targeting was marked as follows:

Three marks were given for the ball going into square, Two marks were given for the ball going into square and One mark was given for the ball that goes into square. The final mark was given to the best attempt regarding time and accuracy of performance.

Pilot study: The researcher conducted a pilot study on a sample of (10) students of the research community without the main experiment on Wednesday (24/10/2018). The exploratory experiment for the researcher was considered a practical training for identifying obstacles to the main experiment, identifying the time allotted for tests and extraction of scientific bases for tests.

The scientific foundations of the tests

Test validity: The researcher presented these tests to the experts and specialists who examined the test forms to verify validity of the content.

Test Reliability: To determine the reliability of the test, the researcher tested a group of (10) students from outside the sample and, after (7) days, the researcher

again tested the students themselves. The researcher used the simple correlation coefficient.

**Objectivity of the test:** The researcher extracted the coefficient of objectivity through the results of two arbitrators using the correlation coefficient (Pearson).

**Main experiment procedures**

**Pre-Test:** The experimental tests were conducted on control and experimental groups with the help of the auxiliary team.

**Educational Curriculum:** The two groups were subjected to a curriculum for composite skills over period of (8) weeks with two educational units per week and as follows:

**The control group:** Members of this group applied educational units for teaching of composite skills according to the method followed by the teacher. The units were conducted on Monday and Wednesday of each week.

**The experimental group:** The researcher prepared a learning curriculum which was applied to members of the experimental group. The curriculum included (32) exercises to teach composite skills in the practice of flexible circles, which was initiated on Sunday (11/11/2018) (6/1/2019) and ended on Sunday 16/1/2019. It lasted for 8 weeks, two learning units per week. It included (16) units and each unit contained (2) exercises. The unit time was (45) minutes, and the components of the learning unit were divided into three main sections: 10 minutes preparatory section, 30 minutes time for the main section and (5) minutes for the final section. The teacher played the role of a guide and director and feedback provider. The teacher and the student used the element of suspense and encouragement.

**Post-Test:** After completion of the curriculum, the tests were carried out for both groups during two days (Tuesday and Wednesday) corresponding to (8-9/1/2019), adopting the same conditions of the pretests.

**Discussion**

The results shown in Tables (4 and 5) indicated that there were statistically significant differences between pre- and post-tests for the benefit of the post-tests according to the second hypothesis of the research, which was attributed by researcher to validity of the learning curriculum of both groups (experimental and control) specifically the main section, which contained scientifically-selected exercises with correct and consistent repetitions. “It is of a natural phenomenon that the process of education will be evolved if the coach or teacher follows the sound basic steps in learning and exercising to attain the correct Performance” [5]. The careful and organized selection of exercises contributed directly to the development of level of performance of students of both groups, as well.

The results presented in Table (6) showed that there were significant differences between the post-tests in favor of the experimental group according to the second hypothesis of the research. The researcher attributed the progress to students’ positive receptiveness of information and its implementation which was revealed through development of skills level and planning of composite skills of Futsal balls [6]. In addition, this was in line with results reported by [7].

The researcher also attributes the superiority of the experimental group to the exercises they practiced according to the flexible circles, which were practiced systematically within the graduation of difficulties as per the prepared curriculum. This gave learners greater and important role in solving the tasks and kinetic duties, whereas the control group practiced the adopted normal learning [8].

| Table 6: Mean and standard deviations, (t) value and the significance level of post-tests results for the two groups |

* Significance level at \( P \leq 0.05 \). Degree of freedom was 28.

**Conclusions**

The methods of the adopted learning composite skills and learning through exercises according to the flexible circles have had a positive impact on learning some of these skills of Futsal ball for students.

Effects of Special Exercises on the Sand on Some Blood Cells, Heart Measurements and Physical Abilities of Advanced Futsal Players

Adnan Ghethan Digham¹, Ameen Khazal Khuzaie¹
¹Faculty of Physical Education and Sports Sciences, University of Dhi Qar, Iraq

ABSTRACT

Background: Among methods of training of power and explosive ability are to exercise on sandy land where this technique has multiple physical and physiological benefits as it promotes the development of cardio-respiratory endurance. This study was aimed at checking up the effect of exercising on the sand, in training of futsal, on some blood cell variables, heart rate and physical abilities.

Method: Sixteen male players were chosen as a study sample from Al-Nasiriyah City Club. Their age ranged between 21 and 23 years. This study sample was divided into two eight-player groups; the experimental group who performed exercises on sandy field and the control group who exercised inside a closed hall. Exercises and training were conducted for two months, 3 days a week. Red blood cells, heart rate and physical capabilities were analyzed and assessed as per appropriate methods. Data were statistically analyzed by using SPSS and t-test.

Results: The study showed changes in the variables of the study and demonstrated that exercises on the sand field produced better effects as compared to those conducted on the closed hall.

Conclusion: Exercising on the sand is a good factor to reduce the breakage of red blood cells caused by solid surfaces and it is one of successful methods in the development of heart measurements and prepares it for the sport effort it faces.

Keywords: special exercises, red blood cells, physical abilities, sandy field, closed hall.

Introduction

The game of Futsal requires that a player has to attain a high level of all different aspects of training, particularly in the physical side, and in order to achieve the required level, exercises should be well chosen so that the aim is accomplished. Among methods of training of power and explosive ability are to use these exercises on sandy land where this technique has multiple physical and physiological benefits as it promotes the development of cardio-respiratory endurance as well as the foresaid physical qualities. Previous studies showed that there was a decrease in the fatigue index of trainees who exercise on the sand as compared to their counterparts who exercise on solid ground, which gives better endurance, through training in the sand and the result of the resistance occurs either during running and jumping or while performing exercises using the body weight (where we noticed the resistance to double) the temperature of the body as a whole as well as the temperature of the heart which leads the local blood flow within the muscle by expanding its blood circulation until it reaches the small blood circulation. The latter will improve functional conditions of heart muscle by increasing oxygen supply, which ultimately helps achieve the achievement of the athlete [1].

In addition, bare-footed exercising and walking on the sand helps to connect with the ground. There are many studies that confirmed the benefits of this connection on the cardiovascular system, immunity and blood and rid the body of free radicals. Physiological studies have shown that sand exercises have very important...
physiological effects such as reduction of damage in the muscular tissue caused by playing on solid surfaces. Other studies have shown that futsal training causes a decrease in red blood cells and this will have a negative impact on oxygen transport.

The importance of current study is to search for the most important benefits that can be achieved by exercising on sand, whether on blood cells, the heart rate or the physical side of futsal players.

One of the physiological problems faced by the athlete who plays inside futsal court is the hard ground, as it has been scientifically proven that this type has negative effects through increasing the damage and rupture of muscle tissue. This is evident by increasing the protein components in the bloodstream as well as increasing the fraction of red blood cells in the blood which also adversely affects the transport of oxygen with consequent effects on the level of overall functional performance [2].

**Research Objectives**

1. To design special set of exercises on the sand to develop special endurance during the “ad hoc” preparation course.

2. To identify the effect of exercises on the sand on some blood cells, heart muscle measurements and physical abilities between the pre- and post-tests, and the post- post - test for the preparation period (Ad hoc).

**Method**

The researcher used the experimental methodology by designing the two equivalent groups; control and experimental.

**Research community and its sample:** The sample of the study was deliberately chosen. It was represented by the players of Baladiyat Al-Nasiriyah Sports Club of futsal for the season (2018-2019). The number of players was 95, divided into (5) clubs (Al-Baladiyat, Al-Furat, Al-Gharaf, Al-Nasir, and Al-Nasiriyah). The total number of the research sample was (16) players from Baladiyat Al-Nasiriyah Sport Club divided into two groups; (8) players for the experimental group and (8) players for the control group. They were divided by lottery. Thus, the total sample number (16), representing 16.84% of the total community.

**Tests used in research**

**A. Red blood cells (RBCs) calculation** [3]: Method of measuring: After the player sat and making sure of the appropriate analysis, the special tubes were prepared for each analysis without containing anticoagulant (4ml). The player’s hand was tightened with tourniquet to make sure of appropriate vein of which the blood was drawn and of the needed amount of blood after the area is sterilized. When the blood was drawn with appropriate syringe, the tourniquet was removed and the blood was emptied in a tube on which the name of the player was written. The sample was then transferred to the working room at a temperature of 30°C to be analyzed.

**B. Heart Measurements** [4]: The researcher designed a questionnaire form for surveying the opinions of a group of specialists and experts in physiological sports of training. The researcher conducted some personal interviews with some experts and specialists to be acquainted with their opinions in this context as shown in the annexes to determine some measurements that fit the sample and serve the research. The researcher chose the highly agreed upon measurements, which included measurements of the variables of the heart by use of Eco-M (M-mode), which is used to measure the different dimensions of the components of the heart such as heart cavities and muscle thickness as well as the use of the method (D2), which is used to determine the movements of contraction
and expansion. The frequency level used in the measurement was 3.5MHz.

**Heart measurements included**

1. Left Ventricular Dimension in systole.
2. The percentage of blood pump Ejection Fraction.

The special measurements of the heart muscle were extracted by means of the echo con, measured directly by the echo instrument.

**Field research procedures**

**Pre-Tests:** The pre-tests were carried out with the assistance of assistant staff and the team of study sample, which included the RBC, heart measurements and physical tests for the period from 2-3/9/2018.

**Main experience:** Based on the physiological sports training references and sources, besides experts’ views in this respect, the researcher designed special exercises concerned with training on the sand to determine their impact on study sample and to know the results of this effect on some physical and physiological variables of the futsal players. The implementation of the experiment began on 6/9/2018 and ended on 6/11/2018.

**Post-tests:** The RBCs and heart muscle measurements in question for the two groups were conducted on Saturday, 10/11/2018, and all requirements for the tests were prepared taking into account the temporal and spatial conditions in which the pre-test was conducted.

**Results**

*The tabulated (t) value at the significance level of (0.05) and degree of freedom (7) reached (2.36).

The results shown in Tables (2 and 3), indicated that there was a difference between the pre- and post-tests in measuring the proportion of red blood cells, but it was not significant in the control group, which was attributed by the researcher to the fact that training inside the gymnasium causes lack of red blood cells and this negatively affects the process of oxygen transport, as was confirmed by the study “The training within the gymnasium causes a decrease in red blood cells and this has a negative role in affecting the transfer of oxygen
because it leads to iron deficiency and this leads to early stress of the player”.

As for the experimental group, significant differences were noticed in the pre-test in favor of the post-test. The researcher attributed this to the continuation of training on sand, as sand does not cause any breakage of red blood cells. So the trainers resort in the transitional period to render their players to recover.

The researcher believes that the period in which the experimental group exercised on sand was sufficient to give indications for physiological changes, as was confirmed after 6-9 weeks of practice, and training was enough for the players to adapt or reduce damage in the muscle tissue [5].

A very little evolution was also noticed in the variable (LVIDs) between the results of the pre- and post-tests of control and experimental groups and this development was in the value of arithmetic mean, which was insignificant as it was smaller than the tabulated value of the scale, whereas the arithmetic mean value of the experimental group was better than that of control group and this was attributed by the researcher to the effect of exercises on sand, of the experimental group, on the heart for the training on the sand is one of the most successful methods to protect the heart and prepares to endure the sports effort to which it is to be exposed. Therefore, most of the training methods tended to protect the heart and prepare it to bear the burden of effort as indicated by [6].

Through training on the sand and due to resistance encountered, whether through running or different jumps (as sand resistance appears to double), the temperature of the body rises as a whole, so does that of heart, and this causes blood to flow within heart muscle through the expansion of its blood circulation until it reaches the small blood circulation. In other words, training on the sand leads more effectively to an increase in the blood circulation and prepares the player to exert effort and to the sudden exercise [7].

The researcher also attributed this slight development to the variable of sand training on the special preparation stage. In other words, if sand training was applied in the general preparation stage, the differences might be significant. As for the variables, the percentage of blood and the volume of the beat (EF, SV) showed a significant difference in favor of post-tests of both groups.

</table>

*The tabulated value of (t) at the level of significance (0.05) and degree of freedom (14) reached (2.14).

The researcher attributed the evolution of the experimental group to exercises on the sand as the group that was trained inside the solid pitch was exposed to a lack of RBCs as was indicated by the study of [8] who concluded that“ Intensive training and exercising inside futsal leads to iron deficiency and lack of iron has harmful effects on the physical performance of players and at the cellular level and reduces the possibility of oxygen transport training”. These differences were also attributed to the increase in the amount of blood in the heart chambers when extinction due to adapting of the left ventricle of the endurance of training through the functional burdens resulting from pumping the amount of blood output to all parts of the body, which increased because of sand resistance, as indicated by the study of [9] who concluded that “The volume of blood pumped increases due to the effect of the increase in the volume of blood filling the ventricle during the extinction and increase in the
size of blood leads to an effect pressing on the muscle fibers in the heart, which is reflected on the strength of contraction of the heart muscle and, as a result, the heart pumps a large amount of blood during stroke”.

Conclusions

- Exercising on the sand is a good factor to reduce the breakage of red blood cells caused by solid surfaces and it is one of successful methods in the development of heart measurements and prepare it for the sport effort it faces.
- Composite sand-resistance exercises have a positive effect on the development of some of the physical abilities of the futsal ball for advanced players and this is reflected in the development of athletic abilities.
- Sand training helps the trainer to give resistance exercises that may not be available in the futsal halls at the lowest cost with interaction of training.
- Training on the sandy environment, whether of futsal teams or open courts, has a psychological impact on the recreational aspects of the players and to thrill them with fitness exercises and delayed fatigue.

The Impact of an Educational Program According to the Model 4MAT to Learn the Skill of Attack in Numerical Epee for Students Fencing

Zahraa salim Hussain1, Wissam Salah Abdul Hussein1, Amer Hussein Ali1

1Faculty of Physical Education and Sports Sciences, University of Kerbala, Iraq

ABSTRACT

Background: By observing the majority of educational curricula in the game of fencing and by studying previous studies, there is lack of use of educational models to address the two hemispheres of the brain. Also, by follow-up and watching most of 3rd-year students at Faculty of Physical Education and Sports Sciences/Karbala University for the 2018/2019 academic year, current study was aimed to find educational solutions using an educational programs designed according to an educational model (Format), which aimed to increase the ability of thinking meditation movement of the player and competitor in addition to learning the skills of numerical attack.

Method: The researchers used the experimental approach in the design of one group with pre- and post-testing. The study sample represented by (10) female students. This means that researchers used the method of comprehensive inventory of all members of society.

Results: The researchers attributed the difference between pre-and post-tests results of the study group to the positive effect of educational programs that has been applied and worked with all learners.

Conclusions: The educational programs prepared had a clear and effective impact on learning the skills of numerical attack in fencing. In addition, students acquired the ability to find appropriate solutions for educational situations, because the model had developed their abilities of connection, integration, thinking and perception which helped them keep more information.

Keywords: Educational programs, model 4MAT, fencing, numerical attack.

Introduction

Any development in areas of life a person seeks access to it must invest all the capabilities that are specialized in this area to reach that development. The ambitions adopted by teachers and specialists in the field of sports to reach the highest levels must be coupled with adoption of modern strategies based on effective methods which provide help and practical thinking that lead to increased interaction between learners and the skills to be learned. The educational goal of learners in the various sports is mastering technical performance of those games and when the teacher of a particular method must be appropriate to summarize and to focus on the learner in the light of his activity [1].

The concept of learning is very comprehensive and extensive, which is the basis of the educational process. Almost no pattern of human behavior that lacks some kind of learning has been addressed by many researchers and in line with the scientific trends and fields in which they deal with the definition of concepts based on the principles of psychology.

The idea of the McCarthy learning cycle originated in 1979 when he decided to develop an educational system that works with all learners. As a result of the intensive efforts in researching the Format model, this model works on the natural learning cycle that each
learner receives. It describes the process that each learner gets when he tries to understand himself and the world around him. He interprets meanings, creates relationships, identifies problems, develops solutions, provides alternatives, evaluates and makes decisions. Awareness of the experience and information processing experience represent a learning process that includes awareness of new experience and then being processed.

The game of fencing, like any other sport, requires appropriate teaching methods to teach its movements, especially the defensive and offensive ones, because they are the basic structure of this game. It is not possible to stand on these methods unless they are tried and the best ones are chosen depending on the results reached in order to teach students so that they attain higher levels and become better in the skillful performance of these movements [2].

Hence, the aim of current study was to prepare an educational program according to the educational model is the format system which is through the use of all energies of the brain.

Objectives of the study were:

1. Preparation of an educational programs based on format model in learning the skills of numerical attack in fencing sport.
2. To identify the impact of the educational method according to format model in learning the skills of numerical attack in fencing sport.

Hypothesis: The educational method according to the Format model has a positive effect on learning the skills of numerical attack by students in fencing in pre- and post-tests.

Method

The researchers used the experimental approach in the design of one group with pre- and post-testing, which is the closest and most honest to solve many scientific problems practically and theoretically and it fits in with the nature of the research problem.

Community and study sample: The research community was identified by 3rd-year students at Faculty of Physical Education and Sports Sciences/Karbala University for the academic year (2018-2019) and (10) female students were randomly selected for participation in the study.

Information gathering methods included:

1. Observation.
2. Personal interviews.
3. A questionnaire to survey the opinions of experts and specialists to identify the most important tests of the attacks (complex and simple).
4. A form for measuring and evaluating the technical performance of the complex and simple attack movements.
5. Thinking measurement form.

Instruments and tools used in research:

1. A laptop computer type (hp) number (1).
2. A video camera type Sony number (2).
5. German duel mask made of (10).
7. Colored adhesive tapes number 4 Role.
8. Different explanatory posters with different measurements.
9. Laser tablets number (10).
10. Data show No. 1 Chinese-made.
11. Screen display type Samsung number (2).

Characterization of technical performance of the skills of numerical attack [3]: According to the legal conditions of the game each student was given three attempts to try the skill of numerical attack. The objective of the test was to know the level of technical performance. The tools used were the weapon of the legal Shish, camera video number (2), whistle and drawing scale. The test was performed as follows: The student takes the laboratory to take the status (standby) carrying the weapon and at an appropriate distance from the teacher, and when the whistle is heard the student performs the required skill.

In order to evaluate the performance, the participant was given three attempts. The experts evaluate the performance of each attempt. Each expert gives a specific score for each attempt, and then we collect these scores and the mathematical mean was obtained for their grades.
Pre-Tests: After implementation of two modules within the educational programs, which included explanation of the movements of the composite attack (numerical) and the live presentation by the school and the performance of students, the pre technical performance tests were conducted on Tuesday, 26/2/2019 in the closed hall of the Faculty of Education Physical and Mathematical Sciences/University of Karbala at 12 noon. The researchers have proven the conditions related to the test in terms of time and space, tools used and the method of implementation and the working team to help provide them in the post-test.

Educational programs: Through the study of scientific sources and previous studies and ongoing discussions with supervisors, experts and researchers in the field of fencing, an educational program was developed according to the tendencies and desires of learners and within the privacy of Format model methods. The educational program included a set of learning exercises for learning the skills studied.

Feedback was adopted during performance of the skills. Brainstorming questions were used during the application of educational programs. The number of educational units of the educational program was 8 units. The implementation of the educational programs had taken 10 weeks at a rate of one educational unit in the week. The researchers used a series of skillful exercises that were aimed at learning and mastering skills through diversity. The educational program has been applied to the experimental group in a practical way in which learning was done through experimentation and work versus learning, by thinking and creating a clear picture of the strategy of play through explanation, clarification and video presentation.

Post-Test: After completion of the application of the educational programs to the experimental group and the approach adopted by the teacher of the control group, the researchers carried out tests of the dimension of full thought on (2/5/2019), and all members of the sample of the basic experience of experimental and control groups within the same conditions and specifications, Moreover, data were obtained and recorded in the forms for preparation to be processed statistically. The technical performance of the experimental and control groups was assessed in the same way as in the pre-tests.

Discussion of the pre- and post-tests’ results of study group: The researchers attributed the difference between pre-and post-tests results of the study group to the positive effect of educational programs that has been applied and worked with all learners. As a result of extensive research efforts [6], the format model has been developed. It got to every learner when he tries to understand himself and the world around him, interprets meanings, makes relationships, identifies problems, develops solutions, provides alternatives, evaluates and makes decisions [7].

Figure 1: Mean and standard deviations values of the experimental group with the experimental design of one sample
The explanation, presentation, guidance, instructions and nourishment have had a profound impact on the evolution of the experimental group in the post-test \[6\]. The researchers attributed that to the use of the format model that provides freedom of thought in performance and implementation through the use of this model \[7\] where the learner activated to produce new ideas and creativity in performance. It is learning through connecting and merging the orientation towards facts and concepts in return abstract thinking and orientation towards facts and theories and beyond the meaning so that the learner is able to overcome greater difficulties faced and to make appropriate decisions \[8\].

**Conclusions**

1. The educational programs prepared had a clear and effective impact on learning the skills of numerical attack in fencing.

2. Students acquired the ability to find appropriate solutions for educational situations, because the model had developed their abilities of connection, integration, thinking and perception which helped them keep more information.

Efficacy of Nano-Hydroxyapatite on Enamel Surface of Primary Teeth Following Exposure to Liquid Medications in Comparison with Sodium Fluoride: An in Vitro Study

Hassan NM¹, Jafar ZJ¹

¹Department of Pediatric & Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Demineralization initiated by acids is occasionally resulting from the intake of liquid medicines used to treat children on regular basis. Fluoride and nano-Hydroxyapatite has been broadly utilized in remineralization of erosive lesions.

Aim: To compare the efficacy of nano-Hydroxyapatite with sodium fluoride on enamel surface of primary teeth after exposure to pediatric liquid medications by investigating the topographical and weight changes.

Materials and Method: Thirty posterior primary teeth were extracted from (3-6) years old children. They were assigned to three groups: (A) nano-Hydroxyapatite, (B) sodium fluoride, and (C) artificial saliva (control). Groups A and B were exposed to pediatric liquid medications including: (Cephalexin and ParAzar). Afterwards, they were treated with 1% nano-Hydroxyapatite suspension and 2% sodium fluoride solution. The samples were examined for changes in surface roughness and weight using Atomic Force Microscope and an electronic balance respectively; at three periods: baseline, after 7 days of exposure to liquid medications, and 1 day of exposure to treatment agents.

Results: Group A showed a highly-significant difference in roughness for subgroups treated with nano-Hydroxyapatite. A highly-significant increase in roughness was noticed for Cephalexin between baseline and treatment periods and a highly- significant reduction between baseline and ParAzar exposure periods. Regarding weight, a highly-significant difference was found for Cephalexin, and a significant difference for ParAzar after nano-Hydroxyapatite treatment.

Conclusion: 1% nano-hydroxyapatite suspension had the greatest remineralization efficacy when compared with 2% sodium fluoride solution.

Keywords: Nano-Hydroxyapatite, Sodium Fluoride, Cephalexin, ParAzar, Atomic Force Microscope.

Introduction

Saliva plays an important role in promoting enamel remineralization. However, acidic conditions contribute to demineralization[¹].

Antibiotics and analgesics are routinely used by children. But, different factors such as acidic formulations, recurrent ingestion and between meals utilization might increase the chance of medication- prompted dental erosion [², ³]. Primary teeth subjected to various medicinal liquids could have enamel weight loss due to lost minerals [⁴]. Diagnostic approaches like Atomic Force Microscopy (AFM) can offer a topographic image and surface texture analysis [⁵].

Sodium fluoride (NaF) was recognized to be an efficient remineralizing agent as it promotes fluorapatite development [⁶]. Hydroxyapatite (HAP) [Ca₁₀(PO₄)₆(OH)₂] is a natural mineral component, constituting 30% to 70% of the mass of bones and teeth respectively [⁷]. It is bio-active, biocompatible, osteoconductive, nontoxic and non-inflammatory [⁸].

DOI Number: 10.5958/0976-5506.2019.03280.7
Nano-hydroxyapatite (n-HAP) in dental field is applied as a filler, repairing little holes in tooth structure owing to the minute particles that form it \[^9\]. It has higher bioactivity, solubility and surface energy than hydroxyapatite \[^10\].

So, the purpose of this study was to compare the effect of nano-hydroxyapatite with sodium fluoride on primary enamel surface after exposure to pediatric liquid medications (PLMs). It was hypothesized that there is no difference between the effects of the two treatment agents.

**Materials and Method**

This experimental in vitro study was conducted using 30 posterior primary teeth extracted for different reasons from (3-6) years old children at the Department of Pediatric and Preventive Dentistry/College of Dentistry/University of Baghdad, having at least one surface free of caries, fillings and cracks. The samples were prepared using micro motor handpiece at 4*4 mm width and 2 mm thickness.

All the sample surfaces were coated with an adhesive tape except for the surface that was tested. Then, they were divided in to three groups (2 experimental groups and a control group) and each experimental group was divided into 2 subgroups with 6 teeth each: one was exposed to Cephalexin (as monohydrate -250 mg/5 ml) and the other was exposed ParAzar (Paracetamol 120 mg/5 ml).

Experimental samples were agitated in PLMs every 8 hours 3 times a day for 1 minute up to 7 days \[^2\]. Artificial saliva was used to store the samples to imitate the nature of the oral cavity. It was changed every day to protect ionic balance and preserve \( pH \) \[^11,12\].

Finally, study groups were exposed to the following:

**Group A**: 12 teeth were treated with 1% n-HAP suspension once for 5 sec.

**Group B**: 12 teeth were treated with 2% NaF solution once for 1 min.

**Group C (control)**: 6 teeth were stored in artificial saliva for the whole study.

The samples were attached to a double sided tape and tested individually by Atomic Force Microscope (AFM, NT-MDT, Ntegra/Russian Federation).

The AFM used the tapping mode to display topographic images of surfaces and register average roughness (Ra) changes in nanometers (nm) \[^13\].

The weight (W) changes were measured in gram (0.0000 g) by using an electronic balance (A&D HR-200 Balance, Japan). Prior to weighing, the adhesive tape was removed and the teeth were dried by an air syringe.

Ra and W values were calculated at baseline, after 7-days of exposure to PLMs and after 1-day of treatment.

Statistical analysis was performed using SPSS software (version 21, Chicago, USA). Shapiro-Wilk test was used to test the data distribution normality. Average roughness and weight data were compared using 2-way repeated measurements analysis of variance (RM-ANOVA), Post Hoc Bonferroni test, and Paired T-test statistics. The level of significance was set at probability value of 0.05.

**Results**

Shapiro-Wilk test confirmed that the data were normally distributed. On comparing Ra values using 2-way RM-ANOVA, there was a highly-significant difference (\( P=0.004 \)) in group A. While there were non-significant differences in group B (Figure 1).

Post Hoc Bonferroni test for group A revealed that there was a highly-significant difference (\( P=0.003 \)) in mean Ra value for Cephalexin subgroup between baseline period and treatment period; denoting increased surface roughness after using n-HAP, and a highly-significant difference (\( P=0.002 \)) between baseline period and after 7 days of exposure to ParAzar denoting decreased surface roughness after drug usage, as noticed in (table 1).

There was a highly-significant difference (\( P=0.001 \)) in weight values of group A for subgroup exposed to Cephalexin, and a significant difference (\( P= 0.047 \)) in ParAzar subgroup. The lowest mean values were recorded in 7-days exposure period denoting decreased weight from baseline; which increased again to be near the baseline values after treatment with n-HAP. There were non-significant differences in group B (Table 2).

Using Bonferroni test as a Post Hoc for group A showed that there was a highly-significant difference (\( P=0.001 \)) and significant difference (\( P=0.037 \)) in mean weight values between 1-day n-HAP treatment period and after 7 days of exposure to Cephalexin and ParAzar respectively (table 3).
Paired t-test showed that there were no significant differences in group C regarding weight and average roughness (table 4).

### Discussion

The harmony between demineralization and remineralization is being a significant variable in erosion control [14]. Remineralization has been a valuable asset in interfering the progression of erosive lesions. Different materials were tried to accomplish this objective [15, 16].

Studies have demonstrated that using PLMs may have an impact on enamel roughness and morphology; as primary enamel is thinner and less mineralized than permanent enamel [17, 18].

The results of this research revealed that n-HAP treated group has showed a highly-significant and a significant increase in average roughness (Ra) and weight (W) values of demineralized samples in comparison to NaF treated group; denoting remineralization success. Therefore, the null hypothesis was rejected. Moreover, the highly-significant and the significant decrease in Ra and W values respectively following exposure ParAzar can be explained by enamel degradation in which rough areas forming surface peaks are removed by demineralization caused by PLMs; leading to dissolution, in addition to the remineralization potential of artificial saliva which contains various ions that fill up enamel valleys; thus, creating a smoother surface.

The n-HAP has biocompatible and bioactive properties that offer a defensive effect against enamel erosion [19]. It gives a large amount of calcium and...
phosphate ions, and can drive existing crystals to grow leaving a rougher surface, which can be translated by the way that n-HAP crystals caused the deposition of a new apatitic mineral coating; that increasingly fills enamel surface defects [20, 21]. Moreover, n-HAP group formed uniform cluster shaped crystals overlying enamel pores [10], which is consistent with the AFM images of this study.

Another study conducted by Malik and Ghaib in 2017 postulated that enamel remineralization with 10% n-HAP solution was able to increase the mineral content of enamel in order to resist the destructive forces subjected to enamel while removing the orthodontic adhesive [22]; which provide a confirmation of the efficacy of n-HAP suspension in supplying enamel surface with sufficient minerals to form a layer of protection against the demineralization assaults.

Nevertheless; the results of De Freitas et al. in 2011 disagreed with the results of the current study, they reported that polishing with a n-HAP tooth paste after dental bleaching have decreased the roughness of enamel surface. This outcome might be due to the ability of n-HAP to be deposited in the defects and cavities of enamel, promoting smoothness [23]. This might be due to difference in demineralization method which is bleaching by strong acids, also the application time, and consistencies used for treatment agents.

The results of this study also stated that there were non-significant differences in group B. Surface roughness was decreased and weight was slightly increased to near baseline values. These results came in agreement with other study that found a decrease in Ra value following the use of a fluoridated mouthwash and this might be attributed to the reaction of calcium and phosphate ions with calcium fluoride (CaF2) formed after its use. Thus, fluorapatite was formed; which prevents demineralization and enhances remineralization [11]. Fluoride prevents mineral loss as it leads to the establishment of a fluoride reservoir on enamel surface owing to CaF2 deposition. This layer affords extra minerals to be disintegrated throughout acid attack, thus obstructing demineralization [24]. The benefits of 2% sodium fluoride on reducing surface roughness following bleaching have been also investigated by other researchers [23].

On the other hand, these results disagreed with other study that found a little impact of NaF on decreasing roughness and mineral loss, since it has a high pH and can diminish the concentration of fluoride on enamel and the deposition of CaF2 layer. Accordingly, the higher the fluoride concentration and the lower the pH, the bigger its efficacy in inhibiting erosion [25].

The non-significant differences in (Ra) and (W) values for the control group is in accordance with a study reported that no surface protective layer was noticed in the control group other than trivial crystals [10]; which was caused by the remineralization effect of artificial saliva that was selected to store the samples.

**Conclusion**

Depending on the findings of this in vitro study, one can conclude that nano-hydroxyapatite suspension has the highest remineralization capability of primary enamel surface following exposure to PLMs, and might be recommended as a professional treatment agent when compared with sodium fluoride solution.

Effect of Orthodontic Force on Salivary Levels of Lactate Dehydrogenase Enzyme

Suha Ali Abdul Ameer¹, Akram Faisal Alhuwaizi², Hayder F Saloom²

ABSTRACT

Orthodontic tooth movement is characterized by tissue reactions, which consist of an inflammatory response in periodontal ligament and followed by bone remodeling in the periodontium depending on the forces applied. These processes trigger the secretion of various proteins and enzymes into the saliva. The purpose of this study was to evaluate the activity of the lactate dehydrogenase (LDH) in saliva during orthodontic tooth movement using different magnitude of continuous orthodontic forces.

Thirty orthodontic patients (12 males and 18 females) with ages 17-23 years with class II division I malocclusion all requiring bilateral maxillary first premolar extractions. Those patients were randomly divided into 3 groups according to the magnitude of the force application (40, 60 and 80gm). A sectional fixed appliance was bonded and designed to give labial force to the maxillary first premolar for 3 weeks. Unstimulated saliva was collected from the patients before force application, then 1 hour after force application, followed by 1, 7, 14 and 21 days. Salivary levels of LDH were measured using spectrophotometer and compared with the baseline level.

The results revealed that LDH enzyme level increased with increasing magnitude of orthodontic force (from 40 to 80gm). This was statistically significant after 1 hour, 1, 7, 14 and 21 days of force application. The LDH significantly increased from baseline after 1 hour and peaked at 21 days for all the 3 force levels.

The LDH level reflect the biological activity that takes place in the periodontium during orthodontic tooth movement, and therefore it can be used as a diagnostic tool for monitoring of correct orthodontic tooth movement in clinical practice.

Keywords: Lactate dehydrogenase, orthodontics tooth movement, orthodontic forces.

Introduction

Orthodontic tooth movement constitutes a highly complex process defined as an adaptive biological response to interference in the physiological equilibrium in the dentofacial structures by an externally applied force (1). The host response to orthodontic force has been described as an aseptically and transitory inflammation that mainly alters the vascularity and blood flow of periodontal ligament, resulting in local synthesis and release of different mediators involved in alveolar bone remodeling (2,3).

Progress of tooth movement can be classified into four stages, that is, activation, resorption, reversal, and restructuring of new bones (4). An early response to orthodontic force is acute inflammation followed by bone resorption and formation. The resorption and formation of bone are due to increments of activities of osteoclast and osteoblast cells (5). In order to monitor orthodontic tooth movement non-invasively in human beings, changes have been examined in the profile and levels of various enzymes, cytokines, growth factors, biomarkers and proteoglycans in gingival crevicular fluid and saliva.

Among those components that change and response to orthodontic force are alkaline phosphatase (ALP), tartrate resistance acid phosphatase (TRAP), lactate dehydrogenase (LDH) and aspartate amino transferase.
crevicular fluid and serum (12). The first part was 0.018 inch round stainless steel arch wire with 35mm length, 30mm horizontal end with included non-traumatic coil, the remaining 5mm vertical apically directed. The second part was 0.021x0.025 inch rectangular stainless steel straight wire with length 15mm, 10mm horizontal and 5mm vertical apically directed. The two vertical ends of both wires were welded by welding device in the lab, and act as stopper in front of molar tube to avoid unwanted movements. The first part (round) was inserted in the premolar bracket while the second part (rectangular) was inserted into the molar tube.

Orthodontic brackets and molar tubes were bonded to enamel surface of right and left maxillary first premolars and first molar respectively, using after acid-etching the enamel of teeth. When the bonding material was completely set, the sectional arch wire was checked inside the patient mouth with the vertical arm in touch with the mesial aspect of the molar tube. The arch wire was marked mesial to the first premolar bracket. Then it was removed and a non-traumatic end was made mesially to the first premolar. After reinserion, cinch back was made distal to the first molar. The arch wire was bent just mesial to the molar tube in a labial direction so that when ligated to the premolar bracket it will apply labial force on the tooth. This force was measured by a strain gauge. The arch wire was ligated to the premolar bracket by a stainless steel ligature.

Materials and Method

Subject selection: Thirty patients (12 males and 18 females) were included in this study. They were attending the postgraduate clinic of the Orthodontic Department in the College of Dentistry/University of Baghdad. All patients had Angle’s Class II division I malocclusion with no or mild crowding (about 2-3mm). They all required bilateral extraction of maxillary first premolar teeth as part of their orthodontic treatment. Inclusion criteria was age of 17-23 years, good general health with no history of any systemic disease, no use of anti-inflammatory drugs before and during the study, no history of any oral habit, good oral hygiene, good periodontal health (probing depth values not exceeding 3 mm in the whole dentition and no radiographic evidence of periodontal bone loss seen in dental panoramic tomography. Subjects were examined clinically, 2 weeks before appliance placement where they underwent a session of accurate ultrasonic scaling and polishing and received oral hygiene instructions. They were randomly divided into 3 groups according to magnitude of force application (40, 60 and 80gm).

Placement of Orthodontic appliance: The length of sectional arch wire used was about 50 mm which consist of two parts: The first part was 0.018 inch round stainless
Surgeries Hospital to measure the concentration of LDH in saliva by Colorimetric method (spectrophotometrically) at constant temperature of 37°C, with less than 0.05°C fluctuation. The test for serum LDH enzyme was done by the use of commercial kit manufactured by Linear Chemicals, Spain.

Results

The LDH level under different continuous orthodontic force levels in the 3 groups at the 6 time intervals from baseline to 21 days are shown in table 1.

Effect of force magnitude: At baseline, where there was no orthodontic force applied to the teeth, the LDH level showed a non-significant difference (p>0.05) between the groups (Table 2). While, after 1 hour and 1, 7, 14 and 21 days of force application, the level of LDH varied among the groups with highly significant difference (p≤0.01) in which group III readings were the highest followed by group II reading, while group I showed the least LDH levels (Fig. 1).

LSD test also showed a highly significant difference (p≤0.01) between groups I and II, and groups I and III and groups II and III for the five time intervals (Table 3).

Effect of time duration of force: In each group, with time the LDH level continued to increase and peaked at 21 days (Table 1 and Fig. 1). These differences were shown to be highly significant for the 3 groups (p≤0.01) (Table 3-4).

In each group, LSD test showed a highly significant difference (p≤0.01) between the LDH levels at baseline, 1 hour, 1 day, 7 days, 14 days and 21 days after force application (Table 5).

Discussion

Orthodontics is based on the application of prolonged forces on teeth. Various degrees of force magnitude, frequency, and duration of orthodontic treatment exert a great influence on the surrounding tissue reaction and bone modeling. Interaction between bone formation and resorption during tooth movement results in the release of various biochemical or cellular mediators that can be identified as potential biomarkers (13).

Effect of time: The findings of this study revealed that the level of LDH in the 3 groups of different force levels significantly increased after 1 hour to 21 days of orthodontic force application. This can be attributed to periodontal changes such as tissue resorption or destruction and is in agreement with the results of previous studies (14-21).

Effect of force: LDH, an enzyme normally limited to the cytoplasm of cells, which is released extracellularly only after cell death, thus it is related to cell necrosis and tissue breakdown. In the periodontal ligament, hyalinization of the most compressed area induced by compressive forces. This hyaline zone is described as an area of focal aseptic necrosis persisting in the pressure zone that resists degradation, depending on the magnitude of the force that resists degradation, persists in the pressure zone, and depends on the magnitude of the force.

The findings of the present study revealed that the level of LDH in the saliva increased with magnitude...
of the force, therefore, LDH could be recognized as a potential marker for monitoring periodontal metabolism and it is significantly related to tissue destruction. This is confirmed by the findings of previous studies (14,17,22-24).

**Conclusion**

The salivary LDH can be proposed as a sensitive marker of the periodontal metabolism changes during orthodontic tooth movement. The enzyme LDH has the potential to be used as molecular markers to monitor the progression of orthodontic treatment and its activities can be successfully measured in saliva with orthodontic therapy.

Effect of Staining and Brushing on the Surface Roughness of White Spot Lesions Treated with Resin Infiltration Technique

Karar M. Hussein¹, Abdulla M.W. Al-Shamma¹

¹Department of Restorative and Esthetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq

ABSTRACT

The aim of this study was to investigate the surface roughness of resin infiltration (RI) on the artificial white spot lesions (WSLs) after being stained with discoloring agents and after brushing. WSLs were produced on the buccal surface of 48 tooth samples. Each WSL received ICON treatment (RI). The samples were randomly divided into three main groups (n=16): group A, distilled water; group B, tea; group C, coffee. Each group was sub-grouped (n=8) to non-brushing (1) and brushing (2). The specimens were subjected to a discoloring material for one week, then mechanical brushing for subgroups 2 was carried out. The surface roughness was measured at the baseline, after production of WSLs, after resin treatment, after discoloration, and after the brushing stage. Results were analyzed with repeated measure two-way ANOVA and Bonferroni test.

The surface roughness of WSLs decreased with highly significant value after treatment with RI, the roughness of RI was acceptable and there is no statistical difference with baseline stage.

The surface roughness of infiltrated WSLs was acceptable but higher than that at the baseline. Resin infiltration had a highly staining ability that affect the surface roughness but can be significantly reduced by brushing.

Keywords: white spot lesions, resin infiltration, surface roughness.

Introduction

Early enamel decalcification, demonstrates itself as white spot lesions (WSLs), particularly when detected in the esthetic area that interfere with aesthetic,. Demineralization of enamel resulted in evident change in the appearance of tooth enamel, it begins to lose its gloss and shine and take an opaque and chalky-white appearance (¹).

A WSL shows an apparently intact surface layer, followed beneath by the more porous lesion body, which give a chalky opaque appearance, as light is scattered mainly within the lesion body. Scattering is caused at interfaces between materials with different refractive indices as enamel, water, and air (²).

Sometimes WSLs naturally remineralize; otherwise several ways of remineralization have been recommended such as using saliva, mouth rinses, and toothpastes contains increased fluoride concentrations. Casein phosphopeptide amorphous calcium phosphate, and calcium sodium phosphosilicate glass, micro-abrasion and resin infiltration have also been suggested to increase remineralization (³).

Caries infiltration is a novel treatment option for WSLs and might link the gap between non-operative and operative modalities. It is a technology that infiltrates, reinforces and stabilizes decalcified enamel, without drilling or sacrificing sound tooth structure. It has also been shown to hinder caries progression in lesions that are too advanced for fluoride therapy (⁴), hence ICON™ resin infiltration is selected as the main material in the present study.

Surface roughness is one reason for exterior discoloration, and it is closely associated to the type of the resinous material, polishing and finishing systems used, type of discoloring beverages and the pH of the media, hence ICON not required finishing and polishing steps, this may be led to expect to see some roughness in the surface of infiltrated lesions (5, 6).

The aim of infiltrating WSLs with Icon is to have highly esthetic results, not just directly after treatment but for long-term effect. However, no study conducts the effect of staining agents for long period of time and the effect of brushing after discoloring agent with beverages, such as coffee or tea on surface roughness.

The aim of this study was to investigate the surface roughness of resin infiltration (RI) on the artificial white spot lesions (WSLs) after treatment with discoloring agents and after mechanical brushing simulation.

Materials and Method

Forty eight sound permanent premolar teeth were collected after surgical extraction for orthodontic purposes then cleaned and stored in 0.1% thymol solution until use to prevent microorganism growth and dehydration (7). Sample grouping is described in figure (1). The WSL created at the buccal surface of tooth sample. All tooth surfaces of were coated by acid resistant nail varnish gel (essence, UK) except a round shaped area (made by a special sticker) that is larger about (1mm) in diameter than the head of the portable spectrophotometer (5mm) VITA Easyshade (Zahnfabrik, Switzerland). The adhesive tape sticker is removed when nail varnish coating completed in order to form the required shape that exposed to the demineralization solution. Then the teeth were immersed in the demineralization solution 100ml Methylcellulose gel and covered with filter paper covered by lactic acid 0.1m about 100ml (8).

Figure 1: Schematic view of the method in multiple stages
After seven days of demineralization period WSLs formation obtained and inspected using magnification lens, the demineralization solution placed at room temperature in closed plastic container to prevent dehydration for 7 days; the pH of the demineralization solution monitored by pen-type pH meter (SD Fujian, china) and the solution not changed during the 7 days (9).

ICON application was performed according to the manufacturer’s instructions, samples of groups B and C subjected to tea and coffee respectively for one week and the discoloring material was changed every day (10).

Brushing was accomplished with a special device (figure 2). The machine was set to run with a horizontal path of 3.8 cm, applying a 200g load at 356 stroke per minute for 100 minutes, corresponding to 2 years of standard tooth brushing. A suspension prepared with 70 ml of distilled water and 70 g of dentifrice of medium abrasiveness (Signal, Spain) were poured into each tray (200 ml) and drain the dentifrice suspension in a regulated means (11).

Figure 2: Mechanical brushing simulation Device

At each stage (the baseline, demineralization, resin infiltration, discoloration and brushing simulation) teeth samples were tested for surface roughness using profilometer.

**Surface roughness tester Profilometer device:** Measurement of the surface roughness of the sample teeth by using a calibrated, mechanical 2-D profilometer Surface Roughness Tester, leeb 432A(testcoat,USA) was used to measure the Ra, according to ISO-DIN 4768 for surface roughness measurement, a three measurements in the center of each sample (12).

**Statistical Analysis:** All statistical analyses were performed using SPSS (IBM SPSS Statistics v.22.0; IBM Co, USA), with a significance level of p=0.05. Differences in surface roughness (Ra) were compared among the five stages using repeated measure Two way-ANOVA test and Bonferroni test Dunnett’s post-hoc tests were performed.

**Results**

Profilometer measurement; as in Table (1) shows the mean and standard deviation of the surface roughness of each subgroup at different stages.

Values are presented as mean, ± standard deviation. Groups: A, distilled water; B, Tea; C, Coffee; non-brushing, 1; brushing, 2, R0, Baseline; R1, after white spot lesion formation; R2, resin infiltration; R3, discoloration; R4, brushing simulation stage.

Bonferroni test was made for the roughness at (R3) and (R4) stages to see the source of highly significance change in surface roughness. at (R3) stage, coffee and tea groups increased the surface roughness with a highly significant magnitude in comparison with DW, but it is not significant between coffee and tea. This mean that coffee and tea are responsible for increasing the roughness. For (R4) stage, the same result as mentioned before in (R3). The effect of brushing on the surface roughness at (R4) compared to (R2). For all subgroups it was non-significant, this mean the brushing of tea and coffee subgroups capable of restoring the roughness to comparable values at (R2). To see the difference of surface roughness for the brushing and non-brushing subgroups in the same group RM two-way ANOVA was performed as it prescribed in table (3).
This mean brushing of tea and coffee. Also, the roughness restored for coffee group with a higher value after brushing than the tea group Table (1).

### Discussion

The surface roughness of the resin-based composite is important in determining the performance of the material as a result of brushing and the relation of dentifrice abrasiveness can interfere in this property and the loss of shine and esthetic is the possible consequence (13). This occurs due to the increase in surface porosity and loss of material mass, in addition to water sorption, causing color change, an effective technique to check the action of these factors is the simulated brushing method (14, 15). Infiltration of early lesions with resin infiltrant resulted in a high significantly lower Ra values when compared to the surface roughness after demineralization. However, the roughness of infiltrated lesions was still increased if compared to the roughness of sound enamel at baseline, this finding agreed with the (16) and (17). The mean roughness $R_a$ of all subgroups at $R_2 \leq 1 \mu m$ and this range considers an acceptable value (18).

In recent studies, the effect of resin infiltration on Ra surface roughness of subsurface lesions has been found to be minimal, and improvement of baseline surface roughness by resin infiltration has not been reached (19, 20). Although stylus profilometry has been reported for the precise determination and reliability of the surface roughness profile (20). The results revealed the discolored groups (Coffee, tea) have a highly significant increase in the surface roughness $R_a$ when compared to the control group (DW) also when compared to resin infiltration stage. After brushing, the surface roughness of the discolored ICON resin was decreased with highly significant value than that at the discoloration stage but not as at the resin-infiltrated stage (Tables 1), the average surface roughness (Ra) of the resin infiltrated surface decreased for coffee from 1.994μm to 1.182 and for tea from 1.947 to 1.214 μm, also it is a highly significant change but it is still not acceptable range.

### Conclusions

Resin infiltration technique can reduce the surface roughness of WSLs to an acceptable range but not as the sound enamel, ICON resin staining is high, especially when prolong exposure to tea and coffee, these beverages increase the surface roughness of resin, but brushing can significantly reduce it to a reasonable level.

### Suggestions

ICON resin infiltration technique have an acceptable surface roughness, it is recommended to the patients who have infiltrated WSLs not to drink much tea and coffee, also a good oral hygiene measures should be maintained to minimize further discoloration and deterioration.

Evaluation of Salivary Melatonin and Periodontal Parameters in Type II Diabetic Patients with Chronic Periodontitis: A Comparative Study

Rusul Subhi Hassan¹, Suzan Ali Salman²

¹Dentist in Department of Periodontology, College of Dentistry, University of Kufa, Iraq; ²Assistant Professor in Department of Periodontology, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Diabetes mellitus and periodontitis are complicated chronic disorders with an established bidirectional relationship. Melatonin (MT) is a neuroendocrine hormone, synthesized by the pineal gland. Melatonin acts as an anti-inflammatory and anti-oxidant, thus plays significant role in chronic periodontitis and diabetic mellitus.

Aims of study: To measure and compare salivary melatonin level and periodontal health status among study groups of the chronic periodontitis with and without type II diabetes mellitus and contrast their level with control group.

Materials and Method: Eighty males were selected for the examination, with an age range of (35-55) years. The participants were divided into four groups (each group 20 patients): two diabetic groups (type II): moderately and well controlled both of them with chronic periodontitis and two non-diabetic groups: one of them with chronic periodontitis and the other with healthy periodontium and systemically healthy. Unstimulated salivary samples were collected from all of subjects to measure salivary melatonin (pg/ml) by Enzyme-linked immunosorbent-assay technique. Clinical periodontal parameters included: plaque index, gingival index, probing pocket depth and clinical attachment level had been recorded for all subjects.

Results: The chronic periodontitis with moderately controlled type 2 diabetes mellitus group had worst periodontal health status. The lowest level of salivary melatonin was found in the non-diabetic patients with chronic periodontitis group (25.17) pg/ml. There was a weak connection between clinical periodontal parameters and salivary melatonin.

Conclusion: Patients with moderately controlled type 2 diabetic have more destruction of periodontal tissue than other groups. Salivary melatonin may be a helpful biochemical marker for destruction of periodontal tissues and this will provide better chances in early diagnosis and management of diabetes and periodontal diseases.

Keywords: melatonin, diabetes mellitus, chronic periodontitis, clinical periodontal parameters.

Introduction

Diabetes mellitus is a group of metabolic disorderes in which hyperglycemia happen because of deformities in insulin activity and/or emission. The most common type of diabetes mellitus is type II DM (¹). Periodontitis is a chronic inflammatory disorder, that can lead, if untreated to irreversible damage of supportive tissues (cementum, alveolar bone and periodontal ligament) surrounding the teeth with consequent tooth loss (²,³). There is a close relationship between T2DM and PD that been well recognized in several clinical and epidemiological studies (⁴,⁵). Melatonin is a neurohormone that is basically discharged by pineal gland, salivary melatonin represents the percentage of circulating melatonin that
is not albumin-bound (free melatonin). A recent report demonstrate that there is a correlation between melatonin and PD, the amount of salivary MT may vary based on the extension and seriousness of periodontal disease, the level of salivary MT was lower in the patients with gingivitis compared to healthy persons and patients with severe chronic periodontitis had the least salivary MT level. This finding proposes that MT may possess the capacity to fight against infection and inflammation, probably because of its immune-enhancing activity and anti oxidant of free radicals that burst originating from phagocytic cells, like neutrophils and macrophages that migrate to the place of inflammation and cause damage to gingival tissue. There is prospect that there may be connection between melatonin and T2DM based on findings that insulin discharge is inversely proportional to plasma melatonin concentration. Melatonin inhibits glucose mediated release of insulin from the pancreatic cells emphasizing its activity in the function of insulin.

Because there is no previous investigation on the levels of salivary melatonin in T2DM patients with CP and it is importance in the assessment of periodontal tissue destruction, for these reasons this study was conducted.

Material and Method

The sample and Design of study: The sample comprises of 80 males with age range of (35-55) years and BMI between 18.50-24.99 Kg/m². Subjects collection was begun on November 2018 till February 2019. The T2DM patients were analyzed at specialized center for Endocrinology and Diabetes in Najaf while the control and chronic periodontitis patients were examined at the department of Periodontology, at teaching hospital, in the College of Dentistry, University of Kufa. Every patient in this examination was educated about the aim of investigation and he was free to agree or refuse. Samples of unstimulated saliva were collected from the subjects for biochemical analysis of melatonin level. Then, full investigations of clinical periodontal parameters were done.

Grouping of the subjects: The subjects were divided into four groups:

A. Group 1 (G1) CP with moderately controlled T2DM : included 20 males with CP and HbA1c (≥7% to 8.9%).

B. Group 2 (G2) CP with well controlled T2DM: included 20 males with CP and HbA1c < 7%.

C. Group 3 (G3) Systemically healthy with chronic periodontitis: included 20 males. CP in patients was characterized as the presence of minimally four sites with PPD ≥ 4 mm and clinical attachment loss of (1-2) mm or greater.

D. Group 4 (G4) Systemically healthy with healthy periodontium (Control): included 20 males apparently systemically healthy and with clinically healthy periodontium. This group represents a base line data to salivary melatonin level.

Inclusion Criteria: Incorporate just males with T2DM (diabetic for 5 years) on oral hypoglycemic therapy only, at least 20 teeth present and body mass index between 18.5-24.9 Kg/m². While, the exclusion criteria included: T1DM and T2DM administering insulin, females, smoking and alcohol consumption, presence of systemic diseases other than T2DM, patients who’ve undergone periodontal treatment or administrated medications in the 3 months before the examination.

Method

Saliva collection: Unstimulated salivary samples were collected from all the groups at 7:30 am to 9:30 am., then the samples were centrifuged at 4000 rpm for 15 min to isolate the clear supernatant by utilizing a micropipette into Eppendorf tube to be stored at (~ 20 °C) in a deep freeze until being assessed. All samples were permitted to defreeze and stay at room temperature before being analyzed.

Biochemical analysis: For the purpose of biochemical investigation of salivary melatonin hormone we utilized salivary melatonin ELISA kit (Elabscience, china).
Descriptive statistics: Include mean and median values and inferential statistics which include Kruskal-Wallis H test, Mann-Whitney U test, T test and Pearson Correlation were used in this study. The level of significance (S) was accepted at P-value < 0.05 and non-significant (NS) at P-value > 0.05.

Results

Clinical Periodontal Parameters: Analysis Persons with G1 demonstrated the highest mean values of clinical periodontal parameters, then persons with G2, after that G3 persons. Inter study groups comparisons regarding all clinical periodontal parameters revealed, highly significant (HS) differences between G1 with both G2 and G3 groups and between G2 with G3 groups (table 1).

Biochemical Parameters Analysis: The biochemical analysis (table 2) of the salivary melatonin revealed that the highest concentration was in G4 (103.93) pg/ml, followed by G2(27.23 ) pg/ml then, G1(27.22 ) pg/ml and finally the G3 (25.17) pg/ml. The outcomes of the comparisons for all pairs of the study and control groups in (table 3) about salivary melatonin levels revealed a highly significant differences between the G4 and all of the study groups. While, a non-significant differences between between G3 group with both G1 and G2, as well as between G1 and G2.

Correlations of Salivary melatonin with Clinical Parameters: As can be seen in (table 4), melatonin hormone generally, demonstrated non-significant weak correlations with all of the clinical parameters at all groups except for a non-significant moderate positive correlation with probing pocket depth in non-diabetics with chronic periodontitis group.

Discussion

Clinical Periodontal Parameters Analysis: The altered salivary discharge, altered oral flora and increased viscosity of the saliva in diabetic patients (13), moreover, the raised glucose level in the gingival crevicular fluid(GCF) and saliva all contribute to the higher plaque accumulation in the diabetic patients(14). The DM causes and exacerbates gingival inflammatory response to the bacterial plaque which implies that there is change in periodontal tissue response to local factors in diabetic patients. The inflammatory reactions are intensified during bad metabolic control, as the same amount of plaque causes more gingival bleeding in uncontrolled diabetic patients compared to controlled, therefore more plaque accumulation in G1 leads to more gingival inflammation than G2 group (15). The DM alters periodontitis by dys regulating the immune and inflammatory responses in periodontium, thus more cytokines are collected in the gingival tissues. Also, DM causes diminished function of the neutrophils and hyperactivity of monocytes and macrophages which will result in further periodontal destruction (16).

Biochemical Parameters Analysis: In the present study the melatonin level in chronic periodontitis patients were found to be significantly lower when contrasted with the healthy controls, this study was in agreement with several studies(17,18). Additionally, the level of melatonin in type II diabetic patients were observed to be significantly lower when contrasted with the healthy controls, this study was in agreement with numerous investigations (19). The explanation of this decrease that the periodontal disease related with production of free radicals and some of these free radicals originate from phagocytic cells and from periodontopathic bacteria. It has been proposed that
an elevate in both reactive oxygen and nitrogen during periodontal disease is responsible for oxidative damage to periodontal tissues (20). Melatonin may diminish this oxidative stress and thus, participate in the tissue protection. It has been observed that high levels of free radicals can advance raises in the melatonin utilization (19), thus, the reduce of melatonin levels in periodontitis might be the result of by products or mediators that could interfere with melatonin levels (21).

Cutando et al (22) found that salivary melatonin levels change depend on the degree of periodontal disease. As the level of periodontal disease increased, the salivary melatonin level diminished, demonstrating that melatonin may act to protect the body from external bacterial insults. Thus, melatonin could be potentially significant in the treatment of the periodontal diseases. Earlier investigations represented that the pineal glands of diabetic animal model contain less noradrenaline and produce less melatonin in response to noradrenaline. The melatonin synthesis begins with tryptophan and tryptophan deficiency can prompt decreased pineal and plasma melatonin concentrations. Other explanation to diminish melatonin in diabetes that the expression of the melatonin synthesizing enzymes are altered under diabetic conditions and the concentrations of all precursors are diminished in the pineal gland of the diabetic animals(23).

Correlations of Salivary melatonin with Clinical Parameters: Salivary melatonin exhibited non-significant weak correlations with all of the clinical parameters except for PPD in chronic periodontitis group where there has been a non-significant moderate positive correlation. These outcomes disagreed with Lodhi et al (24) who demonstrated positively significant connection between salivary melatonin and both GI and PPD in chronic periodontitis group. In periodontitis, polymorphonuclear neutrophils infiltration is a key finding, which delivers high amounts of ROS. In addition, a considerable migration of neutrophil to the gingiva and gingival fluid during periodontitis prompts excessive generation of ROS(24), and elevated amounts of free radicals can advance increases in the utilization of melatonin which lead to diminish in the melatonin concentration because of its free radical scavenging and anti-oxidant properties(19).

Conclusion

Moderate glycemic control of T2DM introduce further destruction to the periodontium or may be the poor oral hygiene worsens the glycemic control. Both diabetic and chronic periodontitis influence salivary melatonin, thus the concentrations of melatonin could be utilized as indicators for periodontal disease progression in diabetic with chronic periodontitis.

ABSTRACT

Background: Extracellular superoxide dismutase (EC-SOD) gene polymorphism play an essential role in the progression of diabetic complications. Reactive oxygen species (ROS) were known to damage neurons by enhancing nerve lipid peroxidation, the damaging mitochondrial DNA, break-down the respiratory chain, and the cross-linking of neuron proteins.

Aim: the aim of this study was to investigate the relationship between (Ec-SOD) gene polymorphism and the pathogenesis of diabetic peripheral neuropathy in type2 diabetic patients. Arg(213)Gly polymorphism of Ec-SOD gene polymorphism were studied in type2 diabetic patients with (n=30) and without DPN (n=30).

Results: Polymerase chain reaction (PCR) technique were used for detection Ec-SOD polymorphisms. This technique included the use of PCR primers (Forward and Reverse) to produce a restriction site in the amplified EC-SOD gene product just with the polymorphic base. Then, the product of (PCR) was digested with Eco52I restriction enzyme to detect Arg(-213)Gly polymorphic position. The results of Arg(-213)Gly polymorphism showed that the frequency of Arg/Arg, Arg/Gly, and Gly/Gly were 70%, 13.3%, and 16.6% in healthy control subject and 53.3%, 16.6%, and 30% in diabetic without neuropathy countered by 23.3%, 26.6%, and 50% in diabetic with neuropathy. This proposed that the Arg (-213)Gly polymorphism in the Ec-SOD gene is significantly associated with a risk for progression of diabetic peripheral neuropathy.

Conclusions: Arg(-213)Gly polymorphism of Ec-SOD gene was associated with diabetic peripheral neuropathy in type2 diabetic patients of Babylon Province.

Keywords: Diabetes complication, Superoxide dismutase 2, Arg(-213)Gly substitution.

Introduction

Macrovascular complications is a chronic diseases in which diabetes mellitus considered to be an independent risk factor that increase the probability that an individual will develop cardiovascular disease (CVD)(1), such as coronary artery disease (CAD), peripheral vascular disease (PVD), and cerebrovascular Accidents (CVA), these cardiovascular disease thought to be the primary cause of death in patients with either type 1 or type 2 diabetes2), and are responsible for more than 50% of all deaths in patients with type 2 diabetes. The pathological of macrovascular disease is the process of atherosclerosis that are caused by chronic inflammation and injury to the arterial wall in the peripheral or coronary vascular system leading to narrowing of the arterial walls throughout the body3).

The another strong causes associated with macrovascular complications in diabetic patients, is the increased platelet adhesion and hypercoagulability as a result of impaired nitric oxide generation and increased free radical formation in vascular endothelial cells, altered

calcium regulation increasing platelet aggregation, the high levels of plasminogen activator inhibitor-1 causes reduction of fibrinolysis, the combination of increased coagulability and impaired fibrinolysis will increase the risk of vascular occlusion and cardiovascular mechanisms in type2 diabetes(4).

The long term microvascular complications of diabetes include retinopathy, nephropathy, and neuropathy, and are characterized by damage to vision, kidney failure disease, and neurological lesions respectively(5).

EC-SOD is structurally identical to intracellular SOD, but its located in the extracellular matrix of different tissues including pancreas, skeletal muscle, and blood vessels, is a tetrameric protein containing Cu and Zn atoms and has a high affinity for heparin sulphate allowing its existence in high concentrations in particular regions of extracellular space or on the cell surface(6). EC-SOD expression is regulated mainly by cytokines like IFNγ which stimulates enzyme secretion by the cytokine TNFa and TGFβ inhibit its expression(7) resulting in reduction of mitochondrial glutathione and increasing oxidative stress(8). Sandstrom et al. (2002) have been demonstrated that the superoxide radicals secreted to the extracellular spaces dose not contribute to the β-cell destruction because the high levels of EC-SOD resulted in 6-fold elevation in the total superoxide dismutase activity of the islets(9-13).

The EC-SOD (SOD3) play as a major scavenger of reactive oxygen species in cells and tissues, it is anchored to the extracellular matrix and cell surfaces through binds with heparasulfate proteoglycan and collagen(14)(15). EC-SOD is a homotetrameric copper-zinc glycoprotein, it is reported that the EC-SOD gene has a vital role in protecting various tissues from oxidative stress by catalysis of dismutation of two superoxide radicals to hydrogenperoxide and oxygen(16). Human EC-SOD gene is located on chromosome 4p15.3 and composed of three axons and two introns, the sequence of this gene entirely located within exon 3 and has missense polymorphism(17). The most important SNP that are associated with this gene is Arg213Gly polymorphism in heparin-binding domain affects the function of the carboxy terminus causes several disease(18)(19). Yamada et al. have been demonstrated that the glycine variant of the enzyme is responsible for elevated EC-SOD levels in serum that are associated with reduction in nitric oxide production in epithelial cells and different other metabolic cardiovascular risk factors(20)(21).

### Materials and Method

#### Study Subjects:
The study samples were collected in Marjan teaching hospital in AL-Hilla City/Babylon province-Iraq. Subjects in this study comprised from (30) patients suffer from type 2 diabetes with peripheral neuropathy, (30) patients without peripheral neuropathy as a positive control group with duration of disease (1-5, >5-10, >10 years) and with average age between (35-65 year). In contrast, the study included (30) apparently healthy people aged between (35-65) as control matched with disease group. The presence of type 2 diabetic peripheral neuropathy or not were diagnosed for all patients by a specialized doctor.

Venous blood samples were collected from fasting patients and control subjects after a period of fasting 8-10 by vein puncture using 5ml disposable syringes, 2 ml was placed into EDTA tubes mixed gently for 3 minutes and then being divided into two parts: the first part used in hematological tests and especially for HbA1c assay and the second part was stored in – 20 °C for using later for genetic analysis.

#### DNA extraction and genotyping of Ec-SOD:
The manufacturer protocol (Geneaid/Korea) was followed for extraction the DNA from frozen blood samples by using some components of the extraction kit. The purity of extracted DNA were determined by using Nano-droop apparatus.

Sequences of primers used for PCR amplification this study were shown in table (1).

Polymorphic sites were amplified by using polymerase chain reaction technique (PCR). The PCR reaction mixture considered of < 250ng/μl template DNA, 400μM of each dNTP, 12.5 μl buffer of 1U Go Taq DNA polymerase (Promega), 10 μM of each primer and 3 mM MgCl₂ in 25 μl of total reaction volume.

Amplification reactions were carried out by using GTC Series thermocycler (Cleaver Scientific/UK) apparatus, with 37 cycles of denaturation for 45 second, at 94°C, annealing for 38 second at 65°C, the detection of Arg(-213)Gly gene polymorphism were detected by digestion of PCR product with the restriction enzymes Eco 52I (1μl of restriction enzymes were added to the mixture of PCR product and enzymes buffer for 24 h at 37°C)

**Statistical Analysis:** SPSS version 23 was used for analysis the clinical variables whereas, Chi-square test used for comparison genetic frequencies of Mn-SOD between patients and control group. Odds ratios (ORs) with confidence intervals (95% CL) and their associated P-Values were used to calculate the results. A P-Value of ≤ 0.05 considered statistically significance.

**Results**

1. **DNA extraction:** The results of present genetic study showed that the genomic (DNA) extracted from blood samples has molecular weight (50-200) ng/μl and purity (1.7-2.2) as shown in figure (1).

   ![Figure 1](image1.png)

Discussion

This study were showed that the DNA has (50-200) ng and purity (1.7-2.2) as show in figure (1).

The results of Arg(213)Gly polymorphism of EC-SOD gene amplification by PCR showed 104bp as shown in figure (2). The findings of this study showed that the (A) allele (Arg) of EC-SOD gene was more frequent in control group than (G) allele (Gly), while the (AG) genotype (Arg/Gly) and (GG) genotype (Gly/Gly) were the most frequent in type2 diabetic patients and also in type2 patients with diabetic peripheral neuropathy as shown in table (3), this findings agreed with(21)(24).

The Arg(213)Gly polymorphism of the EC-SOD occurs in the center of the carboxyl-terminal cluster of positively charged amino acid residues defining the heparin-binding domain(25)(26). This substitution of these amino acid results in increased the enzyme dissociation from the cell surface into serum, so that the lower EC-SOD levels on vascular walls were positively correlated with a higher risk of progression of oxidative stress in influenced patients with the (GG) genotype, and also these association have been found only in Japanese populations without diabetic form of neuropathy resulting from tremendous amyloid deposition in nervous tissues(27), but this don’t agreed with Dimitry et al. were they found lack of association of the polymorphic marker.
with diabetic neuropathy indicating that the Arg(213) Gly polymorphism doesn’t affect the enzyme activity but dose affect the amount of the enzyme on the external endothelial cell surface(22).

Several researches gives an evidence suggested that SOD genes play a crucial role in metabolic disorders and insulin resistance participating in the development of type2 diabetes and its complications(28). Oxidative stress is a major linkage between hyperglycemia and the progression of diabetic polyneuropathy where the axons are susceptible to hyperglycemia impairment because of both their direct access to nerve blood supply and nerve supply leading to accumulation the metabolic capacity of the mitochondrial producing oxidative stress(29).

The Value of Metformin in the Treatment of Hidradenitis Suppurativa in a Cohort of Iraqi Patients

Asmaa AbdulJaleel Swadi¹, Akeel Hamed Jabur²

¹Lecturer, Ph.D Pharmacology and Therapeutics, Department of Pharmacology, ²Lecturer, Dermatology Specialist, Department of Medicine, College of Medicine, University of Al-Qadisiyah

ABSTRACT

Aim of the study: The current cohort study was planned and carried out in order to evaluate the role of newly introduced therapeutic approach, low dose metformin, for hidradenitis suppurativa. This cohort study included 20 patients with hidradenitis suppurativa, 5 males and 15 females. The study was conducted at the dermatology unit, Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Province, Mid-Euphrates Region of Iraq. The study started on November the 2nd 2018 and extended to June the 3rd 2019. Variables included in the current study were age, gender, residency, body mass index (BMI) and other associated illnesses. Outcome in the end of the study included clinical response and main side effects. Following one year of follow up the clinical response was recorded for all patients. Complete response was seen in 8 (40.0 %), while, partial response was seen in 12 (60.0 %). The only reported sided effect was gastrointestinal upset and was seen in 8 (40.0 %). There was no significant association between clinical response and any of the demographic characteristics (P > 0.05). Metformin is a safe and efficient oral therapy for the treatment of hidradenitis suppurativa with negligible side effects.

Keywords: Metformin, hidradenitis suppurativa, Iraq

Introduction

Hidradenitis suppurativa is a chronic dermatological disorder which affects regions of skin rich with apocrine sweat glands 1. Clinically the disorder is characterized by remitting and relapsing skin abscesses and nodules that are painful 2. These lesions often rupture resulting in the formation of sinuses 3. The disease is usually encountered after puberty so that the mean age at time of diagnosis is around some point within the third decade of life 4. The disease is more common in females than in males with an estimated male to female ratio of approximately 1:3 6. The etiology of the disease remains enigmatic; however, an interaction between genetic susceptibility and some mysterious environmental factors has been suggested 6. Obesity is nearly a consistent feature in patients with hidradenitis suppurativa 7. The increased sweat production resulted from increased intertriginous skin surface area in obese individuals 8 and hormonal changes that are in favor of excess androgen production have been suggested to increase the risk of hidradenitis suppurativa in obese individuals 9. The pathogenic scenario that has been hypothesized starts with occlusion of an abnormal hair follicle followed by rupture and spread of its bacterial and keratin to surrounding tissue leading to an inflammatory response with neutrophils and lymphocytes being the main players 10,11. It has been shown that microbial agents have no role as a causative agent, since aspirate from virgin unruptured lesions has failed to demonstrate any infectious micro-organism and that bacterial contamination is responsible for secondary exaggeration of the primary sterile lesion 6. The principal aims of treatment are drainage of suppurative lesions, prevention of disease progression, reduction rate of recurrence and pain relief 12. Treatment modalities and agents are multiple. Topical antibiotics and intralesional steroids may be used in early stages; however, systemic agents such as systemic steroids and antibiotics have been advised in resistant cases in addition to surgical intervention 13-18. Nevertheless, the outcome may be unsatisfactory and the need for another mode of therapy has been proved to be mandatory. For that reason, the current cohort study was planned and carried out in order to evaluate the role of newly introduced therapeutic approach, low dose metformin, for hidradenitis suppurativa.
**Methodology**

This cohort study included 20 patients with hidradenitis suppurativa, 5 males and 15 females. The study was conducted at the dermatology unit, Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Province, Mid-Euphrates Region of Iraq. The study started on November the 2nd 2018 and extended to June the 3rd 2019. The study was approved by the institutional ethical approval committee and included a verbal consent was obtained from each participant following full demonstration of the aim and procedures of the study. Every patient has received a daily dose of metformin 500 mg for one year. Variables included in the current study were age, gender, residency, body mass index (BMI) and other associated illnesses. Outcome in the end of the study included clinical response and main side effects. Data were transferred into an SPSS (version 23) spread sheet and presented as mean, standard deviation, range, number and percentage. Mann Whitney U test was used to study difference in mean between two groups, while, Yates correction was carried out to assess association between any two categorical variables. The level of significance was considered at $P \leq 0.05$.

**Results and Discussion**

The present study included 20 patients with hidradenitis suppurativa, 5 males and 15 females, 25.0 % and 75.0 %, respectively. The mean age of enrolled patients was 29.75 ± 9.99 years and the age range was from 15 to 46 years; most of the cases (80%) were below 40. The mean body mass index was 33.08 ± 4.52 kg/m$^2$ and the range was from 24.20 to 41.00 kg/m$^2$. Patients were categorized according to BMI into 1 (5.0%), 3 (15.0 %), 9 (45.0 %) and 7 (35.0 %) as normal weight, overweight, class I obese and class II obessa, respectively. According to residency, the study included 14 (70.0 %) and 6 (30.0 %) from urban and rural areas, respectively. These demographic data are shown in table 1. Eight (40.0 %) patients had no other associated disease, whereas, 5 (25.0 %), 5 (25.0 %) and 2 (10.0 %) patients had polycystic ovary syndrome (PCOS), diabetes mellitus and hypertension, respectively, as shown in table 2.Following one year of follow up the clinical response was recorded for all patients and summarized in table 3. Complete response was seen in 8 (40.0 %), while, partial response was seen in 12 (60.0 %). The only reported sided effect was gastrointestinal upset and was seen in 8 (40.0 %), table 3. There was no significant association between clinical response and any of the demographic characteristics ($P > 0.05$), as shown in table 4.

n: number of cases; SD: standard deviation; ¥: Yates correction; †: Mann Whitney U test; NS: not significant at P ≤ 0.05

The mean age of patients enrolled in the current study was 29.75 years and this is in agreement with most of studies that reviewed hidradenitis suppurativa 4. In the current study, most of cases with hidradenitis suppurativa were females with a male to female ratio of 1:3. This finding is similar to the majority of published articles 5. Obesity and overweight was a predominant feature by nearly all participants in the present study. Obesity is nearly a consistent feature in patients with hidradenitis suppurativa 7. The increased sweat production resulted from increased intertriginous skin surface area in obese individuals 8 and hormonal changes that are in favor of excess androgen production have been suggested to increase the risk of hidradenitis suppurativa in obese individuals 9. Polycystic ovary syndrome (PCOS), diabetes mellitus and hypertension were the main associated disorders seen in our patients. The association between PCOS and hidradenitis suppurativa has been proven by a number of authors and a common hormonal mechanism has been suggested to be shared by the two illnesses 10-21. Diabetes mellitus in association with hidradenitis suppurativa has been also a frequent issue in published dermatological articles and the risk of hidradenitis suppurativa in diabetic patients is higher than the general population suggesting some role for insulin resistance in the pathogenesis 22. Metformin is a well known oral hypoglycemic agent. During the last 10 years it has been evaluated in the treatment of hidradenitis suppurativa 23. Complete response following 1 year follow up was the rule in 40 % and partial response was seen in 60 % of our patients. In one study, subjective clinical response was seen in 61 % of cases and complete response was seen in 19 % of them 23. In another study, 18 out of 25 patients had acceptable clinical response 24. Indeed the mechanism by which metformin act to reduce inflammatory response in patients with hidradenitis suppurativa with accompanied clinical improvement is till now poorly understood 25. However, it has been hypothesized that metformin acts by its anti-androgenic mechanism in addition to reduction in insulin resistance 28. The principal side effect seen in our patients was gastrointestinal upset which was recorded by 40 % of cases. These side effects are clinically negligible and well tolerates by patients, thus, Metformin is a safe an efficient oral therapy for the treatment of hidradenitis suppurativa with negligible side effects.

Conclusion

The only reported sided effect was gastrointestinal upset and was seen in 8 (40.0 %). There was no significant association between clinical response and any of the demographic characteristics (P > 0.05). Metformin is a safe an efficient oral therapy for the treatment of hidradenitis suppurativa with negligible side effects.

Design and Implementation of Physiology Lab Management Blood Analysis System

Ahmed Saleem Abbas¹, Awfa Hasan Dakheel², Ali Hasan Dakheel³

¹Collage of Information Technology, ²Collage of Basic Education, University of Babylon, Iraq; ³Department of Electric and computer Engineering, Collage of Engineering, Altinbas University

ABSTRACT

The objective of this work is to build a database that provides a records of blood disease and accurate statistics as an important source of medical information and to provide assistance to the laboratory worker by conducting electronic blood tests, serial and fast steps and printing the results of the analysis electronically to facilitate the work and make communication between the official of the laboratory and the patient easier and faster and more accurate by using electronic blood analysis system. Where this system to conduct basic screening tests for determining certain blood disorders (anemia’s, abnormal bleeding and clotting, inflammation, infection and inherited disorders of red blood cells, white blood cells, platelets, hemoglobin (HBC), and cell production (hematopoiesis)). In this work we propose a system which can manage the user for each action performed and justifying the authorization used to create a secure and easy log in. The Physiology lab Management System is tested through verification and validation (V&V) that was one of testing elements to uncover errors that were made inadvertently as it was designed and constructed.

Keywords: electronic blood tests, blood analysis experiments, session, SQL, ASP.NET, verification and validation (V&V), alpha test, beta test.

Introduction

A blood test is a laboratory analysis performed on a blood sample that is usually drawn from capillary skin punctures (finger, toe, heel), dried blood samples, arterial or venous sampling using a subcutaneous needle. Blood samples are obtained from the patient by the biologist lap staff in laboratory to perform tests on blood for the purpose of diagnosing diseases of blood disorders ¹. Blood samples may be tested by automated or manual hematology instrumentation and evaluation for the purpose of building a database that provides a record of blood disease and accurate statistics as an important source of medical information. This site is specialized in blood analysis experiments, which consist of eight experiments:

1. The experience of blood groups (ABO): The benefit of this experiment is to know the type of platoon (A+, A-, B+, B-, O+, O-, AB+, AB-) ².

2. The experience of the white blood cell count (WBC): The benefit of this experience is the knowledge of the severity of bacterial and viral infections in the infected person, except in cases where the WBC grows a large number of more than 50 thousand ³.

3. Red blood cell count (RBC): The benefit of this experience is the detection of anemia and anemia.

4. The experience of platelet count: The benefit of this experience is to know the lack of the number of platelets causing the lack of manufacture of blood clot in the event of any injury, it can lead to bleeding for a long time.

5. Experience of measuring the time of red blood cell deposition (ESR): The benefit of this test is used to detect rheumatic diseases and arthritis ⁴.

6. Hemoglobin Hormone Estimation Test (HBC): This test is used to detect anemia or increase blood (Polycythemia).
7. Test of Blood Stimulation (PCV): The Benefit of
this Examination The identification of abnormally
low levels of blood accumulation may indicate
anemia, as well as unusually high levels may
indicate polycythemia.

8. Experience of Blooding Time estimation: The
purpose of this experiment is to know the time
of normal and abnormal bleeding, hereditary
hemorrhage (hemorrhagic diseases) 5.

The language used in this site is (C# with ASP.
net) therefore to provide some of the characteristics
that distinguish it from the rest of the programming
languages:

- It is fast compared to others because it translates,
  not interpretation.
- Security, where there are mechanisms to reduce
  the penetration of sites that have been programmed
  through them.
- A large and large code library is a dot net library.
- Frequent tools.
- Advanced integrated environment is the Visual
  Studio.

In this work we used SQL with ASP.NET. Where the
database is a collection of information or organized data
which is easy to retrieve, manage and update. Therefore,
databases allow us to create interactive sites contain a lot
of information, which consists of a table or more 6.

The need for a system to assist the laboratory officer.
The program has the last steps and accurate results and
a report of this work, through which the results of these
tests and their natural and non-natural conditions, which
are used in the case of statistics.

This system includes several people for each
individual work according to its specific privacy
- The admin has the privacy and absolute management
  of the site.
- The laboratory officer is able to manage the report.
- The patient is able to see the results of his blood
tests.

There are many projects in this Field, but I did not
find a project that serves the biological laboratory, so
this project was designed and implemented to serve the
medical field and improve the biologist lab performance.
The main features are:

- Administration.
- Employee Information.
- Patient Information.
- Experience.
- Reports.

This is the first electronic system for the biologist
lap, this software was done from scratch and based on
the paper style system that the office was using, this
software will speed up the work and make it more
flexible and accurate with better database and it reduces
the employee’s effort. The following will discuss the
paper system.

For an analysis of the patient is the official of the
lab by filling in a report (paper form) with personal
information about the patient.

An official of the laboratory takes a sample of the
patient and then performs an analysis manually Then
writes the test result of the report of the patient and are
printed manually.

**Requirement and Analysis**

In this work we design the UML diagrams like Use
case, a use case can be described as a specific way of
using the system from a user’s (actor’s) perspective 7.
Use cases are best discovered by examining the actors
and defining what the actor will be able to do with the
system 8.

**Identification of Use Cases**

- Use case “is a set of scenarios that describe the
  interaction between the user and the system. The
usage case diagram “Use Case Diagram” shows the
relationship between “actors” and “use cases”. The
two main components of the “Use Case Diagram”
are “use cases” and “actors”.
- The “actor” represents the user or another system
that will interact with the system you modeled.

The use of “use case” is an external view of the
system to review some of the actions a user can take to
complete the task.
1. **Account management:** Site Manager has the privacy and absolute management of the site can create a new account for the lab or the patient and the deletion of any account.

2. **Receiving feedback:** The user sends comments and observations about the site and about the services provided in the laboratory. These comments are received by the webmaster and are able to delete the unintentional comments.

3. **Receive appointment receipt:** Appointment booking shall be within the patient’s account until it is more reliable. Send a reservation to the manager of the website. If the date is already booked, the reservation will be deleted.

**Patient:**

1. **Send an appointment:** The patient is registered with an account and is booked for a specific date the booking are then sent to the site manager because he has absolute authority over the site if the reservation is canceled, the reservation will be canceled and the patient will be sent to another date.

2. **Send feedback:** The user may send a comment and comments about the site and the services provided in the laboratory and also reach these comments to the director of the site to see them for the purpose of taking advantage of these views in order to upgrade the level of service and accurate results.

3. **View and print the report:** After testing the patient and showing the results of the test, he can log in to his account and see the report and can print it.

**Laboratory Officer:**

1. **Introducing new patient information:** The laboratory employee dictates a special form called the report with general information about the patient (patient’s name, age, address) It identifies the name of the test performed by the patient and saves this information.

2. **Conduct tests:** After filling the patient’s report with information, the laboratory employee begins the experiment and saves the results.

3. **View and print the report:** The laboratory staff shall inform the patient of the report and search for the patient through his or her triple name or through the address and print the result.
System Design

In order the design and implementation of a physiology lab management system designed to access as we are shown in figure 1 by the Admin/Patient/Laboratory Officer to provide assistance to the laboratory worker. In this work the flowchart used to clarify the processes that take place in this system starting from the start of the program to the end and each person on this site special operations, according to the authority specified to him using the site as shown in figure 2.

![Figure 2: Admin login flowchart](image)

In this project we used SQL with ASP.NET. The report table used to enter new patient information, including the patient’s name, patient’s age, email, address, name of the experiment to build a database that provides important information on the patient’s condition.

The programming interfaces are designed using ASP.NET Language is an open-source server-side web application framework designed for web development to produce dynamic web pages as shown in figure 3.

![Figure 3: homepage](image)
This page contains several choices when clicking on the home page shows the interface of the program where the program starts, and when you click on the tips and guidance goes to the page contains general information about the laboratories and tests, When you click on the test report, the user will receive a full report of all test results and when clicking on the site containing general information about the program designer. The login page records the user’s name and password to move to his own account which consists of three accounts (Site manager account, laboratory staff and patient). Each account transfers the user to his page according to the user’s specified powers (session)

In ASP.NET Session user can store and retrieve values while the user navigates ASP.NET pages in a Web application. The session can therefore be used to create a secure and easy login by setting a session variable to contain this user account information and allowing the user to browse secure parts of a Web site as long as the session variable is not null. These variables, which are accessed by using the session, are unique to each session instance. A complete security session state of patient information and laboratory information security is provided after a specified period of time. This is because these variables can be adjusted so that they are automatically ended after a specified time and impose the system to log out and return back to main page of inactivity even if the session is not over.

The laboratory employee presents the patient’s report by entering his triple name or place of residence in the search and print report.

The patient is able to send an appointment for the test date through this page and send the booking, if the reservation is canceled, the reservation will be canceled and, a new appointment date will be sent to the patient.

**Experiment**

A questionnaire form was designed and sent to the sample of workers in blood analysis laboratories inside and outside the University of Babylon. The sample consisted of 66 persons divided according to the following age groups (22-30, 31-35, Greater than 36) years old.

The questionnaire asked them the following questions : Is the system useful? Are the reports issued by the system in addition to your area of work? Is the system easy to use? Has the system helped save time and effort? Does the system meet the laboratory requirements? Is the program a real guide to be adopted in the Blood Analysis Laboratory?

**Results and Discussion**

The Physiology lab Management System is tested to uncover errors that were made inadvertently as it was designed and constructed. Verification and validation (V&V) are one of testing elements. Verification refers to set of activities that ensure that system correctly implements a specific function. Validation refers to different set of activities that ensure that system that has been built is traceable to user requirements. In this system we used a process called alpha and beta testing to uncover errors that only the end-user seems able to find.

Alpha test is conducted at developer site by end-users, in this process, we are recording errors and usage problems. The beta test is conducted at end – users sit, end user records all problems and reports these to the developer to find and recover errors and make modification in orderly and effective manner.

The questionnaire form in this work was designed to process the (v&v) testing and alpha & beta testing, the result statistics from questionnaire to the sample consisted of 66 persons was the biologist lap divided according to the following age groups (22-30, 31-35 and Greater than 36) years old, we found the following as we are shown in figure (4). From this figure we found that 6% Greater than 36 from workers in biologist lap 9% for (31-35) and 85% for 22-30.

**Conclusion**

This work was carried out in a laboratory and was worked out by the laboratory employee and found good results in the ease of use and navigation between the pages of the site and the experiments were conducted and the results were withdrawn and the accuracy and high speed, which provided the laboratory staff of the easy to enumerate normal and abnormal diseases. In this work (session) used to create a secure and easy login to provide a complete security session state of patient information and laboratory information security after a specified period of time because the session can be adjusted so that it is automatically destroyed after a specified a specified time and impose the system to log out and return back to main page. The purpose of this system is to provide the registry with satisfactory cases and accurate statistics, which are an important information source for health organizations and the Ministry of Health, through which the database can be built. It provides important information on the patient’s condition, which helps to extrapolate the future and identify blood disorders, diseases for the most prevalent based on the current database.

The Effectiveness of the Model of Active Thinking in the Collection of History and Creative Thinking among Students of the Fifth Grade Literary

Doaa Abdel Karim Rahim¹, Jinan Mohammed Abdul Jassim¹, Anas Hamza Aljilawi¹
¹Faculty of Basic Education, University of Babylon, Iraq

ABSTRACT

The study aims to identify the effectiveness of the active thinking model in the collection of history and creative thinking among fifth grade students. The experimental approach was adopted as the appropriate approach to research procedures. The research community consisted of secondary and middle schools in Babil governorate. (The Shatt al-Arab Preparatory School for Girls) to be a sample of the research. The experiment was applied in two groups: the experimental group studied (the active thinking model) and the second the control group studied in the traditional way. The achievement of parents and the grades of female students in the history subject at the end of the first course, the IQ test scores (Dunliz) and the test of tribal creative thinking), The results showed that the two groups were statistically equivalent, and the researcher used the appropriate statistical means to conduct the research. The results showed the superiority of the experimental group students on the control group students in the achievement test. The test of creative thinking, ie, there is a difference of statistical significance at the level of significance (0.05) for the benefit of the experimental group.

Keywords: Active Thinking Model, Achievement, History, Creative Thinking, Fifth Grade Students

Introduction

Education is a comprehensive social process that aims at preparing the individual who lives in a developed world and gains its meaning from the goals that it seeks to achieve because it is the means of society to ensure its continuity and development, and not only in preparing the individual but also in society,. In addition to the spiritual and philosophical values that he lives ¹. This is what he pointed out ² has become a modern view of education as a dynamic process developed in keeping with modern scientific and technological developments as the use of modern strategies in teaching was not a coincidence, but came as a response to the needs of the educational system in order to achieve its objectives, And lasting not limited by a period of time it includes the entire person from the cradle to the grave and shared by many institutions including family, society and school, it is therefore the result of the interaction of the individual and positive activities and the result of this interaction grows individual personality and is used logical reasoning pray ³. The method of successful teaching is not limited to providing methodological information only, but helps to develop the tendencies of students and push them to work and fruitful participation and the teacher has the largest role in determining the appropriate way to use in the lesson teaching teaching activity in order to lead students to participate actively in the lesson, As a learning assistant, meaning that preparing students for educational content requires the teacher to develop learning methods and methods ⁴.

Methodology

The research methodology and procedures: This chapter will include an explanation of the research methodology and procedures, including the choice of experimental design and the selection of the research community and its model, as well as the procedures of parity between the two research groups (experimental and control), consideration and control of the variables.

The experimental design of the research: includes an independent variable (the active thinking model), the usual method, and two dependent variables (achievement and creative thinking).
The research community and its sample: The current research community represents the fifth grade students in the public schools (preparatory and secondary) of the General Directorate of Education in the province of Babylon (center) for the academic year (2018 - 2019), which has at least two divisions of two divisions, The researcher chose the Shatt al-Arab Preparatory School for Girls in the center of Babil Governorate in order to conduct her research, and found that it includes two divisions (A and B). The researcher chose (B) the method of random drawing to represent the experimental group and the number of its applications (40) According to (active thinking model), and in the same way chose Division A to represent For the control group and the number of female students (36) students, which will be studied according to (the normal method) Thus, the total number of the research sample was (76) students before the exclusion and after the identification of the students' information from the official records of the school. The previous cases were found in the fifth grade in the two research groups.

Parity of the two sets of research: Before the beginning of the actual teaching in the experiment, the researcher made sure to achieve equivalence in some variables, which can affect the two dependent variables. To ensure this, the students of the two groups were rewarded in a number of variables., The academic achievement of the parents, the grades of the students in the history subject for the first semester (the first course) for the academic year (2018 - 2019), the Dunliz Intelligence test and the tribal creative thinking test scores (Table 2)

Adjust some internal variables: In addition to the above measures of statistical equivalence between experimental and control groups, the researcher attempted to avoid the effect of some extraneous variables in the experimental process, which increases confidence in the internal validity of the experiment and then in the results. These variables (differences in sample selection, Experimental extinction, Effect of experimental procedures, Measurement tools.

Search Materials: Determination of Scientific Material (Content): The researcher identified the scientific material that will be taught to the students of the two research groups before starting the experiment. The last three chapters (fifth, sixth and seventh) are from
the history book of Europe and modern and contemporary America, which is to be taught for the fifth grade, the ninth edition of the academic year 2018-2019.

**Preparation of teaching plans:** The researcher prepared a set of teaching plans for the students of the research groups (experimental and control) in light of the behavioral objectives and the contents of the last three chapters (fifth, sixth and seventh) for the date material for the fifth grade students (the research sample) for 2018-2019.) For the experimental group and (18) for the control group and was presented to a group of arbitrators and specialists in education and teaching methods to benefit from their views and observations for the purpose of modifying and improving the formulation of the plans and make them sound to the extent acceptable.

**Research tools (cognitive test, creative thinking test)**

**First: The achievement test:** The test is an organized method that includes asking a variety of objectives to measure what the student learned in a subject she studied for a certain period of time in order to determine the level of her performance.

The survey application for the achievement test: It includes the following:

1. The first survey application (the sample of the clarity of the instructions and the paragraphs)
   The first survey sample (the sample of the clarity of the instructions and the paragraphs) In order to ensure that the test paragraphs and the instructions for the answer and the calculation of the time required to answer the paragraphs in full, the researcher applied the test on a survey sample (30) student of the fifth grade literary in (Residential Bent Al Hussein) for the purpose of knowledge of cases of ambiguity in the instructions or test paragraphs and the extent of understanding and clarity of the paragraphs of the students and the calculation of the time required for the test as the researcher recorded the exit time for each student, and calculating the arithmetic mean of time I found that the time needed to answer all the test paragraphs was approximately (43) minutes.

2. The second survey application (sample of statistical analysis): The test was applied to a second sample of (100) fifth grade students in the two schools (Khadijah Al-Kubra Preparatory School and Bint Al-Huda). The purpose of the test is to analyze the test paragraphs statistically The difficulty of paragraph, paragraph discrimination, the effectiveness of wrong alternatives.

**A. Difficulty of the paragraph:** By conducting statistical analysis of the collection test paragraphs found that the coefficient of difficulty of paragraphs ranged from (0.5 - 0.69) for the substantive paragraphs and (0.36 - 0.56) for the paragraphs of the collection and so the test paragraphs are all good and difficult appropriate.

**B. The coefficient of discrimination of the paragraph:** Of the important qualities and must be provided in the paragraphs of the test is the characteristic of discrimination means the possibility of paragraphs to identify the individual differences of students and the test paragraphs are valid as the coefficient of discrimination of the paragraph is (20,0) and above, Between (0.33 - 0.59) and (0.35 - 0.43) for the glossary sections and thus the test paragraphs are considered to have a good and appropriate discrimination coefficient.
Results and Discussion

Test application for testing: The researcher applied the test to a sample of (100) female students in the sample. Revolution School It turned out that the test instructions, and its paragraphs were clear, understandable. The average time taken to respond to test paragraphs was between (5-6) minutes per paragraph.

Fixed correction: The researcher randomly selected the responses of (10) female students in order to ascertain the stability of the correction of the test. The researcher used the Pearson correlation coefficient as a statistical method to calculate the stability of the correction of the creative thinking test.

1. Stability over time: After two weeks of the first correction, the researcher re-corrected the books without putting a sign or sign indicating the correction, and the coefficient of correlation between the researcher and herself over time (0.99).

2. Stability with another corrector: The same books were corrected again by another corrector with experience in correcting the test. It was agreed with them not to place signs or marks on the response papers to reduce the effect of the corrector. The correlation coefficient between the researcher and the other corrector was (0.95).

Application of the final test: The test was applied by the researcher after completing the teaching of a particular subject, but after the flags of experimental groups and control, the application test date. The researcher supervised the application of the test and after correcting the answers of the students who obtained their grades.

Application of the test of post-creative thinking: The researcher applied the test of creative thinking to the two groups of research after the completion of the application of the experiment and supervised the researcher herself on the process of applying the test, and after the correction process was obtained degrees

Statistical means: To obtain the results and validate the data, the researcher used the t-test equation for two independent samples to make the parity between the experimental and control groups in the following variables (Students’ age is calculated according to months, academic achievement of parents and grades of students in the history subject for the first semester (first cycle) of the academic year (2018 - 2019), The Danlys test for intelligence and the test of tribal creative thinking) And the Kai box And the equation of difficulty and discrimination of paragraphs and the equation of the effectiveness of alternatives and correlation coefficient Pearson and Spur man Brown and The equation of the magnitude of the effect).

Results of the scholastic achievement variable: The students of the experimental group, who studied according to the active thinking model, exceeded the control group students who studied according to the usual method of the achievement test. This indicates that there are statistically significant differences at (0.05) between the mean of the experimental group and the average of the control group in the date collection test.

From the observation of the above table, we observe that the active thinking model has had an impact on raising students’ achievement in history. The effect of the test on the collection test is 0.90, which is large, which explains the superiority of the experimental group over the control group.

Results of the creative thinking variable: The students of the experimental group who studied according to (active thinking model) exceeded the students of the control group who studied according to the usual method in the creative thinking test. This indicates a significant difference at (0.05) The experimental group and the average scores of the students of the control group in the post-creative thinking experiment Table (8) shows that:

Conclusion

The use of an active thinking model in teaching history has helped to raise the level of student achievement and activate their memory by retrieving the previous information and giving the correct answer. The application of the steps of the active thinking model inspires the enthusiasm and vitality of the students and enhances the spirit of cooperation among them and likes to participate in the lesson and appreciation of the students themselves.

Effectiveness of an Educational Program on Nurses Knowledge about Chemotherapy Hazards at Al-Habbobi Teaching Hospital in Al-Nasiriyah City

Hussein Kadhim Abd Ali¹, Wissam Jabar Qassim²

¹Department of Community Nursing, ²Assist. Prof., Department of Community Nursing, College of Nursing, University of Baghdad, Iraq

ABSTRACT

A quasi experimental study design (One-group Pretest-Posttest) study has been carried out at Oncology Center at Al-Habbobi Teaching Hospital in Al-Nasiriyah City from the 26th of Dec. 2018 to 14th of March 2019 to implement the Effectiveness of an Educational Program on Nurse’s Knowledge about Chemotherapy Hazards, who are working in Oncology Center and to find out the relationship between the nurses’ knowledge towards chemotherapy hazards and their demographic characteristics. To achieve the objectives of the present study, non- random (purposive) sample consists of 47 nurses working in Oncology Center have participated in this study. The data are collected through using constructed questionnaire designed for the purpose of the study, which consists of three parts: The first part is related to the demographic characteristics like nurses’ age, level of education, marital status, years of experience in oncology ward, and years of employment. The questionnaire is used in pretest before conduction of the program, after the application of the program post test which is done after one month and half from first post-test repeated doing of participants of this study.

Keywords: Nurses Knowledge, Chemotherapy Hazards, Educational Program

Introduction

Cancer is a cause death or cases many complication for patients with it, which can attack adjoining parts of the body and invade to other organs. This process is called to as metastasis. Metastases are the main cause of death from cancer, leading it to of death worldwide ¹. Cancer Chemotherapy refers to the wide range of therapeutic options used in the treatment of malignant diseases, including categories such as cytotoxic drugs, biologics, immunotherapy’s, targeted drug therapies, hormonal treatments, and high dose chemotherapy regimens supported with hematopoietic stem cell transplant². Cancer chemotherapy encompasses cytotoxic, cytostatic and biologic agents used to modify the body’s response to malignant disorders. These agents can be highly toxic and present specific risks for patients, health care providers and care-givers. As such, the care of patients receiving these drugs requires specific knowledge, skill and judgment within an environment that supports quality practice. Recommendations for the safe handling of hazardous drugs have been available for more than twenty years ³. Evidence for continued risk of occupational exposure is abundant; however, nurses’ use of the recommended precautions is not universal. This may be related to a lack of information or to a lack of serious concern for the potential hazards. Over ten and one half million healthcare workers are potentially exposed to hazardous drugs in the workplace. While most drugs defined as hazardous are cytotoxic agents used in the treatment of cancer, many drugs used for other indications and in other patient populations are equally unsafe World Health Organization, 2014. According to the National Institute for Occupational Safety and Health, there is documented evidence of contamination of the work environment with hazardous drug HDs, which increases the potential for exposure by nurses, pharmacists and other healthcare workers when these agents are handled inappropriately ⁴. A study shows that especially nurses are exposed while preparing...
and administering the CDs (chemotherapy drugs). The level of knowledge of the nurses about antineoplastic
drugs is not satisfactory. The awareness of the nurses
handling the CDs (chemotherapy drugs) is of concern
because it is important in raising standards of safety.
In service training is a very effective tool to increase
the level of knowledge. This study revealed also the
necessity of the improvement of the work environment
and the availability of the protective equipment. As the
primary prevention measures involve the least possible
exposure to CDs (chemotherapy drugs), information
regarding the updated guidelines should be disseminated
both at the practice and administration levels. For that
reason nurses’ information about the possible toxicities
and the protection measures used while preparing and
administering these drugs is gaining more and more
importance.

Results and Discussion

There are highly significant differences between two
periods (Post 1 and post-2 tests) for all items of the Nurse’s
Knowledge about Chemotherapy Hazards at Oncology
Wards of the Study Sample, which reflects that the nurses’
knowledge was affected by educational program when
analyzed by (t-test). there are highly significant differences
among the three period (pre, post-1 and post-2 tests) for
of the Nurse’s Knowledge about Chemotherapy Hazards
at Oncology Wards of the study sample in all Items and
this reflects that the nurses’ knowledge was affected by
educational program when analyzed by ANOVA. There
is no statistically significance at pretest period at p.
value 0.05. At posttest-1period statistically significance
differences at p. value 0.05 and highly statistically
significance differences at posttest-2 period at p.value
0.001. Relative to the table (1) the majority of the study
sample at the middle age ranged (25 - 29) years. And they
are accounted for (19) nurses with percent (40.4%) with
age mean (27) years. This result agree with Wafaa, (2015),
that show the majority of study sample with mean age
(42.4). This may be because the Department of Oncology
wishes to bring middle-aged nurses to be more effective
and tolerant to treat and care for patients. In regarding to
gender it is noticed that (61.7%) of the study sample are
female and the remaining are male. This result is similar
to study done by Najma, (2012), they reported that the
study population consisted of (35) nurses more than half
(80%) of them were female and (20%) male. This may be
because of the desire of the Department of Oncology to
bring large numbers of graduates of the Faculty of Nursing
and medical institutes as they are more knowledgeable
and scientific in the treatment of patients, and it is known
that most graduates of the college of Nursing and medical
institutes from women, this results is supported by Nezar
A., (2014), Who shows that the female rate is higher
than the male rate. Table (3) shows that there are highly
significant differences between two periods (Post 1 and
post-2 tests) for all items of the Nurse’s Knowledge about
Chemotherapy Hazards at Oncology Wards of the Study
Sample, which reflects that the nurses’ knowledge was
affected by educational program. The health education
was effective on study group in present study (Table
3), through the high percent of the nurses responses for
knowledge concerning chemotherapy hazards between
pre and post health education and majority of nurses
responses for the posttest were have been passed compared
with pretest.

Conclusion

During the course of the present study data analysis
and logical discussion and interpretation of result, the
effectiveness of the Education Program was determined.
However, the study concluded that: A poor level pretest
reflects of knowledge and practice. After posttest 1 the
nurses’ knowledge level reflects very well and nurses’
practice level shows a very good level of practice. Nurses’
knowledge and practice become very good after posttest.

Source of Funding: There is no financial disclosure.

Conflict of Interest: None to declare.

In Vitro Assessment of Some Properties of Biocompatable Polymer Dental Implant Consisting from Poly Ether Ketone (Peek) and Silicon Carbide Nanofiller

Mustafa Mahdi Jassim¹, Thekra Ismael Hamad²
¹Lecturer, ²Professor, College of Dentistry, University of Baghdad, Baghdad, Iraq

ABSTRACT

Polyetheretherketone (PEEK) is growing in popularity with an increased interest in the use of polyether ether ketone (PEEK) for orthopedic and dental implant applications due to its elastic modulus close to that of bone, biocompatibility, and its radiolucent properties. PEEK with high chemical resistance, radiolucency, mechanical characteristics compared to those of human bones. Aim of this study was done to evaluate the PEEK and PEEK composite dental implant through mechanical and morphological evaluation. PEEK composites (PEEK and SiC with selected weight percentage ratios of (0, 1.5%, 3%, 4.5%, 6%) were fabricated using a compounding by melt blending by (Internal Mixer) at 365ºC. The study involved Samples preparation (sheets) cutting and machining into desire shapes according to ASTM standards, for mechanical tests which includes tensile strength, elastic modulus and flexural strength, physical tests which include DSC, TGA, FTIR. Morphological test that include SEM, and EDX mapping. The results obtained from the experiments showed that the tensile strength, elastic modulus and flexural strength polymer composite consisting from polyetheretherketone and Silico Carbide nanofiller implant increased comparing with pure PEEK with better distribution of nano filler particles in PEEK composite (concentration 1.5%, 3%, 4.5%) in the scanning electron microscope examination and EDX mapping.

Keywords: PEEK, PEEK composite, SiC nanofiller.

Introduction

There is an increased interest in the use of polyether ether ketone (PEEK) for orthopedic and dental implant applications due to its elastic modulus close to that of bone, biocompatibility, and its radiolucent properties. PEEK with high chemical resistance, radiolucentcy, mechanical characteristics compared to those of human bones. In addition, it can be repeatedly sterilized and shaped by machining and heat contouring to fit the contour of bones. PEEK has been used for load bearing orthopedic applications such as spinal cage, dental implant, and screws. Despite these excellent properties, PEEK is still categorized as bioinert due to its very low reaction with the surrounding tissue, which limits its potential applications. Impregnating bioactive materials into PEEK has become an attractive approach for improving its mechanical properties. Silicon carbide (SiC) ceramics have a great potential for a number of industrial applications due to their high mechanical strength, low thermal expansion coefficient, low value of relative density, high chemical inertness, oxidation and corrosion resistance. Recently, bulk porous silicon carbide ceramics have attracted increasing interest in medical applications as materials with high biocompatibility, for the production of orthopedic and dental implants. Silica-based ceramics are another group of bioactive products, which exhibit better biodegradability in comparison to HA ceramics, Silicon carbide (SiC) ceramic is one of the members of this group which is light weight and has excellent mechanical properties. It has been used in the manufacture of composite bone scaffolds, for example with a coating of bioactive glass, PEEK composites were produced for different applications. The most important application is load bearing implant application.
Methodology

Preparation of Polymer: The specimens were prepared in five groups, the preparation method included preparing the polymer composite of PEEK and SiC with selected weight percentage ratios of (0, 1.5%, 3%, 4.5%, 6%) .

Mixing procedure: The polymer composite was made by mixing of PEEK polymer with SiC nano filler with the following proportions (0, 1.5%, 3%, 4.5%, and 6%). The polymer composite was fabricated via a series of processes as follow: Mixing, compounding and compression molding.

1. Mixing between nanoparticles and polymer granule was achieved by sonication instrument firstly, the mixing was carried out manually by adding the selected percentage of SiC with alcohols then sonication for 15 minutes for better distribution of the nano particles the mixing time continued for (15min) followed by put in an oven for drying at (150 °C) for 15 minutes (6).

2. Mixing and compounding was achieved in an internal mixer (Haake) figure(2-8), the temperature set at 365°C and mixing speed at 70 rpm., the polymer granules added gradually through special opening about 60gm for each mix, The time needed for compounding was about (5) min. after each mix the melted polymer were taken out of the internal mixer and allowed to cool down to room temperature without any further temperature control.

Specimen Preparation:

a. Tensile test: Tensile test was performed with an Intron 5567 tester(Universal test machine), carried out at room temperature, at a cross head speed of (5 mm/min), and gauge-length, 50 mm. The prepared sheets were cutted with CNC machine to the required shape of tensile test specimen, samples were cut according to ASTM D 638-Type3 (ASTM Standard 2011), as shown in Figure (2), the final result represents the average value for the eight tested specimens. Figure (1) shows the standard specimen for tensile test.

Figure 1: Specimen design

b. Flexural tests: Flexural test was performed according to ASTM D790-03 at room temperature by using a three-point test instrument, using the Universal testing machine with velocity (1.28 mm/min). The sample will be cut at length of at least 65 mm, width was about 10 mm and thickness will be not less than 2.5 mm. Flexural modulus and strength were calculated from the load displacement diagrams. Eight specimens were used for most tests, and the final results represent the average values for Eight specimens, as it was reported.

Physical tests and Structural Characterization

a. Differential Scanning Calorimeter (DSC): In this test some characteristic were evaluated, such as melting temperature, crystallization temperature, glass transition temperature, and heat of fusion, etc. The procedure of this test was carried out using samples, weigh about (10.96 mg) heated first from room temperature to 400°C; with 45°C/min. heating rate in order to erase the thermal history of the sample, thereafter cooled from 400°C to room temperature with a rate of 100C/min, and then heated second in a cycle to 400°C at 10°C/min, all in N2 atmosphere. Each sample was subjected to double heating and cooling cycles under a dry nitrogen purge, and data were recorded during the heating and cooling cycle (7).
b. **Thermo gravimetric analysis (TGA):** In this test, thermal stability has been discussed, including the resistances of thermal degradation and flammability of SiC nanoparticles. By heating from room temperature to 700°C, at a heating rate of 20°C/min in N2 atmosphere\(^7\). This test was done on a small sample weighing 12.6 mg put in a small crucible of alumina and the weight loss as a function of temperature was measured, the test was performed by using DSC/TGA (STA System) METTLER – TOLLEDO.

c. **Scanning Electron Microscopy (SEM):** SEM was used to reveal the microstructure of nanoparticles powders samples, neat PEEK, nanocomposites. It was used to diagnose the phases and nanoparticles distribution of samples, SEM (LEO, model 1455VP, UK), with an accelerating voltage of 10–20 kV, the uniformity of distribution and the particle size of the nanoparticle in nanocomposites were also inspected. Before observation, in order to avoid charging during electron irradiation, the composite samples were fractured in liquid nitrogen and covered with (Au) using a gold sputter coating.

d. **Fourier Transform Infrared (attenuated total reflection) analysis (ATR/FTIR):** Thin films (100 microns) shown of the neat PEEK, selected sample from nanocomposite samples. These films were used for crystalline structure characterization on a Bruker ATR/FTIR spectrophotometer (model IFS48, Germany) (spectral range 4000–300 cm\(^{-1}\) and resolution 2 cm\(^{-1}\)).

e. **Elemental Analysis with EDX:** SEM supported by EDX (energy dispersive X-ray analysis) technique was performed to determine the composition polymer composite the main principle of spectroscopy is that each element has a unique atomic structure allowing a unique set of peaks on its electromagnetic emission spectrum, it depends on the interaction of some source of X-ray excitation and a specimen for the emission is the characteristic X-ray of the elements contained in sample which was detected by the detector. The received signal from the detector was analyzed.

### Results

**Mechanical Tests**

**Tensile strength:** Table (1-1) shows descriptive statistics Mean values, standard deviation, Standard error, maximum and minimum of tensile strength test result of pure PEEK, G1 (peek +1.5% Sic), G2 (peek +3% Sic), G3 (peek +4.5% Sic), G4 (peek +6% Sic) respectively as a function of nanoparticle weight percentage, it show increase the tensile strength values of the PEEK polymer composite comparing with pure peek with increase the percentage or volume fraction of the SiC nano composite reach to maximum value at G3 group which represent the PEEK with 4.5% SiC nano filler.

</table>

The average data of the tensile test results modulus table 1-2 showed that elastic modulus are increased with increasing the weight percentage of nano powders PEEK polymer composite comparing with pure peek reaching to its maximum value in G3 group, the inclusion of nanoparticles in first group has raised the tensile strength by 15% and for the composite sample, G3(peek +4.5% Sic) group which its tensile strength value raised by 33% comparing with pure PEEK.
Table 2: The elastic modulus of PEEK, G1, G2, G3, G4 groups nanocomposites as a function of SiC nanoparticles content in the composite

<table>
<thead>
<tr>

<td>7.4771</td>
<td>6.2373</td>
</tr>
</tbody>
</table>

**Flexural strength:** The highest mean value is recorded by the G3 group, while the lower value was in PEEK control group, it is observed that increased of SiC nanofiller content in polymers (PEEK: X% SiC), lead to increase the values of flexural strength for polymer composite except group G4 which show decrease in the flexural strength value. Statistically F-test show a highly significance difference in the transverse strength among the groups.

**Physical tests and Structural Characterization**

**a. Differential Scanning Calorimeter (DSC):** (DSC) was used to analyze crystallization and melting temperatures of polymer nanocomposites which can be determined from the curves accordingly. The percentage of crystallinity can be determined by dividing crystallization enthalpy (ΔHc) (integrating the area under exotherm peak) and dividing it with ΔHco, (the theoretical crystallization enthalpy of 100% of PEEK). That shown in equation

\[ Xc\% = \frac{\Delta Hc}{\Delta Hco} W \text{ polymer} \times 100 \; \ldots \ldots \; (3 - 1) \]

Where, ΔHc refers to heat of crystallization of the specimen, ΔHco fusion heat for pure crystalline PEEK which is 130 Jg-1 [Tg 2011] and W for the weight composition of the polymer, DSC the crystallization temperature (Tc) of PEEK has been raised slightly when SiC nano filler was added, this indicate non significant changes in the properties of material

**b. Thermo gravimetric Analysis (TGA):** TGA characterization has been carried out in nitrogen atmospheres to analyze the thermal stability of the composites and the effect of time and heat on the stability of the nano filler which show that it can withstand the time of processing especially during mixing up to 20 minutes. The degradation curves of pure PEEK, and Sic are illustrated in figure (1-3)

**c. Fourier Transformation infrared FTIR analyses. IR mode:** The FTIR analysis confirms the structure of Poly ether+ ether ketone with the same absorption bands for the polymer composite in the other groups.

**d. Scanning Electron Microscopy SEM:** The scanning microscopy image of SiC nano-particles. The nanoparticles form some agglomerates, the particles are irregular in shape and the distribution of the particles is such that they are loosely packed and are approximately at the range between 500 nm to 1-3 μm long, the cryo-fractured surface morphology of neat PEEK was homogenous accompanied by smooth surfaces and no voids or defects, the surface morphology of G1, G2, G3 group with 1.5,3,4.5 % of SiC nanoparticle content in composites which exhibited a homogenous morphology with uniform dispersion of the nanoparticle, it can be observed that different sizes of spherical shaped of nanoparticle material were dispersed randomly in PEEK matrix with very few of micro-cavities structure, this indicates
a fairly interaction between the components, morphology of G4 group with 6% of SiC nanoparticle content in composites, the dispersion of the SiC nanoparticle in PEEK was much less than the previous groups, with more aggregation behaviors of SiC nanoparticle figure (4).

![Figure 5: SEM of a. pure PEEK, b. G3 polymer composite, c. G4 polymer composite](image)

e-Scanning Electron Microscopy (SEM) with Energy Dispersive X-Ray Analysis (EDX): EDX mapping for the peek composite group G1 group and G3 group figure (1-5a,b) with magnification of 25000 x show uniform distribution of the nano silicone carbide filler that indicate good mixing procedure while in G4 group PEEK composite figure (1-5c)) show the presence of agglomerates in concentration of 6% SiC

![Figure 6: SEM with EDX mapping of PEEK composite a. G1, b. G3, c. G4 material 25000 x where the red spots represent the SiC Nano filler](image)

**Discussion**

There is an increased interest in the use of polyether ether ketone (PEEK) for orthopedic and dental implant applications one of the major reasons to gain interest into PEEK was its closely matched stiffness to bone. This mismatch in stiffness may cause a stress shielding and may lead to bone resorption (8,9). SiC nanostructures are promising candidates in the field of biomedical device, Moreover, the unusual properties of nanoparticles affect the various interactions take place between nanoparticles and the polymer matrix designing to reinforced the polymers to attain desirable macroscopic material properties by combining materials at a microscopic level (10). For the tensile strength mean tensile strength at break show increase in its values of the PEEK polymer composite (G1, G2 G3) with increase the percentage or volume fraction of the SiC nanofiller reach its maximum value at G3 group that represent the PEEK with 4.5% SiC nano filler, the incorporation of the hard nanoparticles powders into the polymer matrix which leads to restricted the movement of polymer chains and, accordingly, increases the tensile strength and elastic modulus for nanocomposite material (11) Group G4 with 6% content of nano SiC show decrease in the value of tensile strength and elastic modulus this may be due to incorporation of nano filler may lead to agglomeration of the filler in some parts of the polymer matrix that proved in the electron (12-17).
Conclusion

Polymer composite consisting from polyetheretherketone and Silicone Carbide nanofiller sow improved in its mechanical properties (tensile strength, elastic modulus and flexural strength) comparing with pure PEEK, with the concentration of (1.5, 3,4.5%) of nano filler with good distribution the filler confirmed by SEM,EDX examinations.

Occurrence of Asymptomatic Bacterial Urinary Tract Infection and Susceptibility Profile among Students of Medical Technical Institute-Baghdad

Najah Ali Mohammed
Ph.D, Science, Microbiology, Assistant professors. Middle Technical University, Iraq

ABSTRACT
Collect the mid-stream of the urine from 350 students (300 female and 50 male). A general urine exam was conducted to determine the presence of bacteria in urine (bacteriuria). The isolated bacteria were identified and diagnosed according to reference manual and standard methods, culture character and VIdex2. The bacterial isolates were subjected to in vitro susceptibility tests against some antibiotic and was performed by Kirby-Bauer’s disc diffusion method done on Mullar- Hunton agar. The overall prevalence of asymptomatic urinary tract infection was (50.57%) in females were 93.78% higher than males 6.21%. Gram Negative bacteria was the predominant bacterial pathogens, and the highest occurring pathogenic bacteria in both sex. The prevalence of bacterial strains, out of the total 177 strains isolated, 166 (93.78%) and 11 (6.21%) strains were isolated from female and male students respectively. Escherichia coli (58.43%), Staphylococcus aureus (27.71%), female students, while the pathogenic isolate from male students were Staphylococcus aureus (45.45), and Escherichia coli (9.09%). Gram-negative isolates showed a high level of sensitivity to GEN and SXT (96%), followed NIT (93%). Gram-positive isolates were highly susceptible to GNE (96.6), SXT (94.9).

Keywords: urinary tract infection, antibiotic susceptibility profile.

Introduction
The lower part of the urinary system is the most affected compared to the upper parts like the bladder and the urethra. E.coli which found naturally in the digestive system are the main cause of urinary tract infections as well as other Gram negative colonic bacteria. Ninety percent of uti infections are caused by bacteria, mainly colonic bacteria, where 80% of infection occur and E.coli the main cause of cystitis and pyelonephritis followed by Klebsiella pneumoniae, Proteus mirabilis and by Gram-positive pathogens, such as Staphylococcus aureus, Enterococcus faecalis and Staphylococcus saprophyticus. Asymptomatic Urinary tract infection are widespread in healthy populations. And it can be diagnosed as ‘significant bacteriuria’ when a person has no symptoms but there is a number of bacteria in urinary tract, the condition is called asymptomatic urinary tract infection (UTI), and this condition is harmless. In most cases urinary tract infection occurs in women more than men, and by. Show that 55-65% almost every woman has UTI even once in their lives, and the incidence of at least three cases of UTI and at a satisfactory offer at the age of 24 and was necessary treatment with antibiotic. Among the diagnostic tests, urine analysis mainly important, especially for excluding bacteriuria. In cases of asymptomatic uti the culture method is not important for evaluation especially when the patients with uncomplicated UTI, but its important for patients with recurrent UTI. The two, Acute and chronic form occur in asymptomatic uti, E.coli is the common cause of UTI but in sexually active women 10-20% of cases of UTI caused by micrococcal and by the ascending route the infection reaches the bladder. The faecal micro flora is the manily source of E. coli uti in female. in male the E.coli originate from the sub pepticual sac. Because of short female urethra the prevalence of E.coli uti is higher comparable to that of men due to bacterial infection. Urination with chronic flora that resides in the perineal skin. it also include the effect of turables occur in urinary stream.

Material and Method
Samples collection: This study is, therefore, designed to determine the prevalence of bacterial UTI and their
antibiotic susceptibility among Students of Medical Technical Institute- Baghdad. Thirty hundred and fifty students of Medical Technical Institute- Baghdad were recruited for this study 300(85.71) female and 50 male(14.29) with asymptomatic UTI and excluded who take antibiotics. All non-repetitive midstream urine (MSU) samples obtained during the study period (September 2016 to August 2019) were included in the study.

**Bacterial count of urine:** All urine samples were examined for "significant bacteriuria by use a modified technique described" by Mbata TI.(2007). A loopful of each urine sample (0.01ml) was spread over the surface of Cystine Lactose Electrolyte Deficient (CLED) agar plates (LabM, UK, and incubated at 370C for 18 – 24 hours. "The number of bacterial colonies were counted and multiplied by 100 to give an estimate of the number of bacteria per milliliter of urine". A significant bacterial count was taken as any count equal to or in excess of 10–5/ml.

**General urine examination:** All samples that recorded significant bacterial counts were subjected to ‘urine microscopy test to detect presence of (5PC/HPF) or 10 white blood cells (pus cells)/mm3 in urine sediments or deposits’ (Smith G.2004). The samples that were positive for bacterial count were conducted it for microbiological analysis.

**Microbiological analysis:** All the specimens that were positive for bacterial count and GUE were cultured on routine culture media where 1 ml of urine was cultured on both MacConkey and Blood agar plate (HiMedia, India) by streaking, incubated overnight at 37°C under aerobic condition. Growth of 100 colonies or more, ‘(10^9) colony forming units (CFU)/mL urine, was considered as culture positive’. Isolated bacteria identified by Gram stain, cultural characters and biochemical tests as per the Manual of Clinical Microbiology10, and confirmed by using Vitek2 system (bioMerieux-France)

**Antibacterial susceptibility:** The sensitivity test carried out on Muller- Hinton agar The bacterial isolates were subjected to in vitro susceptibility tests against some antibiotic and was performed by Kirby-Bauer’s disc diffusion method and interpretation of the results was done as described in CLSI 2013. Antibiotic discs (MAST, UK) used were, ciprofloxacin(CIP:5mg), Nalidixic acid(NA: 30 mg), Gentimycin (GEN: 10 mg), Ofloxacine(SXT:5mg), Nitrofurantion(NIT:300 mg), Cefixin(CEF:10 mg), Amoxicillin(AMX:30mg), Sulphamethoxazole-trimethoprim(SXT:25mg), and Augmentine(AU:30 mg)

**Statistical Analysis:** The data were analyzed using Chi-square (χ²) test, and student’s t-test. All statistical tests were performed by Statistical Package for Social Sciences (SPSS) software.

**Results and Discussion**

Table (1) showed the distribution of urinary tract infection according to gender. It was found that the rate of females with UTI were 55.3% higher than males 22%. Table1: Shown the urine deposits content, urine deposits were microscopically observed in the samples of 300 (94.2%) and 50(55%) female and male students respectively. Pus cells, bacteria, RBC, yeast cells, and spermatozoa were observed in 177(50.57%), 120(34.9%), 22 (2.55%), 6(1.71%) and 25 (7.14%) urine samples respectively. Whereas pus cells were the most observed urine deposits, yeast cells and RBC were the least observed in male. No spermatozoa were seen in the female urine samples. There were more pus cells, RBC and yeast cells in female urine samples than in male samples. Table (3) shown the prevalence of isolated pathogens in the study group, out of the total 177 strains isolated, 166 (94.2%) and 11 (55%) strains were isolated from female and male students respectively. In a decreasing order, the highest occurring pathogenic bacteria in female students were Escherichia coli (58.43%), Staphylococcus aureus (27.71%), Proteus species (3.01%), Pseudomonas aeruginosa (3.61%) Klebsiella species (1.8%), Coliforms organisms (1.2%), Enterobacter species (3.01%), Citrobacter species (0.60%) and Staphylococcus saprophyticus 0.60%. In decreasing order, the pathogenic isolate from male students were Escherichia coli (9.09%), Staphylococcus aureus (45.45%), Proteus spp (18.18%), and each of Pseudomonas aeruginosa, Enterococcus species, and Staphylococcus saprophyticus (9.09%) no isolates of Klebsiella spp Coliform organisms and Citrobacter species. This study showed that the GNB are the predominated isolates, and the highest was E. coli 98(83%), and the Citrobacter spp was the last with 1(1.8%).Gram-negative isolates showed a high level of sensitivity to GEN and SXT (96%), followed NIT (93%). While the high-level resistance showed against OFL45 (38%), and CEF 44(37.3%) as showed in table (4).

Gram-positive isolates were highly susceptible to GNE (96.6%), SXT (94.9%). S. aureus was susceptible to GEN, SXT both with 96.6%, and NIT 36(70.9%), and resistant to CIP and CEF with 36 (70.9%), AU35 (68.6%), and AMX 17(33.3), while the low level of resistance was observed in the remainder of the antimicrobials tested (GEN, NA, and OFL). (Table 5). The results showed that the overall prevalence of UTI was 50.57%. In comparison with that was 50%, but less than. The study found that the rate of females with UTI were 55.3% higher than males 22%. This might be due to the anatomical differences of urogenital organs between the two sexes. The presence of bacteria in fresh urine sample indicates an infection. In current study the highest occurring pathogenic bacteria in female students were E. coli (58.43%), this agrees with many other previous research. And was in agreement with others finding too. This means that infection are more frequent among females because of female urinary tract is more colonized by intestinal bacteria resulting from shortness of their urethra as in addition to shortening the distance between the urethral opening and rectum which makes females more susceptible to UTI 20. Improper cleaning of the perineum with sanitary towel is another additional factors for bladder contamination and UTI. The most common cause of urinary tract infection are secreted out of urine to the environment. Therefore students need to pay more attention to personal hygiene in their homes as well as their surroundings21-25. We reported the second isolates was Staphylococcus species and this agreement with others study findings. In males, the longer length of urethra and the prostate secretions are considered to be excellent immune agents against bacterial infection.
Conclusion

Gram-negative isolates showed a high level of sensitivity to Gentimycin, and Sulphamethoxazole-trimethoprim, followed by Nitrofurantion. While the high-level resistance showed against Ofloxacin and Cefixcin. this is disagreement with the results study of (Otajevwo FD and Eriagbor C.2014) which found high sensitivity to Ofloxacin.

Prevalence of Levels of Examination Anxiety among Undergraduate Students of the Colleges of University of Thi-Qar, Iraq

Rasha Dakhel Abdullah¹, Maan Hameed Ibrahim Al-Ameri²
¹Academic Nurse, ²Assist. Professor, College of Nursing, University of Baghdad, Iraq

ABSTRACT

Objective: To assess the prevalence of examination anxiety among undergraduate Students of the Colleges of the University of Dhi-Qar. A descriptive and analytical study was conducted on a sample of the undergraduate students of the University of Dhi-Qar. Which consist of 400 students. The study was conducted during the period from November 2018 to June 2019 to assess levels of examination anxiety and finding a relationship between levels of examination Anxiety and academic Achievement among undergraduate Students of the Colleges of the University of Dhi-Qar. A set of paragraphs of questionnaire were used for the purpose of assessing examination anxiety to Students. The scale is a used as a screening measure of Levels of Examination Anxiety of Students. The findings reveals that the levels of severe anxiety and extremely severe anxiety for 400 undergraduate student both (male & female) are 47.3% and mild level of examination anxiety 18.2% and moderate level of examination anxiety 34.5%, and that (28.0%) of female students have severe and extremely severe levels of examination anxiety more than (19.2%) of male students.

Keywords: Examination Anxiety, Academic Achievement, Undergraduate Students

Introduction

Excessive fear can make it difficult to concentrate and persons might struggle to recall things that they have studied. In addition, they might feel like all the information they spent some much time reviewing suddenly seems inaccessible in their mind. They might blank out the answers to questions to which they know the answers. This inability to concentrate and recall information then contributes to even more anxiety and stress, which only makes it that much harder to focus their attention on the test (²). Researchers suggest that between 25 and 40 percent of students experience test anxiety (³). Examination anxiety can also be labeled as anticipatory anxiety, situational anxiety or evaluation anxiety. Some anxiety is normal and often helpful to stay mentally and physically alert⁴. Test anxiety can have broader consequences, negatively affecting a student’s social, emotional and behavioral development, as well as their feelings about themselves and school⁵. Researches suggest that high levels of emotional distress have a direct correlation to reduced academic performance and higher overall student drop-out rates⁶.

Methodology

Design of the study: A correlational study design in which association and assessment approaches are applied to achieve the objectives of the study. It was conducted to determine the prevalence of levels of examination anxiety among undergraduate students of the colleges of the University of Dhi-Qar during the period of the study from October 17th 2018 to July 1st 2019.

Sample of the Study: The study was conducted upon non-probability/systematic random sample of 400 students from five colleges of University of Dhi-Qar, which located in Al-Nasiriya city/Iraq.

Data collection: Data was collected by using the questionnaire for the purpose for data collection after the researcher interviewed the students to provide overview and explain purpose of the study in simple way. The data were collected through the period from November
1st 2018 to January 2nd, 2019. The estimated time to complete the questionnaire is 10-15 minute.

**Instrument of the Study:** The questionnaire consists of two parts: demographic characteristics and scale that supposed to measure the levels of examination anxiety and academic Achievement and as following:

**Part I:** This part contains demographic characteristics of the students participated in the study and which include age, gender, college name, Stage and marital status.

**Part II:** Part (2) consists of the Test Anxiety Scale (TAS) of Sarason (1987) which measures levels of examination anxiety. This scale has (38) items. Reliability and validity of this tool is determined through application of a pilot study and panel of 15 experts.

**Statistical Methods:** Data were analyzed through the application of descriptive statistical (Frequencies and percentages) and inferential analysis (chi square).

Table (4) reveals that 13.7% of the total students who have severe and extremely severe levels of examination anxiety are within the 4th stage.

Findings show that the levels of severe anxiety and extremely severe anxiety for 400 undergraduate student both (male & female) are 47.3% and mild level of examination anxiety 18.2% and moderate level of examination anxiety 34.5%. These findings agree with study of Dawood and his team (2016) who studied the relationship between test anxiety and academic achievement among undergraduate nursing students and found that 14.4% of the students had severe levels of examination anxiety; 28.2% mild level of examination anxiety and 50.9% moderate level of examination anxiety.

Findings reveals that 28.0% of the students within age group 21 years old and more have severe and extremely severe levels of examination anxiety higher than 19.3% of the students within age group 20 years old and less with regard to severe and extremely severe levels of examination anxiety. Also 19.5% of the students within age group 21 years old and more have moderate levels of examination anxiety; more than 15.0% of the students within age group 20 years old and less are with moderate levels of examination Anxiety. The reason for the high rates of examination anxiety for the age group of 21 and above could be attributed to that many students repeat the last school year intentionally to obtain a rate that qualifies them to enter to the desired university during the secondary stage. In addition, due to the presence of five stages in two of the colleges studied, which include the age above 21 and who occupy the stage Third, fourth and fifth. It is also possible that the reason for the increasing concern is that the fourth and third stages occupy a larger percentage for the university rate and is necessary for future employment or for the master degree. This study disagrees with a study of Suarez and Quimbo (2016) who studied test anxiety and selected personal factors as determinants of academic performance of undergraduate online learners. In addition, found that the majority of those who belonged to the youngest age group of 16 to 25 years were within the high test anxiety level (13.3%) followed by those falling within the moderately high test anxiety level (10.0%). Meanwhile, most of the next older group of students of 26 to 35 years was also observed to have high-test anxiety level (4.8%) and moderately high-test anxiety level (9.5%).

Regarding findings indicates that it appeared that female students have slightly higher severe and extremely severe levels of examination anxiety. However, the recent study revealed moderate test anxiety equal among both male and female university students (17.2%), but it appears that female students have slightly higher severe and extremely severe levels of examination anxiety compared to their male counterparts. The general reasons for this finding could be numerous; lack of preparation is well-known to cause examination anxiety, the other possible reasons might be the students indulge in last minute cramming, poor time management and/or poor study habits. In addition, inadequate time to prepare, lack of advance notice, lack of clarity in the content of the examination and too much content could all contribute to test anxiety. Perhaps these reasons are applicable more to female rather than male university students for the latter sex generally go by don’t care attitude towards their subjects and exams at university level. However, the findings of present study agree with the study of Rezazadeh and Tavakoli (2009) who studied investigating the relationship among test anxiety,
gender, academic achievement and years of study. A case of Iranian EFL (English Foreign Language) university students and found that there is a meaningful difference between males and females considering the rate of examination anxiety. The mean of test anxiety score for female students ($X^2=123.72$, SD= 35) was higher than the mean of examination anxiety score for male students ($X^2=113.27$, SD= 32.14). According to stages of colleges, findings show that (13.7%) of the total students who have severe and extremely severe levels of examination anxiety are within the 4th stage more than other stages, that could be because it is the university’s final stage for most colleges and has a large proportion of the total university student rate. This study conflicts with a study of Rezazadeh and Tavakoli (2009) (9) show that juniors have the highest test anxiety level; 25 were freshmen, 35 were sophomores, 19 were juniors, and 31 were senior students. Seniors have the lowest level of test anxiety ($X^2=114.35$) and juniors have the highest ($X^2=132$).

**Conclusion**

High percentage of university students (males and females) experience levels of extreme anxiety and extremely severe anxiety before their examinations.

Influence of the Cross Linking Agent “Proanthocyanidins” on the Push-Out Bond Strength of Fiber Posts Cemented with a Self-Adhesive Resin Cement

Hamid Kasim¹, Abdulla M.W. Al-Shamma¹
¹Department of Conservative, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Grape seed extract is rich of Proanthocyanidin as a collagen crosslink which enhances the mechanical properties of dentin. This in vitro study aimed to evaluate the influence of Proanthocyanidin on push-out bond strength of prefabricated fiber post cemented with self-adhesive resin cement in different root canal areas. Method: twenty-four roots were instrumented with hand universal ProTaper System and randomly divided into three groups (n=8), according to final irrigant protocol: group1: distilled water, group 2: 5.25% NaOCl/17% EDTA, group 3: 7% PA. Samples then obturated and coronal 8mm of the obturating materials were removed and space re-rinsed with the proposed irrigating protocol respective to the groups. Fiber posts were luted using self-adhesive resin cement. Two slices from coronal and middle thirds were prepared from each root (2 mm thickness). Push-out test was performed in a universal testing machine. Bond strength data were expressed in megapascal and analyzed by one-way ANOVA and LSD test. Results revealed that, coronally, group 3 showed significantly higher BS. In the middle levels, group 3 showed significantly higher BS than group 1, while no significantly different with group 2. Conclusions: Irrigation with 7% PA showed increased BS of fiber post to root dentin.

Keywords: Proanthocyanidin, Push-out, fiber post, self-adhesive cement.

Introduction

After the finishing of root canal therapy and throughout post space preparation, once again, a heavy smear layer is formed on root dentin. This layer is full of endodontic sealer and gutta-percha remnants plasticized by the generated heat ¹,². If resin cements are used for luting fiber posts, elimination of the sealer-filled dentin is highly suggested to reach clean dentin and make a hybrid layer ³. Chemical solutions can remove the heavy smear layer from post spaces. Consequent dentinal tubules will be opened, thus enhances the intertubular penetration of adhesive materials and increases bond strength ⁴. Sodium hypochlorite (NaOCl) and Ethylene diamine tetra-acetic acid (EDTA) have wide acceptance and recommended as an efficient irrigation protocol to eliminate the remnants of smear layer ⁴. NaOCl acts selectively to dissolve the organic part of the smear layer, whereas EDTA can remove inorganic particles ⁶. Nevertheless the synergistic effect of NaOCl and EDTA may cause deleterious alterations of the biomechanical characteristics of the dentin, such as the fracture resistance, hardness, flexure strength and fatigue strength, consequently render these endodontically treated tooth more prone to vertical root fracture ⁷. Grape seed extract (GSE) mainly composed of Proanthocyanidin (PA) as a natural crosslinking agent ⁸. Several studies reported that PA enhanced the mechanical properties and bond strength of dentin ⁹-¹². To the best of the authors’ knowledge, the collagen cross-linking agents have not been so widely investigated and no study has evaluated the effect of these agents as final irrigation protocol. Hence, the rationale of the current in vitro study was to assess the effects of naturally occurring collagen cross linking agent “Proanthocyanidin” as a final root canal irrigant on the bond strength of glass-fiber post using self-adhesive resin cement, according to root thirds.

Materials and Method

Samples selection: twenty-four human palatal roots of maxillary first molars were selected and stored in 0.2% thymol solution until they were used.
**Samples preparation:** Stainless steel K-File 10# was inserted into root canal until the tip was seen just exiting at the apical foramen (observed under magnifying lens). All roots were standardized at 12mm. WL was determined by subtracting 1mm from this length. The apical foramen was sealed with sticky wax (GC, chemical Co, Japan). To prevent extrusion of irrigant out of the apex. All samples were prepared using hand universal ProTaper system (Dentsply, Maillefer, Swiss), till F4 (0.4/0.06) according to the manufacturer’s instructions. During preparation, the canals were irrigated with 2 ml of DW; this was repeated each time the instrument was removed.

**Samples grouping:** The roots were randomly divided into 3 groups (n=8) relative to the final irrigation protocol. The concentrations of NaOCl, EDTA and PA were 5.25 %, 17% and 7% respectively.

**Group 1:** Irrigation process was performed with DW only.

**Group 2:** The sequence of final irrigation was as follows:

1. 1ml of NaOCl (Wojciech Pawlowski, Poland), Endoactivator for 30s.
2. 5ml of DW and dried with absorbent paper point (#40).
3. 1ml of EDTA (Siaulial, Lithuania), Endoactivator for 30s.
4. 1ml of EDTA, Endoactivator for 30s.
5. 5ml of DW and dried with absorbent paper point (#40).
6. 1ml of NaOCl, Endoactivator for 30s.
7. Canals were finally flushed with 5ml of DW and dried with absorbent paper points (#40).

**Group 3:** The same protocol used in group 2 followed by these subsequent steps:

1. 1ml of PA (HerbStore,USA). Endoactivator for 30s.
2. Fresh 1ml of PA, Endoactivator for 30s, and then the canals were dried with absorbent paper point (#40).

**Root canal obturation:** After final irrigation, the experimentally root canals dried with absorbent paper points and filled with ProTaper F4 gutta-percha (Dentsply, Maillefer, Switzerland), and an epoxy-resin sealer (AH Plus; Dentsply, Konstanz, Germany) using single cone technique. Radiographs were taken to confirm the absence of voids in the fillings. The canal access was restored with a temporary restorative material. The roots were stored in an incubator at 37 °C and 100% humidity for 1 week to allow the sealer to get fully set.

**Post Space Preparation:** Gutta-percha was removed with Peeso reamers from size 1 to 4 at 1500 rpm with water cooling, then the custom drill of the fiber post system was used with the coincide post size. Gutta-percha was removed up to 8mm, leaving 3mm long apical obturation materials (13). The post space was filled with dual-cure self-adhesive resin cement (U-Cem, Vericom, Korea). Photoactivation was performed using LED light unit (GUILIN WOODPECKER, China) with 850 mW/cm² intensity in such a way that the tip of the light unit was directly in contact with the coronal end of the post.

**Mold construction:** A chemically cured acrylic resin was mixed according to the manufacturer’s instructions and poured into a specially designed plastic mold (12mm height and 12mm diameter). Before the acrylic resin reached the dough stage, the root with coronal part of cemented post in situ was dipped into the acrylic resin up to the coronal end of the specimen.

A protractor was used during the mounting procedure to ensure that the long axis of the root was vertically aligned.

**Fig. 1:** The plunger precisely over the fiber post

**Root sectioning:** After complete polymerization of acrylic, the coronal section of the post outside the
specimen was cut and the root was removed from the plastic mold. Two horizontal sections (2mm thick), were taken from coronal and middle thirds of each root using a precision cutting machine with a water-cooled, resulted in 16 horizontal sections of each group with a total of 48 horizontal sections for the three groups.

**Push-Out Bond Strength Test:** The thickness of each slice was confirming with a digital caliper. The push out test was applied with a universal testing machine (Laryee, China) at a speed of 0.5 mm/min. Stainless steel cylindrical plunger (1mm diameter) with a flat tip was placed at the center of the post to maintain the contact with the post only without touching the canal wall (fig.1). A plastic plate with a hole 2mm in diameter was used to provide support for the specimens during the push-out test and to allow the free motion of the plunger.

**Bond strength calculation:** Measurements were made by the device at the time that the post had left the post space. The bond strength, measured in Newton (N), was converted to megapascal (MPa) using the following formula: (16).

\[
\text{Push out bond strength (Mpa)} = \frac{F(N)}{A(mm^2)}
\]

Where,

- F = the force needed to dislodge the post,
- A = adhesion surface area.

To determine the adhesion surface area, the following formula was used:

\[
\text{Adhesion surface area (mm}^2) = 2\pi RH
\]

Where,

- \(\pi\) = the constant 3.14,
- R = the post radius (0.6mm) and
- H = the thickness of the slice in millimeters (2mm).

Since the post was cylindrical-shaped so, the diameter was the same for all specimens (1.2mm) at either the apical or the coronal side.

**Results and Discussion**

Bond strength values in MPa (mean, standard deviation, minimum and maximum) of the three groups are illustrated in table 1.

</tbody>
</table>

Coronally, the results showed that the highest bond strength was observed in G3 (19.38 ± 1.64). The second highest bond strength was of G2 (17.63 ± 1.29) While, the least bond strength was recorded for G1 (13.94 ± 1.36). Rendering the middle third, the highest bond strength was observed in G3 (17.34 ± 1.55). The second highest bond strength was of G2 (16.03 ± 1.47) While, the lowest bond strength was recorded for G1 (12.94 ± 2.00).

To compare the results of the three groups at the coronal and middle thirds, a statistical analysis of bond strength study was performed with one-way ANOVA test (Table2). ANOVA test revealed that there were statistically significant differences among the three groups at both levels.

It has been reported that, irrigants used during root canal therapy are able to affect the composition of radicular dentin. As a result, the capability of the adhesive system in making a strong bond is affected as well. Regarding the results of this test, the lowest bond strength values were found in G1, in which, the canals were irrigated with distilled water only. Followed by G2 where the canals irrigated with NaOCl/EDTA. Removal of the smear layer seems to be the most probable explanation for the positive effect of the chemical agents on the bond strength. NaOCl is the most commonly used irrigant and regarded as an excellent proteolytic agent. EDTA cleaned smear layer and debris and most of the dentinal tubules were open, which may facilitate the penetration of adhesive resin. This might clarify the improved push-out bond strengths in G2. These results were in accordance with several researches who concluded that, NaOCl in combination with EDTA could be advantageous for post space irrigation when fiber posts are bonded with self-adhesive resin cement. The reasons behind this contradictory data could be due to they did not obturate the canals in their study, while in the present study; the canals were filled with gutta-percha and AH Plus sealer. Accordingly, the composition of the smear layer in the two studies was different. Additionally, Garcia et al. revealed that, 17% EDTA and 5% NaOCl provided bond strength statistically similar to distilled water. It was noted that, in their study they applied the irrigation about 3 min for each solution, while in the present study the application time was 1 min for each. According to Jalali et al., the long time of application and a high concentration of NaOCl could affect the mechanical properties of tooth structure, which compromises the bond strength of human dentin.

Conclusion

Within the limitations of this study, irrigation with 7% PA showed higher push-out bond strength of fiber post cemented with self-adhesive resin cement compared with conventional irrigating solutions (NaOCl/EDTA). Based on the methodology used, it can be concluded that: the coronal third, regardless the irrigant employed, presented better adhesive performance than middle area.

Effectiveness of Instruction Program on Pregnant Women’s Practices regarding Anemia at Primary Health Care Centers in Baquba City

Qadessia Mahmod Dawood¹, Rabea Mohsen Ali²
¹Academic Nurse in Rufieda Nursing School in Baquba City; ²Professor, Maternal and Neonate Nursing Department, College of Nursing, University of Baghdad

ABSTRACT

Objective: To identify the effect of the Instruction program on the Practices of pregnant women who suffering anemia. A quasi-experimental design was carried out with the application of pre- post test for the study and the control group. Purposive sample, consists of (60) pregnant women diagnosed with anemia attending four health care centers in Baquba city. The highest percentage of pregnant women (30%) (33.3%), respectively, at age group (25-29) years for study and control, with regard to the educational level (30%) (36.7) respectively intermediate and primary school graduate. (96.7%) (100%) in both groups were housewives. The two groups (36.7%) were within (low socioeconomic status), (43.7%) (56.7%) having (1-2) pregnancies, in which (46.7%) of women are reveal a level of (8.1-9) g/dl that is less than normal pre instructional program and the level is increased to normal level post instructional program (10.1-11) g/dl in (53.3%), and to (> 11) g/dl in (30%) of pregnant women. The results also present that the pregnant women in study group showing fair level of Practices about anemia in pre-instructional program and their level increased to (100%) in post-instructional program. While the level of control group did not changed.

Keywords: Anemia, Pregnant women, Primary Health Care Center, Practices

Introduction

Anemia is public health problem that effects countries with low, middle, or high income (1). Anemia during pregnancy is defined by the World Health Organization (WHO) as a hemoglobin concentration less than 11 g/dL. Also anemia is considered as a condition in which the number and size of red blood cells, or the hemoglobin concentration, falls below an established cut-off value, as a result lead to impairment of the capacity of the blood to transport oxygen around the body (2). It occurs at all age groups, but is more prevalent in pregnant women and children (3). Anemia impairs health and well-being in women and increases the risk of maternal and neonatal adverse outcomes. During pregnancy anemia is responsible for a lot of complications in women. Some of those associated problems are less exercise tolerability, puerperal infection, thromboembolic problems, postpartum hemorrhage, pregnancy induced hypertension, placenta praevia, cardiac failure, low birth weight, preterm delivery, and prenatal death, therefore, children have low hemoglobin are at high risk of long term impairment in mental and motor development, lack of concentration, short attention span, easy distractibility, increased susceptibility to infection and abnormal appetite (4-5). The diet through pregnancy should contain protein, iron, vitamin B12, folic acid and mineral which are required for the hemoglobin production and Iron deficiency anemia (IDA) was considered to be one of the most vital factors of anemia (6).

Materials and Method

A quasi-experimental design was carried out throughout the present study with the application of a pre-test and post –test for the study and the control group for the effectiveness of instruction program on the
Practices of pregnant women with anemia. The study was conducted at primary health care centers in Baquba city that include: Altakia health care center, Alsaraay health care center, Altahrer health care center, Almostapha ideal health care center. The Study implemented for the period of (23th October 2018 through 15th April 2018). Non-probability (purposive) sample, consists of (60) pregnant women diagnosed with anemia attending four health care centers in Baquba city. Thirty (30) women considered as (study group) and another (30) women were considered as (control group). The study sample group was exposed to pretest, instructional program, and posttest, while the control sample group just exposed to pretest and posttest. The steps of the Study carried by assessment of pregnant women’s needs for Practices to manage anemia and by using questionnaire format to fulfill with objective of the study and consisted of demographic, and reproductive characteristics previous and current health history, Hb levels, and pregnant practices concerning anemia. An instrument was constructed through the use of (3) levels of Likert scale for the assessment of anemic pregnant women’s practices. The rating score of the instrument was (2) for I know, (1) for uncertain and (0) for I don’t know, with cut-off point=1.5. A pilot study was carried out between December 13th, 2018 to December 20th, 2018, on (10) anemic pregnant women, attending alsarai health care center, to determine the reliability of the questionnaire and content validity was carried out through 17 experts. Descriptive and inferential statistical analyses were used to analyze the data.

Results and Discussion

The analysis of demographic variable in table (1) reveals that relative to age groups, the highest percentages (30%) (33.3%) respectively for both study and control groups are (25-29) years old. The finding of the study agree with study done by Al-Muktar, (2009) about “anemia among pregnant attending labor units in two maternity hospitals in Mosul”, the study reported that the age range is (15-43) years, with mean ± SD were (28.17 ± 5.57) (7). Regarding to women’s level of education, the highest percentages (30%) for study group are intermediate school graduate, and (36.7%) for control group are primary schools graduates. With respect to women’s occupation, the highest percentage (96.7%)(100%) in both study and control groups were housewives. The study results agree with Asrie, (2017) study about “Prevalence of anemia and its associated factors among pregnant women receiving antenatal care at Aymiba Health Center, northwest Ethiopia” Most of the study participants were educated up to the level of primary school (59.7%), also found about (38.8%) of participants were housewives (8). Additionally with the results of Egryani & colleagues (2017) “about the effect of one-to-one counseling to pregnant women’s knowledge about anemia in Semarang” that found about (52.1%) of women were housewives (9). Concerning Socio-economic status the highest percentages (66.7%) (80%) respectively for both study and control groups within low category (low socio economic status). The finding agree with Prakash & colleagues, (2015) about “Incidence of Anemia and its Socio-demographic determinants among pregnant women attending for antenatal care in Nepal”; also shows that pregnant have low socioeconomic (10). Table (2) showed the distribution of the pregnant women according to reproductive history. Relative to age at marriage, results indicate that the highest percentage (56.7%) of pregnant women for both groups, their age at marriage (15-19) years old. This finding agree with Abu-Hasira, (2007) findings who has reported that the highest percentage (75.7%), is at age group of (14-16) years (11). Concerning gravid, the highest percentage (43.3%) (56.7%) respectively for study and control groups having (1-2) pregnancies. Regarding to Parity, the highest percentage (36.7%) for study group have (1-2), and (46.7%) in control group were primipara. The results agree with Obse & colleagues (2013) study who that the majority reported that average number of pregnancy about (45.2%) of the mother are in their second pregnancy (12). Additionally, A Prospective study done by Suryanarayana, (2017) on the prevalence of anemia of pregnant women and its outcome; the study reported that (45.9%) of the mother are in their primi pregnancy in study sample, and (30.4%) in control sample (13). Regarding to no. of abortions (43.3%) (23.3%) respectively in both groups confirm that they got (1-2) abortions. The study of Ahmed & others (2015) at GMC Hospital, Ajman, UAE”, found that the highest percentage (41.8%) of their findings of one abortion (14). Regarding period between pregnancies, the highest percentages are distributed between less than year and three years and more (26.7%) in the study group, but in the control group, (43.3%) were primipara, and (33.3%) of them have less than one year period between pregnancies. The finding agree with that done by Urvashi, (2018) who has reported that most
in Southern Ethiopia”, half of the pregnant women, 237 (47%) had low dietary diversity score 17. Additionally, most pregnant women have poor dietary habit and lack of nutritional education18. Regarding women’s practices related to prenatal care and visits, the study group showing fair level of practices related to prenatal care and visits in all items pre-test and showing good level of practices post-test in all items, while the control group showing the same level in pre and post periods; except the item related to “adherent to appointment to visits” that is show good level This finding agree with a study about “Anemia in Pregnancy: Prevalence, Risk Factors, and Adverse Perinatal Outcomes in Northern Tanzania”; Women who attended (ANC) or more times had lower prevalence of anemia (17.4%) than those who attended only once (35.3%) 19. Concerning women’s practices related daily habits and events, the study group in pre-test period showing poor level toward doing exercise, showing fair level toward doing hard working and lifting leg during sleeping, and good level in sleeping hours, personal hygiene and taking break or rest periods after works. The post-test showing good practices toward daily habits except doing hard work that still fair level and doing heavy work that showing poor level of practice, while the control group showing fair to good level of practices toward daily habits during pre and post-test periods, Singh, (2013) conducted a study about life behavior affects prevalence of anemia among women in India; the study results, reported that important of rest and sleep during pregnancy conserve energy, provides organ respires, relieves tension (20).

Conclusions

Majority of pregnant women practices in the study group having fair level of practice toward anemia during pre-instructional program, those practices getting better after application of instructional program in which they show good level of practice (100%). While the control group showing fair level of practice toward anemia during pre and post test periods.

Knowledge of Iraqi Midwives and Nurses about Hepatitis C Virus at Maternity Hospitals in Baghdad City

Hawraa Hussein Ghafel
Lecturer, Maternal and Neonate Nursing Department, College of Nursing, University of Baghdad

ABSTRACT

This study conducted to assess the knowledge of Iraqi Midwives and nurses about hepatitis C Virus. This study conducted at maternity hospitals in Baghdad City this hospitals includes (Baghdad Medical City Hospital, Ibn Al-Baladi General Hospital, Karkh Hospital for Childbirth and Al-Elwaya Maternity Hospital). The study starting at October 2018 to March 2019. Non probability (purposive sample) including (150) midwives and nurses that working in the maternity ward and delivery rooms to assess their knowledge about hepatitis C virus, The following statistical data analysis approaches were used in order to analyze and assess the result of the study Frequency and Percentage% & SPSS Version 24. According to the result of this study the highest percentage of Iraqi midwives and nurses have poor knowledge about hepatitis C, the highest percentage of them did not joining in a courses or lectures to increase their knowledge despite they working in the maternity wards and delivery rooms. Iraqi midwives and nurses that working in the maternity wards and delivery rooms have poor knowledge about hepatitis C Virus.

Keywords: Knowledge, Midwives & Nurses, Hepatitis C Virus, Maternity Hospitals, Delivery rooms

Introduction

Hepatitis is the term for several diseases that cause the liver to be inflamed (swollen). The most common types of hepatitis are A, B, and C. These types of hepatitis are caused by 3 different viruses 1. Hepatitis B and C are caused by viruses that are in blood and body fluids. You can get one of these types of hepatitis by being exposed to blood or body fluids from a person who has the hepatitis B or C virus4). The CDC, WHO, USPSTF, AASLD, and ACOG recommend screening people at high risk for hepatitis C infection these populations include people who are workers in a healthcare setting who have had a needle stick injury especially midwives and nurses that works in the delivery room because they are contacted with blood of women that have hepatitis C5). Hepatitis C Virus usually occurs as a result of parenteral contact with infected body fluids. Common modes of transmission for these viruses include receipt of contaminated blood or blood products, invasive medical procedures using contaminated equipment and for hepatitis B transmission from mother to baby at birth, from family member to child, and also by sexual contact 6). Hepatitis C virus (HCV) causes both acute and chronic infection. Acute HCV infection is usually asymptomatic, and is only very rarely (if ever) associated with life-threatening disease. About 15–45% of infected persons spontaneously clear the virus within 6 months of infection without any treatment. The remaining 60–80% of persons will develop chronic HCV infection. Of those with chronic HCV infection, the risk of cirrhosis of the liver is between 15–30% within 20 years. Hepatitis C is found worldwide. The most affected regions are WHO Eastern Mediterranean and European Regions, with the prevalence of 2.3% and 1.5% respectively. Prevalence of HCV infection in other WHO regions varies from 0.5% to 1.0%. Depending on the country, hepatitis C virus infection can be concentrated in certain populations (for example, among people who inject drugs) and/or in general populations. There are multiple strains (or genotypes) of the HCV virus and their distribution varies by region 7). Transmission via blood the most common

Email: hawraa_2004@yahoo.com
way to get hepatitis C is through exposure to infected blood. This can happen if the blood of someone who has hepatitis C enters your own bloodstream. This might happen if you: use a needle or syringe to inject drugs into your body that someone with hepatitis C has already used or are injured by a needle stick in a lab or other healthcare setting, if that needle has come into contact with blood infected by hepatitis C share razors, toothbrushes, or other personal hygiene items that may have touched an infected person’s blood. Sexual transmission According to the Centers for Disease Control and Prevention (CDC), you can also get hepatitis C from sexual contact. But certain sexual behaviors are riskier than others when it comes to increasing your chances of becoming infected. You increase your risk of getting hepatitis C if you: have more than one sexual partner have a sexually transmitted disease have HIV engage in sex that’s rough or could cause bleeding The National Institutes of Health (NIH) advises condom use during sex to help prevent the spread of infection. Tattooing or piercing The CDC notes that infectious diseases like hepatitis C can be transmitted through unregulated settings that provide tattooing, body piercing, or body art. Commercially licensed tattooing businesses are generally thought to be safe. However, more informal settings that offer tattooing or piercing services may not have adequate safeguards to help avoid the spread of infections. The Centers for Disease Control and Prevention (CDC) state that approximately 70 to 80 percent of people with hepatitis C don’t have symptoms. While this is true, some people report mild to severe symptoms. These symptoms include: fever dark urine loss of appetite abdominal pain or discomfort joint pain jaundice. The symptoms may not show up right away. Some may take six to seven weeks to appear. Learn more about the symptoms and delayed symptoms of hepatitis C. Several risk factors have been studied, in which many have been determined as independent risk factors of HCV infection. Well known risk factors for HCV infection take in Intravenous Drug Use (IVDU) contact with infected blood products, and intranasal drug use. High-risk sexual activity, tattooing, and skin piercing have also been recommended to be associated with increased risk for HCV. As well, mother-to-infant transmission has been established, but it is a rare cause of transmission of hepatitis C. Nurses should include patient education in their responsibilities to patients with hepatitis C. With 3.2 million Americans carrying the hepatitis C infection, according to the Centers for Disease Control and Prevention, most nurses will encounter patients with the chronic liver infection at some point in their career. Nursing responsibilities when caring for hepatitis C patients include educating patients and families about the disease and preventing transmission of the infection to themselves or other patients.

Materials and Method

Descriptive study conducted to assess the knowledge of midwives and nurses about hepatitis C virus at maternity hospitals in Baghdad city. Midwives and nurses are usually in contact with human blood and fluids. It is useful to study their knowledge about Hepatitis C virus. The study was conducted at the following maternity hospitals: (Baghdad Medical City Hospital, Ibn Al-Baladi General Hospital, Karkh Hospital for Childbirth, Al-Elwaya Maternity Hospital). The study started at October 2018 to Mach 2019. Non probability (purposive sample) consist of (150) midwives and nurses that working in Maternity wards and delivery rooms. Participation in this study was voluntary. Data was collected after obtaining ethical consent from all participants. A developed questionnaire by the researcher was used to collection of the data from the sample this questionnaire consist of two main parts:

Part 1: Demographic Data: this part contain demographic data about the study sample such as (Age, occupation, Current work department, Name of the current Hospital, the number of years employed in this profession, educational level, Educational Courses and Continuing Education in their work place about Hepatitis, the source of information about Hepatitis. Part 2 consist of 22 questions regarding hepatitis C virus to assess the Knowledge of Midwives and nurses that participants in this study. Descriptive and inferential statistics were used through the Microsoft Excel Database jointly with the Statistical Package for Social Sciences (SPSS, Version 24). The P value of ≥ 0.05 was considered as non-statistically significant. The P value of ≤ 0.05 was considered as statistically significant. The P value of ≤ 0.01 was considered as highly statistically significant.
Results and Discussion

Figure 1: Distribution of the Nurse-Midwives according to their Age (N = 150)

Figure 1 shows that nurse-midwives are young with age of (20 -29) years which refer to the highest percentage among sample (29.3%).

Conted…

Table 1 reveals that the highest percentages of nurse-midwives are working at Al-Elwiya and Al-Karkh hospital (28.7% and 28%), (69.3%) of them are working in delivery rooms. About half of them are working for period of (1 – 5) years of service (49.3%). They refer that (64.7%) are participating in training courses. Regarding source of information about viral hepatitis C, they show that half of them are getting information from training courses (50.7%) and remaining were getting information from posters, scientific symposium and television.
Poor = 22 – 36, Fair= 37 – 51, Good= 52 – 66

Table 2 indicates that more of the nurse-midwives are having poor level of knowledge about viral hepatitis C (88.7%) while only (11.3%) of them are showing fair level of knowledge.

P: probability, H.S: High significant, N.S: Not significant

Table 5 depicts that there is high significant relationship between nurse-midwives’ knowledge with regard to department they are working in and participation in training course at p-value (0.002 and 0.001) respectively and no significant relationship has been seen with regard to years of service and source of information. This study shows that nurse-midwives are young with age of (20 -29) years which refer to the highest percentage among sample (29.3%). Nurses and midwives are more likely to be women, with women making up 89.3% of all employed nurses and midwives in 2015, around the same as in 2014 (89.4%). The average age of employed nurses and midwives in both 2011 and 2015 was 44.4 years. The proportion aged 50 and over grew from 38.3% to 39.0%, although this was less than in 2014 (39.4%). Between 2011 and 2015, increases occurred in the number of employed nurses and midwives in both the 25 to 34 age group (51,686 to 65,099) and the 55 and over group (63,170 to 77,608). Between 2011 and 2015, there were more employed nurses and midwives in the 50–54 year age group than any other age group. The finding of this study agrees...
with that study the incidence in (25-54) year’s age group (9). This study shows that (36%) of nurse-midwives are graduated from nursing school and (33.3%) are graduated from nursing school. American College of Nurse-Midwives represents over 11,000 Certified Nurse-Midwives (CNMs) and Certified Midwives (CMs) in all 50 states and most US territories. In 2005, In terms of gender, only 2% of CNMs are men. They are able to prescribe some medications, use certain medical devices, and implement therapeutic and diagnostic measures. The finding of this study disagrees with Iraqi midwives and nurses (10). The highest percentages of nurse-midwives are working at Al-Elwaya and Al-Karkh hospital (28.7% and 28%), (69.3%) of them are working in delivery rooms. About half of them are working for period of (1 – 5) years of service (49.3%). They refer that (64.7%) are participating in training courses. Regarding source of information about viral hepatitis C, they show that half of them are getting information from training courses (50.7%) and remaining were getting information from posters, scientific symposium and television. Nursing midwives may choose to work through private clinics, but some also work in hospital settings and the clinics of other physicians and nurses to provide care alongside other medical professionals. This can be a highly stressful job depending on the circumstances, and a nurse midwife is always on call when a patient suddenly goes into labor. CNMs work in many places. Most often, they work in private practice, hospitals, birthing centers, health clinics and home birth services (11). Most of the Iraqi midwives and nurses are having poor level of knowledge about hepatitis C virus (88.7%) while only (11.3%) of them are showing fair level of knowledge. A contributing factor for the transmission of Hepatitis B and C virus in developing countries is poor awareness of the population. Almost all types of health care workers are at the risk of having Hepatitis B and C virus and they must acquire a higher level of knowledge for protection. Awareness about modes of transmission of Hepatitis B and C virus and vaccination is essential for universal precautions among the health care workers, where it was found that the knowledge is correlated positively with the behavior. In this study there is significant relationship between nurse-midwives’ knowledge with their age group at p-value ≤ 0.05 respectively, there is significant relationship between nurse-midwives’ knowledge with their level of education at p-value ≤ 0.05 respectively, there is high significant relationship between nurse-midwives’ knowledge with regard to department they are working in and participation in training course at p-value (0.002 and 0.001) respectively and no significant relationship has been seen with regard to years of employed and source of information. Cetinkaya S. stated that it is so important to investigate the factors that affected Hepatitis-B Vaccination (HBV) knowledge of the nurses and midwives, serving at various medical facilities as part of the primary healthcare services in Konya, Turkey. The study was including 127 consentient nurses and midwives (out of 161) serving at 22 different healthcare centers in the region. In the survey, their source of information with regards to HBV vaccination varied from continuing education programs (37%) to book or brochure reading (11.8%), and their formal nursing education (11%) (13)(14)(15).

Conclusion

Iraqi midwives and nurses that working in the maternity wards and delivery rooms have poor knowledge about hepatitis C Virus. The highest percentage of them did not joining in a courses or lectures to increase their knowledge despite of their working in the delivery rooms and maternity wards. So, special training programs should be given to Iraqi midwives and nurses to prevent transmission of hepatitis C virus.

Source of Funding: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: The first approval was obtained from the Council at College of Nursing, University of Baghdad; the second approval was obtained from Iraqi Ministry of Health, official permission was obtained from the following maternity hospitals: (Baghdad Medical City Hospital, Ibn Al-Baladi General Hospital, Karkh Hospital for Childbirth, Al-Elwaya Maternity Hospital). Participation in this study was voluntary. Data was collected after obtaining ethical consent from all midwives and nurses they were participants in this study.

The Impact of Strategic Defense in Attainments and Growing the Mind Thinking for the Students

Qais Talib Abdul-Zahraa1, Firas Saleem Hayawi1, Hamdan Mahdi Abbas Al-Juburi1

1The Basic education College, Babylon University, Babylon Province, Iraq

ABSTRACT

This studying aims to knowing the impact strategic defeuce about views in at tainmeut History Subject and retaining it at fourth literary students, Which depends on experimental approach to be appropriate approach for searcho’s proceeding, so, the search sociy familiarized from the preparatory and secoundary school in Babylon province Al-Hashimyha magistracy, It had choiced one of these school which is Al-Quds preparatory to be search’s sample and the experiment applied in to two groups : The first is experimental group which studied with strategicedefeuce about views, and the second group is tuned group which studied in traditional way. The searcher proportionated between the two search group in some changes like the student’s age counted in months. The results of search showed that the experimental group supermacied to the tuned group in the attainment test which means that there is a differentiate that countably denote at denote level (0.05) and for experimental group. Also this studying showed the thinking mind role in expressing opinions and discussing between the participated parties for getting the right idea or right opinions that getting the agreement of all.

Keywords: Strategic defence about views, attainments and growing the thinking mind at students.

Introduction

Pedagogy is repansible about the trends development to the Society’s Individuals around the prodtactive work and encourage the students to join the occupational and Technical education programme. This obligates that the pedagogy in stitions don’t care only of thierotical side but it must can cent rate on the applicative side too 1. This instution must encourage students to work and doing occupational activities and participate in lot of activities that accidence their thencies and serves their sociy needs 2. It must belive that the students directions to work will not be only and by actualpartic pation in working and do not achieve iust by casting moralizaing and lectures 3. The social subrects conected tightly to arael life with in it different externals and it initialize varity domains helps to desired social growth. also, it helps the students to grow perfectly by warions activity dials Gunected to it studying. The history science cousider establisher and devices that makes it functional, great science has a distingushible slature between the sciens effect 4. History is inveterate roots in depth at now days that man live in. In addition to it deep root which extended to very old past assets in all stages So, studing history be coms scientific, social, educational can’t dispensable from it at any time. It surround the students with useful science historical events that the word and the Arab home passing. History is honest log to historical event over the ages. So, The searcher thinks that history subject gets areigious stature in approach to all stages, because it instilled the scientific thinking at students demodulation lessons and expressive and forming the thinking that studs on historical understandings knowledge, express the historical event scientific expression. The importance of views stout on that there is direct interaction between all participater inorder to achieve aims and reconciled which usually be has a combined ben fit between them 5. The purpose of defence about views is either discussions or dialogue or opponion’s excretion between all sides inorder to arriving to right idea and right opinion or views that will be all individuals agree dresn’t stauds on

DOI Number: 10.5958/0976-5506.2019.03295.9
losing or benefit principle. Attainments has an important by what individual can achieve to himself in all his life stage serially and graduated from childhood to advanced steps of his age from science and knowledge, within the science can move from the present stage to the next are and continuous in development. Searchers think the lever of education attainments is the mark that students can got at any mastered exam or any school exam at subject. Searcher thinks that education attainment has a great importance in student’s life and his family. It not just exceeding an education stage successfully and getting high marks qualified him, but it has an important sides consider it the obligated way to choose kind of studying and the job that he will get it, also attainment has very great importance in social view to individual and his attainment level and dis satisfying the person himself and don’t feeling demerit.

Methodology

It represent in usage’s approach in search, the samples individuals, valence his two group tuned and experimental, disciole the inner changings, and search supplies ; his devices and the setting ways and its honest and it fixity, The experimental application procedure, the counled means which depend it lok now, the impact of strategic defence about views in attainment history subject retaining it to students the fourth literary class.

The experimental design: The experimental design individuate between all the search approach. The experimental search be distinguish in uniqueness for two reasons : It’s the only kind that try to effect directly on certain changing also can test the assumptions truth around called (The cause and effect relation) the below table explain that

Table 1: The modern design to search

The search so city and the sample: It includes the search so city to forth literary students all of then in preparatory and secondary governmental for boys following to the general directorate for pedagogy in Babylon province Al-Hashimyha magistracy 2018-2019 after knowing the names of preparatory and secondary schools governmental followed to the general alirectorate for pedagogy in Babylon province, Al-Hashimyha magistracy. The user chose randomly Al-Quds preparatory among 13 schools to applied his experimental in after choosing the school which will make the experimental in by the searcher which visit the school according to facilities errand expropriation from the general directorate for pedagogy in Babylon province, He founds that the sechdil two classes for fourth literary class. The searcher choose B class by randomly hauling to represent the experimental group. The student number is 33 student which will their student study according strategic defence about views and at the same way the searcher choose randomly class A to represent the tuned group and their students is (32) which will study according an usu all studying. After knowing don the student’s impormation from the formal logs of school. It had found that there was pervions precipilate of fourth liter vary include the search two grous. They found 3 status failure within the experimental group and one within the tuned group to be to total number for search sample (61) student after improbabilities. The reason in probabilities of the failure student from the counted procedure. Is the keen ness of the because they have previons experts in scientific matter table number (2) explain that.

**The Intruder changes disciple:** In addition to what proceeding to valence countably procedure among the experimental and tuned search group, the search try to avoid the impact of some Intruder changes (in experimental) in the experiment happened, the thing that increase the confidence with inner honest to experiment then in results, one of the se changes (the sample choosing, the accompanying accidents, the experimental absorption, the maturity process, the device’s measurement and the Impact of the experimental procedure.

**The search Supplies:** The scientific subject limitation (content): The searcher limits the scientific matter that will studied to the two group search student the experimental and tuned which repersnt the last five doors in the Arab Islamic civilization history 2018-2019. In order to check its expiry, the searcher showed on experts and specialists in pedagogy and teaching modalities. the searcher depends on (80%) percent the validity normative of these aims after some suitable modifying procedures so the behavioral aims (125) goals after improbabilities of 2 aims by experts the table 7 show that. The searcher make attain mental test according to scientific subject content that it decided to studying in the experiment from History subject that it decided to study for fourth literary class and the behavioral aims for Bloom’s sixth levels which are (knowledge – understanding – application – forming – Analyzing and assessing). this test consider as measurement device to attainment fourth literary class student in five doors matters from Arab Islamic civilization History. After finishing from History book studying Arab Islamic civilization, limit number test paragraph with (50) a pligatory paragraph. In order to check the test history. The searcher use phenotype honest and in order to check this type of honest. It had distributed the test on group of specialist and arbitrtors to judge on paragraphs validity and
it’s inclusion extent to the decided subject and it’s right distribution according to six knowledge levels (Bloom’s classification). The paragraph considered useful if it got on dealing (80%) percent above from the arbitrators and specialist totals. First, the test applied on two sample, in order to be sure from the test instruction clarity and the countable analyze to it paragraph as following: The first sample reconnaissance. It’s sample of clarity of instruction and paragraph. To know the extent of clarity of the paragraph test, it’s instruction and the ambiguous paragraph, diagnosing the time that taken on answering about it. The searcher applied the test on Wednesday 10/4/2019 on the sample consist of (40) student in Al-Hakeem’s preparatory in Al-Hashimyha magistracy after it and distributed the test and enquire on any phrase they found it unclear. It had check the extent of the test clarity and it’s paragraph because the enquire and question lack from the students side about how to answer, with exception some words that not understood which had explained. It had connected the answers time which the students take in answering about the test paragraph, and record the time of each student at the end of answering according to Equation. The second reconnaissance sample, the countable Analyzing. The aim of Analyzing of the paragraph test is to improving the test by reveal about weak paragraph and to work on reforming, delete or excused the un useful one. Also, doubtlessness that the test paragraphs care of individual distinctions among students where by easiness, difficulties and the ability of characterizing among students that have high and weak lienability inorder to make countable Analyzing to paragraph’s test. It has counted each paragraph difficulty level and distinguished power and the effectiveness of the wrong alternative. So the searcher applied the test 14/4/2019 in Al-Medhatiyya preparatory on asc wound sample consist of (100) answers then it has arranged the marks descend from higher to lower marks. It has chosen (27%) percent from the sample student who get higher marks and 27% from the sample, student who get lower marks. The totaled number of students become (27%) in each group. This percent had chosen because it represent all the samples, Next explaining to analyzing countable test paragraph. It had used equation paragraph difficulty modulus by using equation difficulty modulus is between the difficulty modulus to the paragraph objective test (0.70-0.37) while the difficulty modulus to the essay objective paragraph. It had found that between (0.43-0.33) while the distinguish power to the essay paragraph is between (0.43-0.33). During the anylaze procedures that the searcher followed in finding distinguish paragraph power showed all paragraphs is valid according to distinguishing power. The searcher arrange the students answer and he distributed between two group, supreme and minima and after counted the effectiveness of the wrong alternative showed that it limits between (0.04-0.26) this denote that the wrong alternative attracted number of minima group student more that supreme group. So, it had maintained on this alternatives. In order to check the zero assumption results which stipulate on “There is no difference that countable denotator at the denotation level (0.05) among the average marks of experimental group who will study according to strategic the defence about views and the average marks to the students within the tunned group who will study according the traditional way in attainment and retaining history subject to fourth literary class The results showed that there is difference the countable denotation between the marks average of the two search group (experimental and tunned) in attainment test and for the experimental group.

**Conclusion**

At the search results it had come up to that effectiveness of strategic defence about views works on attainment students increasing to history fourth literary class student. So, they transcendence on the tunned group who study in traditional way and that the studying of fourth literary students according to strategic defence about views to history subject make them attentive in the lesson, woke up to what happened around them that what the searcher touch along the search period. This stratagy contributed in make the students effective and participated. In the lessons during the dialogue and the discussion and answering the questions which raised during the lesson. Consequently this stratagy had the role in increasing the students attainment toward the subject and keeping information for period of time.

Assessment Nurse’s Knowledge toward Nursing Management for Patients Post Cholecystectomy in Kirkuk City Hospitals

Tholfikar Haider Selman Hussein¹, Khalida Muhammad Khudair²
¹Academic Nurse, Ministry of Health, Iraq; ²Professor Doctor, Nursing College, Baghdad University, Iraq

ABSTRACT

Objectives: To assess nurse’s knowledge toward nursing management for patients post cholecystectomy. 20 nurses chosen by non-probability sampling (purposive sample). The study instrument was a questionnaire (multi choice question) consist of 20 items nurses had low level of knowledge when response to the study questionnaire and the grand mean was (1255). The critical care need to professional nurses working at this situation to provide a high level of care.

Keywords: nurses, knowledge, post cholecystectomy management

Introduction

Cholecystectomy is removal of gallbladder through an abdominal incision (usually right subcostal) after the cystic duct and artery are ligated. The procedure is performed for acute and chronic cholecystitis. In some patients a drain is placed close to the gallbladder bed and brought out through a puncture wound if there. (1) Surgical complication include wound infection, adverse reaction of anesthesia, injury of liver, pancreatitis occur about 5%at time laparoscopic procedure open cholecystectomy have more complication; bleeding, Injury to the bile duct, deep vein thrombosis, Injury to the intestine, bowel and blood vessels, Bile leakage. (2) Nurses who provide postoperative care must have knowledge and practice of the implications of the procedure, clinical manifestations of complications, and risk factors. Identifying patients at high risk for adverse outcomes allows the nurse to anticipate the needs of the patient and provide a less stressful postoperative experience. (3) Nursing care is important during recovery. Nurses must be prepared to prevent postoperative complications, rather than waiting to treat them. Nurses can provide excellent care if they are able to anticipate a patient's needs, intervene early when symptoms first appear, provide reassurance to alleviate patients’ unease during the recovery process, and educate patients to alleviate unnecessary anxiety related to discharge expectations. (4)

Methodology

Subjects: (20) nurses from Kirkuk General Hospital and Azady teaching hospital working in surgical care units chosen by non-probability sampling (purposive sample).

Instruments: The study instrument was constructed depending on literature reviews and previous studies related to the management for patients post cholecystectomy. It is a questionnaire format for the research purpose and composed of 2 parts and these parts are 1st part (general information part which include age and gender) and 2nd part (The knowledge instrument is consisted of (20) items). The knowledge part was a multi choices question for the nurses knowledge, multi choices question has been scored and rated on two levels dichotomous scale (2) points for the correct answer and (1) point for the un correct answer which assessed by cutoff point (0.33) due to scores (1 and 2) respectively. Scores of responses are categorized according to the following level of nurses’ knowledge: (1-1.33) = low level of knowledge, (1.34-1.67) = moderate level of knowledge and (1.68-2) = high level of knowledge.

ABSTRACT

This study aims to find whether the elevation or the reduction of ChEs levels can be related to the diabetes mellitus and/or dyslipidemia. This study is considered as case-control comparative study. The human plasma and erythrocyte cholinesterase activity was tested in 5 groups. Groups 1 and 2 were type 2 hyper- and normo- lipidemic diabetic patients respectively with good control of diabetes. Groups 3 and 4 were type 2 hyper- and normo- lipidemic diabetic patients respectively with inadequate control of diabetes. Group 5 included patient with hyperlipidemia only. The control group consisted of apparently healthy subjects with no history of diabetes or hyperlipidemia or exposure to anti-ChE insecticides or drugs. Also fasting serum glucose, HbA1c and the serum lipid profile were estimated in these groups. The results indicate that there is a relation between the BChE and diabetes, but no such relation could be seen with AChE. Also there is similar relation between the dyslipidemia and the both types of the ChE. The combination of inadequately controlled diabetes with dyslipidemia can cause elevation in both types of ChE enzyme but less than that of dyslipidemia alone.

Keywords: Cholinesterases - Diabetes - Hyperlipidemia - AChE - BChE.

Introduction

Cholinesterases (ChE) are enzymes that catalyze the hydrolysis of the acetylcholine into choline and acetic acid to allow a cholinergic neuron to return to its resting state after activation. There are two types of cholinesterases enzymes. 1. Acetylcholinesterase (AChE), also known as true or erythrocyte cholinesterase, found primarily in the erythrocytes and some neural synapses. Pseudocholinesterase (BChE), also known as plasma cholinesterase, butyrylcholinesterase with a lower specificity for acetylcholine, found primarily in the plasma, liver, glia and many other tissues. The physiological functions of plasma ChE are not known, but one idea is that they protect the body from natural anti-ChE agents (e.g. physostigmine, a plant alkaloid) encountered during the evolution of species. Also it has been shown that BChE is involved in lipid/lipoprotein metabolism. Diabetes mellitus (DM) is defined as an elevated blood glucose associated with absent or inadequate pancreatic insulin secretion, with or without concurrent impairment of insulin action. Hyperglycemia is a common end point for all types of diabetes mellitus and is the parameter that is measured to evaluate and manage the efficacy of diabetes therapy. In these studies, BChE activity correlates strongly and positively with serum levels of low density lipoprotein (LDL)-cholesterol and triglycerides (TG) and inversely with serum high density lipoprotein (HDL)-cholesterol. All these observations suggest a relationship between BChE activity and lipoprotein metabolism, but the rationale for this connection is unclear. On the other hand other researchers indicated the opposite, as their results indicated that the relationship between serum lipid/lipoprotein metabolism and BChE activity
in diabetes lacks any strong supportive evidence. So there is a controversy about the level of plasma and erythrocyte ChE that may be increased or decreased or even remain normal in diabetic and in hyperlipidemic patients. However, other studies have suggested BChE may not have a direct pathophysiological role in the development of metabolic syndrome and diabetes. This study’s objective is to find whether the elevation or the reduction of ChEs levels can be related to the DM and/or dyslipidemia. Such a relationship could be considered as a diagnostic parameter for such diseases, if proved.

**Materials and Method**

This study is a case-control comparative study. The study took place in Al-Wafaa Center for Diabetes. The subjects included in this study were male and females, whose age not less than 30 years. The human plasma and erythrocyte cholinesterase activity were tested in 5 groups (30 patients for each group). Groups 1 and 2 were hyper and normo-lipidemic type 2 diabetic patients respectively (duration of diabetes and hyperlipidemia was not less than 3 years) with HbA1c = 5-8% (indicating a good control of diabetes). Groups 3 and 4 were hyper and normo-lipidemic type 2 diabetic patients respectively (duration of diabetes and hyperlipidemia was not less than 3 years) with HbA1c >10 (bad control of diabetes). Group 5 were patients with hyperlipidemia only whose duration was not less than 3 years. The control group consisted of apparently healthy subjects with no history of diabetes or hyperlipidemia or exposure to anti-ChE insecticides or drugs. Patients taking any medications other than oral hypoglycemic and antihyperlipidemic drugs (as these drugs have no effects on the ChEs levels) or exposed to anti-ChE insecticides or drugs were excluded. Also patients were excluded if they had chronic cardiac illness (ischemic heart disease, heart failure, cardiac arrhythmias), chronic liver disease (hepatic failure, active hepatitis, liver cirrhosis), renal complications and any other chronic debilitating illness. Blood samples were collected in 5 ml EDTA-treated test tubes then centrifuged at 3000 rpm for 15 min. The erythrocytes and plasma were separately kept on ice for ChE assay. The rest of the sample was used for the glucose and lipid profile assay. In our work we used the modified electrometric method for the assay of ChE activity, validated in humans. The reaction mixture in a 10 ml beaker contained 3 ml distilled water, 0.2 ml plasma or erythrocytes and 3 ml pH 8.1 barbital-phosphate buffer. The pH of the mixture (pH1) was measured with glass electrode using pH meter, then 0.1 ml of aqueous solution of acetylthicholine (7.5%) was added to the reaction mixture which was incubated at 37°C in water bath for 20 min. At the end of the incubation period, the pH of the reaction mixture (pH2) was measured. The enzyme activity was calculated as follows:

\[
\text{ChE activity (pH/20 min.)} = (\text{pH1}-\text{pH2})-\Delta \text{pH of blank}
\]

The blank contained no blood aliquot. The barbital-phosphate buffer solution consist of 1.24 g sodium barbital (BDH), 0.163g potassium dihydrogen phosphate, and 35.07g sodium chloride (BDH) dissolved in one liter distilled water. The pH of the buffer was adjusted to 8.1 with 1N HCL.

Fasting serum glucose (FSG) was estimated by glucose–oxidase–peroxidase colorimetric method (spectrophotometer (Optima) Japan), by using a kit supplied by Biocon company (Germany). Glycated hemoglobin HbA1c was measured in whole blood sample by ion-exchange resin quantitative colorimetric determination, using a kit supplied from Stanbio (USA). Determination of serum TC concentration was done by the enzymatic colorimetric method, using total cholesterol BIOLAB kit (France). Determination of serum TGs concentration was done by the enzymatic colorimetric method, using triglycerides BIOLABO kit (France). Determination of serum HDL-c concentration was done by the precipitation method, using HDL-c BIOLABO kit (France). Low density lipoprotein cholesterol (LDL-c) was calculated by Friedewald formula:

\[
\text{LDL-c} = TC - (\text{HDL-c} + \text{TGs/2.2})
\]

VLDL-c calculated according to the following formula.

\[
\text{VLDL-c} = \text{TGs/2.2 (mmol/l)} \ (29)
\]

Analysis of variance (ANOVA) followed by the least of significant difference test (LSD) post hoc test was used as the statistical method. Additionally, simple Student’s t-test was used for the comparison between the means of all groups (30). The level of significance was set at P<0.05.
Results and Discussion

Table 1 represent the results of the FSG, HbA1c, TC, TGs, HDL-c, LDL-c VLDL-c, BChE, and AChE of the control and the tested groups. The current study demonstrated that Group 1 shows significant alterations and changes in the lipid profile since the patients were already hyperlipidemic, the HbA1C also showed elevation as compared with control group, although the FSG was slightly elevated, this could be attributed to the lipid profile derangements which may affect the liver parameters. In this group the BChE was also significantly elevated with no change in AChE. Published data suggest association between BChE activity and lipid metabolism and weight and body mass index (BMI) 31,32. Moreover, mean BChE activity tends to be higher in obese subjects than in nonobese individuals. Obese humans have high plasma BChE activity, whereas starved humans have low plasma BChE activity 33. Group 2 shows little change in the lipid profile parameters as there is a little elevation of LDL and decrease in HDL, this can be attributed to the eating habits of fats in our locality. Also in this group the BChE shows a significant elevation as compared with the control group. Group 3 like Group 1 shows remarkable changes in the lipid profile as they were initially diagnosed as dyslipidemic patient, also the FSG and HbA1C were significantly elevated as they were uncontrolled diabetic patients. The ChE shows different picture in this group as the BChE was significantly elevated higher than all other diabetic groups and the control group, also the AChE in this group was elevated significantly. This may explained by the inadequate diabetic control (elevated FSG and HbA1C) 34 and having dyslipidemia 35. Coexistence of diseases may affect lipid metabolism and its hemostasis causing abnormality and remarkable change in BChE (more than that of the other groups), resulting in changing the hemostasis between the two types of the enzyme (from their site of production) that may cause change in the AChE level. The results by Mushtaq et al., indicated altered levels of AChE and BChE both in Alzheimer’s disease (AD) as well as in T2DM imply that those two enzymes may be playing a pivotal role in the pathogenesis of the two disorders. AD and T2DM are both characterized by elevated levels of AChE and BuChE in the plasma 36.

Conclusion

There is a relation between the BChE and diabetes (as there is an elevation of its level in all diabetic groups), but no such relation could be seen with AChE. There is similar relation between the dyslipidemia and the both types of the ChE. The combination of poor control of diabetes and dyslipidemia can cause elevation in both types of ChE enzyme but less than that of dyslipidemia alone (i.e. the diabetes may reduce the effect of the dyslipidemia on the production of the two types of the ChE, as seen in group 3, or the diabetes and dyslipidemia are both affecting the ChE level in different ways -each one act alone- as the diabetes is affecting BChE only and the worse dyslipidemia is affecting both ChE types).

The Impact of the Formal Strategy of the Theory of Cognitive Burden in Acquiring the Concepts of Middle School Students

Nada Khudair Ali al-Shammari¹, Hamdan Mahdi Abbas al-kraee¹, Abbas Karim Abd al-Khafaji¹

¹Faculty of Basic Education, Babylon University

ABSTRACT

The present research aims to identify the effect of the formal strategy based on the cognitive burden theory in acquiring the historical concepts of the fourth grade students. The research was conducted on the fourth grade students. The school was randomly selected (Al-Mahaweel Preparatory School for Girls with 61 students). The researcher used the experimental method as the most suitable method for this research. The experiment was applied to the two research groups with a period of (1) years (8 weeks), and used the methods (t-test, kai square (k²), coefficient of paragraph distinction, coefficient of paragraph difficulty, effectiveness of wrong alternatives, Pearson correlation coefficient, Spearman-Brown correlation coefficient). The researcher found that there was a statistically significant difference between the two groups of research in the post-acquisition experiment in favor of the experimental group.

Keywords: Formal strategy, cognitive burden, historical concepts, preparatory stage.

Introduction

Education comes as a mainstay in the building and individualization of the individual as it includes the types of activities that affect the individual and his preparations, behavior, mental orientation, intelligence and skills, and the installation of its effects on his personality in physical, mental and psychological dimensions. The duty of education is the responsibility of building a scientifically educated person who must possess a degree of knowledge and awareness of the general issues related to the various spheres of life so that he can make the right decision regarding the situations and problems he has faced in a society that is constantly changing and evolving. The impact of this development in the field of education and teaching methods. It is also reflected in the need to teach the teacher to acquire modern teaching skills, which may facilitate the process of learning and teaching, and promote his role as a guide, facilitator and facilitator of the teaching process through modern and unconventional teaching methods. In recent years, several educational theories have emerged, based on a number of methods and strategies used in teaching. These theories include the theory of cognitive burden (John Sweller). A University of New South Wales University of Psychology, where this theory is based on the concepts of information processing in memory and the development of schematics and the mechanism of procedural knowledge. The cognitive burden is the total mental activity that occupies the capacity of the working memory during a certain time. Based on this theory, the theory emphasized that limited working memory capacity is one of the obstacles to learning, and that these obstacles must be addressed through the change of traditional learning and teaching designs. Therefore, the theory of the cognitive burden of many of the design of learning and education is based on knowledge of cognitive engineering. One of these strategies (formal strategy) aimed at expanding the limited working memory through the use of visual learning or audio learning. Historical concepts form a broad base based on the use of a single type of historical material, where the understanding of the teachers of the events is determined by the depth, breadth and diversity of their achievements of the concepts. As the learner gains from concepts, new attitudes and experiences lose their difficulty and thus the learner is able to interpret and think well. Thus, the acquisition of students of historical concepts is one of the most important
fundamentals of the study of history, in turn, constitute the necessary basis for the cognitive behavior of learners and it constitutes an important educational goal at all levels of study because they contribute significantly to the learning process.

**Methodology**

The researcher followed the experimental approach in the conduct of the research because it is characterized by two reasons: It is the only type that directly try to influence a particular variable and also he can test the validity of hypotheses about the so-called reason relationship and the following table shows this:

**Research community and design:** The research society included fourth grade students in the preparatory and secondary day schools in Mahaweel district/Babil governorate.

The sample of the study was randomly selected. The Mahaweel Girls’ Preparatory School was the site of two groups, one of which was chosen randomly to be experimental group, and the other group was a total of 63 female students with 31 experimental students. The following table shows the following:

**Table 1: Distribution of students of the research sample before and after exclusion on the two research groups**

</tbody>
</table>

**The control of extraneous variables:** Although the researcher investigated the equivalence of the two sets of research in variables that I think affect the course of the experiment, they tried to avoid the effect of some extraneous variables in the course of the experiment. These variables are: Accidents associated with the experiment: The sample was randomized and the two groups were confirmed.

**The maturity factor:** Because the duration of the experiment was uniform between the two research groups, and the age of the students in both groups was close, this will affect the experimental measures. The researcher worked to limit this factor because it affects the dependent variable during the course of the experiment.

**Research tool:** Test the acquisition of historical concepts and designed the researcher tested the research and then was presented to a group of experts and specialists and after the amendment and then test students.

**Determine the purpose of the test:** The purpose of this test is to measure the acquisition of fourth-grade literary female students of historical concepts.

**Determination of the objectives of the test:** The researcher identified behavioral goals that are (60) behavioral goals after setting the purpose of the test.

**Determination of the test paragraphs:** The test paragraphs were formulated in their preliminary form and consisted of (20) paragraphs divided into three levels (definition, discrimination, application)

**Test instructions:** The instructions for the test and how to answer (selecting one correct alternative to the paragraph, answering all paragraphs, the time period for answering, typing the triple name, the class and the division in the assigned space).

**Correcting the test answers:** After the test paragraphs have been formulated, a standard has been set to correct the answers, with one score for each correct test paragraph, zero for the wrong answer, and the left over paragraph that the student answers. Therefore, The historical concepts are (60) degrees and the minimum is (zero).

**The truth of the test:** Honesty: It is to measure the test in what is put for it

In this way, the researcher relied on the veracity of the test to verify that the test verbs actually measured the behavioral objectives. It can be defined as the simplest and most reliable types of honesty and used in the tests because it is the easiest in terms of its procedures and its reliance on the logic guaranteed by the test and its relevance to the measured attribute.
Statistical analysis of the test paragraphs: The test paragraphs were analyzed as follows:

A. Coefficient of difficulty paragraph: It means the proportion of the number of students who answered the paragraph answered correctly to the total number and called the amount of this ratio “difficulty coefficient”. If the value of the amount increases, it indicates the ease of the paragraph, and if the value of the value decreases, it indicates that the paragraph is difficult. After calculating the difficulty factor for each test paragraph, it was found to be between 0.39 and 0.7. All the test paragraphs were acceptable, as Sawalma (2009) noted, that the test paragraphs were good if their coefficient of difficulty was between 0.20-0.80. The test paragraphs are therefore acceptable and applicable in terms of difficulty factor.

B. The power of paragraph discrimination: Is the ability of the paragraph to distinguish between the upper group (the students with the high grades in the test) and the minimum (students with low grades in the test) that means the ability to distinguish individual differences between students who know the correct answer and students who do not know the correct answer (Dulaimi and Adnan, (E), (1972: 66). When we calculated the specific force of each paragraph of the test using the parity equation, it was found to be between 0.33 and 0.52. Ebeal (1972) 20-0.80).

C. The effectiveness of wrong alternatives: The wrong alternative is effective when the number of students selected in the lower group is more than the number of students who chose the same alternative in the upper group. All alternatives were found to have attracted more female students in the lower group than the upper group students, and thus were recognized to be retained.

Statistical means: The researcher used the following statistical means:

1. Frequency and percentage of the calculation (Honesty reaches an 80% virtual honesty ratio).
2. Pearson equation to extract the coefficient of stability, reaching (0.86).
3. The researcher used the Spearman-Brown equation to correct the coefficient of stability (0.92).
4. The researcher used the square Kay (Ka 2) to indicate the differences between the two groups of research at the parity of the academic achievement of parents and the calculated value of parents (0.791), less than the value of (k 2) table of (7.815) and freedom degree (3) 0.05, as in Table (1). The calculated value of mothers (1.461) is less than the value of (ka2) of the table (7,815) and the freedom level (3) at the level of (0.05) as in Table (3).

The researcher used the t-test to show the first grade of the history of the Arab Islamic civilization for the fourth quarter, the experimental average of the experimental group (66.32) and the standard deviation (18.17) and the difference (330.15), while the arithmetic average of the control group (67.47) and the standard deviation (17.18) and variation (295.15). When we used the t-test to find out the difference between the grades of the students in the first course, it was found that the difference is not statistically significant at the level of 0.05. The calculated T value is 0.277, (2,000) and a degree of freedom (61) This indicates that the two groups are equal in the grades of the first course The history of the Arab-Islamic civilization and the table (6) illustrate this:

The average results were that the average grades of female students, the experimental group that studied the formal strategy, was 42.97. The difference was 79.74 and the standard deviation was 8.93. The average score of the students in the control group was 35.3, the difference was 111.94 and the standard deviation was 10.58. 3.211. It is smaller than the value of T table (2.000) at the level of significance (0.05) and degree of freedom (61). This is the superiority of students of the experimental group on the control group and thus reject the zero hypothesis developed by the researcher and accept the alternative hypothesis. The students of the experimental group, which studied the history of the Arab Islamic civilization for the fourth grade literary according to the formal strategy on the students of the control group, which studied the same article in the traditional way in the acquisition test. This result can be attributed to:

1. The formal strategy has benefited the students of the experimental group by observing the increasing degrees of testing the acquisition of historical concepts, as they outperformed the students of the control group.

2. This strategy is appropriate to the level of students of this stage because they enjoy mental and intellectual maturity and the ability to analyze and summarize.

3. The formal strategy led to the excitement of students and their interest and suspension for the material history and their desire to know the subject or prepare them, which increased their education of the subject matter.

4. The subjects studied during the experiment may be suitable for the use of formal strategy, which led to increased understanding of students in these subjects.

5. The novelty of the strategy has encouraged students to study history and increased their desire to know the concepts.

**Conclusion**

The research was conducted on the fourth grade students. The school was randomly selected (Al-Mahaweel Preparatory School for Girls with 61 students). The researcher used the experimental method as the most suitable method for this research. The experiment was applied to the two research groups with a period of (1) years. 8 weeks), and used the pat The statistical methods (t-test, kai square (k2), coefficient of paragraph distinction, coefficient of paragraph difficulty, effectiveness of wrong alternatives, Pearson correlation coefficient, Spearman-Brown correlation coefficient). The researcher found that there was a statistically significant difference between the two groups of research in the post-acquisition experiment in favor of the experimental group.

Effect of Black Seed Oil on Some Physiological Parameters in Female Rats Treated with Aflatoxin B\textsubscript{1}, B\textsubscript{2}

Athraa Harjan Mohsen\textsuperscript{1}, Israa Harjan Mohsen\textsuperscript{2}

\textsuperscript{1}College of Sciences, University of Babylon, Iraq; \textsuperscript{2}College of Nursing, University of Kufa, Iraq

ABSTRACT

This study was conducted in order to determine the effect of Black seed oil on the reduction of the negative effects of the Aflatoxin B\textsubscript{1}, B\textsubscript{2} produce from \textit{Aspergillus flavus} in white rat females and effect it’s on the physiological blood parameters. The results of isolation and initial diagnosis showed \textit{Aspergillus flavus} and \textit{Aspergillus niger} in all samples studied percentage (100%) and isolated from the seeds of rice while the percentage of the emergence of fungi \textit{Penicillium} spp and \textit{Trichotheccium} spp and \textit{Rhizopus} spp rates ranged (50, 45, 14)% respectively of the samples studied. The results showed that Black seed oil had a significant effect on the physiological parameters of blood. The rate of white blood cells (WBC) increased to $(15 \times 10^{3}$ and $21 \times 10^{3}$) cells/mm\textsuperscript{3} when treated with Aflatoxin B\textsubscript{1} (AFB\textsubscript{1}) and Aflatoxin B\textsubscript{2} (AFB\textsubscript{2}) compared to control treatment. The results showed that the Black seed had decreased the rate of white blood cells when used with aflatoxin (AFB\textsubscript{1} + 800) and (AFB\textsubscript{2} + 800) mg/kg oil to $(11.5 \times 10^{3}$ and $7.5\times 10^{3}$ cell/mm\textsuperscript{3} respectively.

**Keywords:** physiological parameters, Aflatoxin B\textsubscript{1}, B\textsubscript{2}

Introduction

Aflatoxins are a group of mycotoxins, which are toxic metabolites produced by fungi during their growth in various food and cereal crops \textsuperscript{1}. These metabolic compounds have relatively low molecular weights, where contamination of human food and animal feeds from the field to the consumer. The human exposure to Aflatoxins leads to serious diseases according to the dose exposed to it as liver cancer, bone abnormalities, embryonic mutations and fetal deformation as well as its effects on sexual efficiency. In studies conducted a significant correlation between human cancers and the contents of food contaminated with aflatoxins \textsuperscript{2}. In a study conducted by \textsuperscript{3} suggests that aflatoxin has effects on physiological blood parameters, including lowering the number of white blood cells. Mohsen (2006) found that \textit{A.flavus} and \textit{A. niger} had effects on white rat tissue by decrease in body weight weight of ovaries in the rat and a significant increase in the weight of the uterus as well as in the thickness, and cause infertility. \textit{Nigella sativa} is a plant belonging to the family Ranunculaceae. It is used to treat head pain, bladder and kidney stones, chest pain and nausea. It also has a role in reducing the blood sugar level in test animals, also it have a role in reducing blood pressure and the tension of the presence of glycoserin and saponin, which is useful in the treatment of spasticity either directly or in the form of oil \textsuperscript{4} \textit{It} is medicinal plants containing antimicrobial agents and germs. and has an effective role in the treatment of chronic asthma, chronic colds, and used against gastrointestinal bacteria and currently as a disinfectant for harmful intestinal flora for young children and adults \textsuperscript{5}. Due to the lack of available studies on the effect of oils and plant extracts on some fungi producing toxins within the body of the organism, this study was conducted, which included:

1. Isolates and identification \textit{Aspergillus flavus} of rice seeds.
2. identification \textit{Abilaty Aspergillus flavus} on the production of aflatoxin B\textsubscript{1}, B\textsubscript{2}.
3. Test the efficiency of different concentrations of the Black seed oil on the growth of isolated fungi in laboratory.

4. Studying the effect of different concentrations of Black oil on some of the physiological parameters of blood. In the Albino rat, it is infused with aflatoxins.

Method

1. Potato extract and dextrose Agar (PDA) The medium was prepared according to the procedure of (Colle et al; 1996)
2. Coconut extract Agar medium. The medium was prepared according to the procedure of (Dianese and Lin, 1976).
3. Isolation and Diagnosis of *A. flavus* from Rice Seeds
   The seeds of rice were brought from the local markets of the city of Najaf in the year 2017 and using the sterilized seeds for isolation of *A. flavus* according to procedure of (Fennel and Raper, 1965, AL-Ansii1999).
4. Testing ability of *A. flavus* on the production of aflatoxin, steps were followed according (Wyllie and Morehouse 1977; Mohsen and Risan 2009)
5. Preparation of concentrations of the Black seed oil and study the effects in medium
   In this experiment, two concentration (200, 800) mg/L were mixed with the sterile PDA after cooling. all dishes were vaccinated with 0.5 cm disc from the fungus at the center of the dish. Their last rate fungi and calculate the amount of orthogonal inhibition according to equation:

   In this experiment used 16 animals divided into 7 groups:
   1. Two rats were injected orally with 0.5 ml of aflatoxin B₂ and Black seed oil at a concentration of 200 mg/kg of 0.5 ml daily for one week.
   2. Two rats were injected orally with 0.5 ml of aflatoxin B₂ and Black seed oil at a concentration of 800 mg/kg of 0.5 ml daily for one week.
   3. Two rats were injected orally with 0.5 ml of aflatoxin B₁ daily for one week.
4. Two rats were injected orally with 0.5 ml of aflatoxin B₁ and Black seed oil at a concentration of 200 mg/kg of 0.5 ml daily for one week.
5. Two rats were injected orally with 0.5 ml of aflatoxin B₂ and Black seed oil at a concentration of 800 mg/kg of 0.5 ml daily for 1 week.
6. Two rats were injected orally with 0.5 ml of aflatoxin B₂ per day for a week.
7. Included 4 rats without any dosage as control treatment.

   Two days after the last dose, the animals were sacrificed, The blood was collected to calculate some physiological blood parameters.
8. Blood parameters:
   1. Estimation of leucocytes count: The blood cell count method and the Turks solution were used to calculate the total number of white blood cells (Brown, 1976).
   2. Estimation of Red Blood corpuscles: The blood cell count method and the Hymes fluid solution were used as a dilution solution for total red blood cell count (Hall and Malia, 1984).
   3. Hemoglobin Estimation: Hemoglobin Meter and Drabkin fluid as a dilution solution were used to estimate hemoglobin concentrations in the blood sample (Sood, 1996).

9. Statistical analysis: All experiments were carried out according to (C.R.D) as single-factor experiments. The averages were compared with the least significant difference of L.S.D and below the level of significance (0.05) (Al-Rawi and Khalaf Allah, 1980).

Results and Discussion

1. Isolation and diagnosis of fungi associated with rice seeds: The results of isolation and diagnosis showed an *A. flavus Aniger*; (100%) of the studied samples, followed by *penicillium spp, Trichothecium spp and Rhizopus spp* (50, 45, 14)% respectively for the studied samples. Figure (1).
2. *Aspergillus spp* is due to simple dietary requirements as well as its ability to produce a large number of non-homogenous reproduction units. As well as the increase in the proportion of carbohydrates and easy to be represented in rice as the fungus *A. flavus* prefer carbohydrate materials on oily materials in addition to the moisture content if referred to *Aspergillus* with a wide range of temperatures and humidity as well as poor storage and accompanied by the production of toxins at different temperatures.

3. Evaluation of the efficacy of Black seed oil in reducing the effects of aflatoxin B₁, B₂ in white rats females.

**White blood cell count:** Figure (2) shows that AFB₁, AFB₂ had a negative effect on the white blood cell count its reached (210 × 10³, 15 × 10³) cell/mm³ compared to the control treatment of (5.5 × 10³ (cell/mm³). The Black seed oil has a positive effect in reducing the rate of white blood cells in which it is used with a (AFB₁ + 800) and (AFB₂ + 800) mg/kg reaching to (11.5 × 10³, 7.5 × 10³) cell/mm³ respectively compared to control group.

The increase in rate of (WBCs) is due to metabolic products by *A. flavus*, causing excessive secretion of immune response factors Tumor necrosis factor, Interleukin-6, cytokines especially that responsible for the occurrence Primary inflammation and immune regulation. The excessive production of these components is important reason to increase the number of (WBCs) in the treated rats or a result of increasing the number of acidic blood cells that work to offset or remove toxic substances from the body, (Pearce and Pearce, 2013), confirming that metabolic products affect the immune system response.

In addition, the dosage of poultry with a different dose of the metabolic products of *A. flavus, A. fumigatus* led to an increase in the number of (WBCs) and anemia thus lead to stimulate the body’s immunity and increase the number of acid cells in response to the exotic substances in the body which acted as competitive inhibitors of the enzymes responsible for the synthesis of red blood cells (Croopman et al., 2003)
**Red blood cell count (RBC):** Figure (3) indicates a reduction in RBC to (1.5.2.5) cells/mm$^3$, respectively for rats treatment in AFB$_1$, AFB$_2$. While RBC was observed to increase to (3.3.4.5) cells/mm$^3$ when treated with (AFB$_1$ + 800) and (AFB$_2$ + 800) mg/kg respectively, while (8) cells/mm$^3$, in the control treatment.

![Figure 3: Red blood cells in animals treated with aflatoxin and Black seed oil with different concentrations](image)

The fungal toxins sometimes act as competitive inhibitors of enzymes responsible for the bio-synthesis of (RBC). The ability of the seed oil to play an important role in increasing the rate of hemoglobin and increase the number of (RBC) due to its effect in the activation of bone marrow and spleen responsible for the manufacture of (RBC).

In a study conducted by Mohsen et al. (2009), the toxic effects of *Aspergillus parasiticus* and *Bipolaris micropus* in white rats showed a reduction in the weight of animals treated with fungi, where (10.2, 7.2) % respectively. The results indicated that the preparation of white blood corpuscles was increased in the blood of animals treated by *A. parasiticus*, which amounted to (6600) cells/ml, while reached (10500) cells/ml in the blood of animals treated with the *B. micropus* and at the same time did not change values ESR in all transactions in addition to the high Hb values was (15-18) % for animals treated with *A. parasiticus* and *B. micropus* compared to the control treatment of (13) %. Either the level of P.C.V has risen to (45, 52) % on the respectively.

**Hb concentration rate:** Figure (4) refer that AFB$_1$, AFB$_2$ had a negative effect on the concentration of hemoglobin as the rate was reduced to (3, 5) g/100 ml respectively compared to the control treatment of (15 g/100 ml) on the other hand, a positive effect on a significant increase in the concentration of hemoglobin concentration in animal blood treated with (AFB$_1$ + 800) and (AFB$_2$ + 800) mg/kg respectively to (11.9) g/100 ml compared to control treatment.

![Figure 4: Concentration of hemoglobin in animals treated with aflatoxin and Black seed oil with different concentrations](image)
The high rate of hemoglobin in the use of black seed oil with aflatoxin is due to lowering the level of hemostatin in the blood. In addition, low levels of hemoglobin in animals treated with aflatoxins (B1, B2) cause increased production of immune response factors, including cytokines in animals that gave toxins, which have increased oxidation in the cell, increasing the free radicals that attack red blood cells, Hemoglobin deficiency or aflatoxin has a strong correlation with blood proteins responsible for the synthesis of red blood cells, which results in a small amount of it. It also affects the blood balance 9-13.

On the other hand, in an experiment with the use of the grain of the pond led to an increase in the concentration of hemoglobin in laboratory animals and increase the immunity of the body through lymphocytes and protein and kidneys and globules to contain the grain of the pond on the most important elements of iron, which enters the construction of hemoglobin and copper 14-19. The reason attributed to raise the proportion of hemoglobin when used The oil has the most effective substances Nigellone, Nigelline, which has the medical effect in addition to the matter of phosphorus and carotene (vitamin A generator) 20-25.

**Conclusion**

The results showed that Black seed oil had a significant effect on the physiological parameters of blood. The rate of white blood cells (WBC) increased to (15 × 10^3 and 21 × 10^3) cells/mm^3 when treated with Aflatoxin B1 (AFB1) and Aflatoxin B2 (AFB2) compared to control treatment. The results showed that the Black seed had decreased the rate of white blood cells when used with aflatoxin (AFB1 + 800) and (AFB2 + 800) mg/kg oil to (11.5 × 10^3 and 7.5× 10^3 cell/mm^3 respectively

Rehabilitation Program Impact in the Treatment of Injury to the Cruciate Ligament of the Knee Joint Care of Five Players Lounges

Naghm Salman¹, Aseel Naji¹
¹College of Physical Education and Sports Sciences, University Muthanna

ABSTRACT

The study of the effect of rehabilitation exercises and physical efforts to determine the impact of these exercises on the functional state of muscles because its main work is to accelerate the process Hospitalization of the incident of injury to perform various physical efforts, as these exercises work to increase the vital interactions rate and speed within the human body, and to identify those changes will help us also in the process of understanding the development of therapeutic and rehabilitative appropriate exercises that the research problem lies in the spread of this case between the members of the community All ages, races and jobs, as well as the seriousness of the complications of this problem as well as reducing the intake of medicines and replace them with rehabilitation exercises. So the researchers decided to study this problem and know the impact of the therapeutic program to overcome this problem, which young players face. The research aims to identify the therapeutic effect of exercise on the knee joint and link the injured anterior cruciate ACL from where: Lower limb circumference (knee circumference - leg circumference). Motor range (positive range of the knee joint - negative range of the knee joint).

Keywords: rehabilitation program, cruciate ligament injury, five futsal

Introduction

The scientific development that the world is witnessing today is a milestone of progress, culture and creativity, and this Creativity must be preceded by full and directly informed of what is happening around us, whether inside or outside the country. From this point it became important and necessary scientific research went to study the various applications of pure science, including chemistry and physiology of sports in all areas of basic movements and sports because of the importance of these sciences in the development of performance and motor duty and evaluate methods and knowledge of the responses that occur during the practice of movement, and would contribute to raising the level to be the motor, since the knowledge of biochemical changes that occur within the muscle cell to produce the necessary performance sports powers are important and resulting from the increased activity of enzymes and hormones and materials energy Left in the metabolic processes to achieve adaptations in the vital body and members of organs in order to face the fatigue or the resulting injury from physical effort, especially in games where direct contact, such as five - Futsal, bringing the science of sports medicine has taken a new turn in the development of exercise Therapeutic and rehabilitation of muscles that can play an important role in the detection of the effects and physiological responses to people from the implementation of physical loads and lack of attention to physical therapy, which leads to the deterioration of the case of the patient and his failure to restore the full function of the injured part and deprivation of the practice of Nash The daily fold is temporary or final, especially since the knee joint is the most complex of the joints of the body. Hence the importance of research in the work to alleviate or remove these pain during the preparation of a rehabilitation program to reduce the pain rather than the use of drugs.

DOI Number: 10.5958/0976-5506.2019.03300.X
Methodology

The researcher used the experimental approach to suitability and experience as Experimental Method with Tribal and Remote Tests. Sample Was selected sample purposively from the players quintet young people with a torn anterior cruciate ligament and the number was 10 players from the players clubs for the province of Baghdad five Futsal and to determine the sample, the researchers follow the personal interview style with five coaches Futsal As well as with specialists in the field of physiotherapy to determine the conditions of selection of the research sample as follows:

1. Diagnosis and identification of infection by a specialist doctor and the use of the latest methods of diagnosis such as magnetic resonance MIR.
2. The exclusion of people with other injuries in the same knee.
3. Approval of the competent doctor for patients to participate in the program.
4. Not to undergo any other treatment methods during the application of the program.

Data collection methods:

Tools Devices used:

First: Search Forms: To gather information for research the researchers guided by references and previous studies followed the follows - how to record the occurrence of injury form:

They include some questions that explain how the injury (as a result of friction, without) and the degree of pain experienced by the injured in the performance of different movements and detailed degree of assistance received from others.

- Expert consultation form for the determination of measurements of the muscles working on the knee joint.
- Measure the circumference of the thigh and leg using the measuring tape cm.
- Weight using the medical balance.
- Measurement of length using the measuring tape cm.
- Measuring the positive and negative range of the knee joint using the genome.
- Data registration form:

It is a data registration form for each case and includes data

(Age - height - weight - positive and negative range of the knee joint - the circumference of the knee and the circumference of the thigh and the circumference of the leg).

Second: Tools used:

- Medical balance for weight measurement
- Measure tape inserted in centimeters.
- Infrared and sound waves.
- Electrical stimulators tens).
- Stop Watch.
- Weights starting from half a kilo, whether the dumbbells or fixed on the man.

Third: Measurements used:

1. Measurement of length (Rstrometer).

Measurement Description: Where the individual stands on the wooden base and the back facing the sign so that it touches the three points, the area between the two boards and the farthest point of the pelvis from the back and the farthest point for the safety of the legs and must take into account the individual body lift and look forward is lowered the pregnant until touching the top edge of the skull where the figure opposite to the pregnant Length of the individual.

2. Weight measurement: Measurement description: The measurement uses the medical balance where the patient stands vertically in the middle of the balance with both feet and does not look down when making the measurement.

3. Measure the circumference of the thigh and leg using the measuring tape cm (measurement description): Measure the circumference of the thigh muscles above the circumference of the patellar muscle.

Measure the leg circumference at the extremity of the leg muscle.

Measurement of the knee arthroplasty is divided into three parts directly above the patellar and
mid-knee bone at a distance of four fingers from the first and below the knee at a distance of four fingers from the second measurement.

4. Measuring the motor range of the knee joint:
   (measurement description)
   - Measuring the extent of positive flexion of the knee joint.
   - Measuring the negative bend of the knee joint.

   A. The electronic genometer shall be placed on the end to be measured by the adhesive tape.
   B. The locomotor is cleared to start the patient moving the party to measure the range of motor
   C. The injured party moves in the direction required to know the range of motor and take the reading of the device.

   Repeat the measurement three times and take the best.

   After recording the device, the patient will hold the flexive knee and pressure behind the pain limits and take the machine’s reading to record the negative dynamic range.

Steps numbers of the proposed therapeutic program:

   Therapeutic programs are concerned with determining the type and size of work to be carried out in order to achieve agreed goals. These programs are based on long-term and short-term goals. The objectives of this course will focus on the short-term goals in their simplest form

   The concept of therapeutic program

   The training program is defined as the processes to be implemented so that the start and end date of these operations is according to a specific time and goal. The remedial program is considered as one of the elements of the planning process to achieve the goal of the plan.

   * The proposed therapeutic program objectives:

   - Restoring basic functions of the knee joint.
   - Improves the muscular capacity of the affected muscle groups.
   - Increase the flexibility of muscles working on the injured joint and improve its movement.
   - Reduce the feeling of pain to the least possible.
   - Exercise should be in line with the overall goal of the program with gradual easy to difficult and gradual in the intensity of pregnancy.
   - Restore the basic functions of the muscles working on the knee joint.
   - The return of the main functions of the joint and the muscles working on it as close as possible to the correct member of the same player.

Suggested therapeutic program content:

   - Method of the treatment program used in the search (therapeutic exercises).
   - Period of application of the proposed program (12 weeks).
   - The program is divided into three phases each stage four Weeks.
   - The application took one training session (35 minutes: 55 minutes) by six training units per week and on the basis of individual differences.
   - Number Units during the program (72).
   - Number of units per week (6 units).

The first step was to find the scientific parameters under study and find the stability of the tests using the re-test method. This method requires the application of the test twice on the same group under the same conditions and the appropriate time difference between the two applications. The test was applied to the survey sample of Outside the basic study sample. The test was re-applied to the same individuals after a period of one week. This method is statistically called the method of re-testing.

Table (2) shows that there are statistically significant differences between the tribal measurements and the experimental measurements of the experimental group in all the variables of the lower and right periphery. Table (2) shows the mean of the arithmetic mean of the femoral circumference (46.17), and with a standard deviation of (4,646) and for the femoral measurements of the hip circumference, the mean of the mean (50.22), the standard deviation was (6,000) and the value of (T) was (11,98), and the arithmetic mean of tribal measurements of the knee circumference was 37, 83) and standard deviation reached (3617) and measurements dimensionality of the ocean knee reached the arithmetic average (40.33) and the standard deviation was (5.54) and the value of (v) amounted to (15.89), and the arithmetic average of the measurements Tribal perimeter leg reached (35.67) and the standard deviation was (The mean value of the circumference of the thigh, the circumference of the knee, the circumference of the leg (11), and the mean value of (13), 98,15,89, 13,07), greater than (t) the table, which amounted to (2.37). Which indicates that there are significant differences between the tribal and remote measurements, and for the benefit of the measurement algebraic and attributed the researcher the reason for the development to appropriate training exercises inevitably lead to a positive effect in raising the functional and motor level of the knee joint, and the return of nature functions in the joint closest to the proper joint. Mohammad Adel Rushdie asserts that the use of appropriate exercise exercises results in good results for the knee joint in general and the front cruciate ligament in particular. This result responds to the imposition of the first research 6. Positive therapeutic exercises affect the lower limb (circumference Thigh - circumference of the knee - circumference of the leg) for those who have torn the cruciate ligament with the front knee joint.

Presentation of the results of the second hypothesis:
To respond to the second hypothesis of the research, which provides: Positive therapeutic exercises on the motor range of the knee joint (positive and negative)

Table (3) shows that there are statistically significant differences between tribal measurements and algebraic measurements and the following table shows this.

Table 3: The mean value of the positive range of the knee joint in tribal measurements

Results and Discussion

To respond to the first hypothesis of the research that provides (therapeutic exercises have a positive effect on the lower limb (thigh circumference, knee circumference, circumference of the leg). The researcher extracted the arithmetic mean, standard deviation and the value of (T) measurements and tribal dimensions of variables lower limb (thigh circumference, knee circumference, leg circumference) The following table shows that.
Table (3) showed the mean value of the positive range of the knee joint in tribal measurements (95.24) and the standard deviation (7.0065). The mean value of the mean measurements of the positive range of the knee joint was 100.00 and the standard deviation) while the value of the arithmetic mean of the negative extent of the knee joint in the tribal measurements (15.003) and standard deviation (5.89) and the value of the arithmetic mean of the traditional strategies measurements negative for the extent of the knee joint (7.01) and standard deviation (7.55) and the value of (C) for the positive range (10.6) and the value of (v) for the negative range (7.55) greater than (t) the table which amounted to (2.37). There are statistically significant differences between the measurements of tribal and remote and good dimension measurements in the variables of study and this improvement in the measurement of distance is due to the rapid improvement in the frontal cruciate ligament to contain the program therapeutic exercises to general exercises with the gradient from simple to complex and easy to difficult and choose appropriate and standardized exercise. This improvement in measurement results is due to the regular exercise of the program. This result responds to the imposition of the second research. The therapeutic exercise positively affects the motor range of the knee joint (positive and negative) for those with the cruciate ligament rupture of the front knee.

**Conclusion**

In the light of the objectives of the research and data that have been presented and discussed researcher concluded that there are statistically significant differences between the results of the tribal and posttraumatic measurements in the femoral, knee, leg and posterior groups. There were statistically significant differences between the tribal and the remote measurements in the range of positive mobility of the knee and the negative range of the knee and the remote welfare.

The Proportion of the Contribution of Some Muscular Capabilities of the Arms to yhe Accuracy of the Performance in Foil

M. M. Mohamed Qais Mubder¹, Noor Hatem², Kamil Malykh Hussein³

¹Collage of Physical Education and Sports Science, University of Muthanna; ²Collage of Physical Education and Sports Science for Girls, University of Baghdad; ³Collage of Physical Education and Sports Science, University of Muthanna

ABSTRACT

The study aims: Identification of the muscular abilities of the arms (characteristic strength of speed, carrying force, explosive power of the arms), which affect the accuracy of the performance of skill in foil. Identify the percentage of the contribution of muscular abilities to the arms that affect the accuracy of the performance of the skill With a gun. The researcher used the descriptive method in the method of correlative relations to his suitability to the nature of the problem. The sample of the research was selected from the community of origin, represented by the dueling team of the students of the College of Physical Education and Sports Science for Girls/University of Baghdad. The number of (20) And the number of (4) students became the sample research (16) from the original community. Applied testsswere conducted for the capabilities of muscle and Performance evaluation skills in foil on Wednesday in the Fencing Hall Faculty of Physical Education and Sports Sciences. Through the statistical treatments and the results obtained by the researcher, the following conclusions were reached: The existence of a significant correlation relationship with muscular capacity performance skills in foil.

Keywords: Contribution Ratio, Muscle Capabilities, Blinds

Introduction

Weapon fencing is one of the oldest known games, which is the use of weapons in different ways and methods during the attack and defense between the competitors as they try to record touches within the target of the weapons and laws agreed within the specified time ¹. The sport of fencing is one of the sports that has special requirements and determinants as well as its sports, social, psychological and educational goals ². It is practiced in accordance with certain laws and special rules governing competition among competitors. The ability of the swordsman to exert effort and win depends on many variables, Mental, physical and muscular, through which to achieve advanced results, the player who is integrated physically, psychologically and skillfully can get good results in competitions as this sport is characterized ³ by the speed of attack towards the opponent suddenly, and precision in the direction of the weapon fly To the goal of the competitor, for the purpose of obtaining a touch, any weakness in the muscle capacity causes weakness in the accuracy of access to the touch and thus not achieve the desired results in the competitions, muscle capacity as other abilities that should be concerned ⁴ by each coach in the field of sports training are physical and skill. Hence the importance of research in the identification of the most important muscular capabilities of the arms ⁵ and the proportion of their contribution to the accuracy of the performance of skill With the duel of female students of the College of Physical Education and Sports Science for girls/University of Baghdad in order to focus on them by the trainers to reach the best results in sports competitions ⁶. Many studies, field and laboratory research have dealt with most of the physical abilities of the fencing game,
which directly affect the development of the physical aspect to improve the technical and skillful aspects. However, most of these studies have training curricula based on the development of special physical abilities and skill, advanced we must stand at the points that have not previously observed by the trainers that affect the results and the level of the player, acknowledge the proportion of the contribution of muscular capacity of the arms in the performance of performances skills and thus Tozviha within the training modules, fencing streaking Anaj to special abilities must know the coach and focus on the training modules to obtain good results. Research Objectives. Identification of musculoskeletal abilities (characteristic strength of speed, bearing force, explosive force of arms) that affect the accuracy of performance of skill in foil. Identify the percentage of the contribution of muscular abilities to the arms that affect the accuracy of the performance of the skill of in foil.

**Methodology**

The researcher used the descriptive method in the method of correlative relations to suit the nature of the problem.

**Research Sample:** The sample of the research was chosen from the community of origin, represented by the dueling team for the students of the College of Physical Education and Sports Science for Girls/University of Baghdad. The number of (20) female athletes was adopted by the intentional method in selecting the sample. We excluded the students who participated in the exploratory experiment of (4) 16 of the original community.

**Research tools Information collection methods:**
- Arab sources and references.
- Questionnaire.
- Information and Data Dissemination Form.
- Interviews.
- Observation and experimentation
- Information Network (Internet)
- Expert Consultation Form Annex (2,4,6)
- Duel Mask Number.
- Abdul Shish number 16.
- An electric vest for the gun which represents the legal target number 16.
- Electronic stopwatch.
- Registered device.

**Tests used in research**

**Muscle capacity tests:**

**Test characteristic force as fast as armrests (10 Tha) (1:56)**
- **Objective of the test:** Measure the speed of the arms.
- **Tools used:** Stopwatch.
- **Performance description:** The slant position (the number of folds and the length of the arms in 10 tha).
- **Recording method:** The number of folds and arm lengths is calculated in 10 seconds.

**2 - 4 - 1 - 2 test the performance of the armed arm.**
- **Test Name:** Hold the performance strength of the armed arm.
- **Objective of the test:** Measure the performance of the armed arm of the duel.
- **Tools used:** Stopwatch - Blind.
- **Performance description:** From the standby mode, extend the armed arm towards the person to touch it, and then the back of the arm so that the hand attachment touches a tool placed between the trunk and the heel of the player to show the sound when it is touched to ensure that the arm is properly returned to the player within 60 seconds.
- **Method of recording:** The number of times the performance is calculated within 60 th.

**Test payment of medical ball 3 kg hands(2:73)**
- **Purpose of the test:** Measurement of muscle strength (for the arms).
- **Performance Specifications:**
  - The laboratory sits on the chair holding the medical ball in the hands so that the ball is in front of the chest and below the chin level and the trunk must be attached to the edge of the chair.
A rope shall be placed around the chest of the laboratory so that it is held from the back by an airway, in order to prevent the movement of the experimenter forward while pushing the ball with the hands.

- The movement of the ball is done using only hands.

**Test Instructions:**
- The laboratory gives an independent attempt at the beginning of the test, such as performance training.
- The laboratory is given three attempts.
- When the laboratory vibrates or moves on the chair during the performance of an attempt, the result is not counted and another attempt is made instead.

**Calculation of grades:**
- The degree of each attempt is: the distance between the front edge of the chair and the nearest point on the floor of the chair hand rounded to the nearest (1.5) cm.
- The degree of testing is the best attempt of the three attempts.

**Performance evaluation skills:** In order to know the level of skillful performance of the fencing players picture the game researchers karma video and then distributed to the expert performance skills that have already proven validity and reliability and objectivity of the disc with the video to give each of each player to form the banner of an expert evaluation form

**Reconnaissance experiment:** Conducted researcher of this exploratory experiment on 29/11/2018, at ten o’clock in the morning in the Fencing Hall at the College of Physical Education and Sports Science on (4) players, it has applied the researcher tests after conducting measurements tests in order to reach the following:

- Know the obstacles encountered by the researcher when conducting the main experiment.
- To determine the accuracy and validity of measurements and tests for research.
- The extent to which the research sample understands the tests used.

- Install Task Assistant Tasks.
- Check the validity of the tools and the appropriate place to carry out the tests.
- Exceed errors that occur in the main experiment.

**The scientific basis of the test:** The researcher adopted the scientific bases in the tests for the purpose of determining the validity of these selected tests, ie, their validity, stability and objectivity.

**Certification of the test:** The tests differ in their levels of honesty according to their approach and distance from the assessment of the attribute that aims to measure them, and because honesty is not absolute but varies from one test to another, the researcher used the honesty of the virtual within the validity of the content has been verified by the researcher of this truth using a group of experts (75) More than (75%) of their views were taken into account and amendments were made in the light of their observations.

**Test Stability:** To determine the stability of the test, the researcher used the method of retesting that «if the test is re-applied to the players themselves, it gives the same results or close results.» (3:23)

The researcher applied the tests on 2/12/2015 and a sample of (4) of the selected fencing players were selected by the intentional method. The test was re-applied on 9/12/2015. The stability was obtained using the simple correlation coefficient as shown in Table 1

<table>

It is noted from the table that all correlation coefficient values were greater than r (0.811) under the free degree (4) and the significance level (0.05).
**Objective of the test:** The researcher used a clear and understandable test by the testers, where the registration was done using the units of measurement which are (time, grades). Therefore, this test is of good objectivity. When applied “(4:26)

**Main experience:** Applied tests of the capabilities of the muscle was conducted on Tuesday, 14/12/2018 Fencing College of Physical Education and Sports Science Hall. Either evaluate the skill performance With the weapon of the blinds on Wednesday, 15/12/2018 in the Fencing Hall Faculty of Physical Education and Sports Sciences.

**Statistical means:** The researcher used the statistical bag (SPSS).

**Results and Discussion**

Table (2) shows that the coefficient of correlation between the test carrying the speed of performance of the armed arm by skill performance Blinds with a weapon of (.77) and contribution rate (60%) and reached the revised value of the ratio of contribution (57%).

This means that the relationship between the test characteristic force as quickly as armrests Bperformance skills with a weapon blinds were significant correlation when compared to the value of $\text{Tabulated (0.9 4)}$ at the 14 degrees of freedom and the possibility of error (0.05), theresearcher attributes the reason for this is that the greater the susceptibility player to withstand the speed of performance increases the performance of the movement to challenge the accuracy as seen (SMA intruder) «the fundamental cause of the development of basic and carry speed due to the choice of the appropriate method for training endurance speed» (5:74). And that the value of the correlation coefficient between the endurance test the performance of the armed force of the arm with the skill of performance weapon blinds reached (.81) and contribution rate (66%) and reached the revised value of the ratio of contribution (64%). And this means that the relationship between the endurance test the performance of the armed force of the arm with the skill of performance weapon blinds were significant correlation when compared to the value Tabulated amounting to (0.49) at the 14 degrees of freedom and the possibility of error (0.05)

**Conclusion**

Through the statistical treatments and the results obtained by the researcher, the following conclusions were reached: the existence of a relationship of significant correlation between the muscular abilities to the skill performance of the weapon of the blinds. The proportion of the contribution of high muscle capacity appeared in the B performance skills with a weapon blinds.

The Impact of the Strategy of the Three-Step Interview in the Rugby Thinking and the Accuracy of the Performance of the Skill of Students

Fadya Abdul-Hussein Kadhim¹, Nihad Mohammed Alwan¹

¹College of Physical Education and Sports Sciences for Girls, University of Baghdad

ABSTRACT

The study aimed to prepare educational units using the strategy of the three-step interview and identify its effect on the rugby thinking and the accuracy of the performance of the skill of the volleyball team. The researchers followed the experimental research method by designing the experimental and control groups with the strict control of the pre- and post- In the College of Physical Education and Sports Science for Girls at the University of Baghdad for the academic year (2018/2019), the number of (42) students randomly chosen by (44.681%) of their community of origin, The school is presented with a skillful part of the learning, accompanied by details of how to master it. The information that the learner may encounter when performing to build a knowledge base is the experience of the learners in their performance and the questions they ask in the applied part of the unit. allocated for this skill (30) minutes of section Chief of time (60 minutes), it has been allocated (4) educational units by its educational unit and one in the school week, and the results were processed were processed results of the study statistical system bag SOCIAL Yeh (SPSS)

Keywords: strategy, rugby thinking, performance, skill

Introduction

Not only motor skills learning is limited to traditional methods, most of which remained constant in their specific steps in the duties of the teacher and the learner, although some allow the latter to be active in his lesson in the lesson considering that modern schools in this learning aims to increase the activity of the learner More than the teacher, which casts a shadow on those conducting academic studies to address the methods and strategies that take into account the privacy of learners and target their thinking by adopting the theories of cognitive structure in learning on the one hand, and the privacy of the game or effectiveness on the other hand, It is essential that the strategy and the contents of the exercises are as close to the nature of this game as the study is important in that it simulates the actual reality and facilitates its application without exaggerating the concepts as the need arises. Here is the strategy of the three-step interview to activate the role of learners in the lesson by sharing ideas and asking questions and taking notes in light of the determinants of this strategy to be applied to a degree of easy and easy to allow them freely in the lesson and in line with the same Time with the goals of modern schools in learning . Recalling Moston and Ashort (Mosston & Ashworth) “ That The foundations upon which the choice of teaching in physical education strategy is the abilities of students, age and content to be taught to them and abilities of self and environmental teaching teacher (tools and facilities), weather conditions, time. ”¹⁴ and refers that Indian Muhammad that» recommended DEWEY that learners They need to acquire, discover and interact with the environment around them and then increase their ability to solve the problems they encounter in the environment and society. The psychological basis of the survey is based on the cognitive theory that interpreted learning as the result of the interaction of the mental powers of the individual

Corresponding Author:
Nihad Mohammed Alwan

University of Baghdad
Email: aseellnaji@gmail.com
with the stimuli that exist in the environment. Around it, the authors of this theory pointed out that the learner can be contained in the learning process by allowing him to choose, exercise, think and make his decisions based on his analysis and self-evaluation of the information provided to him, so the activity of the learner in the educational situation according to that theory is a mental activity based on interaction mental powers of the learner with stimuli and educational experiences, and then understanding and awareness of stimuli and phenomena and the relationships between them, and thus have been learning. (13) also deals with (Douglas Llewellyn) to that modern learning theories have shown that learning is to build knowledge through the involvement of the learner in the process. The knowledge-based strategies are no longer available, so strategies based on information transfer are no longer valid for educational goals. The learner must participate in the learning process. He should ask questions, draw hypotheses, collect information and draw conclusions. This is the scientific survey that is the focus of learning science. « (1) make Tawfiq and Muhammad a clarification that “when we imagine the skill is composed of the components of cognitive, mental, emotional and emotional performance, no effective skill in the absence of the basic knowledge necessary for them, without exaggerating the role of knowledge as a component of skill and skill conditions to be Quickly and efficiently, with little effort and at a low cost. “ (1) Wei Abdulla Suleiman presented the determinants of those questions they “questions should be consecutive to make it easier for the learner to identify the skill sequence parts and must be based on the assumption and give the reason for the evaluation of the answer, and must possess the skills of asking these questions should not be dull or very complex or deceptive or ambiguous or non-productive questions and balanced in terms of bifurcation or assembly also takes into account the chronological age of them and able to control the lesson time as it is waiting for a response time of 3 seconds and must allow a greater number of learners to participate, whether they are volunteers or non-volunteers, namely It is a learning method Direct. “ (7) To put Abdullah Khatib and other determinants in the questions and codification in that it is “waiting time of the components of the questions of class is the period of time in which it is expected to hear the answer of the learner and the length of time that awaits after the learner gave his answer and before the teacher’s reaction to what the learner said”.(8)

Methodology

The researchers used the experimental approach to find solutions to the problem of the study and achieve its objectives, and the design of the experimental and control groups, which are controlled by the tribal and remote tests.

Search community and design: That the boundaries of the research society of the study is represented by the second stage students in the College of Physical Education and Sports Science for Girls in the University of Baghdad for the academic year (2018/2019) the number of (94) students distributed by nature on four divisions (A, B, C, D) The sample of the study was randomly selected by two groups (A and D) to represent 42 students with 44.681% of their origin. Both were randomized to be experimental and control groups in each group, the selection of students of the Division (c) of their number (27) students experience as required by the scope of the study of Procedures.

Measuring tools and tests in the study: T researcher deliberately tan to choose the rate of wishful thinking born scale crusader in favor of Shima (5) the number of paragraphs (37) with five alternatives to paragraph (Annex 1) degree range (37-185) degree in central Varzi (111), and choose your test Skillfully wall block (11) degree range (0-12) degree, and after checking the foundations of scientific transactions of the two tools of measurement after applied to the exploratory sample and validated, were prepared exercises technique for improving the two variables officers recruited triple the corresponding strategy steps, as it offers school Part educational skill accompanied by details of how mastered is information you may encounter educated at the performance to build a knowledge base as an experience based on the learner’s data when performance n ask questions n that inquires n in the applied part of the unit, as it was dedicated to the skill offline (30) flour (60) minutes, 4 educational units were allocated to them By one educational unit in the school week, and the results were processed. SPSS) Release (V 25), (statistical package for social sciences) , By calculating both the percentage values, the arithmetic mean, the standard deviation, the median, the torsion coefficient, and the test T-test) For interrelated samples, and test T-test) For interrelated samples.

Showing the significance of the results of the table (2) Exceeded the improvement of the two groups in the two variables in the table, showing the significance of the results of the table 3) The improvement of the learning group of the experimental group surpassed those of the control group. The researchers attributed the emergence of these results to the effectiveness of the strategy in question and its role in improving the thinking of the rugby among the educated as the step of the responsibilities involved helped the thrill and excitement and continued desire to continue according to the nature of the human psychologically, it looks to identify and find out what is the answer to the question raised and reinforced by the use of thinking Asking questions that are in fact supportive of how to reach the proper application of the skill of the wall of the resistance, especially as it is a skill characterized by the change of the ocean and depends on the different positions shown by the opposing team of attempts to deceive or from overwhelming blows Surprised him, which helped to adopt more than an educational position helped by the exercises matched with the use of strategy in order to improve this type of thinking, which is necessary in the lesson of physical education, as modern schools emphasize the increased activity and role of the learner in the lesson, at the same time emphasizes the lack of The learner in circumstances compelling or philosophical to bring about the process of learning.
and must be excluded or increased in the learning to be meaningful and meaningful learning can be reliable to be free of mistakes, and here the teacher must be familiar with how to control or control the thinking of learners to reach them Pric without Hilji to limit the freedom of the learner or restricted within the lesson, and this is evidenced by the results of the strategy that targeted the structure of knowledge of the educated and expand the horizons of knowledge application to have the skill performance volleyball skill wall block.

Considering Kawthar Abdul Rahim as a “clear of ideas and opinions” Piaget “for cognitive learning and growth of thinking Ongoing away is that learning is active and continuous process leading to the creativity of the learner ‘s new knowledge of structures (systems knowledge), check interaction is successful with environmental stimuli perceived and benefit Which gained the learner from experience, in new positions.\(^{(9)}\)

The more these methods are related to the nature of the learning process and the cognitive, emotional and social factors that affect them, the more successful and effective it will be in the emergence of new meanings and ideas that may be used in new educational situations or in solving problems,\(»\) said Thaer and Khaled .\(^{(2)}\)

Talha Hussein pointed out that “there are several variables that affect the accuracy of performance of the most important sense of direction and distance and timing and the amount of strength required and the ability to control and control muscle work. \(»\)\(^{(3)}\)

It is reported Chnov, a Russian scientist, quoting Mohammed Shehata, «that man remembers responses because of the interdependence of experiences.\(^{(10)}\)

Hani and others note that this type of learning works to fix new information in the learner’s cognitive structure, making it easier to remember and retrieve in the future to be used to learn, understand and recognize the new information that he or she faces.\(^{(12)}\)

**Conclusion**

The application of the students to the strategy of the three-step interview in the lesson of physical education helps them to improve their thinking rugby, to implement this strategy a positive role to improve the learning of the skill of the volleyball wall of students, and it is necessary to pay attention to the level of thinking rugby among the educated To initiate the learning of the motor skills in the lesson of physical education, and it is necessary to increase the knowledge of teachers and enable them to apply the strategy of the three-step interview with motor skills learning in the lesson of physical education.

Measuring the Therapeutic Calendar of the Elbow Joint According to the Rate of Change of Rehabilitation Exercises

D.r Imad Kadem Yasser¹, Dhulfiqar Ali Abdul Hussein¹
¹Physical Education and Sports Sciences, Dhi Qar University, Iraq

ABSTRACT

The importance of physical fitness by the safety of the affected parts is of great importance, it works to restore the joint function appropriately if the diagnosis is appropriate according to the nature, type and severity of the injury in addition to the level, the goal of the research is the calendar through the exercises articulation elbow attachment., By (10) injured players, and that the type of rehabilitation exercise indirectly helps to restore work as a simple comfort without complicating the work of the muscle part of the injured, and by achieving the goals and obtain the positive results, the researchers have to pay attention to the side application Exercises that match the nature of the level of injury in order to restore the work of the injured part gradually.

Keywords: Measurement, therapeutic calendar, elbow joint injury

Introduction

The great attention given by nations and peoples to the subject of human health and the establishment of special standards for the human body that the health level of society is a measure of the progress of each nation, and the most prominent ¹ science examined in this area is the science of therapeutic sport through its various therapeutic means to treat injuries and Rehabilitation of injuries resulting from some excessive use or friction and bruises and others ², where the strength is one of the most important manifestations of the individual health, and has long been successful scientific research to provide several studies to find the optimal methods and the best both to retain or return the body to its natural composition. Physical fitness contributes to the development of the individual in several different aspects, including physical, which is reflected positively on the health side through the direct impact in the functional organs ², as many studies and research that there is a close link between physical fitness and public health, The health and safety of the body’s organs and their adequacy in the performance of their functions to the fullest. The importance of fitness for the public health of the individual is confirmed by many studies conducted in different parts of the world. The rate of infection occurs in those who work in occupations and work requiring movement and activity less than people who work in offices and for long periods without movement and this activity represents our physical aspect is an important element to maintain and maintain the integrity ³ of the devices by maintaining a certain level of fitness, and the other side Physical exertion may have other positive outcomes by utilizing energy to stimulate the organs by moving the organs in order to perform all sports activities, as well as other vital functions such as cellular building process, growth process, and tissue reconstruction in the body ⁴. The research problem came through the follow-up of the field researchers and for several years his participation in several courses for sports injuries and field follow-up to the level of injuries that occur during the matches and the acceleration and through his meetings with many of the workers in this field in the sports clubs, noted the lack of scientific research that dealt with this type of injuries ⁵ As well as lack of interest in the diversification of exercises and methods applied after the diagnosis of injury in the annex Tennis, as well as most handball players do not give enough physical exercise in both preparation stages

or before the start of the game, which is Which is one of the most important elements to avoid sports injury and also lack of interest by the trainers to give a variety of ways to achieve the dimensions of mobility greater than required by the joint during the deliveries and delivery as well as scoring in various aspects of handball game.

Methodology

Research Methodology: The way in which a human finds a logical scientific method consistent with reality to realize the truth of the scientific facts, which is the way to acquire the real knowledge... The curriculum is one of these methods that regulate the side or the intellectual steps taken by the researchers To solve a certain problem. The research in all scientific fields resort to the selection of a curriculum that is appropriate to the problem. The nature of the problem requires a specific approach to reach the truth, it is the primary tool to collect information and impose hypotheses and set goals to solve the problem and access to it. Therefore, the descriptive approach is used in the survey method. This approach is considered an appropriate method for studying social phenomena. It presents data on the reality of these phenomena and the relations between their causes and their results.

The research community and its design: Among the procedures that the researchers are interested in is the selection of the community and the sample that is being tested. The research community is identified as the tennis players in the specialized handball schools in the governorates of Iraq who are injured for the sports season (2017-2018) of the research community. The researchers conducted a homogeneity of the research sample in order to determine their distribution under the Kaus curve as shown in Tables (1) and (2).

Tests used

Test of plutonium ball spherical distance (15) meters [4]
- Name of test: plump ball zigzag (15) meters.
- The aim of the test: to measure the level of skill Albatba.
- The tools needed: 5 high profile, stopwatch, handball.
- Method of performance: Five characters are shown on the ground in a straight line, the first is from the starting line (3) meters and the distance between the characters is 3 m.
- The player stands behind the starting line when the signal starts to flatten the ball with running in the form of winding between the flags back and forth until the finish line.

Registration: Calculates the recorded time back and forth from the start to the student’s graduation

Test (handling from head level to flat wall (30 ths) from distance (3 m): Purpose of the test: Measuring the handling skill.
- The tools: flat wall, handball number (3), measuring tape, stopwatch, adhesive tape.
- Performance and calendar specifications: The player stands in front of a line drawn on the ground about 3 m away from the wall and with the word (start) the player handles the ball from the level of the head to the wall and received it and the most number of times during (30 seconds). Calculate the correct number of times the ball is handled and delivered to the wall.

Test accuracy of correction on overlapping rectangles: Test the accuracy of the drawing on overlapping rectangles.
- Purpose of the test: Measurement accuracy.
- Tools: Five tennis balls, wall in front of paved ground. Draws on the wall three overlapping
rectangles whose dimensions are the bottom border of the large rectangle rising from the ground by 180 cm, drawing a line on the ground that is about 5 meters from the wall.

- **Performance specifications:** The student stands behind the line, and then straighten the five balls (consecutive) on the rectangles trying to hit the rectangle small student the right to use any of the hands in the correction.

- **Registration Method:**
  1. If the ball hit the rectangle (inside the rectangle or on the lines specified for him) is calculated for the student (3) degrees.
  2. If the ball hit the middle rectangle (inside the rectangle or on the lines specified for him) is calculated for the student (2) degrees.
  3. If the ball fit the large rectangle (inside the rectangle or on the lines specified for him) is calculated to the student one degree.
  4. If the ball came out of the three rectangles calculated for the student zero.

**Test Ball Throwing:** Purpose of the test: Measure the explosive force of the arms of the arms and trunk.

- **Tools:** medical ball weighing (3 kg), measuring tape.

- **Performance specifications:** The laboratory stands behind the starting line, holding the medical ball trying to throw it to the farthest point.

- **Registration:** The distance is calculated to the farthest point recorded by the laboratory.

**Main experience:** The researchers prepared a curriculum for the duration of this curriculum is (6 weeks) by three units per week for the duration of the unit from 10-1,50 minutes depending on the nature of the program which is a physical exercise intended to restore the work of the injured joints gradually according to the intensity used and the program began after the stage. The appropriate diagnosis through the resonance of the magnet with the appropriate rest period through the opinion of the specialist doctor and these exercises are performed without the use of any devices or any tools and applied to the first group of (10) injured players. These exercises were used for the purpose of achieving the desired level of physical, where the start of the use of exercises in a streamlined and gradual from easy to difficult as required by the severity of the program and began to work hard (10%), according to the opinion of the doctor as the injury type. The second was known as the intermediate injury, and the gradient in the intensity required according to the gradient increase in an orderly manner, taking into account the nature of rest that must be proportional to the nature of intensity used during the rehabilitation program, and the size of the frequencies on the first day (10) This is the first period after the positive rest. These exercises are a sense of the work of the joint after the rest period. These exercises during this day are a group of movements performed by the patient to include movements of the joint and muscles surrounding the work. Joint with the element of the exercises and tandem with the movements of the rotation that occur to us some contractions in the muscles surrounding the injured joint as well as the exercises and tandem that allows the appropriate range of motor during this intensity used and all these exercises result from a set of physical characteristics of the goal Is the sense of the detailed work of the injured facility, and then begin the process of increasing the intensity required with the necessary repetitions and in a proportional fit with sufficient rest appropriate to the intensity used until we reach the injured player at the end of the rehabilitation period to a severity of up to (90%).

**Statistical:** The researcher used the SPSS ver20 program to process the data. The following treatments were extracted from the program: * - arithmetic mean * - standard deviation * - torsion factor (t) for interrelated samples.

### Results and Discussion

Both tables show that the amount of differences in the group of exercises that were applied to the members of the research sample as well as the statistical ratios that clearly show the amounts of the significance of the change due to the application of rehabilitation exercises, which have a positive effect in improving the level of injury which result from a number of reasons. The rehabilitation programs carried out by the members of the research sample showed a clear percentage of differences between the two tests, which helped to reconstruct and adapt the muscles working in the elbow joint. It can give relative reactions in the development of these muscles of the affected arm, Repeat and strengthen. The training exercises in sports injury are of great scientific importance in terms of the use of any type of injury because the actual practice of exercises mainly stimulate blood circulation and that such activity in the circulatory system significantly helps the flow of lymphatic fluid, which has the most role in the structure of the joint. And the amount of movement produced by these exercises improve the movement of muscles, which leads to an improvement in nutrition within the tissues, which is one of the positive indicators of therapeutic exercises, and this in turn leads to increase the functional efficiency of the affected part through the amount of improvement of nutrition d Remove the tissue as an appropriate reaction to the exercises used. Exercise also plays an important role in acquiring the appropriate motor range for the affected part and depending on the type of exercise. “Any practice of sports activities has benefits, but with the presence of injury because they increase the flow of appropriate amounts of substances, components and elements in the healthy. For any of the infected parts 5. It is noted scientifically that the use of rehabilitation exercises for any infected part that comes after the rest of the time allocated by the therapist or the specialist and the exercise and exercise according to the type of injury and severity that suits the type and severity of the injury is a positive rest for the work of the injured part, and the period of the part of the injured part of the injury until the disappearance Pain and swelling are considered a passive comfort which follows the type and severity of injury because it is a period free of any action and may be limited in motion due to injury and comes the rehabilitation stage that contributes to the return of this part to work gradually without stress. In the injured part which is a positive rest as a result of the practices of exercises may be simple or recreational and then vary according to the intensity of the injured part. All the rehabilitation exercises that have been applied in the field have a high correlation with the muscular ability, which was highlighted during the special rehabilitation program used by the researchers on the sample, and the development in the results of these tests indicated the effect of these exercises in the development of muscle groups working in arm movements 5 The two researchers adopted a range of the kinetic range, the tidal and flexural movements of the joint and the muscles associated with the joint, which have a relationship between the length of the force arm and the strength of the muscle, which represent an important scientific fact determined by Which determines the strength resulting
from muscle contraction whether it is positive against gravity or negative with the gravity of the work of the muscles working on this joint if it is a driving force or a resistance force. This is what the researchers adopted in his rehabilitation program, which achieved the purpose of using these exercises. The results were significant for the members of the research sample in this field. Most exercises have different characteristics and have the effect in many fields but most often they are related to motor efficiency. Mechanical, chemical and other order attainment type of development in muscular work.

**Conclusion**

In the light of the results obtained by the researchers through this applied study we can conclude the following: Therapeutic exercises have an effect in the rehabilitation stage as a result of giving the affected organ the increased kinetic action of the muscles involved in the performance. All the exercises that have been implemented and through the positive results of the level of improvement evidence that the injured member began to receive nerve cells correctly. In the light of the results also achieved the period of time to give such exercises that helped give the joint flexibility that helped achieve the goal of performance during the rehabilitation period.

Effectiveness of an Instructional Program on Promoting Lifestyle of Patients with diabetes Mellitus type 2 at Diabetes and Endocrinology Center in Missan City

Sarah Falah Hassan¹, Khalida Alwan Mansur²
¹MSc Student, ²Professor, Adult Nursing Department, College of Nursing, University of Baghdad, Iraq

ABSTRACT

Diabetes in adults is a global health problem. Diabetes mellitus is a disorder of the endocrine system characterized by abnormal fluctuations in blood glucose levels, usually related to a defect in insulin production and glucose metabolism. Aim: To assess effectiveness of the instructional program on promoting lifestyle of patient with diabetes mellitus type 2. A quasi-experimental design (two-group pretest-posttest) was used to conduct this study. The present study was carried out at Diabetes and Endocrinology Center in Missan Governorate/Iraq for the period 8th of October 2018 to 28th of April 2019. A non-probability (purposive) sample of (100) patients was selected. a 28 item self-rated questionnaire was constructed for the purpose of the study. Validity and reliability of the instrument were determined through a pilot study. Data were analyzed through the use of Statistical Package for Social Sciences (SPSS) version. Descriptive and inferential statistical measures were employed. The study indicated that the life style levels of participants were inadequate for both groups in the pre-test, but the study group life style levels scores have increased after introducing them to the instructional program. Thus, there were significant differences between both groups.

Keywords: Promoting Lifestyle, Patients, diabetes Mellitus type 2, Endocrinology

Introduction

The proportion of people with type 2 diabetes is on the rise and is a major cause of death world-wide. Type 2 diabetes is a major risk factor for vascular disease with 65% of all diabetic deaths being due to cardiovascular disease. Lifestyle characteristics, such as physical activity, diet, and stress are important factors that influence development and prognosis of type 2 diabetes. Changes in diet and increase in physical activity (walking, etc.) and exercise (running, cycling, etc.) are key components of the management of type 2 diabetes, and guidelines recommend changes in these lifestyle characteristics for both prevention and management of the disease.(¹) The number of people with diabetes has risen from 108 million in 1980 to 422 million in 2014. The global prevalence of diabetes among adults over 18 years of age has risen from 4.7% in 1980 to 8.5% in 2014. Diabetes prevalence has been rising more rapidly in middle- and low-income countries. (²) Diabetes is a major cause of blindness, kidney failure, heart attacks, stroke and lower limb amputation. In 2015, an estimated 1.6 million deaths were directly caused by diabetes. Another 2.2 million deaths were attributable to high blood glucose in 2012. (³)

Methodology

A quasi-experimental design was carried out at Diabetes and Endocrinology Center in Missan Governorate from 8th of October 2018 to 22 of May 2019. The sample involved patients at Diabetes and Endocrinology Center which is divided into two groups, one is study group (50) patients and one is control group (50) patients. A non-probability (purposive) sample of (100) patients was selected. The researcher depends on Type 2 Diabetes and Health Promotion Scale (T2DHPS) which is a 28-item self-rated questionnaire that assesses six domains related to lifestyle. Reliability was determined through collecting the data from 10 patients and performing test and re-test, the reliability coefficient results are significant for knowledge and validity of questionnaire was determined through the experts.

n= number of samples, S.D = Standard Deviation, Ass. = assessment L= Low level of life style (1-2.5), M= moderate level of life style (2.6-3.5), G= high level of life style (3.6-5).

Table (4-5) Demonstrated the items of life style of diabetes mellitus patients related to Health responsibility and healthy Diet that shows all patients life style levels were low at pre and post-test for the control group while low life style at pretest and high at posttest for study group. Analysis of diabetes mellitus patients’ demographic characteristics revealed that the half (50%) of the study group and (32%) of the control group were (50-59) years old. This study congruent with (Al-Ebrahimy, 2003; Upadhyay,2008). Regarding gender, the study finding revealed that more than half (52%) in the study group were males while the control group, female patients were recorded slightly increased than male and they are accounted 29 (58%), and 21(42%) respectively. Viera et al 2006 mention that the male/female ratio, is now equivalent or minimally favors females and is due in great part to the healthier lifestyle followed by women. One explanation for this difference in sex distribution of the disease may be that females use more health services and pay more attention to their health. Regarding educational status, the study finding displayed that (58%) majority of study and (36%) of control were low educated levels (Primary School). This study was supported by Saffari et al,2015 who reported that the majority of patients low educated levels. Concerning to occupational status of the patients, a high percentage (44%) of study and (58%) of the control, were House wife. This study was supported by Saffari et al,2015 who reported that House wife present the majority of patients. Regarding Marital status, the
study finding most patients were married, and they are accounted 46(92%) and 37(74%) in study and control group. This finding was supported by Awodele, 2015. Data analysis of present study have revealed that most participants reported a level of life style were Low at pre and posttest in all items of scale (all domains) for control group, while Low level of life style at pre and high level of life style at post the implementation for the study group. The implementation of instructional program has a positive effect on patients regarding (physical activity, risk reduction, stress management, enjoyment of life, health responsibility and healthy diet) tables (4-3, 4-4, 4-5). The data analysis of six domains of Health promoting lifestyle domains of DM patients shows that the control group had revealed that there are no significant differences between pre and posttests of Health promoting lifestyle domains (physical activity, risk reduction, stress management, enjoyment of life, and health responsibility domains) except (healthy diet domain) (p-value = .019) table (6). Sone et al 2010; Schellenberg 2013 both these studies found a lack of involvement by patients in activities, and total physical activity after intervention was significantly higher in the study group than in the control group. There is a statistically significant difference in Risk Reduction for participants in the instructional program this study was supported by (Perreault et al, 2012). Krishna, (2018); Zhang et al 2009 found that psychological distress is an important concern of many type 2 diabetes patients and coping with that distress is their main priority to improve stress management levels (11,12) This finding indicates the positive influence of the instructional program in improvement patient’s health responsibility. This study is supported by Mary (2008): Chang, et al (2015), the statistically significant difference in healthy diet Responsibility for patients (pre – post) periods through implementation of instructional program shows the positive influence of the instructional program in improvement patients healthy diet responsibility. This study is supported by Evert et al, (2014), the difference in Physical Activity for participants in the study group between the pretest and posttest time (p-value = .001). supported by Kirk 2004; Balducci 2017; Johansen 2017 where intervention included 5 to 6 weekly aerobic training sessions (duration 30-60 minutes).

**Conclusion**

The instructional program was effective in promoting patient’s lifestyle related to T2DM (for all domains).

**Source of Funding:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the University of Baghdad, College of Nursing, Iraq and all experiments were carried out in accordance with approved guidelines.

Outcomes of Laparoscopic Appendicectomy in Al-Diwanyiah Teaching Hospital

Zaman Alrekabi¹, Muayad Alkafaji¹, Shakir Abid Jassim¹
¹General Surgery, Al-diwaniyah Teaching Hospital, Department of Surgery, AL-Diwania, Iraq

ABSTRACT

Aim of the study: To evaluate the clinical results of laparoscopic appendectomy for the treatment of chronic or recurrent appendicitis and interval appendicectomy. A prospective analysis was conducted at Al-Diwanyiah Teaching Hospital on 100 cases of laparoscopic appendicectomy over a period between January 2013 to January 2016. The diagnosis of appendicitis was established with history, physical examination, laboratory tests and ultrasound examination. The patients were analyzed for age, sex, conversion rate, operation time, postoperative complications, length of hospital stay, time to return to work and cost effectiveness. The postoperative complications including wound infection and ileus were generally low in our study with short hospital stay and early return to work and normal activity. Complication rate is higher after interval laparoscopic appendicectomy than laparoscopic appendicectomy for chronic appendicitis as well as operative time, conversion rate and hospital stay. Laparoscopic appendicectomy is a safe and effective procedure in the management of chronic or recurrent appendicitis and as interval appendicectomy after non-operative management of appendicular mass. There is an indication that laparoscopy is becoming an excellent method for management of recurrent or chronic appendicitis.

Keywords: Recurrent appendicitis, chronic appendicitis, interval appendicectomy, laparoscopic appendicectomy

Introduction

Laparoscopic appendectomy has become a common procedure worldwide in recent years. Numerous studies tried to define the role of laparoscopic appendectomy in the treatment of chronic appendicitis. Interval appendectomy is defined as performing an appendectomy following initial successful non-operative management of appendicular mass. Most patients underwent interval appendectomy 2 to 4 months after their acute presentation. The major argument against interval appendectomy is that many patients treated conservatively never develop manifestations of appendicitis, and those who do generally can be treated without additional morbidity. The major argument for interval appendectomy is to prevent future attacks of appendicitis and the need to establish a definite diagnosis and to rule out an underlying malignancy. The precise etiology is unknown. Recurrent appendicitis is thought to occur from transient obstruction of the appendix or secondary to excessive mucus production, while chronic appendicitis is secondary to partial but persistent obstruction of the appendiceal lumen. In both cases, luminal secretions accumulate until they are subsequently released.

Methodology

A prospective clinical analysis on 100 cases of laparoscopic appendicectomy over a period between January 2013 to January 2016 was conducted at Al-Diwanyiah Teaching Hospital. The diagnosis of appendicitis was established with history, physical examination, laboratory tests and ultrasound examination. Operations were performed by many surgeons who are licensed to practice laparoscopic surgery. The inclusion criteria for our study on laparoscopic appendectomy were:

- chronic recurrent symptoms that could be attributed to appendicitis.
- interval appendicitis after 2-4 months of non-operative management of appendicular mass.
- age 15 years or more.

All patients in whom we performed a laparoscopic appendectomy or an appendectomy with conversion to an open procedure were included in our analysis (100 pts). The patients were categorized for age, sex, conversion rate, operation time, postoperative complications, length of hospital stay, time to return to work and cost effectiveness.
Surgical team and surgical technique: The surgical operations were performed by a surgical team consisting of an experienced surgeon, a surgical trainee and a scrub nurse. Laparoscopic appendicectomy was performed under general anesthesia and all patients received prophylactic antibiotics (ceftriaxone 1 gram IV) at time of induction of anesthesia followed by 2 subsequent doses at 8 and 16 hours post op. Laparoscopic appendicectomy was performed with 3 ports; a 10-mm umbilical, a 10-mm suprapubic, and a 5-mm port in the left iliac fossa. Intraabdominal pressure of approximately 12 mm-Hg was provided by CO\textsubscript{2} insufflation. The mesoappendix was divided using harmonic ace. The base of the appendix was ligated twice with 2/0 vicryl endo-loop. The appendix was cut out with scissors. The appendix was removed from the abdominal cavity with a plastic bag or a piece of glove through the 10-mm port site. Peritoneal suction-irrigation with normal saline solution was performed in some patients.

Results and Discussion

A total of 100 patients examined. There were 81 (81%) appendicectomies for chronic or recurrent appendicitis (Group I) and 19 (19%) interval appendicectomies Group (II). 58 male and 42 female patients included in the study.

M:F ratio was 1.38 : 1 (table 1) Mean age for all 100 cases was 20.1 years, range from 15 to 30 (table 2)

The mean operative time was 44 minutes while it was 41 min for group I and 56 min for group II. The operation times were shown in (table 3). Post op. complications occurred in 9 cases: 3 wound infections and 6 cases developed paralytic ileus. Postoperative complications were shown in (table 4). Conversion rate in our study was 5% as shown in (table 5). 86 patients (86%) were discharged from the hospital in the first postoperative day, 8 patients (8%) in the second, and 6 patients (6%) in the third day. Mean hospital stay was 29 hours while in group I it was 27 h and in group II was 36 h. (table 6) Patients returned to work or full activity within 5-7 day (mean 5.77 days).

The first laparoscopic appendectomy was performed by Semm in 1983. Laparoscopic appendectomy is being done at a time when laparoscopic cholecystectomy has shown definite benefits over open technique. A number of meta-analyses have been performed evaluating the cumulative outcomes of multiple prospective studies and randomized controlled trials around laparoscopic appendectomy. Laparoscopic appendectomy is associated with fewer incisional surgical site infections compared to open appendectomy. There is less pain, shorter length of stay, and quicker return to normal activity and better cosmetic results. Laparoscopic appendectomy is associated with increased operative duration and increased operating rooms costs; however, overall costs are likely lower when compared to open appendectomy. Patients tend to have improved satisfaction scores with laparoscopic appendectomy compared to open appendectomy. Laparoscopic technique also provides a clear view of the whole abdominal cavity and pelvic organs in female patients for example. A study reported a fewer intra-abdominal adhesions after laparoscopic appendectomy compared to open appendectomy by reducing tissue trauma which in turn reduces circulating inflammatory mediators. Relative risk factors of laparoscopic surgery includes:

- Bleeding
- Visceral injury
- Incomplete appendicectomy

These are significantly reduced with surgeon’s experience.

There are relative contraindications to laparoscopic appendicectomy given by surgeons which include previous operations on the lower abdomen and situations where a pneumoperitoneum may has deleterious hemodynamic effects.

**Wound infection:** The average wound infection rate for laparoscopic appendectomy is reported to be 2.8% in a meta-analysis and 2.5% in a big prospective multi-center study. While infection rate is reduced by a half in the most recent meta-analysis based on the study of more than 6000 cases of laparoscopic appendicectomy.

Wound infection rate in our study was measured and was 3 cases (3%) one case from group I and the other 2 from group II. Although wound infection was higher after interval appendicectomy it was statistically not significant due to small number of cases of wound infection. All three cases of wound infection treated conservatively as out patient. **Post op. paralytic ileus** occurred in 6 cases (6%) and treated conservatively as in-patient.

Paralytic ileus occurred in 3 cases in group I (3.7%) and 3 cases in group II (10.5%).

The percentage of post op. complication is much higher in group II may be due to the small sample.

**Conversion Rate:** Conversion rate ranges in meta-analyses between 0% and 23% but there are studies which report conversion rates as high as 39%. In everyday practice conversion rate typically seems to range between 10 and 20%. In our study the conversion rate was 5% and the incidence was higher in group II than in group I. (15.7% vs. 2.5%).

Causes of conversion were mostly due to excessive adhesions, phlegmonous mass or difficulty to visualize or find the appendix. This is mainly encountered in cases of interval laparoscopic appendicectomy.

**Operative times:** In considering operating time the exact identification of the timing of the start of the procedure and its conclusion vary. In general the time should be calculated from the insertion of the first trocar to the end of skin suturing, which is the time calculated in our study. Generally all laparoscopic procedures are more time consuming for the following reasons:

1. Inherent nature of slow maneuver of laparoscopic techniques.
2. Time taken by careful slow insufflation.
3. Routine diagnostic laparoscopy before starting procedure.

A meta-analysis of randomized controlled trial has been reported showing the mean operating time was 52 minutes.
In our study the mean operating time was 44 minutes with prolongation of mean time in interval appendicectomy cases 56 minutes vs. 41 minutes in chronic or recurrent appendicitis group.

**Hospital stay:** In a retrospective study on 176 patients, the mean hospital stay was 37.2 h. All the patients in our study were discharged from hospital between day 1 and day 3 post op. but the majority discharged on the first post op. day (86%). Patients who delayed were those who developed complications mostly ileus or those who live in rural areas. The mean hospital stay after laparoscopic appendicectomy in our study was 29 hours.

The mean hospital stay was longer in group II due to more percentage of ileus than group I (36 h vs. 27 h).

**Time to return to work or normal activity:** In a randomized prospective study the average time to return to work was 8 days. In our study the patients returned to normal activity and work in 5-8 days. The average time was 5.77 days. Those who delayed were mostly the patients with post operative complications.

**Cost effectiveness of laparoscopic appendicectomy:** Debate still exists about the cost comparison between laparoscopic and open surgery. Most surgeons believe that laparoscopic appendicectomy is cost effective. It may be more expensive for the hospital due to the cost of laparoscopic equipment, but it offers diagnostic accuracy, lower complications and among employed patients offer cost savings to society as a result of faster return to work.

**Conclusion**

Laparoscopic appendicectomy is a safe and effective procedure in the management of chronic or recurrent appendicitis and as interval appendicectomy after non-operative management of appendicular mass. It resulted in minimal morbidity in experienced hands and it presents advantages such as short hospitalization and early return to work and cost effectiveness. For this reason disadvantages such as longer duration of surgery, higher hospital costs as well as technical limitations must be overcome. There is an indication that laparoscopy is becoming an excellent choice for management of recurrent or chronic appendicitis.

**Source of Funding:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved and all experiments were carried out in accordance with approved guidelines.

Thyroid Hormone Changes in Early Pregnancy Bleeding
Versus Normal Healthy Pregnancy

Samah Radhi Lateef
Maternity and Children Hospital in Al Diwaniyah, Ministry of Health, Iraq

ABSTRACT

This study was done to measure the thyroid hormones levels in patient with unexplained early pregnancy bleeding at their first half of gestation and to compare it with those of normal healthy pregnancy from the period of first of October 2017-first of July 2018. This is a case control study conducted in Basra maternity hospital which includes two groups of patients: A: Case group: This include 40 pregnant patients with history of un explained early pregnancy bleeding taken as a case group, with gestational age of up to twenty weeks, with parity range of 05, after we took their consent to be included in the study. B: Control group: Including 58 pregnant healthy women taken as control group they had approximately the same age and parity range those patient was selected from out patient who attend for other cause other than early pregnancy bleeding or those who brought our patient as an attendant. There was a significant decrement in the level of T4, with significant changes in the level of TSH among cases with early pregnancy bleeding compared with normal healthy pregnancy while T3 show no significant changes.

Keywords: Thyroid Hormone, Pregnancy, Bleeding Versus Normal Healthy.

Introduction

Thyroid disease is common in general population, and especially in young women. The incidence of thyrotoxicosis, hypothyroidism, and thyroiditis is probably approaches 1 % for each condition (1). The impact of pregnancy on maternal thyroid physiology is substantial. There are changes in the structure and function of gland that confusing in the diagnosis of thyroid abnormalities, consequently evaluation of thyroid disorders and proper interpretation of thyroid function tests during pregnancy requires an understanding of these changes (2). Thyroid gland is the biggest gland in the neck, the normal adult thyroid gland weight about 15-25g and consists of two lobes connected by an isthmus each thyroid lobe is divided in to lobules consisting 20-40 follicles (3). Thyroid gland volume determined, ultrasonographically, increases during pregnancy, although its echo structure and echogenicity remain unchanged (4,6). Anatomically, there is moderate thyroid gland enlargement as result of glandular hyperplasia and increased vascularity Conversely, pregnancy, usually dose not cause impressive thyromegally and thus any goiter or nodule should be approached as pathological (11). The thyroid gland is responsible for synthesizing and secreting thyroid hormones, L-thyroxine (T4) and L-iodothyronine (T3). The concentration of circulating free thyroid hormone is closely regulated by hypothalamic-pituitary-thyroid axis. This free thyroid hormone enters the cell, where T4 is converted to T3. T3 then control the metabolism (5). The synthesis of thyroid hormone regulated by thyroid releasing hormone (TRH) which is secreted by hypothalamus and stimulates the production of thyroid stimulating hormone (TSH) from the anterior lobe of pituitary which then stimulates the production and release of T4 and T3 from the thyroid gland (7). The synthesis of these hormones by thyroid gland requires iodine. After releasing of T3 and T4 they exert negative feedback mechanism on TSH production. T4 is the main hormone produced by the thyroid gland while T3 is mainly produced by peripheral conversion of T4, both T3 and T4 are largely protein bound in the plasma, mainly to thyroxin-binding globulin (TBG), only the un bound or free portion (FT3,FT4) is active (5). Iodine is a major component of thyroid hormones with dietary requirements increasing in pregnancy due to the enhanced transplacental uptake of iodide and increased maternal renal clearance (8). Hence pregnancy is a state of relative iodine – deficiency (9).
**Spectrum of Thyroid Disease in Pregnancy:** Several of thyroid disorders which tend to occur during pregnancy are autoimmune in nature, by this we mean that the body develops antibodies directed against thyroid cells, which then affect the way the thyroid gland functions. Antibodies which damage the thyroid cells may result in lymphocytic thyroiditis (inflammation of the thyroid), also known as Hashemite’s disease. These damaging antibodies can reduce the function of the thyroid and lead to hypothyroidism. On the other hand, our body can make antibodies against thyroid tissue which can stimulate thyroid cell function, in this case, hyperthyroidism due to over-function of thyroid (graves’ disease) may be the result. Postpartum thyroiditis is recently discovered problem that span the spectrum of both hyper-and hypothyroidism this condition, which tends to occur immediately after pregnancy, may produce antibodies which damage thyroid tissue, thereby releasing thyroid hormone passively into the blood stream and producing either temporary or permanent thyroid failure. Since this condition is common, occurring in 8-10% of all women after pregnancy, so postpartum thyroid testing is advisable for all women. Thyroid nodules, goiter, and other thyroid problems are also sometimes first detected in pregnancy but are less common.

**Hyperthyroidism and pregnancy:** Hyperthyroidism occurs in two of every 1000 pregnant women. This common disease of pregnancy may go undiagnosed because the clinical presentation of thyrotoxicosis is difficult to distinguish the apparent hyper metabolic state of pregnancy particularly in the second and third trimesters as perhaps expected mild thyrotoxicosis is difficult to diagnosis during pregnancy but some helpful sign include:

1. Tachycardia that exceeds the increase associated with normal pregnancy.
2. An abnormally elevated sleeping pulse rate.
3. Thyromegaly.
4. Exophthalmos.
5. Failure in a non obese woman to gain weight despite normal or increased food intake.

Confirmation has been made easier by assays to determine elevated serum free thyroxine levels along with recent development of assay that reliably measure thyrotropin level less than 0.05 µu/L. Rarely hyperthyroidism may be associated with normal serum thyroxin values but, so called T3 - toxicosis. Untreated or inadequately treated hyperthyroid women deliver Babies having higher incidence of minor fetal anomalies.

**Hyperthyroidism can affect the pregnancy:**

1. Preterm labour.
2. Increase Peri-natal mortality.
3. Maternal Heart failure where significantly increased in women who remain thyrotoxic despite treatment and in those, never treated.
4. Preeclampsia.

**Etiology of thyrotoxicosis in pregnancy:**

2. Toxic multi-nodular goiter.
3. Toxic adenoma.
4. Hyper emesis gravid arum.
5. Gestational trophoblastic neoplasia.
6. Pituitary hyper secretion of TSH.
7. Metastatic follicular cell carcinoma.
8. Exogenous T4 or T3.
9. De Quatrain’s thyroiditis.
10. Silent lymphocytic thyroiditis.
11. Struma ovarii.

**Graves’s disease and pregnancy:** The overwhelming cause of thyrotoxicosis in pregnancy is graves’ disease an organ specific autoimmune process usually associated with thyroid stimulating antibodies. These auto antibodies mimic thyrotrophic in it’s ability to stimulate thyroid function, consequently, they appear to be responsible for both thyroid hyper function and growth in graves disease, it has been reported that thyroid - stimulating antibody activity in graves disease usually declines during pregnancy.

**Hypothyroidism and pregnancy:** Hypothyroidism occur in pregnant women with frequency of about 1 in 1600-2000 deliveries, women with hypothyroidism had a higher incidence of:

1. Preeclampsia.
2. Placental abruption.
3. Low birth weight.
4. Still born infants.
5. Gestational hypertension.
6. Postpartum hemorrhage.
7. Anemia.
8. Cardiac dysfunction.

All pregnant women should be carefully asked about any personal or family history of thyroid disease or treatment directed at thyroid gland particularly of external radiation to the head and neck (26). The best biochemical tests for diagnosis of hypothyroidism are measurement of serum sensitive TSH and free T4. In primary hypothyroidism, the TSH level is elevated and free T4 level is low. If TSH level is elevated and free T4 level is normal, the patient may have sub clinical hypothyroidism. In secondary or pituitary hypothyroidism the TSH level is normal or low in setting of a low free T4, 10 % of patients with hypothyroidism have pernicious anemia, but neither vitamin B12 nor foliate deficiencies explain the macrocytic anemia that occurs in approximately one third of patients with hypothyroidism and anemia. Hypothyroidism usually is associated with mild normochromic, no myocytic anemia. Patients with insulin-dependent diabetes mellitus should be watched closely for development of hypothyroidism during pregnancy (14).

Differential diagnosis of hypothyroidism (22)

1. Hashimoto’s thyroiditis.
2. Post therapy hypothyroidism.
3. Suppurative and sub acute thyroiditis.
4. Drugs (thionamide therapy, iodides, and lithium, which inhibit the synthesis of thyroid hormones, secretion of thyroid hormone or both).
   Carbamazepine, phenytoin, and rifampicin can increase thyroxin clearance.
   Ferrous sulfate and sucralfate can interfere with intestinal absorption of thyroxin.
5. Lymphocytic hypophysis.
6. Iodine deficiency.

Iodine deficiency: Iodine deficiency is a common cause of hypothyroidism in many parts of the world, although it is exceeding rare in the united status. The hypothalamic - pituitary axis responds to iodine deficiency with hyper secretion of TSH. That is probably responsible for the formation of goiters and nodules (22). The goiter frequently grows during pregnancy, and multiple pregnancies result in much larger goiters than those occurring in nulliparous women. Many women may be clinically euthyroid but show biochemical hypothyroidism upon careful testing. The treatment is iodine supplementation, most practically accomplished when potassium iodide is added to salt (22).

Materials and Method

This is a case control study done in Basra maternity and children hospital aimed to study thyroid hormone change among pregnant women with history of early pregnancy bleeding during the period of first October 2007-first of July 2008, the study includes:

A. Case group: This includes 40 pregnant patients with history of un explained early pregnancy bleeding taken as a case group, with gestational age of up to twenty weeks, with parity range of 0->5, after we took their consent to be included in the study. Detail history was taken from them including their age and parity with detail previous obstetric history and history of past medical illnesses. Those patients with any of following events were excluded from the study:
   1. History of trauma.
   2. History of fever.
   3. History of maternal infection during gestation.
   4. History of drug intake like embryotoxic and other for chronic diseases.
   5. History of irradiation during pregnancy.
   6. History of repeated abortion.
   7. Medical illness like hypertension, sickle cell problem etc.

B. Control group: Including 58 pregnant healthy women taken as control group they had approximately the same age and parity range those patient was selected from out patient who attend for other cause other than early pregnancy
The pregnancy of the both groups was confirmed by the following criteria:
1. History of missed period.
2. History of morning sickness.
3. Clinical examination confirms pregnancy with soft and bulky uterus.
4. Laboratory confirmation by pregnancy test and ultrasonography.

Parity of the patient were classified as 0-1 nullipara or primiparous patient, 2-5 multiparous patient and >5 as grand multiparous patients. their age also classified as those <20year, 20-39year. So clinical and laboratory investigations confirming the presence of pregnancy were carried out for every candidate in each group.

**Specimen collection and handling:** 5ml of blood samples were collected by venipuncture from each candidate included in the study case and control group. The sample then centrifuged for 5 minutes then the serum was collected for immune enzymatic determination of TSH,T3,T4 using ELFA technique (enzyme linked fluorescent assay). This procedure carried out by VIDAS which is an automated quantities test and used for quantities measurement for TSH, T3,T4.

**Principle of the procedure:** By using of human serum of lithium heparinate (in amount of 0.1ml for TSH, 0.1ml for T3 and 0.2ml for T4) the assay principle combines an enzyme immune assay competition method with final fluorescent detection (ELIFA).

**Results and Discussion**

Table one shows the difference in thyroid hormone level according to parity among the two study group which evidently show no significant differences in TSH, T3, T4 values in both groups, except among grand multiparous women (5 parity) in which T3 value is about 1.76 µiu/l in case group compared to 1.2 µiu/l among control group with a significant P value of 0.44. Table two shows the thyroid hormone differences between cases and control according to the age as we see there was significant differences in T3 and T4 values in those with age (20-39) years, T3 values was 1.83 µ mol/l (p-value in cases which is higher than in control group 1.43 µ mol/l(p-value 0.49 significant) and not significant in those with age more than 40 years. T4 value 96.64 µ mol/l in cases which is lower than control group 105.8µmol/l (p-value 0.498 significant) and not significant in those with age 40 years or more. Table three TSH value in those with age 40year or more than was 2.165µiu/ml in cases which was also higher than control group 1.54iu/ml (p-value 0.499 significant) but not significant in those with age (20-39) years. Show thyroid hormone differences between cases mean level and control mean level where TSH value was 1.717µiu/ml in cases which is significantly higher than control group 1.311 (p-value 0.49 significant) T3 value was 1.735 µmol/l in cases and 1.564µmol/l in control group in which the difference is of no significant.

Although thyroid hormone had definite impact on fertility and on the outcome of pregnancy and because of the vitality of thyroid hormone and the pregnant lady, that why we see definite diffuse enlargement of thyroid gland during normal healthy pregnancy this explain the increase demand of the pregnant women to the thyroid hormone, unfortunately no studies found similar to our study and In spite of many studies available regarding the physiological changes In the thyroid during pregnancy, it is uncertain if functional disorder of thyroid play a role in the etiology of spontaneous abortions. Maruo et al. proposed that maternal thyroid hormone level are one of endocrine Factors responsible for the threatened abortion. Ross et al. Indicated that Functional disorders of thyroid are not effective in the outcomes of miscarriage, this is in contrast to our study where we found that there is significant decrement in the level of T4 among those with early pregnancy bleeding. Lower TT3,TT4,FT3,FT4 levels and higher TSH values was obtained in the spontaneous abortions group are an indication of the presence of a hypothyroidism situation in this group which goes with our study which evidently showed an increment in the level of TSH among case group as was shown in Table III with a significant decrement in the level of T4 among the same group thus, there are several publications indicating that the ratio of spontaneous abortions rises two -fold in women with hypothyroid as compared to euthyroid women this in turn indicate the importance of thyroxin hormone in the continuation of normal healthy pregnancy.

Conclusion

There was a significant decrement in the level of T4, with significant changes in the level of TSH among cases with early pregnancy bleeding compare with normal healthy pregnancy while T3 show no significant changes; this is possibly because T4 is the main circulating hormone in the blood.

Impact of Danger Signs During Pregnancy Upon Pregnancy Outcomes among Pregnant Women in Al-Diwania City

Fatima S. Baker¹, Hala S. Abdulwahid²

¹Clinical Nurse Specialist, Al Diwania Health Directorate, Iraq; ²Assistant Professor, Community Health Nursing Department, College of Nursing, University of Baghdad

ABSTRACT

Objective(s): To determine the impact of danger signs during pregnancy upon pregnancy outcomes and their relationships with pregnant women demographic characteristics at hospitals and primary health care centers in Al-Diwaniya City. A descriptive design, using evaluation approach, is carried throughout the present study for the period of November 3rd 2018 through May 27th 2019. A purposive sample of (200) pregnant women is selected for the study. A self-report questionnaire is constructed for the purpose of the study which is comprised of (7) Parts that include demographic characteristics, medical history, family history, obstetric history, danger signs during pregnancy and pregnancy outcomes. Data are collected the use of the questionnaire and the structured interview. Data are analyzed through application of descriptive statistical data analysis approach of frequency, percentage, total score and inferential statistical data analysis approach of Multiple Linear Regression. The study findings indicate that the study has confirmed that there is significant impact of danger signs during pregnancy upon pregnancy outcomes of pregnant women in Al-Diwaniya City. The study concludes that the study approves those pregnant women who are housewives with low education and unhealthy medical, family and obstetric histories may experience more danger signs during pregnancy than others.

Keywords: Impact, Danger signs during Pregnancy, Pregnancy Outcomes

Introduction

Pregnancy related complications are among the greatest killers of women of reproductive age in developing countries. Many pregnant women may face the risk of sudden, unpredictable complications that could end in death or injury to herself or to her baby (¹). Studies suggest not all women regard pregnancy complications as abnormal, owing to a lack of knowledge about ‘danger signs’. Danger signs in pregnancy include vaginal bleeding, persistent severe headache or blurred vision (visual disturbances), severe nausea and vomiting, severe abdominal pain, swollen hands and face during the third trimester, reduced fetal movement (baby’s activity level significantly declines), weakness and difficulty in breathing, contractions early in the third trimester, water breaks (rupture of the membrane) and flu symptoms (²). World Health Organization (WHO) estimates that about (300) million women in the developing countries suffer from short and long term illnesses due to complications related to pregnancy and childbirth. About (529,000) mothers die each year from maternal causes, out of which (99%) of deaths being from the developing world (³). As literatures indicate about (75%) of maternal deaths are due to direct obstetric complications, such as hemorrhage, sepsis, hypertensive disorders of pregnancy, obstructed and prolonged labor, and unsafe abortion. Maternal morbidity and mortality could be prevented significantly if women and their families recognize obstetric danger signs and promptly seek health care. The (4) commonest danger signs during pregnancy include severe vaginal bleeding, swollen hands and face and blurred vision. Key danger signs during labor and childbirth include severe vaginal bleeding, prolonged labor, convulsions, and retained placenta. Danger signs during the postpartum period include severe bleeding following childbirth, loss of consciousness after childbirth, and fever. Raising awareness of pregnant women on the danger signs would improve early detection of problems and reduces the delay in deciding to seek obstetric care (⁴). Based on the early stated evidence, the present study attempts to investigate the impact of danger signs during pregnancy upon the pregnancy outcomes among pregnant women in Al-Diwaniya City.
Methodology

A descriptive design, using evaluation approach, is carried throughout the present study to determine the impact of danger signs upon pregnancy outcomes of pregnant women and their relationships with pregnant women demographic characteristics in Al-Diwanyia City for the period of November 3rd 2018 through May 27th 2019. A purposive sample of (200) pregnant women is selected for the study. A self-report questionnaire is constructed for the purpose of the study which is comprised of (7) Parts that include demographic characteristics of age education and occupation, medical history (21) item, family history (21) item and obstetric history (7) items, as well as danger signs during pregnancy (16) item and pregnancy outcomes (11) item. Pilot study is conducted on (10) pregnant women with danger signs for the purpose of determining content validity through panel of experts and internal consistency reliability of the study instrument that employment of split-half technique and computation of Cronbach alpha correlation coefficient of (r=87) from January 17th 2019 to March 2nd 2019. Data are collected the use of the questionnaire and the structured interview technique for the period of March 6th 2019 through May 2nd 2019. Data are analyzed through application of descriptive statistical data analysis approach of frequency, percentage, total score and inferential statistical data analysis approach of Multiple Linear Regression.

Dependent Variable: Pregnancy Outcomes

B= Regression Coefficient, Std. Error= Standard Error, t= T-test, Sig.= Level of Significance

Results out of this table reveal that there is no significant relationship between women’s pregnancy outcomes and their demographic characteristics. Throughout the course of data analysis, the study findings depict that danger signs during pregnancy can create major impact upon pregnancy outcomes (Table 1). A health facility-based cross-sectional study has been conducted. Throughout the course of the study, data are collected through interviewer-administered questionnaires. Descriptive and inferential statistics are used to analyze the data. The study enrolled (384) women from two health centers in Kinondoni Municipality, Dar es Salaam, Tanzania. The study findings present supportive empirical evidence that danger signs can create critical impact upon pregnancy outcomes (4). A cluster randomized controlled trial is carried out and in which the study findings have approved that danger signs can initiate an influential impact upon maternal outcomes (5). Analysis of such relationship illustrates that pregnant women’s education, occupation, medical history, family history and obstetric history have made critical contribution to that of pregnancy danger signs (Table 2). Such findings can be interpreted in a manner that pregnant women who are housewives with low education and unhealthy medical, family and obstetric histories may experience more danger signs during pregnancy than others. A health facility-based cross-sectional study is conducted. Quantitative data are collected through interviewer-administered questionnaires. Descriptive and inferential statistics are used to analyze the data. The study enrolled (384) women from two health centers in Kinondoni Municipality, Dar es Salaam, Tanzania. Among the (384) participants, 67 (17.4%) had experienced danger signs during their pregnancy and five (1.3%) have no education, 175 (45.6%) have primary education, 172 (44.8%) have secondary education, and 32 (8.3%) have post-secondary education as their highest educational levels (4). Analysis for such relationship depicts that pregnant women’s age, education, occupation, medical history, family history and obstetric history do not make any influence to pregnancy outcomes (Table 3). Cohort study assessed whether maternal employment during pregnancy – overall and in selected occupational sectors – is associated with birth weight, small for gestational age (SGA), term low birth weight (LBW), length of gestation, and preterm delivery in a population-based birth cohort design. Data from >200 000 mother-child pairs enrolled in (13) European birth cohorts are collected and compared employed versus non-employed women. Among employees, we defined groups of occupations representing the main sectors of employment for women where potential reproductive hazards are considered to be present. The comparison group comprised all other employed women not included in the occupational sector being assessed. Meta-analyses of cohort-specific estimates and explored heterogeneity have been performed. The study found that employees had a lower risk of preterm delivery than non-employees [adjusted odds ratio (OR adj) 0.86, 95% confidence interval (95% CI) 0.81–0.91]. Working in most of the occupational sectors studied was not associated with adverse birth outcomes. Being employed as a nurse was associated with lower risk SGA infants (OR adj 0.91, 95% CI 0.84–0.99) whereas food industry workers had an increased risk of preterm delivery (OR adj 1.50, 95% CI 1.12–2.02). There was little evidence for heterogeneity between cohorts. This study suggests that, overall, employment during pregnancy is associated with
a reduction in the risk of preterm birth and that work in certain occupations may affect pregnancy outcomes. This exploratory study provides an important platform on which to base further prospective studies focused on the potential consequences of maternal occupational exposures during pregnancy on child development (6).

Cohort study was conducted to investigate the association between maternal job strain during pregnancy and neurodevelopment in infancy. Job strain during pregnancy was measured using Korean version of Job Content Questionnaire (JCQ). Infant neurodevelopment was assessed using Korean Bayley Scale of Infant Development II (K-BSID-II) at 6 and 12 months of age. A total of 343 mother-child pairs that completed JCQ and K-BSID-II more than once were included. Mental Developmental Index (MDI) and Psychomotor Developmental Index (PDI) defined in the K-BSID-II were used as outcome variables. Compared to infants from mothers with low job strain, significant ($p<0.05$) decreases in PDI were found in infants from mothers with active and passive job at 6 months of age. After stratification by infant sex, boys in the high strain group had a lower MDI score than boys in the low job strain group at 12 months. On the other hand, girls in the high strain and active groups had lower PDI scores than girls in the low job strain group at 12 months. MDI at 12 months also showed different results by sex. Boys in the high strain and active job groups had lower PDI scores than boys in the low job strain group. However, such difference was not observed in girls. The findings of this study suggest that prenatal job strain affects infant neurodevelopment in a gender-dependent manner (7).

A case-control study of (n=2543) nested within a cohort of (58316) births in Los Angeles County, California investigated preterm birth (PTB) in relation to maternal occupational exposure and whether effect measures were modified by Hispanic ethnicity and nativity in a population-based sample with high proportion of Hispanics. The study categorized prenatal occupations using the US Census Occupation Codes and Classification System and developed a job exposure matrix. Odds ratios for PTB were estimated using logistic regression. The study indicated that odds ratios for PTB were increased for all women in health care practitioner and technical occupations, but the 95% confidence intervals included the null value; effects were more pronounced among Hispanics. We estimated elevated odds ratios for foreign-born Hispanic women in building and grounds cleaning and maintenance occupations. Shift work and physically demanding work affected births among US-born but not foreign-born Hispanics. The study concluded that Hispanic women are at particular risk for PTB related to adverse prenatal occupational exposure. Nativit may moderate these effects on PTB. Maternal occupational exposures likely contribute to ethnic disparities in PTB (8).

**Conclusion**

The study confirms that danger signs during pregnancy have a major impact upon pregnancy outcomes. The study approves those pregnant women who are housewives with low education and unhealthy medical, family and obstetric histories may experience more danger signs during pregnancy than others. The study supports that pregnant women’s age, education, occupation, medical history, family history and obstetric history do not make any contribution to pregnancy outcomes.

The Exercises by Limbs Efforts Unilateral Bilateral and its Impact on Indicators of Electrical Activity Muscular Capacity and Long Pass of Football to Reduce Bilateral Deficits for Young Players

Khalid Oudah Gshayyish1, Habeeb Shaker Jebur2, Riyadh Hassan Salah3
1College of Physical Education and Sports Sciences, University Muthanna, Iraq; 2Asst. Prof., College of Physical Education and Sports Sciences, University Muthanna, Iraq; 3Directorate Generate of Muthanna Education, Iraq

ABSTRACT
Identifying the exercises by limbs efforts (unilateral - bilateral) and its impact on indicators of electrical activity, muscular capacity and long pass of football to reduce bilateral deficits for young players of Samawa Sports Club. Identifying the differences between the two groups of research in the indicators of electrical activity, muscle capacity and long pass of football to reduce the double deficit of the players of the players of Samawa Sports Club. In order to achieve these objectives, the researcher used the experimental method in the two groups approach, the research tools were the emerging football players belonging to the Samawa Sports Club, (16) players, as well as data collection methods. After a series of field procedures to ensure the validity of the tests, the researchers began the procedures of tribal testing and then apply exercises by the work of the terminal (unilateral - bilateral) the first experimental group operates the bilateral terminal work while the second experimental group operates the unilateral terminal work. After completion, the remote tests were carried out.

Keywords: terminal work (unilateral - bilateral), electrical activity, muscular capacity, long pass, double deficit

Introduction
There is a growing interest in the game of football in the developed countries, whether developed or developing, because of the role of this game in the status of everyone. This game has received a lot of research and this research has played an important role and the development of the level of players, and countries are making great efforts to provide material and moral facilities to upgrade these game for different categories and ages. The modern scientific devices, in particular EMG and its programs in measuring and analyzing the electrical activity of the muscle, were introduced to determine the work of the motor units of these working muscles. In order to upgrade the players level, it is necessary to focus on all aspects of physical, skill, planning and psychological depending on all the scientific devices and upgrade them because the game of football is complex and changing circumstances and often imposed on the player to be in all situations and situations and efficiency. The phenomenon of bilateral disability is a phenomenon especially for the upper and lower limbs, which we observe often at the weak end, because when the player plays the ball with the non-preferred man, he has difficulty in the strength, speed and accuracy of performance. The result of the game in general.

The theoretical importance of this study lies in the development of a knowledge framework for trainers on:

- The electrical activity of the active muscles of the preferred and non-preferred limbs for the purpose of reducing bilateral disability.
- The efficiency of the muscular system.

Methodology
The researcher used the experimental method in the style of the two groups with the tribal and remote test to suit the nature of the study and its objectives.
**Tools, instruments and devices used in research**

**The Research Tools:** The researchers used the following research tools to reach the results and achieve the objectives:

**The Research community:** The research community is represented by the beginner players from the Samawa Sports Club, with a total of (16) players.

**Means of data collection:** This research required many means of data collection:

**Note:** Through the follow-up and naked observation of football matches, as well as the use of new technologies (Internet), the researcher identified the problem of the study.

**Testing and Measurement:** The researchers used the appropriate tests to gather the data necessary to achieve the research objectives

**Hardware and tools (number), assistance:** The researchers used many devices and tools in the process of obtaining the required data, including: Football, handball, personal computer (lab tub), stationery (papers and pens), test results registration form

**Identification of the tests concerned with the research variables:** In order to determine the test for measuring the variables of research, a survey of the relevant scientific sources and references was conducted, resulting in the nomination of one test for measuring each variable. The researchers distributed a questionnaire to survey the opinions of (7) experts and specialists\(^1\) in this field to determine its validity \(^5\).

**The test Instructions:**
- The player stands behind the starting line directly.
- Do not support on the left leg.
- Three consecutive hops and Instability between any hops

1 \(^1\) The specialists who were referred to the questionnaire:
1 - Aqil Muslim Abdul Hussein, Professor, physiology specialist, football, college of Physical Education and Sports Sciences, University of Muthanna
2 - Salam Jabbar Sahib, Assistant Professor, Test and Measurement, Football, Faculty of Physical Education and Sports Sciences, University of Qadisiyah
3 - Mohammed Matar Arak, Assistant Professor, Test and Measurement, Football, college of Physical Education and Sports Sciences, Al-Muthanna University

- Each laboratory has three attempts to calculate the best.
- Test Management:
- Recorder: to call on testers and record results.
- Monitor: Calculates distances and monitors performance \(^6\).

**Calculation of grading:** Calculating the distance between the starting line and the last part of the ground-based foot is the same as the test for the left foot and the same procedure \(^7\).

**Electrical activity test (EMG):** In order to measure the electrical activity of the muscles with the help of the auxiliary team, the Myotrace 400 device was used by Noraxon to record the electrical activity of the 4 Channel structural muscles with a practical application program (1,07,41) which is the latest portable laboratory technology, And recording the electrical activity of four muscle groups at the same time and via Bluetooth signals to the limits of 20 meters away from the computer and requires action to take several steps are:

**Preparation:** After determining the target muscle groups of the work are:
- Quadriceps muscle
- Bilateral muscle.

To install the clamp on the surface of the muscle stabilizes in the middle third of the muscle, remove the hair and skin cornea located above the area to install the picker to ensure a good connection and then give you gauze and alcohol before installing the pickup.

**The exploratory experiments:**

**First:** First exploratory experiment: To verify the validity of the procedures used to conduct the tests, to know the availability of the conditions and to implement them, is a basic requirement, and its achievement necessitated conducting a survey on Sunday, 26/1/2019, on a sample of (8) selected players In a random way, from the club of Samawa – beginners.

The results of the researcher revealed all the purposes for which the experiment was conducted, which indicates the good response of the players and their rush to carry out the test, and the appropriate time for him and the good output and organization, how to conduct and apply and record the results.
Second: Second exploratory experiment: The researchers conducted the second exploratory study during the preparation period on Tuesday and Wednesday, 28-29/1/2019. The aim of the study was to determine whether there are differences between the productive force of the two feet and the collection of each foot separately.

- Choose the most appropriate one-way (single-bilateral) exercises to develop the speed of strength and long-distance handling of the emerging players belonging to Samawa Club.

- Apply two training modules to determine the components of the training load for these exercises.

The number of (18) exercises were chosen by the terminal, including nine unilateral side exercises and nine bilateral terminal exercises to develop the speed of strength of the muscles of the two men and the long pass of football.

The scientific factors for tests used in research:

First. The Honesty: The researchers concluded that the truth, based on the extent to which the test was measured for the phenomenon they measured (speed of force, long pass), was distributed by 7 specialists who indicated the validity of the tests by the following: (100%) of the total experts opinion to approve the representation of the test for the phenomenon measured by).

After collecting the data and unloading, the researchers used (the ka 2) test. The results showed that the two tests were accepted for values greater than (the ka 2) value of (3.84) at the degree of freedom (1) and the significance level (0.05).

Second: The Stability: The researchers tried to find the stability factor for the tests under study (muscle capacity, Long pass), by finding the correlation between their results, the results of retesting after a period of time 7 days.

After the correlation coefficient (Pearson) was calculated between the two test scores, it was found that the correlation was significant at the degree of freedom (6) and the significance level (0.05), indicating that the tests under examination were highly stable.

Third. Objectivity: The researchers tried to find the objective coefficients for the tests under consideration (muscular ability, Long pass), by finding the correlation between the results of the two arbitrators. After the correlation coefficient (Pearson) was calculated between the scores of the arbitrators, it was found that the correlation was significant at the degree of freedom (6) and the significance level (0.05), indicating that the tests under examination were highly objective.

The exercises in the limbs work (unilateral - bilateral): The researchers carried out the exercises in the limbs work (unilateral - bilateral) for the sample in question from 10/2/2019 to 30/4/2019 with three training units per week for a period of (12) weeks.

The post-tests: Post-tests on the sample were conducted on Sunday (2/5/2019) at 2:30 pm, including the same conditions and procedures as in the pro- tests.

Statistical Methods: The researchers used the statistical bag (SPSS) to process the data and show the results.

Results and Discussion

Based on the data extracted for the members of the research sample, Table (5) shows the differences in the values of the variables under study in the pre-test and post-experimental tests of the first experimental group. As shown in the table above, the nature of the sample showed a difference in the differences between the tribal and post-test. The results showed that there was a significant difference in the mean activity of the preferred leg and the use of the T test of the interrelated samples to extract the differences, with significant differences (2.69, 7.00 and 9.22) respectively at the mean level (0.03, 0.00, 0.00) Respectively.

In the light of the data extracted for the members of the research sample, Table (6) shows the differences in the values of the variables under study in the post-test of the first experimental group between the preferred and non-preferred men. As shown in the table above, the nature of the sample showed differences between the preferred and non-preferred. In the electrical activity (quadriceps, biceps), the speed of force, the accuracy of handling and the use of T test to extract the differences showed significant differences with their calculated values (7.57, 6.63, 8.64, 10.46) respectively at the level of 0.00, 0.00, 0.00, 0.00) respectively and for benefit of the favorite leg. It is clear from tables that there are statistically significant differences between the mean and the pro tests in the tests of electrical, physical and skill activity under study in favor of the post-test of the second experimental group, which works as a unilateral action, which is the performance of each individual leg.

Conclusions

Through the results and in light of the objectives and methodology used and within the sample of the research and the fact that the data collected by the researchers and in the framework of statistical treatments, it was possible to reach the following conclusions: There is a positive effect of the use of unilateral work of the two men in the electrical activity of the muscles of the two men to reduce the bilateral deficit of players in the football in question. There is a positive effect of the use of unilateral work of the two men in the speed of strength of the two men and the long handling of football to reduce the bilateral deficit of the players in the search

The Kinetic Compatibility of the Upper and Lower Limbs and their Relation to the Skill Level of Tennis for the Emerging Players

Wafaa Faeq Hammoodi¹, Aseel Naji²

¹Collage of Physical Education and Sports Science for Girls, University of Baghdad; ²College of Physical Education and Sports Sciences, University Muthanna

ABSTRACT

The duties of educational, educational and training is to pay attention to the physical compatibility of the players, where they must be prepared skillfully and physically for the purpose of performing motor skills and planning so that the player has a valid base to reach a high level in the performance of skills, hence the importance of research in identifying the relationship between compatibility of parties Upper and lower, and their relation to the skill level of the players. The researchers used the descriptive method of associative study on the 16 players. Of the academy and in the intentional manner. Thus, the measurement of the compatibility of the two men and the eyes was tested, the compatibility between the arms and the eyes was tested and the skill level of the accuracy of the transmitter was measured. Simple correlation Pearson and concluded that the existence of a significant correlation between the compatibility of the upper and lower limbs and the level of skill performance of the accuracy of the transmitter. Therefore, the researchers recommend the need to care about the motor capacity of the upper and lower limbs when performing the level of See for the accuracy of the transmitter.

Keywords: kinetic compatibility, upper and lower limbs.

Introduction

The tennis ball of important sports games that have an important role in the number of educated ¹ physically through Oak Lea motor compatibility development for novice players, where kinetic compatibility is necessary for any Sporting event in terms of achievement depends on the learner Maimitleke of these capabilities ², “can not master basic motor skills for the type of physical activity specialist for the type of skill in the case of lack of consensus motor necessary for this particular type of physical activity. One of the educational, educational and training duties is attention to compatibility Kinetic learner in order to be prepared Mharria and physically for the purpose of the performance of the motor and tactical skills so that the player has a valid base to reach a high level in the performance of the skill level ³. h At the tennis game you need a dynamic compatibility upper limbs and lower in all skills and in most of the time, both in the case of Attack or defense needs. The player to the compatibility so that he can perform skill correctly and harmoniously and have a high skill level to overcome the difficulties and positions that will be faced in competitions. Hence the importance of research in identifying the relationship between the kinetic compatibility of the upper and lower sides and their relation to the performance of the skill level of the players. Tennis is a sport that is characterized ⁴ by the speed of skill performance because it requires the strict compatibility of the learners. Through the experience of the researcher being a tennis teacher noted that most learners have a weak muscle compatibility and difficulty in performing ⁴ skills due to poor compatibility and the occurrence of excessive movements. The question is whether there is a relationship between the motor compatibility abilities of the upper and lower sides in
performing the skill level of the players? research goals: Identify the compatibility relationship between the upper and lower limbs and the skillful performance of the emerging players.

Force search. The existence of a significant correlation between the motor compatibility of the upper and lower limbs and the skill performance of the emerging players.

Methodology

The appropriate approach is one of the most important steps that result in the success of the research, “as the approach depends on the nature of the problem and the goal to be achieved.

Where the researcher used the descriptive method of associative study “which aims to determine the degree of relationship between two or more variables.

The research community and its design: The goals set by the researcher and the procedures used in the research determine the nature to be chosen.

The research community was deliberately chosen as the junior players Academy in a tennis (18) players. The researcher chose a sample of (16) players, representing (88%) of the research community, as well as taking (2) players to conduct the exploratory experiment.

means, tools and equipment used in the collection of information:

Data collection methods:

Arab and foreign sources.
International information network.
Equipment and Search tools
Tennis Court.
Tennis Balls.
Tennis rackets.
stopwatch.
Colored pens.

Tests Used:

Circuit test numbered: 5

Purpose of the test: measuring the compatibility of both men and eyes

Tools: Stopwatch, the drawing on the ground eight circles that Qatar will be all of them (60) o m, numbered circuits.

Method Performance: The laboratory stands within the circle (1). When the start signal is heard, the two feet are brought together into the circle (2), then to the circle (3) and then to the circle (4) until the circle (8).

Registration: Records the time it takes to move through the eight

Test Throw and reception the ball

Purpose of the test: Measuring the compatibility between the eye and the hand

Tools used: (10) tennis ball, wall, drawing line at a distance (5 meters) from the wall.

Performance Method: The laboratory stands in front of the wall and behind the line drawn on the ground where the test is conducted according to the following sequence:

1. Throw the ball five times in a row with the right hand, and the laboratory will receive the ball after it is rebounding from the wall with the same hand.
2. throwing a ball five consecutive times with the left hand and that the laboratory receives the ball after rebounding from the wall with the same hand.
3. throw the ball after five consecutive times with the right hand and the laboratory to receive the ball after the rebound from the wall with the left hand.

Registration: In every correct attempt, the laboratory is assigned a score of (15)

Measurement the level Mahari

The purpose From Test: transmitter accuracy 7

Measures:

- The player must hit (12) three consignments to the wide area in the first transmitter box and three consignments to the central area of the first dispatch as well as three consignments to the middle area of the second dispatch and three consignments to the wide area of the second dispatch.
- The score is calculated by the light of the first ball falling.
Calculate Accuracy Transmitter:

First transmitter:

1. Two points when the ball falls in the correct transmitter area (center area).
2. (4) points when the ball falls in the area where the first transmitter is intended (in the wide side area of the transmitter area).

Second Transmitter:

1. One point when the ball falls in the correct transmitter area (center).
2. Two points when the ball falls in the target area of the transmitter (the side area of the transmitter area).

Note: To calculate the skill level, the sum of the precision points/speed of performance is calculated.

Experience Exploration: The researchers conducted the pilot experiment on 16/10/2018 on (2) players who were excluded from the main experiment. The aim of the exploratory experiment is to identify the obstacles that may hinder researchers during the experiment and to identify the validity of the tools used in the research.

Experience Home: After the experiment was carried out and the validity of the test and the availability of scientific filters, the tests were applied to the sample of the (12) player on the playgrounds of the College of Education for Girls/University of Baghdad on 21/10/2018 until 23/10/2018.

Means Statistics: The researchers used the ready-made statistical bag spss.

Results and Discussion

Presentation of the results of the computational circles and the standard deviations of the tests for the research, analysis and discussion

Table 1: Shows the computational and standard deviations of the search variables

<table>
<thead>
<tr>
<th>The exams</th>
<th>Measuring unit</th>

<th>Link indication</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance level skill</td>
<td>0.82</td>
<td>0.75</td>
<td>moral</td>
</tr>
</tbody>
</table>

The value of the correlation coefficient ( 0.49 ) at the degree of freedom ( 14 ) and the probability of a line (0,05)

Table (2) shows that the correlation coefficient between the numbered circuit test and the skill level performance was 0.82. This means that the relationship between the test of the numbered circuits and the skill level was significant when compared with the scale value of (0.49) Freedom degree 14 and probability line (0,05) . The researcher attributed the reason that the compatibility of motor between the two men and eyes is important in tennis, the player needs to agree to the length of the performance of the skill level, especially
that the accuracy of the transmitter requires the player compatibility while hitting the ball through the transfer of body weight from the back foot to the front in a consistent movement The arm.

And this is Mayakde Louay “and the compatibility of motor between the eye and hand is one of the most important factors for the performance of the athlete as it through the performance there is a transmission of nerve signals between the nervous and muscular systems and therefore all movements that require sports performance is very important compatibility.

As shown in Table (2), the correlation coefficient value between the test The correlation between the eye and the hand and the level of performance reached (0.75). This means that the relationship between the eye and hand compatibility test and the performance level was significant correlation when compared to the scale value of 0.49 at the freedom level 14 and the probability of a line (0.05).

The researcher points out that the accuracy of the transmitter requires the player to agree for the performance of the skill correctly and there must be coordination and compatibility in motion, especially when the arm is weighted so that there must be consistency between the eye and the movement of the arm and ball in a manner aimed at hitting the ball as soon as possible until the level of performance good.

Also, we note the importance of motor compatibility in all movements that depend on the physical according to the different motor tests performed by the player, and because tennis requires a kind of compatibility between the eye and the arm and the man to perform the skill level with high flow.

Good compatibility requires the elements of balance, speed, motor sense and accuracy of motor performance, the need to distinguish the player and the total body and the compatibility between the upper and lower sides where the compatibility component of the most important mechanisms that contribute to the success of the player to perform the skill level.

Conclusions

By discussing the results of the research within the sample limits, the following researcher concluded: There is a significant correlation between the compatibility of the higher limbs and the performance of the skill level. There is a significant correlation between the lower limb compatibility and skill level performance.

Serum Lipid Profile in Healthy Collegian Women During Consumption of 25 and 13 G of Ukrainian Walnut

Noran jameel Ibraheem¹, Ghadeer hamid AL-Ardhi²
¹Department of Biology, Faculty of Science for Women, ²Department of Biology, DNA Research Center, University of Babylon, Al- Hila, Iraq

ABSTRACT

Objective: Nuts offer many health benefits, this study conducted to estimate the effect of different dose and period of Ukrainian walnut consumption on lipid profile parameters among healthy young collegian women. subjects of this study were feed on two different dose of walnut including 13 g and 25 g for 10 days each dose, fasting blood sample had been drawn pre- and post-walnut consuming, entirely period of this experiment last for 20 days, tested parameters included Total cholesterol (TCH), high density Lipoprotein (HDL), low density lipoprotein (LDL) and triglyceride (TG). Body mass index (BMI) was conducted for study population pre and post consumption of walnut. highly significant decrease ($p<0.001$) was detected in the serum total cholesterol, Triglyceride and LDL-cholesterol level in the women when eat 25g of walnut for 10 days interval pre-consumption of walnut. Highly significant increase ($p<0.01$, $p<0.05$, $p<0.01$) respectively was found in the total cholesterol, LDL-cholesterol and Triglyceride after the same subjects were had 13 g of walnut for the other 10 days. HDL-cholesterol level was non-significantly ($p=0.05$) difference neither eat 25g nor 13 g of walnut consumption against pre- take walnut.

Keywords: lipid profile, collegian women, Ukrainian walnut.

Introduction

There is a significant amount of research now which highlights the importance of eating nuts regularly for health benefits, nuts are a particularly nutrient dense food [1,2]. A large number of clinical studies has been conducted looking at the effect of walnut consumption on blood fats, and showed that regular inclusion of nut in the diet can lower both total and LDL-cholesterol [3,4], other studies revealed the role of nuts in weight management [5,6]. This study was concerned on Ukrainian walnut to evaluate whether the different quantity of walnut nourishment if have the same effect on lipid profile and body weight management on the healthy young women.

Methodology

This study conducted in college of science for women in Babylon University, features of subjects participated in the present study were young women their age arranged between 20-26 years, free of chronic disease, non– smoker, and not have allergic to walnut. At first, the fasting blood samples have been taken from women pre-consumption walnut, after that, population study were feed with 25 g of walnut plus their normal meal lasting for 10 days, then blood fasting sample was withdrawal, the same subjects feed with 13 g of walnut lasting for further 10 days, thereafter fasting blood sample has been withdrawal and separated by device centrifuge to get serum protein.

The TG, cholesterol, HDL-cholesterol were measured by using (BIOLABO Kits), but LDL-cholesterol was calculated depending on friedwald formula [7].

Body mass index BMI for subjects were twice calculated after body weight and height measured for women [8] on pre and post walnut consumption.
Statistical Analysis: Data were analyzed with spss software version 24.0 used repeated measurement ANOVA test, and paired T-test method have been done to data analysis.

Results and Discussion

The data of lipid profile as consuming walnut or without walnut eating were plotted in figure (1).

Decrease significant p<0.001 was exhibited in the mean level of total cholesterol (109.9 ± 39.4 mg/dl) and triglyceride (29.2 ± 14.5 mg/dl) and LDL- cholesterol (59.1 ± 25.1 mg/dl) after had 25 g of walnut for 10 days period in comparison to the same parameters when estimated pre- consumption of walnut, TCH (213.9 ± 79.1 mg/dl), TG (52.2 ± 20.1 mg/dl) and LDL-cholesterol (154.5 ± 74.2 mg/dl). While the same subjects when had 13 g of walnut for the other 10 days highly significant increase was found (p<0.01, p<0.05, p<0.01) for total cholesterol(136.5 ± 30.5 mg/dl) and LDL- cholesterol (72.9 ± 27.3 mg/dl) as well TG (59.8 ± 22.7 mg/dl) upon their level after consumption of 25 g walnut. Neither consuming of 25 g nor 13 g from walnut significantly impact (p>0.05) on the HDL- cholesterol level (45.1 ± 18.0 mg/dl), (51.1 ± 16.1 mg/dl) respectively opposite pre- consumption of walnut (49.3 ± 19.6 mg/dl).

Our result agreement with studies which suggested that fatty acids found in walnut would lower serum cholesterol levels, as nuts contain plant sterols including beta-sitosterol, campesterol and stigmasterol [9,10,11] since the plant sterols can reduce total and LDL cholesterol [4,5] by lowering cholesterol reabsorption from gut. Although walnut are high in fat, but most of fatty acids are polyunsaturated fatty acid and free of trans fatty acids and is unique due to having alpha-linolenic acid ALA [3,4] notable, walnut is a rich source of fiber in which there is almost 9.7 g of fiber per 100 g of it, it was shown that fiber rich foods can reduce cholesterol levels and prevent heart disease and st Dak [6,7,8], another previous study accordance with us results noted that nuts are rich source of mineral including magnesium, copper, zinc, potassium and selenium, all of which may play a role in heart health [6,8,9] accordingly, there was decreased in TG level as women consumed 25 g of walnut but increased level in TG as eating 13 g of walnut, this occur may owing to that 13 g was not enough to show positive effect on TG concentration, but in the same time there was increase HDL level in accordance with increased TG level during eating 13 g of walnut, this may due to protective role of unsaturated fat as reported by Balk et al [12] who confirmed that marine sources of omega -3 fatty acid such as fish oil have higher hypotriglyceridemic effects, as well as another study [13,14] confirmed that walnut intake reduce TG level in healthy people. In concerning with HDL level there were non- significant difference in pre and post consumption of walnut, previous literature was founded increase in HDL level as eating 30 g of black walnut per day for an eight-week period [12] this disagreement with our results may owing to that different kind of walnut and to long period of eating, however our results agreement with Rose et al [14] in which reported that walnut consuming per day regularly for four weeks, the good cholesterol in participants remained the same. The present study don’t showed significant difference (p>0.005) in BMI between pre- and post-consumption of walnut (22.9 ± 2.6 kg/m²) (23.0 ± 2.7 kg/m²) respectively as revealed in table 1, these finding are supported by researches [14,15,17] in which has shown that nuts do not cause weight gain when included as part of cholesterol lowering diet.

The Association between (CT60) Cytotoxic T-lymphocyte Antigen-4 Gene Polymorphism with its Plasma Levels in Alpecia Areata Patients

Sarah Isam Al-Rubaye1, Abdulsamie Hassan Alta’ee1, Zena Saeed Al-Fadhily1

1College of Medicine, University of Babylon, Iraq

ABSTRACT

Alopecia areata (AA) is a dermatological disease featured by non-scarring hair loss of the scalp and/or body, with a variable and unpredictable development in the patients in whom, despite diverse efforts, its cause is not yet fully known, some signs suggest that genetic, environmental and immunological factors may cause the disease. Cytotoxic T-lymphocyte antigen-4 (CTLA-4) said negative T cell proliferation regulator by attenuating either T-cell response post-activation or by preventing the activation of self-reactive T cells. The present study, aims to report the impact of the (CT60) CTLA-4 gene polymorphism (rs3087243) on the CTLA-4 levels in plasma samples of AA Iraqi patients.

Keywords: Alopecia areata, Hair loss, CTLA-4, CT60 Polymorphism.

Introduction

Alopecia areata (AA) is a dermatological disease characterized by hair loss and no scars on the head and/or body, manifested by a different and unpredictable development for patients in which, despite various experiments, the cause is not yet known, some evidence suggests for the genetic, environmental and immunological factors to cause the disease. 1. AA is a chronic, inflammatory, autoimmune disease that attacks the hair follicles and causes hair loss. Hair loss is usually on the scalp, but it can also affect the beard, eyebrows and other areas of the body. Genes of the immune system have been implicated in AA pathogenesis 2. The CTLA4 gene (2q34) produces a full-length CTLA4 protein, predominantly expressed in activated T cells, and a soluble CTLA4 protein, predominantly secreted by resting T cells 3. CTLA-4 is a negative regulator of the T-cell proliferation either by reducing T-cell response post-activation or preventing the activation of self-reactive T cells 2.

CTLA-4 polymorphisms are associated with a lot of human autoimmune-diseases, including systemic lupus, Graves disease, rheumatoid arthritis and type I diabetes (4,5). More than 100 single-nucleotide polymorphisms (SNPs) have been identified in the CTLA4 region 2q34 and several variants have been associated with autoimmune disorders 6. However, some of these associations have not been confirmed, and some contradictory data are evident in different populations. Two recent articles show that certain genetic variants of the CTLA4 gene promote AA sensitivity. The strongest relationship was found in the change of + 49AG infection (rs231775), resulting in a threonine to alanine amino acid substitution at codon 17 in the leader peptide, and for the (CT60) dimorphism (rs3087243), which is located 236bp downstream of CTLA4 gene (2,7). The present study, aims to report the impact of the (CT60) gene polymorphism (rs3087243) on the CTLA-4 levels in plasma samples of AA Iraqi patients.

Patients and Control Groups

One hundred (100) distinct patients with AA were selected in this study. The patients had mean standard deviation age of (26.00 ± 9.47), for males and (23.68 ± 11.65) for females and age range of 15-48 years. These patients were selected from Baghdad teaching medical city and diagnosed by neurologist based on the McDonald criteria 8.
Besides, one hundred (100) ethnically, age, and sex matched healthy individuals with no personal or family history of autoimmune diseases were selected. Control group had mean age of (29.42 ± 12.93) for males and (31.53 ± 7.078) for females and age range of 15-48 years. All controls were informed of the research and gave their full written consent.

**DNA Extraction and Genotyping:** Five mL of blood sample was collected from each individual in EDTA tube and plasma isolated. DNA was extracted from peripheral blood samples by DNA extraction kit. Then DNA sample was subjected to restriction fragment length polymorphism PCR (RFLP). 100 nanograms of extracted DNA were amplified using specific primers: CT60-forward 5'-ATCTGTGTTGTCGTT TTC-3’ and CT60-reverse 5’-CCATGACAACTGTATA GCCTGTT-3’ primers The PCR conditions were 95°C for 3 min followed by 35 cycles of 45s at 95°C, 45s at 60°C, 45s at 72°C, and a final prolongation step of 7 min at 72°C.

The PCR amplification yielded a band of 382 bp. After digestion by HpyCh4IV restriction enzyme (New England Biolabs), the PCR products were digested 252 and 130 bp fragments. 2% agarose gel electrophoresis was used. Plasma levels of CTLA-4 were detected using a Human CTLA-4 ELISA kit purchased from eBioscience company (http://www.eBioscience.com). The kit was used according to its manufacturer’s instruction. Finally, the comparison between CT60 genotype and CTLA-4 plasma level was done.

**Statistical Analysis:** To examine the effect of CTLA-4 polymorphism and its plasma levels, independent Student’s t-test was performed. Differences between the parameters measured in patients and control group were compared, and P value was <0.05 considered significant. Gravepad Prism version 6 (Gravepad Software Inc., La Jolla, CA) for windows software was utilized.

**Results and Discussion**

The frequency of the G allele at the (CT60) polymorphism was insignificantly higher in patients than controls (OR: 0.8851 CI: 0.3825 to 2.048, and P = 0.8323). Moreover, the A/G genotype was more frequent in patients than in control (68% versus 50%, OR: 2.125, CI: 0.6308 to 7.159, and P = 0.3772) as shown in Table 1. Allelic Association of (CT60) CTLA-4 Gene Polymorphism in Promoter AA patients and Healthy Control was shown in Table 2. Relation between CTLA-4 and genotyping of (CT60) CTLA-4 gene polymorphism in promoter were shown in Table 3.

The patients who carried A/G genotype had higher plasma levels of CTLA-4 compared to that measured in controls (P= 0.0312). Figure 1 showed that CTLA-4 levels were lower in patients than in controls.
CT60 G/A genotype of CTLA-4 gene may have an effect on decreasing CTLA-4 plasma level in general population (e.g., control group). Since carriers of G/A genotype in the AA patients group have significantly lower CTLA-4 levels in comparison to healthy controls, it seems that maybe there are additional mechanisms that affect or control the relation of G/A genotypes and CTLA-4 levels in AA patients.

In this study, we investigated the association of the G/A genotype at the CT60 position of the CTLA-4 gene with the plasma levels of CTLA-4 in Iraqi AA patients. We observed that this effect is significantly higher in AA patients than in healthy controls. It shows there would be relation between this SNP and level of CTLA-4 in AA patients. It seems that studies with large sample size are required to bring about more authentic results. CTLA4 is an important negative regulator of T-cell activation, whose polymorphisms have been reported to be implicated in the genetic susceptibility of several autoimmune diseases, recently also Alopecia Areata. In this study, we evaluated the association between CT60 SNPs in CTLA4 gene using 100 patients and 100 healthy individuals from Iraq. Using a case–control approach, we found that AA was significantly more frequent in patients carrying the (CT60) G allele (G/G and A/G genotypes) than in A/A homozygotes, while A/A genotype seemed to have a protective effect. Our findings are agreed with those obtained in the German study performed by John et al. in which a significantly decrease of (CT60) A variant was present in AA cases than in controls. Even the fact that the association is specific for A/G G/G genotypes agrees with the dominant effect of the G allele that we speculated. Furthermore, a specific haplotype of the CTLA4 gene, carrying the (CT60) A variant, resulted to be negatively associated to AA evolution. A previous study suggested that CTLA4 molecular pathway plays a major role in the AA pathogenesis, and might also manifested that the two genetic risk factors, CTLA4 and HLA, act autonomously of each other. The study continued saying “Regarding +49AG CTLA-4 SNP, very similar frequencies for either genotype or allele were observed in patients and controls. These data, however, did not replicate the
association with the +49G CTLA-4 variant reported in German people and genetic heterogeneity among European populations, SNP interactions might explain this result (2,11). We cannot exclude the possibility that other CTLA-4 genetic variants present are involved in the autoimmune etiology of the disease. In conclusion, the carriage of the (CT60) G allele participate, even if moderately, as a disease risk factor of AA, which is encourage the importance of CTLA4 as an autoimmune susceptible locus. Since CTLA4 molecule has a major role in the measurement of immune response and tolerance, it is probably that some particular CTLA4 polymorphisms could be causes the differences in the individual capability to have autoimmune diseases, altering the function of the protein itself. Notice that, the (CT60) SNP is located near the 30 un-translated region of CTLA4 gene, and the association of several diseases with the G variant has been explained as the result of a reduced CTLA4 expression with a subsequent reduced inhibitory function 12. Further investigations is required to investigate the effect of the (CT60) G allele on the possible binding of some major genetic factors, for example the microRNA regulatory molecules and the concentration and function of the CTLA4 translated protein with a view to find out new molecular mechanisms implicated in the AA development. Moreover, the research for disease preparing genetic variants in other immunological pathways and co-stimulatory molecules must be investigated to give clear vision into the AA pathogenesis.

**Conclusion**

Lower plasma levels of CTLA-4 in AA patients appeared in those who carried G/A genotype.

A Study for Detection the Causes of Vaginal Bleeding in Pregnant Women at 1st Trimester in Bint al-Huda Teaching Hospital at al-Nasiriyah City, Iraq

Doaa Sami Rashash1, Sinaa Saber Kadhim2, Wahran Hassan Mohammad2

1Maternal and Neonatal Health Nursing Department, College of Nursing, University of Thi-Qar, Nasiriyah, Dhi-Qar, Iraq; 2Bint Al-Huda Teaching Hospital, Nasiriyah, Dhi-Qar, Iraq

ABSTRACT

The present study was aimed to detect the more suspected causes related to incidence of vaginal bleeding (VB) in pregnant women during 1st trimester. Using specific questionnaire forma, the required information were obtained from a totally 50 pregnant women at 1st trimester of gestation. Collected data were divided into three parts; socio-demographic, reproductive, and other-related factors. Regarding to socio-demographic factors, significant increase (P<0.05) for affected cases were showed in women 21-25 years of age, uneducated or primary school graduated, housewives, resident in urban, and poorly economic status. In reproductive factors, significant elevation (P<0.05) were detected in women married at 16-19 years of age, 4-8 gravida, 4-8 para, 1-2 abortions, 3-6 live children, 3-5 years interval for last pregnancy, irregular attended to hospital and singleton pregnancy. Among other factors, significant increasing (P<0.05) were detected only in mother-related factors including abnormal mother’s weight, have reproductive illness, Rh incompatibility, non marriage to relatives, non infected, received medication, smoking passively, and having previous history for abortion and curettage.

Keywords: Women, Vagina, Bleeding, Trimester, Thi-Qar, Iraq

Introduction

Abnormal vaginal bleeding (AVB) is one of the most frequent reproductive problems for women, which categorized as irregular, inter-menstrual and excessive menstrual bleeding 1. It occurs more widely in women aged (25-44) years per year, and reported in 15-25% of all pregnancies particularly at 1st trimester of gestation (2,3). Meta-analyses were detected that this event is more related with increasing the risks of other complications occurred during gestation 2. Although, VB can be seen as a normal sign for implantation of gestation, it may refer to a pathologic condition/s such as gestational trophoplasic disease or ectopic pregnancy 5. Also, VB may indicate for an initiation of spontaneous abortion 6. Further assessment of VB after confirmation with the positive pregnancy test is required in order to identify the normal or abnormal development of gestation or existence of pathologic condition/s that may require as soon as an intervention (7,8). However, many diagnostic tools can be used to provide a primary decision on the cause/s of VB. Physical examination of pelvic region in addition to laboratory testing and imaging methods are used usually to diagnose VB particularly with the closed cervix 9. In early months of gestation, many pregnancies are losses their fetus due to VB 10. Several studies reported that the more serious causes of 1st trimester VB include the ectopic pregnancy, induced abortion, spontaneous miscarriage, and molar pregnancy in addition to uterine problems (11,12). It looked that there is a specific relationship between VB and miscarriage which usually conducted to the women recruit to emergency departments or hospitals 13. Although, many VB episodes may require an immediate medical intervention, these studies do not provide the useful information about the risks of miscarriage on women who experience VB 14. As the most miscarriage
cases occur during the 1st trimester period of gestation, detailed data about the characteristics of VB is important for early identification of miscarriage.\(^{15}\)

**Materials and Method**

**Samples and Data collection:** During 6 months of 2018, a total of 50 pregnant women attended to Bin Al-Huda Teaching Hospital (Dhi-Qar province, Iraq) with VB at 1st trimester of gestation were submitted for this study. The required information was obtained from study’s women after an extensive interview by using a special questionnaire form in addition to independence on their hospital profiles. The collected data were divided into three parts; socio-demographic, reproductive, and other-related factors. In 1st part, the data include specific information about the characteristics of age, level of education, occupation status, resident and the economic status of study women. While the 2nd part was involved specific information related to age of study’s women at marriage, gravid, para, number of abortion/s, number of live children, interval with last pregnancy, type of last delivery, attention to hospital, and the pregnancy status. In 3rd part, other factors were comprised three categories are the mother-related factors (mother’s weight, reproductive system illness, Rh compatibility, marriage to relatives, infections, therapy, smoking, and previous history), in addition to fetus-related factors, and environment-related factors.

**Data analysis:** All obtained data were introduced firstly into the computerized Microsoft Office Excel (2013) program, and analyzed statistically using IBM/SPSS (V23) programs. Significant differences among study values were detected with Chi-square (\(\chi^2\)) test at a level of P<0.05. In addition, the credibility of the contents was estimated through a panel of (5) experts, whereas, the stability of the items in based on internal consistency of the questionnaire was evaluated by calculating Alpha Cronbach equal to 0.72.

**Results**

Significant elevation (P≤0.05) in characteristics of socio-demographic factors was encountered in 21-25 years of age, uneducated or primary school graduated, housewives, resident at urban, and with insufficient economic status, (Table 1).

Association of socio-demographic factors to other factors was presented in (Table 4). However, significant variations (P<0.05) in values of age, level of education, occupation status, and economic status with the mother, fetus and environment factors were appeared statistically.

Observational studies suggested that there are many factors have a prognostic value regarding to outcome of a subsequent pregnancy 17. In this study, the results of socio-demographic and reproductive factors in addition to VB causes were appeared to play an important role in incidence of bleeding and/or miscarriage during the 1st trimester of gestation. Also, most studied factors might overlap or act together to induce of VB. Results of marriage’s age with maternal age were detected in this study at 16-19 years and 21-25 years, respectively.

Table 3: Results of other factors
The elevated VB rates at this level of age could be attributed to complications that studied extensively such as the hypertension, uterine decompression, placental abruption, prolonged rupture of membranes, and short umbilical cord. However, many studies dealt separately with the influences of maternal age on risks of VB, were reported that the increased maternal age will heighten the fold-rates of VB. Among the socio-demographic factors, there positive correlation between the levels of education, occupation status, resident, and economic status were observed in this study. In many countries, despite the elevated degree of opportunity equality; family background still plays great roles in an inheritance of income, education and social class. Many studies have been suggested that the economic conditions are of great importance at early childhood as the parental characteristics can be influenced on education more during adolescence. In contrast, suggested that the economic conditions of less value than other factors. However, other causes could heighten the negative role of socio-demographic factors such as the psychological stress, family structure and low-life experience. It appeared that the numbers of abortion/s and live children were intermediate, whereas interval to last gestation was elevated among VB pregnant women at 1st trimester disregarded on types of last delivery. In addition, irregular attention to hospital or physician might increase the chance for frequent bleeding in pregnant women as reported in present study. In women with previous history of abortion, expectant management has a variable success rates, but with medical therapy, it provide a high success rate for completion of reproductive problems without surgical intervention. Heavy or irregular VB is important medical issue which can lead to diminished quality of life and consequential anemia. Currently, there no available standardized clinical tools are reliable to obtain data regarding to severity of patient’s bleeding. However, gynecologists and emergency room physicians can regularly provided the suitable medical care to patients requesting an evaluation and/or treatment to decrease bleeding, decrease a risk, and improve a quality for life.

Regarding to pregnancy status, the results of present study were showed that VB in 1st trimester of gestation more prevalence in women with single than twin pregnancies. Very few studies have specifically examined the relationship between 1st trimester VB and pregnancy outcome in single or twins. However, these findings might be explained by the fact that more samples involved in this study have single pregnancy. Results reported by were showed that VB in case of singleton correlates with an increased rate of preterm and very preterm birth and consequently a lower birth-weight. In other factors of this study, mother related-factors were revealed on significant variations in their characteristics but neither in fetus- nor environment-related factors. According to new reporters, the obese or overweight pregnant women having higher blood glucose result in fetus larger than normal. Up to now it has been unclear the factors might be important in linking a mother’s size to that of her fetuses. In low mother’s size, placental or uterine problems might be incriminated in incidence of vaginal bleeding during 1st trimester of gestation particularly in younger pregnant women.

**Conclusion**

In reproductive factors, significant elevation (P<0.05) were detected in women married at 16-19 years of age, 4-8 gravida, 4-8 para, 1-2 abortions, 3-6 live children, 3-5 years interval for last pregnancy, irregular attended to hospital and singleton pregnancy. Among other factors, significant increasing (P<0.05) were detected only in mother-related factors including abnormal mother’s weight, have reproductive illness, Rh incompatibility, non marriage to relatives, non infected, received medication, smoking passively, and having previous history for abortion and curettage.

Analysis of Meiotic Genes Under Different Temperatures

Zena Faris Alwash
Assistant Lecturer, Collage of Pathological Analysis Technologies, Al-Bayan University

ABSTRACT

One of the most consumed crops globally is bread wheat (Triticum aestivum). This crop possesses a hexaploid genome that makes it possible to manipulate its genome and produce new mixtures of desirable traits. However, the fertility of bread wheat is highly affected by heat stress occasioned by global warming. In this study, wheat spikes RNA was extracted and used for cDNA synthesis. The conventional PCR approach was used to amplify some gene prior to gene cloning and determination of genes expression via quantitative PCR. The differences in genes expression were determined over a range of temperatures. Heat stress effect on the activity of meiotic genes, transcription factors, and chromatin organization was showcased in the varying levels of genes expression at the studied temperatures.

Keywords: Triticum aestivum, meiotic genes, genes expression, heat stress, sterility.

Introduction

Among the most planted food crops in the world is bread wheat (Triticum aestivum) due to its significance in human nutrition. It is also an economic crop in most countries, like in the UK where contributes nearly in £1.6 Billion to the country’s economy. However, it is exposed to some issues that may reduce its yields. These issues include the global warming and overpopulation. The global warming is increased every 10 years by 0.2 °C. This increase could affect the fertility of wheat. The other problem is concerned with the overpopulation that could reach 8.9 billion in the next 40 years. This causes highly consumption of bread wheat. From another point of view, bread wheat has an interested genome which subjected to series of manipulations and adaptations throughout decades to be in its current hexaploid form. In addition, its genome is still not fully sequenced. The first step in meiosis involves reduction in the number of chromosomes by half. In the second step, fertilization takes place to restore the number of chromosomes to the original diploid homologues. During meiosis Chromosomes undergo homologous crossing-over to rearrange their traits and produce new chromosomal combinations. TaDMC1 locates on chromosome 5 of (A, B, and D) genomes of T. aestivum. It is about 1035 bp and its protein (TaDMC1) has 344 a. a. According to RT-PCR analysis, gene expression was detected in both reproductive and vegetative cells with more levels of expression in meiotic tissues. Moreover, TaDMC1 produces higher level of expression in B and D genomes than its expression in A genome. TaDMC1 is a meiotic-specific protein, its action starts after the formation of DSBs. It stimulates homologues recombination instead of the sister chromatid to form a double holiday junction. A mutated dmc1 in yeast resulted in sterility due to the accumulation of disabled dmc1 and subsequently the DSB repairing system and SC are defected. Crossing-over regulation in most organisms is maintained by Synaptonemal Complex (SC). This complex is initiated by ASY1, ASY3, and ZYP1 during zygotene. The activity of these different protein complexes that involved in (SC) formation in most organisms is regulating the crossover formation between homologous chromosomes. SC is necessary for the progression of meiosis and maintenance of normal homologous crossover levels.

The first SC gene in T. aestivum, (TaASY1) has a significant similarity to other ASY1 sequences in plant...
species such as BoASY1 in (Brassica oleracea). Its location is on chromosome 5 of each ancestral genome in Triticum aestivum with 6.5 kb in length, 22 exons and 21 introns. Northern analysis, microarray and qPCR methods were performed by (4) to identify the expression of TaASY1. These methods were helpful to follow the expression of TaASY1 which starts before meiosis and continues to pachytene where it ends there.

The other SC gene (TaASY3) is still not well identified. Therefore, AtASY3 in Arabidopsis was a good alternative to understand its characteristics. AtASY3 length is 3kb and encodes about 793 aa. It is important for stabilizing protein structure and maintain normal protein-protein interactions. According to RT-PCR, ASY3 expression was noticed in reproductive tissues. This means it contributes in reproductive processes. Knocking-out AtASY3 reduced 75% of the fertility in the plant. That means it has an important role in meiosis. During cytological analysis of normal pachytene, synopsis between the homologues chromosomes is normally processed while synopsis failed in the mutated version. This results in producing univalent chromosomes and consequently produce aneuploidy tetrads.

Finally, the last SC gene (TaZYP1) has counterparts in other plant species such as maize (ZYP1), Arabidopsis (AtZYP1a, AtZYP1b), and rice (ZEPI). Transverse filament (TFs) protein of the SC in plants is encoded by ZYP1. TF is important in the formation of CE (central element) which is included in SC formation. In the three genomes of T. aestivum (A, B and D), TaZYP1 founds on chromosome 2. qPCR was used to detect the first signal of TaZYP1 expression. This signal started at leptotene, increases during prophase I substages, and finally disappears during diakinesis. In Arabidopsis the same behaviour has been noticed. This behaviour leads to estimate that ZYP1 foci are continued to be formed during synopsis. ZYP1 is considered to have a noticeable contribution in meiosis. This consideration is generated from firstly the immunolocalization studies on (TFs), which found that there is a significant homology in (TFs) among plants. Secondly, qPCR results showed that the youngest meiotic tissues exhibit the highest level of ZYP1 expression. Moreover, ZYP1 has an important contribution in controlling COs formation and consequently in producing the normal haploid gametes. This contribution was estimated from ZYP1 function in building a normal chiasmata structure. Finally, ZYP1 was knocked down in Barley. This resulted in producing less seeds per spike in the transgenic plants. The explanation of this defects at the molecular level is that many univalents were produced from the transgenic plants, which resulted in reducing the number of bivalents per cell.

This study aims to detect the temperature level that influences wheat sterility by growing different wheat varieties at different temperature ranges.; another aim is the detection of some meiotic gene expression levels at varying temperatures in a bid to understand their role in wheat sterility using qPCR and bioinformatics databases. This study mainly focuses on some of the selected wheat genes that are implicated in DSBs formation, SC formation, and homologous recombination.

**Experimental Method**

**Plant Material:** Six anthers from six Apogees grew at six different temperatures were used to extract RNA and later reverse transcribed 5µg of it into cDNA using Bioline kit. My Taq- red mix (Bioline) was used for PCR amplification of ASY1 and ZYP1, ASY3.

**Gene Purification:** 1% agarose gel was used for electrophoresis. The gel purification kit was supplied by OMEGA company. The column was evaluated for gene concentration using NanoDrop.

**Gene cloning and transformation:** The TOPO® XL PCR Cloning Kit was used for cloning and transforming the genes.

Minipreps were prepared to isolate DNA by E.Z.N.A.® Plasmid Mini Kit I.

**Genomic sequencing:** The cloned vector was sequenced by GATC Service. For this process, 5 µL of the vector and its inserted gene was placed in a tube before adding either the forward/reverse primers to get the sequence from either direction (this requires two microcentrifuge tubes). The primers from the vector sequence surrounding the inserted sequence were used to obtain the sequence of the inserts. The sequence was finally downloaded from the website of GATC.

**SYBR Green qPCR:** The amplification and detection of the sequences via qPCR require small sizes of the sequences; thus, the size of the amplified sequence...
must range from 150-300bp. The primers work better at a concentration of 250nM while the best annealing temperature is 60°C.

The qPCR machine (Model: ABI 7500 Real-Time PCR System) was used to perform the PCR.

Results and Discussion

Real-time-based meiotic gene expression quantitation at varying temperatures: RNA was extracted from Apogees, that grew at different temperatures (20°C - 30°C), and reverse transcribed into cDNA. ZYP1 and DMC1 were amplified from the cDNA using qPCR. Their relative expression levels were calculated using the ΔΔCT method, (Figure 1 and Figure 2). The expression level at 20°C served as the reference level for benchmarking those from the other temperatures. The highest level of ZYP1 expression was at 24°C. Then it starts to decrease gradually at 26°C and 28°C. Then surprisingly increased at 30°C in a U-shaped curve.

![ZYP1 expression graph](image1)

**Figure 1:** The relative expression of ZYP1. ZYP1 was amplified from Apogee spikes grown at six different temperatures. Setting the expression level of ZYP1 from the 20°C tissue as a control, and the relative expression at other temperatures.

![DMC1 expression graph](image2)

**Figure 2:** The relative expression of DMC1. DMC1 was amplified from Apogee spikes grown at six different temperatures. Setting the expression level of DMC1 from the 20°C tissue as one as a control, and the relative expression at other temperatures.
The expression level of DMC1 at 22°C was a bit higher than its expression level at 20°C; however, it takes the U-shaped curve where there was a significant increase in the expression level at 24°C before gradually decreasing at 26 and 28°C. It increased later at 30°C.

**Gene Sequencing:** ASY1, ASY3 and ZYP1 were amplified via PCR from wheat spikes cDNA and later they were sequenced. The identity of the purified DNA sequences was confirmed by BLASTing them in ENSEMBL. These genes were cloned as well to determine their genome origin. Then, the gene sequences were finally matched to the wheat genomic sequence database in ENSEMBL, followed by the determination of the phylogenetic tree using Geneious software.

The whole sizes of the whole cloned meiotic genes were determined to be: ASY1 =1.8kb, ZYP1 =2.7kb, ASY3 =3kb.

These genes were successfully sequenced and matched to their ancestral genomes, hence, their phylogenetic trees were produced to estimate their evolutionary relationships and to determine the genome with more manipulations over time (based on the length of the horizontal branches; where longer branches indicate larger genetic manipulations over time). It also discloses the similarity of the individual clones to their respective genome in ENSEMBL.

Figure 3 depicts the phylogenetic tree of ASY1 in the ancestral genomes of the wheat tree. This figure displays the relationship of each genome with the other 2. Expectedly, there was a close relationship between B and D genomes compared to A genome, indicating that A genome has undergone more manipulations compared to the other 2 genomes. Meanwhile, ASY3 and ZYP1 trees depicted exhibited unusual outcomes regarding the relationship between the 3 genomes. From the two trees, A and D genomes are closely related but B genome is the most unrelated.

**Figure 3:** ASY1 tree shows the alignment of the cloned sequences to their similar sequences that were obtained from ENSEMBL.
Discussion

Real-time PCR-guided quantitation of meiotic gene expression at varying temperatures: Six anthers were picked from 6 different Apogees growing at 6 different temperatures. From these anthers, cDNA was synthesized from their RNA and used for ZYP1 and DMC1 amplification in qPCR. The ΔΔCT method was used to calculate the relative expression levels of these genes at different temperatures. The expression level at 20°C served as the reference point (Figure 1 and Figure 2). This experiment mainly aims at checking the influence of different temperatures on certain meiotic genes, as well as clarifying the role of increased temperature on the sterility of wheat plants. The highest levels of ZYP1 and DMC1 expression were achieved at 24°C. However, the lowest expression level was at 28°C, followed by an abrupt increase at 30°C. This gradual decrease could be due to the effect of increased temperature on the activity of the transcription factors (TFs) which are subtle to heat shock. Similarly, the organization of chromatin can be transformed at increased temperatures, thus, limiting the transcription of TFs from chromatin. Meanwhile, the outcome of heat stress on multiple factors could be the reason for the unexpected high expression of the genes at 30°C.

Gene sequencing: Based on ASY1 tree depicted in Figure 3, ASY1 on chromosome 5 is oldest in the A genome (ASY1 5A) compared to the other 2 genomes (B and D) as it aligned far from them. This is an expected result since it is established that in the T. urartu (AA), the A genome appears before B or D genomes. Meanwhile, the 2 other trees produced different results regarding the oldest genome. These trees presented B as the oldest genome while D genome was more related to A genome. This observation could be attributed to the phylogenetic tree-associated restrictions which could cause major alterations in any of the related sequences (such as a new alteration affecting the reading of B genome sequence, hence, making A and D genomes look more related).

Conclusion

In this study, the levels of expression of 2 genes (ZYP1 and DMC1) were determined at 6 different temperatures and the obtained results from the qPCR analysis showed a real effect of temperature on the expression levels of these genes which could be the reason for most cases of sterile wheat plants. The molecular analysis showed that this effect on the genes was due to the destruction of the genes at higher temperatures, thereby making them lose their function. The effect was more on the transcription factors such that their activity was altered at higher temperatures. From the phylogenetic trees for the 3 genes (ASY1, ASY3, and ZYP1), it was shown that ASY1 in the 3 genomes exhibited the expected evolutionary history, where A was shown as the oldest genome, followed by B, while D is the newest one. Meanwhile, the 2 other genes exhibited a different genomic order for the 3 genomes; B genome was shown as the farthest from the other 2 genomes probably due to the alterations of its genome, making it be different from the other two genomes.

Conflict of Interest: The researcher has no conflict of interest to report.

Using the Level of Serum YKL-40 as an Indicator to the Pathogenesis of Allergic Asthma and Helminths Infection

Narjis Abdul Rahman Oudah¹, Kareem S. Chead Al-Teea², Ahmed A. Mohammed³
¹Dept. of Biology, College of Science, Mustansiriyah University, Baghdad, Iraq; ²Ministry of Health, Baghdad, Iraq; ³Branch of Clinical Laboratory Sciences, College of Pharmacy, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

The aim of this study was to investigate the role of YKL-40 as a possible marker in the diagnosis of allergic asthma and to study its relationship with the level of total and specific serum IgE in allergic asthmatic patients and allergic asthmatics with helminths infection. This study included 150 patients, 100 patients with allergic asthma and 50 patients having allergic asthma and helminths infection, fifty subjects of them were males and 100 females, age 15-60 years. In addition, 30 healthy individuals were depended as a control, divided into 14 males and 16 females age 15-60 years. For each subject, the medical history was considered. The total and specific IgE, as well as the YKL-40, were determined in the patients’ sera using ELISA technique. The mean serum level of total IgE was 374.540 IU/mL in allergic asthmatic subjects, which is significantly different from its value in the healthy control, mean 29.216 IU/mL, and in the group of allergic asthma with helminths infection, mean 472.242 IU/mL. In addition, the IgE level was also significantly different in the subjects of allergic asthma with helminths infection from its level in healthy control.

Keywords: Allergic asthma, asthma with helminths infection, YKL-40, Chitinase-like protein, Asthma biomarkers, total and specific IgE.

Introduction

Allergic asthma is a chronic disorder of airways with acute lung inflammation and bronchial hyperresponsiveness. Its airway inflammation is heterogenic in its type and intensity and characterized by different respiratory symptoms including dyspnea, wheezing, chest discomfort and cough, and variable airflow limitation. These symptoms are often triggered by several factors such as allergen exposure, irritant exposure, exercise, viral respiratory infections, or change in weather. Asthma is a major public health problem which affects many people, young and old, males and females, all over the world. However, its thought to be caused by a combination of complex genetic and environment interactions, and it may be divided into extrinsic (allergic asthma) and intrinsic asthma (non-allergic asthma), which are both have the same signs. Allergic asthma is characterized by airway eosinophilia, goblet cell hyperplasia with mucus hypersecretion and hyper-responsiveness to both inhaled allergens and nonspecific stimuli. The mast cells also play an important role in the pathogenesis of allergic asthma by releasing its inflammatory mediators. The severity of allergic asthma is affected by the presence of helminths infections as it induces an immune response by activating some immune cells especially eosinophil. In addition, parasites like helminths are stimulating a strong polarization of Th2 response which correlates with the development of allergic diseases and IgE production. Moreover, some parasitic helminths can secrete and encode certain proteins which have are highly similar to known allergens, so that, after a helminth infection, the host develops an IgE response to the helminth which can interact with the aeroallergens. A YKL-40 is a chitinase-3-like protein1 (CHI3L1) which is produced at the sites of Inflammation. It has been identified in 1993 as a product secreted by articular chondrocytes and synovial cells. The

Corresponding Author:

Email: springlife.na@gmail.com
name of YKL-40 is derived from the three N-terminal amino acids: tyrosine (Y), lysine (K) and leucine (L) which are found in its structure and its molecular mass. YKL-40 is a glycoprotein (40 kDa in size) that binds to chitin and encoded by the CHI3L1 gene \(^{(10,11)}\). YKL-40 is secreted and expressed by a variety of cells including the chondrocytes, macrophages, vascular smooth muscle cells, fibroblast-like synovial cells and hepatic stellate cells. Its expression is associated with pathogenic conditions such as allergic asthma, allergic diseases, tissue inflammation, extracellular tissue remodeling, carcinomas and fibrosis \(^{(12,13)}\). The measurement of YKL-40 levels has a useful prognostic and diagnostic value in asthma. The high serum levels of YKL-40 are correlated with the severity of allergic asthma, airway remodeling and decreased pulmonary function \(^{14} \). Importantly, the elevated serum levels of YKL-40 protein in allergic asthmatic patients are positively associated with the total serum IgE levels (T.IgE). Therefore, YKL-40 is believed to contribute in the pathogenesis of allergic asthma and it has been found to be either the cause or a biomarker of allergic asthma \(^{(15,16)}\).

**Materials and Method**

**Subjects:** The current study included 150 allergic asthmatic patients immunologically confirmed (100 with allergic asthma and 50 having allergic asthma and helminth infection together). This group was comprised of 100 women and 50 men aged 15-60 years. These Patients were adopted from the Specialized Center of Allergy in Baghdad/Al-Rusafah and Al-Zahraa Center of Allergy in Baghdad/Al-Karkh for the period from July 2018 to January 2019. Allergic asthmatics was firstly diagnosed by physicians specialized in Respiratory diseases and in Ear, Nose and Throat (ENT) diseases, according to the international criteria based on the clinical details of the medical history, chest X-ray, physical examination, medicines and the history of recurrent episodes of wheezing and chest tightness. Exclusion criteria were included: smoker, oral corticosteroids, respiratory tract infection, cancer, any chronic disease other than asthma, parasite infection and pregnancy. In addition, parasitic infections were diagnosed by stool examination (SE) of asthmatic patients. The control group included 50 healthy individuals, 20 males and 30 females, in age of 15-60 years. Exclusion criteria were chronic respiratory disorders, current or past history of allergy, having or not helminths infection and all chronic diseases mentioned in reference to the study group.

**Study Design:** All patients underwent a detailed clinical examination and complete total immunoglobulin E test (T.IgE), specific immunoglobulin E test (S.IgE), general stool examination (GSE) and determination of serum YKL-40.

Five milliliters of peripheral blood sample were collected from each subject using a plastic disposable 10ml syringes under sterile conditions. The blood collected in a gel tube to get the required serum for serological tests (T.IgE, S.IgE, YKL-40). After blood clotted, it was centrifuged for 10 minutes at 2500 rpm, then the serum divided onto three Eppendorf tubes, one for each test. All serum samples were kept frozen at -20°C until they are used.

The stool samples have been taken from all the participants. The specimens were collected in clean dry plastic jars. Samples were treated with normal saline and/or Iodine dye and examined under the microscope to investigate the presence of helminths infections. For the best outcomes, the stool samples should be conveyed to the examination immediately.

**Determination of T-IgE:** The T.IgE levels were estimated using a sandwich Enzyme Linked Immunosorbent Assay (ELISA) kit (Euroimmune, Germany) according to the manufacturer’s instructions. Each well in the microtiter plate was coated with polyclonal anti-IgE, then samples were applied followed by adding the conjugate enzyme. The IgE concentration was determined in the end using a calibration curve.

**Determination of S-IgE:** The determination of S-IgE was performed using an enzyme immunosorbent assay (polycheck kit, Germany). The inhalation profile kit that used to diagnose the types of allergens contains 20 parameters from the common allergens as shown in Table 1. The polycheck strips first wetted with buffer solution then coated with allergens and calibrators (Figure 1) before starting the work. Patient’s serum and control were added following this step and incubated on rocker shaker (according to the manufacturer’s instructions). In the next step, the conjugate was applied followed by the substrate.

**Determination of serum YKL-40:** The levels of patient serum YKL-40 were determined using a sandwich enzyme linked immunosorbent assay (ELISA) kit (My BioSource, USA) based on the manufacturer’s instructions where microtiter plates have pre-coated with the anti-YKL-40 antibody. The YKL-40 will bind to the anti-YKL-40 in the first step. This is followed by adding the biotin and the conjugate to detect the pre-coated antibodies in the wells. Adding the TMB substrate will produce a blue color which will be changed to yellow when adding the stop solution. The concentration of CHI3L1 is proportional to the density of the produced yellow color, which is read using the microplate reader at 450nm to find the concentration of CHI3L1.

**Investigation of helminth infections:** The association of parasitic helminths infection which may found in the group of allergic asthmatic patients were investigated using general stool examination. Fecal samples were collected from the patients and control groups. The specimens were directly examined under 10X and 40X objectives.

**Statistical analysis:** Data were analyzed using statistical software (IBM SPSS Statistics 23.0). Demographic data were analyzed with a t-test to compare among two means. The concentration of YKL-40, T.IgE and S.IgE were compared in allergic asthmatics, allergic asthma with helminths infection and in the control groups. For these analyses, the least significant difference test (LSD) was utilized to significant comparison among means over than three where data were expressed as (mean ± SE). Level of significance was defined as 0.05 by using ANOVA test, with probability $P \leq 0.05$ (significant), $P > 0.05$ (none significant) or $P < 0.01$ (highly significant).

**Results**

Studying the relationship between the infection with allergic asthma and serum level of YKL-40 as well as its relationship with the level of total and specific IgE has been addressed in this study for the first time in an attempt to find the potential role of YKL-40 in asthmatic patients. In addition, the effect of the association of helminths infection with allergic asthma and the effect of this association on the immune response of allergic asthmatic patients was also investigated for the first time, particularly in regard with the biomarkers mentioned above.

The current study has observed a significant elevation in the levels of the total serum IgE and serum level of YKL-40 in allergic asthmatic subjects and allergic asthmatics with helminth infection compared with healthy individuals. The mean serum level of total IgE of asthmatics was 374.540 ± 10.394 IU/mL which is highly significant than its level in the healthy control (mean value 29.216 ± 1.786 IU/mL, $p < 0.01$). In addition, the mean T.IgE level in allergic asthmatic subjects with helminth infection is 472.242 ± 6.273 IU/mL which is more highly significant than that of the
control. However, the T-IgE levels in the patients with allergic asthma and helminth infection was higher than its level in the patients only having allergic asthma, the full comparison is presented in Figure 2.

![Figure 2: The levels of total IgE in allergic asthma, allergic asthma with helminths and the control](image)

Allergens sensitization test was also performed in the current study by evaluating the level of serum S.IgE. The results have disclosed that 113 (75%) patients were positive reacted to S.IgE, whereas 37 (25%) patients were negative in this test. A percentage of 72% of allergic asthmatics were positively reacted, while 28% were negatively responded to the S.IgE test. In addition, in the group of allergic asthmatics with helminths infections, 82% of patients were positive to S.IgE test, and only 18% of them were negative to S.IgE, Figure 3.

![Figure 3: positive and negative specific IgE in the groups of allergic asthma and allergic asthma with helminths](image)

*The most common aeroallergens were house dust mites D1 and D2 (27%, 26%) respectively, whereas Guinea epithelia (E6) and Hamster epithelia (E84) have the lowest percentage (1%, 1%). In addition, the groups of allergic asthma’s subjects were also showed that D1 and D2 have the highest rate of sensitization with a percentage of 23, 19, respectively. While subjects of allergic asthma with helminth infection had the percentage of D1 (36%), D2 (34%), as it can be seen in Table 2.

Table 2: Aeroallergens type in the groups of allergic asthma and allergic asthma with helminths
In allergic asthmatic patients, the mean level of serum YKL-40 was 993.595 ± 27.995 pg/mL which is significantly different from its level in the healthy control where it was 358.712 ± 5.676 pg/mL. In addition, highly significant differences \((p < 0.01)\) has also been observed between the level of serum YKL-40 in allergic asthmatics with helminths infection and healthy control where it was 1204.722 ± 38.009 and 358.712 ± 5.676 respectively. The YKL-40 levels were also higher in allergic asthmatic patients with helminths infection 1204.722 ± 38.009pg/mL compared to allergic asthmatic patients 993.595 ± 27.995 pg/mL. The full details are displayed in Figure 4.

![Figure 4: Serum levels of YKL-40 in the groups of allergic asthma, allergic asthma with helminths and control](image)

There was a significant correlation between the high levels of T.IgE and the increased YKL-40 concentration in all the study groups as it can be seen in Figure 5.

![Figure 5: the positive correlation between T.IgE and YKL-40 in the groups of allergic asthma, allergic asthma with helminths and control](image)

Discussion

Allergic asthma is one of the most common chronic diseases and it is a major public health problem that affects many people, young and old, men and women, all over the world. Although any age can be infected with this disease, the rate of allergic asthma was found to be higher in the fourth decades of age in the present study, which is quite similar to the result of Peng et al., (2019) who found that allergic asthma sensitivity was replicated in the midchildhood. Jarvis et al., (2012) whom found that the symptoms of asthma appear under 50 years of age. However, Milgro and Huang (2014) have expected that the prevalence of allergic diseases, particularly allergic asthma, in elderly people may be a result of the gradual decline in immune function and changes in tissue structure that related with ageing, which may affect the development of these diseases.

The present study indicated that allergic asthma is spread among women more than men in Iraq at a ratio of 2:1, which is in agreement with another study in Iraq of Wahhab (2013) who found that the females were more severely affected by asthma compared with men. Such results may correlate with many important factors such as the biochemical and hormonal differences associated with patients’ gender which play a role in the pathophysiology of asthma.

The innate and adaptive immune response plays a key role in the severity and pathogenesis of allergic asthma. IgE is well known component of allergic reactions since it produced through the process of sensitization which is initiated on the first exposure to the allergen. Additionally, the T.IgE level increases also with helminths infections; it binds with specific receptors (Fc Epsilon RI) on the mast cells and basophil’s surface. The observed results of the T.IgE are indicating that the T.IgE plays a central role in the initiation and propagation of the inflammatory cascade in the allergic response and in the immune response to helminths infection, as in figure 2. This is agreeing with other previous studies in Iraq of Abood et al., (2013), Wahhab, (2013), Hassan, (2015), Brakhas et al., (2016) and Rasheed, (2016) who claimed that the level of T.IgE is significantly increasing in asthmatic patients compared to controls.

Conclusion

As YKL-40 has a prominent correlation with the pathogenicity and some clinical features in allergic asthma and helminths infection such as the total and specific IgE levels, it can be suggested that YKL-40 can be used as a biomarker in asthma and also in the helminths infection.

Assessment of Anxiety Level among Women Prepared for Cesarean Section at Babylon Hospitals

Ali A. ALHatab1, Amina Abd AL-Hassan Jabur2, Tabark Sattar Skhail3, Diyar Ghaleb Abdul Kadhim3, Zahraa Fouad kadhim2, Khalid Salman Abdul Sada4

1Department of Psychiatry and Mental Health Nursing, 2Department of Adult Health Nursing, College of Nursing, University of Babylon, Hillah City, Iraq; 3Bachelor of Science in Nursing, Babylon Health Directorate, 4Bachelor of Science in Nursing, Najaf Health Directorate

ABSTRACT

In the preoperative period, women prepared for the cesarean section have anxiety associated with many factors. Anxiety about their surgery, any minor health problem during pregnancy, the number of abortions, etc. All these factors can increase the level of anxiety prior to cesarean birth. Objectives: To assess of Anxiety level among women prepared for cesarean section at Babylon hospitals. A descriptive-correlational study design using (a purposive sample) non-probability of women prepared for cesarean section (N=90) at Babylon hospitals. Taylor manifest anxiety scale was used anxiety levels. The tool consists of 20 questions, the person answers the questions by interview. The analyzed data during descriptive statistical analysis application (mean of score, frequency and percentage) and (SPSS) version 25 with, inferential data analysis (Chi-square) and Microsoft excel (2016) to assess and estimate the study sample. The findings of the study indicate that most women prepared for a cesarean section of samples (65.6%) were moderate anxiety. Moderate anxiety level has highly significant relation with Socio-demographic data (age, education level, occupation) and has highly significant correlation with matters related to pregnancy (primipara, minor health problem and diseases during pregnancy).

Keywords: Anxiety, women, cesarean section.

Introduction

Pregnancy state is within psychological, physiological, social and hormonal changes will be present, the psychiatric morbidity and emotional hurting probability high the risk within phase of a female’s life. A few women may experience pregnancy state associated with self-fulfillment, satisfaction and happiness as a source. Some others, in their mental health, may experience alteration in this period, such as the progress of worry 1. The psychological condition between several cultures that considering the belief of the mother can affect the child in her womb, one of the risk factors is anxiety disorder in pregnancy development 2. The emotional condition characterized through fear and worry leading a threatening event anticipation that called anxiety. In preoperative anxiety, the incidence within adult patients range from (11-80 %) and between several surgical in different groups, there is variation finding 3. It has been observed that obstetric patients have a higher level of preoperative anxiety levels compared to general surgery. Extreme anxiety adversely influences both induction of anesthesia and its recovery. In the caesarean section, increased consumption of anesthesia affects the mother and the baby as well 4. In this study, it is important to know the degree and causes of anxiety for understanding a patient’s psychology. In the preoperative period, women prepared for the cesarean section have anxiety associated with many factors. Anxiety about their surgery, any minor health problem during pregnancy, the number of abortions, etc. All these factors can increase the level of anxiety prior to cesarean birth 5.

DOI Number: 10.5958/0976-5506.2019.03315.1
Objectives

1. To assess the level of anxiety among women prepared for a cesarean section.
2. To find out the relationship between various socio-demographic variables and the level of anxiety.
3. To find out the relationship between matters related to pregnancy and the level of anxiety.

Methodology

- **Study design:** (A descriptive-correlational) study is conducted throughout the period of (1st December 2018 to 19th January 2019).
- **Sample of the study:** study design using (a purposive) non-probability sample of women prepared for cesarean section (N=90) at Babylon hospitals.
- **Study instrument:** Data were gathered retrospectively through Taylor manifest anxiety scale is a widely used to measure the level of anxiety among women prepared for a cesarean section at Babylon hospitals. This scale is a self-reported instrument consists of 20 items. The instrument is measured and rated on three levels rating scale from 1 to 3 respectively; 1 indicates never, 2 indicates sometimes, and 3 indicates always. The level of anxiety among women prepared for cesarean section are determined based on the mean of items score. Mean of scores was calculated as follow:
  - Range: 3-1=2
  - Mean of score=2\(\div3\)=0.66
  - Level of score
    - I. Low = 1-1.66
    - II. Moderate = 1.67-2.33
    - III. Sever = 2.34-3

As independent variables, this study focuses on the two part that including socio-demographic and matters related to pregnancy, either dependent variable focuses on one part that include the checklist of Taylor manifest anxiety scale.

Part 1. Socio-demographic data

**Information regarding this part contains:** (Age, level of education, occupation, economic status, address)

Part 2. Matters related to pregnancy

**Information regarding this part contains:** (primipara, gestational age of pregnancy, number of abortions, number of cesarean deliveries, minor health problem during pregnancy {anemia, high blood pressure, diabetes during pregnancy, vomiting and nausea, varicose veins, hemorrhoids, shortness of breath, muscle spasms, constipation}, the reason of cesarean section{ non-dilation of the cervix, deterioration of fetal health, abnormal position and presentation of the fetus, twins, multiple cesarean births, problems in placenta}, date of caesarean section).

Part 3: the checklist to assess level of anxiety: it consisted (20) items.

Data Analysis: Several statistical measures were used by using Statistical Package of Social Sciences (SPSS) version 25, and Microsoft excel (2016) in order to assess and estimate the study sample. A descriptive analysis includes frequencies; percentage and inferential data analysis included the Chi-square test.

### Table 1: Description the level of anxiety according to the sample

<table>
<thead>
<tr>
<th>Levels</th>
<th>Status</th>

<td>26.7 %</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td></td>
<td>90</td>
<td>100 %</td>
</tr>
</tbody>
</table>

Results and Discussion

The table that most of the samples (65.6%) were moderate anxiety level, (26.7%) of the samples were sever anxiety level, and (7.8%) of the samples were mild anxiety level. demographic data (age, education level, occupation) that there is a highly significant relation at \( p \leq 0.01 \), also this table shows between anxiety level with sociodemographic data (economic status) that there is a significant relation at \( p \leq 0.05 \), also this table shows between anxiety level with sociodemographic data (address) that there is a non-significant relation at \( p > 0.05 \). anxiety level with matters related to pregnancy (primipara, minor health problem and diseases during pregnancy) that there is a highly significant relation at \( p \leq 0.01 \), also this table shows between anxiety level
with matters related to pregnancy (Number of previous caesarean deliveries, the reason of cesarean section, date of caesarean section) that there is a significant relation at \( p \leq 0.05 \), also this table shows between anxiety level with matters related to pregnancy (gestational age of pregnancy, number of abortion) that there is a non-significant relation at \( p > 0.05 \).

The result shows that the majority of the samples (65.6%) were moderate anxiety level, (26.7%) were sever anxiety level, (7.8%) of them were mild anxiety level.

This result is supported by (Al-Amoody, K. 2011) who found that (61.6%) of the patients were moderately anxious.

The physiological functions could be that significant changes through a perinatal stage lead to increase levels of anxiety symptoms, such as hormonal dysregulation, also recent studies showed that the high fear of childbirth during pregnancy was common in women. The result also shows between level of anxiety and age at \( p \) value (.000) that there is a high significant relationship. This may be because the Babylon hospitals were accepting pregnant women’s admission at any age. These results are supported by (Hassan, et., al 2018) who found a high significant relationship between age and anxiety. Also, results are supported by (Bansal, T., & Joon, A. 2017) who found a significant relationship between anxiety and age. The education level, the result shows between education level and level of anxiety at \( p \) value (.000) that there is a high significant relationship. This may be because lack of interest in the educational level by the government led to the neglect of study in Iraq. These results agree with the findings of (Nekoe, et., al 2015) who found a significant relationship between education level and anxiety. The result also shows between occupation and anxiety at \( p \) value (.000) that there is a high significant relationship. These results agree with the findings of (Hassan, et., al 2018) who found a high significant relationship between anxiety and occupation. The result also shows between anxiety and economic status at \( p \) value (.010) that there is a significant relationship. These results disagree with the findings of (Hassan, et., al 2018) who found a non-significant relationship between anxiety and monthly family income. The result shows between anxiety and address at \( p \) value (.347) there is no significant relationship. These results disagree with the findings of (Piščalkienė, et al., 2012) who found a significant relationship between anxiety and place of residence. The result also shows between anxiety and primipara at \( p \) value (.000) that there is a high significant relationship. These results unaccepted with the findings of (Kuo, et al., 2016) who found between anxiety and parity there is a non-significant relationship. The result shows between anxiety and gestational age of pregnancy at \( p \) value (.017) there is no significant relationship. This result disagrees with (Silva et al., 2017) who found between anxiety and gestational age of pregnancy there is a non-significant relationship. Also, the result shows between anxiety and number of cesarean deliveries at \( p \) value (.310) there is no significant relationship. These results unaccepted with the findings of (Nekoee, et., al 2015) who found between anxiety and history of abortion there is a significant relationship. The result also shows between anxiety and number of cesarean deliveries at \( p \) value (.009) that there is a significant relationship. The result also shows between anxiety and minor health problem and diseases during pregnancy at \( p \) value (.000) that there is a high significant relationship. These results are supported by (Hassan, et., al 2018) who found between anxiety and associated medical disorder there is a high significant relationship. The result also shows between anxiety and the reason of a cesarean section at \( p \) value (.006) that there is a significant relationship. These results agree with the findings of 3 who found no significant relationship between anxiety and elective or medical cesarean section. The result also shows between anxiety and date of a caesarean section at \( p \) value (.006) that there is a significant relationship.

Conclusions

Most pregnant women of a preoperative cesarean section have moderate levels of anxiety in different levels. Moderate anxiety level has highly significant relation with Socio-demographic data (age, education level, occupation) and has highly significant correlation with matters related to pregnancy (primipara, minor health problem and diseases during pregnancy). Pregnant women who undergo a cesarean section after half an hour to 3 hours of an interview have moderate anxiety more than other pregnant women. Pregnant women who undergo to cesarean section for medical reasons have moderate anxiety more than others. Regarding levels of education in the moderate anxiety found in read and write levels are more than others.

Biofilm Producing by *Staphylococcus aureus* and *Lactobacillus* spp. Isolated from Urogenital Tract Infections of Women

Oruba K. Al-Bermani¹, Zainab H. Alsaadi²
¹College of Science for Women, ²College of Medicine, Babylon University, Babil, Iraq

Abstract

**Aim:** To assess the ability of vaginal lactobacilli and staphylococci that associated with urinary tract infection to form biofilm. Out of sixty vaginal samples, thirty samples were positive culture for *Staphylococcus aureus* which were cultured on congo red agar medium for determined their ability for biofilm formation, only 19 isolates were able to form biofilm. whereas out of sixty vaginal samples forty two samples were positive culture for *Lactobacillus* spp., 16 isolate were able to form biofilm. Genetic detection of icaD gene by PCR of *Staphylococcus aureus* isolates was don and 86% of isolates give positive result of this gene. Not all isolates of vaginal lactobacilli and staphylococcus were able to produce biofilm.

**Keywords:** *Staphylococcus aureus, Lactobacillus spp., UTI*

Introduction

There are two types of the mode of growth in the cells of bacteria i.e. planktonic cell and sessile accumulation that is called biofilm. Biofilm is participation of microorganisms in which cells adhere to each other on a surface coated within extracellular polymeric substance that is bacteria produce it. Biofilms are co from microorganisms in which microbes formed an extracellular polymeric component like proteins (<1-2%) including enzymes, DNA (<1%), polysaccharides (1-2%) and RNA (<1%), and besides to these ingredients, water (up to 97%) is the main part of biofilm that plays an important role in the influx of nutrients in biofilm. The cells of bacteria inside the biofilms are regulated in method with a various physiological and physical characters. Biofilms of bacteria prevent of antibiotics arrival and the action of immune elements. Microorganisms that form biofilm improved effort to hold and manage antimicrobial materials that need for a period of therapy. Production of biofilm is converting of the planktonic bacterial growth to sessile type. It was found production of biofilm is related to the some genes that instruct to the constitution of biofilm. Biofilm begin with the bacterial attachment to a surface then formation of small colony after that building of three dimensional structure then this process ended with biofilm formation, maturation and detachment.

**Biofilm forming bacteria:** The ability to form biofilm were detected in many types of bacterial genus It was mentioned that *H. influenza* has ability to produce biofilm in the body of human and can elope from effect of body immunological elements. Biofilm formation was mentioned in different types of bacteria like *P. aeruginosa, S. epidermidis, E. coli* and *S. aureus*. *Staphylococcus aureus* was well known by their ability of preventing the action of multiple kinds of drugs which consider the main cause of nosocomial infections. *Staphylococcus aureus* grow well on catheters and chronic wounds as biofilm. *Staphylococcus epidermidis* was classified an opportunistic pathogen that has major action to infect the persons with immune-compromised state, patients that need for intravenous administration drug, patients with immuno deficiency diseases, immuno-extinctive therapy patients and new born infantile. Using of polymeric devices during surgical operation increases the chances of contamination with *S. epidermidis* that can grow and form biofilm on them. Production of biofilm is considered the main cause of infections with *S. epidermidis* that related with device and consequently effect of bacterial pathogenesis. *polysaccharide intercellular adhesion* (PIA) is responsible for adhesion of *staphylococci*. *Staphylococcus* cells are surrounded with PIA that stich them together as the most important compositions of the extracellular substance. Study of showed presence of PIA in 27% of *S. epidermidis* that isolated from infections associated with prosthetic joint.
Bacterial Vaginosis: The indigenous microbiota of the vagina contains high numbers of lactobacilli that play a protective role by disturbance the adhesion and growth of the pathogen. \(^8\) documented that vaginal lactobacilli can produce protective biofilm.

Bacterial strains which have the ability to form biofilm could be the main cause of the recurrence of urogenital infections (UGI). \(^10\)

**Material and Method**

**Samples Collection**

Vaginal samples: The study involved 60 women infected with urinary tract infection who admitted to maternity and children hospital in Hilla city. The ages of women were between 21-55 years. The vaginal samples were taken from infected women by sterile cotton swabs by physician. Each sample was placed in sterile tube contain 0.5 ml of transport media in order to reaching the samples to the laboratory.

**Culturing on Selective media**

A. Culturing on manitol salt agar medium:
Manitol salt agar was prepared according to the manufactured company (HiMedia). The vaginal samples were inoculated into Manitol salt agar and incubated aerobically at 37°C for 24 hours. Manitol salt agar agar is a selective medium used for growing and diagnosis of *Staphylococcus aureus* isolated from vaginal samples.

B. MRS agar medium: MRS was prepared according to the manufactured company (HiMedia). The vaginal samples were inoculated into MRS and incubated in aerobic conditions at 37°C for 24 hours. MRS agar is a selective medium used for growing and diagnosis of *Lactobacillus* spp. which obtained from females.

**Microscopically and Morphologically diagnosis:** The colony shape and colony color on the above selective media give characteristic features for diagnosis of bacteria. Gram stain and biochemical tests were useful for Further diagnosis of bacteria.

**Biofilm Detection Method (Congo Red Agar method):**
Congo Red Agar method (CRA) CRA medium consist of brain heart infusion broth 37 g/L, sucrose 50 g/L, agar 10 g/L and Congo Red indicator 8 g/L. Congo Red stain was prepared as a concentrated aqueous solution and sterilized by autoclave separately from the other medium compositions. Then it was added to the sterilized brain heart infusion agar with sucrose. CRA plates were inoculated with tested bacteria and incubated at 37°C for 24 hours aerobically. Appearance of black colonies indicated for biofilm production. (Freeman *et al.*, 1989).

**Molecular detection of icaD gene of Staphylococcus aureus**

A. DNA extraction: The bacterial genomic DNA was extracted according to the protocol supplied by the synthesized company (Promega, USA), additionally with using lysozyme enzyme 10mg/ml

B. Primer sequence and PCR amplification: The primer sequence F 5'-ATGGTCAAGCCCAGACAGAG-3' and R 5'-AGTATTTTCAATGTTTAAGC-3 was used for detection of ica D gene in all *S. aureus* isolates Hussein, (2017), this primer was melting and prepared according to the manufactured company (alpha-canda).

It was designed for amplifying 198 bp for ica D gene.

In the PCR reaction mixture was composed from 5μl of the template DNA, 1μl of each primer (10pmole/μl, 1μl forward and 1μl revers), 12.5 master mix (promega, USA) and 5.5 μl Nuclease free water to gain final volume 25 μl in each PCR tube.

PCR amplification was achieved through using of DNA Thermal cycler with an initial 94 ºC for 5 min, and 30 cycles including denaturation at 94 ºC for 1 min, and annealing at 55 ºC for 1 min and extension at 72 ºC for 1 min followed by a final extension at 72 ºC for 10 min. All reaction mixtures were held at 4 ºC. Finally, 16μl of PCR mixture was detected by 1.5% agarose gel electrophoresis. After electrophoresis, gels were seen under UV light. The Gene Ruler 100 bp was used as a DNA ladder.

**Result and Discussion**

**Bacteriological investigation:** A total of 60 vaginal samples were collected from women infected with urinary tract infection who admitted to maternity hospital in Hilla city, the ages of patients were between 21-55 years. The samples collection were done by physician.
Among 60 vaginal samples, 30 isolates (50%) of *Staphylococcus aureus* were detected by using selective media and 42 isolates (70%) of *Lactobacillus* spp. were recovered by using selective media. (Table -1).

**Table 1: Number and percentage of bacterial types isolated from vaginal samples**

</tbody>
</table>

The results of the present study demonstrated that *Staphylococcus aureus* associated with urinary tract infection, similar results were mentioned by\(^9\). Also our results showed presence of high percentage of *Lactobacillus* spp isolated a Varity of vaginal lactobacilli from 215 sexually active women. *Lactobacillus* species has been reported to be the predominant vaginal flora. It was documented that if H2O2-producing Lactobacillus species are not present this will lead to elevation of growth of catalase-negative organisms an absence of H2O2-producing Lactobacillus species could allow an overgrowth of catalase-negative organisms, like organism present in females infected with bacterial vaginosis \(^1\). found that (36%) of women suffering from bacterial vaginosis have non producing hydrogen peroxide anaerobic Lactobacillus.

**Biofilm Formation:** The results of our study showed ability of *Lactobacillus* spp. and *Staphylococcus aureus* for biofilm production on CRA, were the biofilm producing bacteria appear as black colonies comparison with non producing biofilm bacteria appear as red colonies (figure-1). The recovered *Staphylococcus aureus* were tested for biofilm production, our results showed that out of 30 isolates 19 isolates (63%) of *Staphylococcus aureus* were able to produce biofilm (table-2). The recovered *Lactobacillus* spp. were tested for production of biofilm, it was found that out of 42 isolates 16 isolates (38%) of *Lactobacillus* spp. were able to produce biofilm (table-2).

**Table 2: Percentage of biofilm-production**

<table>
<thead>

</tr>
</tbody>
</table>

![Figure 1: biofilm-producing bacteria, showing black colonies on CRA plate](image)

Our results was consisted with those presented by\(^8\) who found that vaginal Lactobacilli have the ability to produce biofilm.

Studies demonstrated that Gt lactobacilli have ability to produce biofilm that contributes with health and immune modification \(^11-13\). The present results were consistently with those conducted by \(^14\) who found that *Staphylococcus aureus* have a strong ability to produce biofilm.

**Genetic investigation:** According to the result of PCR amplification test, our results showed out of 30 isolates 26 (86%) of 26 *staphylococcus aureus* explain positive result for icaD gene. The PCR product size was 198 pb (figure-2)

![Figure 2: Agarose gel electrophoresis of PCR assay showed icaD gene of Staphylococcus aureus, lane (M) DNA Marker (100-1500 bp); lane (1-12) icaD gene at 198 bp PCR product size](image)

Our study showed that the percentage of biofilm formation that detected by icaD gene are higher than
those detected by biofilm formation on Congo red plate method. This result may be caused by the protective effect of biofilm of Lactobacilli which contribute with decrease the biofilm formation rate of Staphylococcus aureus. 14 found that most strains of Staphylococcus aureus isolated from catheter gave positive result for icaD gene. 15-19 found that the Staphylococcus aureus isolated from various clinical specimens produce biofilm by CRA plate at percentage (65 %) while all these isolates (100%) were positive for detection of icaD gene by PCR method.

The Impact of Teaching Critical Thinking Skills to Develop the Habits of Mind for Students

Alaa Abduladeem Abdulabbas¹, Muna M.A. Al-Khateeb¹
¹College of Basic Education, University of Babylon, Iraq

ABSTRACT

This study intended to assess English questions for 3rd intermediate stage by analyzing Ministerial English questions for the years 2017 and 2018 and for all attempts (1st, 2nd and 3rd attempt). The questions analysis in this study collects information on the variables: Remember, knowledge, apply, analyze, create and evaluate. Conclusion Depending on the results obtained, the following points are outlined: There is a significant difference between the ministerial questions and Bloom’s levels of knowledge. Bloom’s level of knowledge depends on an old approach while the ministerial questions depend on a new approach. Bloom’s specification tables focus on knowledge and understanding while the new approach in teaching focuses on creative and communicative skills. The ministerial questions don’t focus on creative, analytical and communicative skills. From all the above we can conclude that there is a deficiency in both the ministerial questions and Bloom’s specification tables.

Keywords: ministerial English questions, Bloom’s taxonomy, third intermediate, assessment.

Introduction

Given the great role played by the test so, the researchers give it great importance in the field of education. In general, testing is an integral part of any teaching and learning process. Fortunately, some hopeful progress has been noted in the area of testing. As awareness is increasing, some testing methods are being curtailed as strenuous efforts have been made to improve this situation. So, an attainment progress in language teaching was included into language testing. The methodology and content followed-up to measure the performance of learners is very significant because the methodology that will be followed will affect the process of learning and education in full, according to the form and content. Evaluation is a part of our daily life activities. Where we are continuously evaluated and where we are constantly evaluating others. We assess what others say to us, their facial expression, their choice of words, and their attitudes. We evaluate their reactions to what we say and do. We often study who and what are around us to decide what to do or where to go. Above all, the past researches reveals that exercising “executive control” over one’s language learning through planning, monitoring and evaluating. They are techniques that are used for organizing, planning, focusing and evaluating ones’ learning. Although it was indicated that the Effectiveness of the proposed educational units for general teaching methods subject through the use of cognitive maps. The achievement of the experimental group in the post test is significantly superior to that of the control group. The achievement of the experimental group in the post test is significantly superior to that of the control group. So, There are many interesting questions to be asked: How does the exam influence the day to day activity in the classroom? Do we teach for the test? Are the pupils familiar with the evaluation criteria? Do teachers around the country feel they have sufficient knowledge and competence to guide their pupils through the preparation day and the final exam? As teachers today we are constantly faced with changes, and from time to time it is pertinent to ask teachers about their opinions. What do they actually think about the changes of curriculum or exam? The English occupies an important role in Iraq educational system. In examination system of schools, teachers are responsible for writing and marking the final exam papers. Every teacher has to prepare a new test paper for each term. In terms of the measurement and enhancement of the students thinking abilities, teachers usually use questions that start with words like, what, list, define, and give examples which merely measure and enhance the student’s lower levels
of thinking abilities (Knowledge and Comprehension). They rarely use words like solve, apply, and give reasons which measure and enhance the students’ higher levels of thinking abilities (Application, Analysis, Synthesis and Evaluation).

At the end, the statement of the problem could be summarized in the following question. It is a process through which an information is get for some known goals or objectives. Assessment is a wide expression that involved testing, where the test is a particular format of assessment. The tests are about assessment performed under invented conditions so that they can be managed. It can be said that all tests are reported as assessments, but all assessments not test. Where the teacher can test at the end of the unit or lesson. Assessment of progress can be made by means of the test at the end of the school year, and the quantitative or verbal skills can also be assessed through such tools as GRE and SAT. A person’s knowledge can be assessing in a different of ways, but always there is a jump, any conclusion is made about what a person is doing relates to what he or she knows. A knowledge of weaknesses and strengths of students can assist to plan better for teaching and how to teach . To assess texts, there are conditions in which the specific behavior of a goal can be ascertained, and that these conditions are usually in the form of goals written described . Test is a manner consists of a set of procedures, techniques and test elements that form a tool of some kind. Firstly, the purpose of the test is to gauge the performance of the maintenance specialist in specific mathematical terms or the expression of evaluative qualification e.g. poor, fair, good, excellent and etc. In addition, the purpose of the test is to gauge the person’s knowledge or ability. In other words, the general goal of any form of language testing is testing the linguistic abilities of the candidates in a way that ensures realistic representation to the extent of knowledge of their skills in using the language in the case of non-testing . “A test accurately measures the content or ability it purports to measure. And it is essential to devise and determine some measuring tools, yardsticks, criteria, and points to be added for specific ability or should be deducted on certain mistakes, but they must be same for all assessors. However, the language tests vary in how they are designed and what they are like. In other words, regarding the method of testing and the purpose of the test. According to the method, the tests can be broadly distinguished the language tests with traditional paper and pen from performance tests. Language tests based on paper and pencil are usually used to evaluate the discrete components of language knowledge (vocabulary, grammar, etc.) or comprehension (listening and reading comprehension). As for the performance-based tests, language skills are assessed in the communication process. performance tests are the most frequent tests of writing and speaking. As for the purpose, many kinds of language tests have placed to compute the educating outcomes appropriately.

**Methodology**

The researcher followed descriptive research to analyze the content of test questions because it is the appropriate method for analyzing questions, which is one of the research methods used in education and psychology. It is defined as: ((trying to access the precise and detailed knowledge of existing problem or phenomenon elements, in order to gain a better and more accurate understanding or development of future policies and procedures). The aim of this approach is to provide data and facts about the problem of the subject to be interpreted and to identify its implications. Descriptive research is characterized by the fact that it is used primarily to describe a particular case or event, which is the collection of descriptive data. And that the descriptive research is not limited to the collection and classification of data, but rather to the analysis, interpretation, evaluation and comparison, so the description was compared in comparison, although the collection of data and description of educational cases and phenomena is one of the necessary steps, but the essence of descriptive research is to organize, analyze and interpret these data and the development of significant results and significance for the problem.

**Methodology**

The target population comprised a total of fifteen Professor, Asst. Prof and Lecturer selected from Faculty of Education of different universities (University of Babil, University of Baghdad, University of Kufa, University of Misan and University of Karbla’) in different states (Baghdad, Najaf, Hilla, Karbla’ and Ammarah) which are full time teaching students from different ages, from both genders and with different teaching experiences.

**Research Population:** The major samples are divided into two main samples:
1. The third intermediate student book: the book taught to the third intermediate students in the education institutes in Iraq which contains eight units.

2. The final test of the third intermediate students for the years 2017 and 2018 and for the three attempts.

Research Tool: The process of building analytical tool is the first step to conducting research on evaluation of questions. So, the researcher adopts several steps to prepare and formulate tool in its initial formula. The tools were personally administered by the researcher with assistance of the teachers of the selected universities to ensure a hitch free administration. The tools were spelt out uniformly. There was no time limit. Fifteen questionnaires have been completed. The major tool used for collection of primary data was validated questionnaire titled “Evaluating central English questions for third intermediate level according to the specification tables”. This tool was divided into two tables.

A. The First Table (The Questionnaire): Is dealt with evaluating the student book units and divided into 8 sections which are the units of the book. The questionnaire is a document designed with the purpose of seeking specific information from the respondents.

B. The Second Table (The Table of Specifications): Was further meant to collect information on the variables: Remember, knowledge, apply, analyze, create and evaluate with whole sum of 100% entitled “The table specification of third intermediate school”. The instrument was adopted based on 3-points which are acceptable, unacceptable and need modification (Appendix 2).

Presentation of the results of the analysis in the light of the indicators: The researcher presents what has been achieved of the main standards of the total quality and the indicators, the achievements of frequencies, percentages in a descending order for all units in the English book.

View and interpret the results: The researcher presents the results in the light of the evaluation criteria.

Bloom’s Levels of Cognitive Field: The researcher analyzed the questions of the English language examinations for students of the third intermediate grade for the first, second and third turns of (2016-2017) and the first and second turn of (2017-2018) according to Bloom’s levels of knowledge. The total number of questions in the English language exam (5) questions and included (14) branches. The results obtained for the two years were examined and it was found that the total frequency for all questions in 2016-2017 (1) is (191). Where the percentage of the (remember) is (38 %), the understand is (38 %), the Apply is (7%), the Analyze is (5%), the Evaluate is (7%) and the Create is (5%). While in 2016-2017 (2) it was found the total frequencies is (207). Where the percentage of the (remember) is (37 %), the understand is (37%), the Apply is (9%), the Analyze is (5%), the Evaluate is (7%) and the Create is (5%). Also in 2016-2017 (3) it was found that the total frequency for all questions is (249). Where the percentage of the (remember) is (35 %), the understand is (39 %), the Apply is (12%), the Analyze is (4%), the Evaluate is (6%) and the Create is (4%). And the total of frequencies in the year 2017-2018 (1) is (237). Where the percentage of the (remember) is (33 %), the understand is (40 %), the Apply is (13%), the Analyze is (4%), the Evaluate is (6%) and the Create is (4%). At last, it was found that the total of frequencies in the year 2017-2018 (2) is (249). Where the percentage of the (remember) is (34 %), the understand is (40 %), the Apply is (12%), the Analyze is (4%), the Evaluate is (6%) and the Create is (4%).

Conclusion

Conclusion Depending on the results obtained, the following points are outlined: There is a significant difference between the ministerial questions and Bloom’s levels of knowledge. Bloom’s level of knowledge depends on an old approach while the ministerial questions depend on a new approach. Bloom’s specification tables focus on knowledge and understanding while the new approach in teaching focuses on creative and communicative skills. The ministerial questions don’t focus on creative, analytical and communicative skills. From all the above we can conclude that there is a deficiency in both the ministerial questions and Bloom’s specification tables.

Investigation of Bioactive Natural Compounds of *Diplotaxis cespitosa* Using FTIR Spectroscopic Profile and Evaluation of its Anti-Bacterial and Anti-Fungal Activity

Amenah Kadhim Murad¹, Ali Hussein Deman Al-Khafaji², Imad Hadi Hameed³

¹Department of Biology, College of Basic Education, University of Babylon, Hillah city, Iraq; ²Medical Laboratory Techniques, Islamic University, Iraq; ³Biomedical Science Department, University of Babylon, College of Nursing, Hillah City, Iraq

ABSTRACT

Genus *Diplotaxis* (Brassicaceae) is represented by more than 30 species mainly distributed in the north Mediterranean. In the current study, the anti-microbial activity of *Diplotaxis cespitosa* methanolic extract was evaluated by determining the zone of inhibition against nine bacteria and eight fungi and yeast. Maximum zone formation was against *Staphylococcus aureus* (5.96 ± 0.19). *Diplotaxis cespitosa* was very highly active against *Aspergillus flavus* (6.34 ± 0.21). The FTIR analysis of *Diplotaxis cespitosa* proved the presence of functional group assignment Alkyl halides, Aromatic, Amide, and Alkane with Intensity 71.703 (Strong), 66.405 (Strong), 81.325 (Strong), 80.732 (Strong), 80.345 (Strong), 76.852 (Medium), 70.901 (Bending), 87.336 (Strong), 82.720 (Strong) and Peak (Wave number cm⁻¹) 1001.06, 1049.28, 1238.30, 1386.82, 1394.53, 1517.98, 1635.64, 2854.65, and 2926.01.

**Keywords:** *Diplotaxis cespitosa*, Bioactive Natural Compounds, Anti-microbial Activity

Introduction

Flavonoids are considered members of a class of plant phenolic constituents that have received increasing interest over the last decades. Thousands of them have been isolated and identified, most of which are from food plants. Flavonoids are divided into several subgroups, and their chemical and biological properties can be quite different. Flavonoids are regarded among the main dietary phenolic compounds. That flavonoids possess bioactive effect has been recognized for long, but until recently, data about their bioavailability, metabolic fate, and health effects were limited. It is well known that flavonoids are potent antioxidant metabolites, and therefore one of the main interests in the compounds has involved protection against cardiovascular disease. Lipids, proteins, DNAs and RNAs undergo gradual changes due to the formation of toxic free radicals and auto-oxidation by reactive oxygen species (ROS) into the organisms or the food. Several synthetic antioxidants, such as butylated hydroxyanisole (BHA) and butylated hydroxytoluene (BHT), are currently used as food supplements and stabilizers. However, these synthetic antioxidants have disadvantages due to their possible toxicity and injurious properties to human health. Thus, most consumers prefer additive free foods or a safer approach like the utilization of more effective antioxidant and antimicrobial agents from natural origins. Accordingly, plant extracts and their derived secondary metabolites, such as phenolic components, offer an opportunity in this regard. Flavonoids are present in photosynthetic cells and are usually found in fruits, vegetables, nuts, seeds, stems, flowers, etc. This class of compounds has become well known for its antifungal, antiviral and antibacterial activities. However, several studies have examined the structure–antibacterial activity relationship of these compounds. In addition, several research groups have sought to explain the antibacterial mechanisms of action of selected...
flavonoids. The activity of quercetin, for example, has been at least partially attributed to inhibition of DNA gyrase. It has also been proposed that sophoravflavone G and (−)-epigallocatechin gallate inhibit cytoplasmic membrane function, and that licochalcones A and C inhibit energy metabolism. Available data dealing with phenolic compounds and biological activities of Diploptaxis extracts are very scarce.

Materials and Method

Collection and preparation of plant material: The leaves were purchased from local market in Hilla city, middle of Iraq. After thorough cleaning and removal foreign materials, the leaves were stored in airtight container to avoid the effect of humidity and then stored at room temperature until further use.

Preparation of sample: About 20 grams of the plant sample powdered were soaked in 100 ml methanol for 16 hours in a rotatory shaker. Whatman No.1 filter paper was used to separate the extract of plant. The filtrates were used for further phytochemical analysis. It was again filtered through sodium sulphate in order to remove the traces of moisture.

Fourier transform infrared spectrophotometer (FTIR): The powdered sample of Diploptaxis cespitosa was treated for FTIR spectroscopy (Shimadzu, IR Affinity, Japan). The sample was run at infrared region between 400 nm and 4000 nm.

Determination of antimicrobial activity of crude bioactive compounds of Diploptaxis cespitosa: The test pathogens were swabbed in Müller-Hinton agar plates. Sixty μL of plant extract was loaded on the bored wells. Antifungal activity was evaluated by measuring the zone of inhibition against the test microorganisms. Methanol was used as solvent control. Amphotericin B and fluconazole were used as reference antifungal agent. The tests were carried out in triplicate. The antifungal activity was evaluated by measuring the inhibition-zone diameter observed after 48 h of incubation.

Results and Discussion

Identification of biochemical compounds: Analysis of compounds was carried out in methanolic extract of Diploptaxis cespitosa shown in Table 1 and Figure 1. The FTIR analysis of Diploptaxis cespitosa proved the presence of functional group assignment Alkyl halides, Aromatic, Amide, and Alkane with Intensity 71.703 (Strong), 66.405 (Strong), 81.325 (Strong), 80.732 (Strong), 80.345 (Strong), 76.852 (Medium), 70.901 (Bending), 87.336 (Strong), 82.720 (Strong) and Peak (Wave number cm⁻¹) 1001.06, 1049.28, 1238.30, 1386.82, 1394.53, 1517.98, 1635.64, 2854.65, and 2926.01. The very strong absorption band observed may be due to the presence of bonded N-H/C-H/O-H stretching of amines and amides. The observed very strong absorption band indicates the presence polymeric hydroxyl derivatives. The plant kingdom is a very promising and probably inexhaustible source of drugs and nutraceuticals. However, very few plants have been well studied and a large majority expects to be interested. Many previous studies refer to the genus Diploptaxis as traditionally used plants with therapeutic properties. Moreover, several species of Diploptaxis are reported as food crops in different regions. In fact, these herbs are appreciated for their strong pungent flavour and they are consumed raw or cooked, in salads and soups. Eating wild edible plants can be a good alternative? Med Aromat Plants Recently, it was shown that this species suppresses postprandial hyperglycaemia in mice by inhibiting key-enzymes linked to type 2 diabetes.

Conclusion

Medicinal property of *Diplotaxis cespitosa* methanolic extract is due to presence of secondary metabolites. Nine phytoconstituents were identified by (FTIR) analysis. This plant derived bioactive compounds used as source of antibiotic properties and pharmaceutical industries used for drug formulation.

Detection of Bioactive Compounds of *Celosia argentea*
Using Fourier-transform Infrared Spectroscopic Profile and Evaluation of its Anti-fungal Activity

Abeer Fauzi Al-Rubaye¹, Lena Fadhil Hamza², Imad Hadi Hameed³

**ABSTRACT**

*Celosia argentea* is a smooth annual herb type plant and routinely used as leafy vegetable in the rainforest zone of Africa. In India and China, it is known as a troublesome weed. It is a herbaceous plant and is known for its very bright colors and traditional uses. This is plant of tropical origin; they grow best in full sunlight and should be placed in a well-drained area. The purpose of our research were analysis of the bioactive chemical compounds of selected medicinal plant of *Celosia argentea* using fourier transform infrared spectrophotometer analysis. Seven bioactive compounds were identified in the methanolic extract of *Celosia argentea*. The Fourier transform infrared spectrophotometer analysis of *Celosia argentea* proved the presence of functional group assignment Alkenes, Alkyl halides, Amide, and Alkane with Intensity 70.097 (Strong), 79.917 (Strong), 65.933 (Strong), 83.395 (Strong), 73.966 (Bending), 87.917 (Strong), 83.461 (Strong) and Peak (Wave number cm⁻¹) 667.37, 794.67, 1020.34, 1236.37, 1631.78, and 2854.65. In the current study, the anti-fungal activity of *Celosia argentea* methanolic extract was evaluated by determining the zone of inhibition against fungi. *Celosia argentea* was very highly active against *Aspergillus fumigatus* (4.98 ± 0.18).

**Keywords:** Anti-Fungal Activity, FT-IR analysis, *Celosia argentea*

**Introduction**

*Celosia argentea* Linn. Commonly named as semencelosiae, cock’s comb, quail grass, the wool flower is a herbaceous annual plant widely grown in many regions of tropical Africa especially Nigeria, Benin and Congo. In India and other tropical regions of the world such as Sri Lanka, South Asia, and America, it grows as a post monsoon weed ¹. It is highly consumed as a leafy vegetable because of its high nutritive value. The whole plant of *C. argentea* is well known as a traditional medicine in India for the treatment of diarrhea, piles, bleeding nose, disinfectant, inflammation, hematological and gynaecologic disorders. The plant is enriched with primary and secondary metabolites such as carbohydrates, lipids, amino acids, peptides, phenols, phenolic acids, flavonoids, terpenes, and alkaloids; the important being bicyclic peptides, celogenamide-A, celogentin-A-D, H, J, and K, moroidin, celosian, citrusin C, cristatainetc. Hayakawa and co-workers reported the anti-metastatic effect of *C. argentea* seed extract based on its immunomodulation properties ²-⁹ including induction of cytokines such as interleukin (IL)-12, IL-2, and interferon-gamma that led to a Th1 dominant immune state activating macrophages to tumoricidal state causing basis for the inhibition of cancer metastasis. The plant is also reported to contain flavonoids like 5-methoxy-6,7-methylenedioxy-2’-hydroxyisoflavone and its 2’-methoxy derivative: Tlatlancuayin. Flavonoids play an important role in a plant as a defense and signaling compounds in reproduction, pathogenesis and symbiosis, by inhibition of proliferation of peripheral blood mononuclear cells, two-way MLR and natural

Amphotericin B and fluconazole were used as reference antifungal agent. The tests were carried out in triplicate. The antifungal activity was evaluated by measuring the inhibition-zone diameter observed after 48 h of incubation.

Results and Discussion

Identification of biochemical compounds: The common names of *Celosia argentea* as semen celosiae, celosia, silver cock’s comb, cock’s comb, quail grass, woolflower in English. Analysis of compounds was carried out in methanolic extract of *Celosia argentea*, shown in Table 1. Analysis of the methanol extract of *Celosia argentea* showed the presence of seven major peaks. The Fourier transform infrared spectrophotometer analysis of *Celosia argentea* proved the presence of functional group assignment Alkenes, Alkyl halides, Amide, and Alkane with Intensity 70.97 (Strong), 79.917 (Strong), 65.933 (Strong), 83.395 (Strong), 73.966 (Bending), 87.917 (Strong), 83.461 (Strong) and Peak (Wave number cm⁻¹) 667.37, 794.67, 1020.34, 1236.37, 1631.78, and 2854.65. In the current study, the anti-fungal activity of *Celosia argentea* methanolic extract was evaluated by determining the zone of inhibition against fungi. *Celosia argentea* was very highly active against *Aspergillus fumigatus* (4.98 ± 0.18). The very strong absorption band observed may be due to the presence of bonded N-H/C/H/O-H stretching of amines and amides. *Celosia argentea* plant shows different physiological effects because of different bioactive compounds present in it and therefore is widely used to cure several disorders such as fever, diarrhea, piles, bleeding nose, mouth sores, itching, wounds, jaundice, gonorrhea, and has different pharmacological activity such as immunological activity, cytoprotective, inflammation, antioxidant, haematological, anti-diarrheal, anticancer, antimimotic activity, hepatoprotective, antimetastatic, antioxidant, antibacterial, antifungal, anti-diarrheal activity, gynaecologic disorders, anti-urothiatic, growth activity and also as disinfectant; the dry powder of seeds are useful in diarrhea, aphrodisiac, reduce the inflammations, strengthen the liver, gonorrhea, clearing the vision and healing diseases of the eye; burnt leaves are styhorse (Unani). The dried plant is considered antiscorbutic and cooling in China. Herbal drugs are being proved as effective as synthetic drugs with lesser side effects. Plants have formed the basis of sophisticated
traditional medicine systems that have been in existence for thousands of years and continue to provide mankind with new remedies. From ancient literature to modern scientific records of traditional medicinal knowledge, there is evidence that plants supply the main medicinal source for peoples' healthcare in developing Asian countries. The presence of antimicrobial activity in a particular part of a particular species may be due to the presence of one or more bioactive compounds such as alkaloids, glycosides, flavonoids, steroids, saponins etc. Recently, a number of plants have been reported for antibacterial properties across the world.

In vitro Antimicrobial Activity of Methanolic Extract of Apium graveolens

Lena Fadhil Hamza, Ameer Ibrahim Abdulzahra, Imad Hadi Hameed

1College of Pharmacy, 2College of Basic Education, 3Biomedical Science Department, College of Nursing, University of Babylon, Hillah city, Iraq

ABSTRACT

The aims of our research were analysis of the secondary metabolite products and in vitro antibacterial and anti-fungal activities. Apium graveolens has been used as a food, and at various times both the whole plant and the seeds have been consumed as a medicine. The FTIR analysis of Apium graveolens leaves proved the presence of functional group assignment Alkyl Halides, Amide, and Alkane with Intensity 75.578 (Strong), 87.413 (Strong), 86.158 (Strong), 84.616 (Bending), 88.087 (Strong), and Peak (Wave number cm⁻¹) 1020.34, 1238.30, 1317.38, 1608.63 and 2918.30. In the current study, the anti-microbial activity of Apium graveolens methanolic extract was highly against Klebsiella pneumoniae (4.27 ± 0.16). Apium graveolens was very highly active against A. terreus (5.01 ± 0.17).

Keywords: FT-IR analysis, Apium graveolens, Anti-Bacterial, Anti-Fungal Activity

Introduction

Celery (Apium graveolens) is widely used as a medicinal herb or spice, with prominent antioxidant properties, due to the presence of many bioactive components, mainly phenolic compounds. An understanding of changes in phenolic content and antioxidant activity occurring during preservation of celery is important to develop appropriate drying method and optimal conditions of drying. Apium graveolens is a marshland plant in the family Apiaceae that has been cultivated as a vegetable since antiquity. Celery has a long fibrous stalk tapering into leaves. Depending on location and cultivar, either its stalks, leaves or hypocotyl are eaten and used in cooking. Celery seed is also used as a spice and its extracts have been used in herbal medicine.

Materials and Method

Collection and preparation of plant material: The leaves were purchased from local market in Hilla city, middle of Iraq. After thorough cleaning and removal foreign materials, the leaves were stored in airtight container to avoid the effect of humidity and then stored at room temperature until further use.

Preparation of sample: About 20 grams of the plant sample powdered were soaked in 100 ml methanol for 16 hours in a rotatory shaker. Whatman No.1 filter paper was used to separate the extract of plant stored at room temperature until further use.

Fourier transform infrared spectrophotometer (FTIR): The powdered sample of Apium graveolens was treated for FTIR spectroscopy (Shimadzu, IR Affinity, Japan). The sample was run at infrared region between 400 nm and 4000 nm.

Determination of antimicrobial activity of crude bioactive compounds of Apium graveolens: The test pathogens were swabbed in Müller-Hinton agar plates. Sixty μL of plant extract was loaded on the bored wells. Antifungal activity was evaluated by measuring the zone of inhibition against the test microorganisms. Methanol

was used as solvent control. Amphotericin B and fluconazole were used as reference antifungal agent. The tests were carried out in triplicate. The antifungal activity was evaluated by measuring the inhibition-zone diameter observed after 48 h of incubation.

Results and Discussion

Identification of biochemical compounds: Analysis of compounds was carried out in methanolic extract of Apium graveolens, shown in Table 1. Analysis of the methanol extract of Apium graveolens showed the presence of five major peaks. The FTIR analysis of Apium graveolens leaves proved the presence of functional group assignment Alkyl halides, Amide, and Alkane with Intensity 75.578 (Strong), 87.413 (Strong), 86.158 (Strong), 84.616 (Bending), 88.87 (Strong), and Peak (Wave number cm⁻¹) 1020.34, 1238.30, 1317.38, 1608.63 and 2918.30. In the current study, the anti-microbial activity of Apium graveolens methanolic extract was highly against Klebsiella pneumoniae (4.27 ± 0.16). Apium graveolens was very highly active against A. terreus (5.01 ± 0.17). The effect of Apium graveolens essential oils on bacterial and yeast growth was studied by the Paper-Disk plate method by measuring the inhibition zone. Based on the present study, it is concluded that the whole plants of Apium graveolens contain various bioactive components with high degree of antibacterial activity against various pathogens. It is hoped that this study would direct to the establishment of some compounds that could be used to invent new and more potent antibacterial drugs of natural origin. Further work will emphasize the isolation and characterization of active principles responsible for bio-efficacy and bioactivity. Flavonoids and other phenolic compounds spread widely in plants, and their diverse biological activities such as antioxidant effects have been investigated in many studies such as coronary heart diseases, diabetes, and cancer. Medicinal herbs have fewer side effects than chemical drugs and their antioxidant attributes decrease the toxicity of these drugs. Today herbal drugs are used as an alternative to chemical drugs and the main reason is their low level of side effects compared with chemical drugs. WHO encourages countries to provide safe and effective traditional remedies and practices in public and private health services and it also published two monographs on medicinal plants with information on pharmacopoeial summaries for quality assurance: botanical features, distribution, identity tests, purity requirements, chemical assays, and active or major chemical constituents, clinical applications, pharmacology, contraindications, warnings, precautions, potential adverse reactions, and posology.

**ACE gene Polymorphism on Diabetic Type 2 Patients and their Susceptibility to Diabetic Nephropathy**

Alaa Shakir Al-Nahi1, Murtadha Jawad Al-Barqaawee1

1Department of Biology, Faculty of Science, University of Kufa, Iraq

**ABSTRACT**

One of diabetic type 2 (T2D) complications is diabetic nephropathy, the glycated hemoglobin, poor diabetic control, are considered as risk factors for renal damage. Current study aim the I/D polymorphism ACE gene and serum ACE levels may increase the diabetic nephropathy complications susceptibility in a sample population of Al-Najaf in Iraq, a total of 90 T2D patients (about 32 without nephropathy and 58 with nephropathy) and 50 healthy persons, all groups age were > 45 years old. The ACE I/D polymorphism was performed by polymerase chain reaction (PCR) using special primers, followed by electrophoresis on 1.5% agarose gel. We record significant differences between the ACE I/D polymorphism in T2D and control was (P < 0.01). The DD genotype of ACE I/D polymorphism the risk for T2D increased (OR = 7.2 fold), as well as, the carriers D allele, the risk (OR = 0.55). Also T2D patients had a significantly higher level in ACE in diabetic nephropathy (DN) and lower level in T2D without nephropathy if compared with controls (P < 0.01). Our evident show the carriers DD genotype had more serum ACE levels than carriers II genotype in T2D.

**Keywords:** type 2 diabetes mellitus, ACE1, insertion/deletion polymorphism ACE gene

**Introduction**

Disturbance in glucose homeostasis and absolute or relative insulin deficiency in addition to resistance to this hormone of diabetes mellitus are widespread in the world population, Type 2 diabetes mellitus (T2D), is characterized by changes in action of insulin and secretion, being linked with genetic susceptibility. It is developed to macrovascular and microvascular complications that constitute a risk for developing diabetic nephropathy1. Powerful system of RAS is responsible balance in fluid-electrolyte and systemic blood pressure2. The release of renin is triggered by a number of physiological stimuli, including PGI2, decreased Na+ concentration in the distal tubule, reduced arterial pressure, renal sympathetic nerve activation and stimulation of β1-receptors. Following secretion, action of renin in synthesis of angiotensin I (ang I) from angiotensinogen protein3. At the chromosome 17q23 position is ACE gene. The product of ACE gene is a zinc metallopeptidase widespread in endothelial and epithelial cells surface4 and activate renin to convert angiotensinogen to angiotensin I, by having two homologous domains and two active sites, that shutout the C-terminal dipeptide from angiotensin I to form the potent vasoconstrictor and growth-promoting substance angiotensin II5. There is variation within the gene, a 278 base pair (I/D) polymorphism, produced different three ACE genotypes: I/I, I/D and D/D6. As the polymorphism present in an intron, not change in enzyme structure. However, the polymorphism is highly related to the plasma ACE level, while I/I, I/D and D/D have low, medium and high levels respectively7. ACE was chiefly present on endothelial cells surface of lungs, intestines, brush border membranes of renal, placenta and choroid plexus8. The D/D genotype carriers correlate with the increase in the ACE activity in cardiovascular disease and renal disease9 causing the increased conversion of ang. I to ang II10, other researchers also linked the D-allele to progression of native kidney diseases such as DN11. The frequencies for ACE genotype are differed according to ethnic groups12, observed DD genotypes distribution were 50% in Arab population. These frequency varies from 25% to 30% in Caucasian and African American populations, while less than 20% in Asian populations13.
Material and Method

Study population from AL-Najaf province in Iraq, we taken 90 patients with diabetes mellitus type 2 and 50 non infected persons as control, they were >45 years of age, were referred to Al-Sadder Hospital (located in kufa, Iraq) for diabetes center from November 2017 to September 2018, patients and control groups were approved for sampling and then informed of the results. Evaluation criteria for patients history are considered conventional risk factors for diabetes diabetes mellitus type 2 based on fasting blood sugar (HbA1c (4.8-6.0%), high blood pressure (systolic blood pressure >140 mmHg and diastolic blood pressure >90 mmHg, micro albuminuria >30 mg/24 hrs and creatinine >1.2 mg/dl for diabetic nephropathy.

Determination of ACE polymorphism: Extracted DNA from whole blood by using DNA isolation kit (Geniad gSYNCTM DNA Extraction Kit). the primers synthesis by (Bio Synthesis, USA)were performed for detection of I/D ACE polymorphism.

forward primers were 5’-CTG GAG ACC ACT CCC ATC CTT TCT-3’

reverse primer 5’- GAT GTG GCC ATC ACA TTC GTC AGA T-3’

The amplification of PCR was carried out in a total volume of 25 μl containing 5 μl DNA, 12.5 μl Go Taq green master mix 2X (PCR PreMix from Bioneer) is a premixed ready to use solution contains Taq DNA polymerase. Amplification was performed in Gradient Thermo-cycler (Agilent, USA), the program of PCR amplification were initial denaturation step at 94°C for 5 min followed by 30 cycles, each consisting of denaturation at 94°C for 1 min, annealing at 58°C for 1 min and extension at 72°C for 2 min, followed by final extension step at 72°C for 5 min. Positive control samples (samples showed II genotype in first PCR) were used to confirm the reliability of genotyping, finding of I allele at 335 bp.

Detection of Angiotensin I-converting enzyme: ACE concentrations in serum detected by ELISA kit from Elabscience, cat.no.E-EL-H0002, which applies to the in vitro quantitative determination of human ACE concentrations in serum, plasma and other biological fluids.

Statistical Analysis: Mega stat software used to statistically analyzed to obtained mean ± standard deviation (SD), the odds ratio (OR) and P < 0.05 were considered significant.

Results

Renal functions were established on the basis of the mean serum concentrations of creatinine and Microalbuminuria in urine, this study record in T2D with nephropathy highly creatinine 5.48 ± 2.00 mg/dl than 0.56 ± 0.26 mg/dl in control in addition to Microalbuminuria (mg/24 hrs) was significant P<0.01 than control in table 1.

Discussion

There is many factors effect on patients with diabetic type2 such as variation in genetic factors, hydrodynamic and metabolism, these alterations responsible for developed diabetic nephropathy.

The high sugar levels in blood for long period causes injuries in most of nephrons lead to disability of kidneys to performed fluid and electrolyte balance. In our study, duration and severity of diabetes strongly correlated with high serum creatinine and Microalbuminuria levels in urine can be used as useful prognostic markers and predictors of renal damage in diabetic patients\ref{15} our findings agree with\ref{16,17}. High level of serum creatinine result from decreasing of glomerular filtration rate, the serum creatinine level is related to measure of glomerular filtration, this rise indicates progression of kidney disease and thus serum creatinine has greater prediction ability\ref{18}.\ref{19}findings an increasing in serum creatinine level is signal of kidney injuries in patients with hypertension in diabetic people who are suffering then kidney disease. the microalbuminuria result from leak small amounts of the blood protein albumin into the urine\ref{20}, this one symptoms of DN, our study show significantly differences in microalbuminuria and agree with\ref{21} of diabetic nephropathy than diabetic without nephropathy and control(P<0.01). The important genes in RAS pathway, \textit{ACE gene} is one of them, the polymorphism of this gene has effect in progression diabetic nephropathy in T2D patients, when compared with healthy non diabetic control subjects and also compared with T2DM patients without nephropathy, The our results observed the DD genotype was significantly higher (P<0.01) in DN than healthy non-diabetic control subjects and T2D patients without nephropathy, besides, the frequency of the D allele was more in diabetic nephropathy than other groups control and diabetic without nephropathy patients, this finding supported with many studies suspected that the D allele or DD is associated with the progression of nephropathy in type 2 diabetic patients\ref{22,23,17,20}. In UAE observed association of ACE polymorphism with diabetic type2\ref{24}. others studies involved the association of \textit{D/D} genotype with increased T2DM risk in Tunisia\ref{25} and with DN in Iran\ref{26} and in Egypt\ref{27}. Japanese studies considered the D allele is an independent risk factor for DN in T2D patients\ref{28}, other study showed that patients who were DD genotype had diminished in renal function and the D allele revealed significantly associated with DN\ref{29}.We reported an increase in plasma ACE level in individuals with T2D (p<0.05) especially in diabetic nephropathy, these findings are in agreement with several previous Studies\ref{17,26,30}, the rapid damage in nephron function is suspected in DD genotype carriers which is related with raising serum ACE levels than DI and II, The elevated ACE expression caused increases in the plasma angiotensin II level, and enhanced damaged in podocyte then result in developed kidney.

Conclusion

Our current study suggest that D/D genotype of \textit{ACE gene} associated with susceptibility to diabetes and DN than I/I genotype, we found there is relation between level of serum ACE in D/D genotype carriers.

The Epidemiology of Hepatitis a Virus in Iraq

Nisreen Kaddim Radi, Tsahel H. Al-Dulaimi, Amal Raqib Shamran

ICollage of Science for Women, University of Babylon Iraq

ABSTRACT

Is liver infection resulted from the infected with Hepato-virus A (HAV)[1]. The time between symptoms and infection (incubation period), in the affected people, is amid (2-6)weeks.[2] vomiting, diarrhea, nausea, fever, jaundice and abdominal pain represented symptoms of infection.[2] In old patient Acute liver failure occur, Many patients have few or even no symptoms, particularly in the young. The spreading of infection can occur throw ingestion of contaminated food and water with infected feces. there is no symptoms when Children have the infection, but they can capable of transfer the virus to others. Diagnosis need blood testing, because the symptoms mimic those of another infection.[3,4].

Keywords: Epidemiology, Hepatitis A virus, Iraq

Introduction

As other Middle Eastern countries, Iran was marked as a high prevalence area. In the last three decades the hygienic level has been improved significantly like sanitation, and teaching Thus researchers predicted a decreased rate of viral hepatitis-A spreading [5]. Multiple studies that performed in Iran studying the prevalence of HAV infection. These studies were carried in different areas of the country with different designs and results. In a study in southern Iran, out of 1050 participants, 88.2% were positive for anti-HAV, a positive serology was documented in 79.3% of participants greater than (20y) old compared to 99% of those greater than 30 years of age. The rate of positive serology was more in rural areas (95.9%) compared to urban regions (85.1%). Family number was associated with higher antibody levels[6]. In some Asian and countries of Middle East like Lebanon and Saudi Arabia, which are enduring epidemiologic transition of HAV as hyper-endemic toward intermediate pattern. There is a vital treatment for a program that used national vaccination in order to prevent HAV infection and its consequence [7]. The infection of hepatitis A is increased in Iraq from 1802 in 2009 to 4473 in 2014 between nationals. Because of many factors like poor hygiene, contemned drinking water and unsafe food that facilities mode of HAV, HAE [8].

Vaccination: Now are found two deactivated vaccines in USA and the Canada, contain a collective of Hepatitis A and Hepatitis B vaccine.[9]. Hepatitis A vaccines offer protection for long-term. [10].

Several countries arranged universal vaccinations for prevention of HAV, but such decision to adopt national vaccinations in the Middle East countries needs additional evidence. The burden of vaccination costs and HAV infection are important considerations for making such decision, particularly in a low resource setting. There are multiple of HAV vaccine brands where the cost of single dose is between 15 to 65 USD. In comparison to other viral infections that carry greater disease load but minor cost for vaccination such as hepatitis B virus (HBV) infection, meanwhile, there is no clear evidence for suggesting mass vaccination for HAV in our region[10].

In the future if vaccination for HAV is proven necessary, it can be included in the routine vaccination program such as HBV for all neonates and children. A combined single HBV/HAV vaccine can also be injected by the age of entry into high school as a catch up vaccination for both viruses[11].

When occurrence of HAV infection occurs, we should vaccinate susceptible individuals. This method of prevention found to be cost-effective in multiple studies.

Application of accelerated vaccination needs adequate abilities for early diagnosis of an outbreak, to identify susceptible persons. In the setting of an outbreak, the injection of a vaccine during the pre- and post-exposure period is more effective than an immunoglobulin injection. An accelerated vaccination can be performed for a more rapid effect. One trial studied the combined, accelerated HAV/HBV vaccination injected at 0, 7, 21 days and a 12 months booster dose offer good efficacy and safety.

The World Health Organization has proposed routine vaccination for all children with rapid outbreak diagnosis and control by accelerated vaccination in countries with intermediate prevalence such as the Middle East when the significant infection of HAV is occur.

Viral hepatitis in the Middle East July 28, 2014 marked World Hepatitis Day, and this year people around the world were encouraged to “think again about viral hepatitis”. The Lancet has published hepatitis is one of the major global health care problems and kills around 1·5 million people worldwide every year. The prevalence of viral hepatitis varies from region to region, but is generally higher in Middle Eastern countries than in Europe and the USA. The main causes of viral hepatitis include hepatitis A, B, and C viruses. Hepatitis A virus (HAV) is the most common cause of acute hepatitis in children in the Middle East. However, only a few studies of the epidemiology of HAV in the Middle East have been done. The disease can easily be mistaken for a common cold and the reported prevalence can therefore be underestimated.

The prevalence of HAV in Iran (and probably in most countries in the region) is very high. In a 2006 study of 1869 people 18–65 years of age, the seroprevalence of HAV was 85% in the capital Tehran, 96% in Hormozgan in southern Iran, and 99% in Golestan in the north of the because of improved sanitation, and the average age of infection with the virus has been increasing in the country, children and young adults remain the primary targets; most children in Iran contract the disease and have immunity by 10 years of age. In most areas of Iran, more than 90% of people aged 33 years or older are in the prevalence of HAV has also been reported in Saudi Arabia.

**Taxonomy:** Hepatitis A virus considered as a member Picornavirales order that belong to Picornaviridae family and Hepatovirus genus. Natural hosts of this virus are vertebrate and humans. [14]

**Genotypes:** Single serotype with seven dissimilar genetic groups (4 infect human plus 3 simian) ensured. [15] genotypes that infect human are I, II plus III. subtypes that described are six (IA, IB, IIA, IIB, IIIA, IIIB).[7,16]

**The Structure of virus**

**Capsid:** HAV capsid is formed with subunits called capsomeres (Figure 1,2). every capsomere consist of of 5 protomers. (Figure 1,2). every capsomere consist of of 5 protomers. All HAV protomer is created of three proteins; VP1, VP2, and VP3, their function in the cell entry.

The core of all viruses is known as The nucleocapsid, which is consist of nucleic acid and protein. The protein coats protects genome of the virus [17].

HAV varies from other hepatitis strains as it’s belong to the picornavirus family. This family are little germs, non-enveloped, icosahedron-in their shapes, viruses have RNA single strand. [18].

**Figure 1, 2:** HAV structure every capsomere consist of of 5 protomers. All HAV protomer is created of three proteins; VP1, VP2, and VP3

![HAV structure](image-url)
Genome

Figure 3: HAV genome is consist of RNA single strand of three section. The genome of HAV is positive-sense, single-stranded RNA, written as ss(+)-RNA. Because the virus is positive-sense RNA

Viral Replication

Figure 4: HAV life cycle

The natural hosts of HAV are human and vertebrate. fecal-oral Routes the principle road of Transmission plus blood. HAV enter blood stream Following ingestion, by cross the oropharynx epithelium or intestine epithelium. The virus reach to the liver, and start their replication inside of hepatocytes and Kupffer cells (liver macrophages). The replication of HAV completed in the cytoplasm. Translation of viral protein initation. then virus leavings the host cell via cell lysis plus viroporins. Virions then exude into the bile and discharged into stool. HAV is liberated in large numbers about 11 days before the symptoms appear or anti-HAV IgM antibodies in the blood are elevated. The incubationperiod is 15–50 days. % [19]. There is No virus-mediated cytotoxicity happens, apparently as of the virus’ own requirement for an intact eIF4G, and liver pathology is likely mediated by immune system.

Conclusion

In old patient acute liver failure occur, many patients have few or even no symptoms, particularly in the young. The spreading of infection can occur throw ingestion of contaminated food and water with infected feces. There is no symptoms when Children have the infection, but they can capable of transfer the virus to others. Diagnosis need blood testing, because the symptoms mimic those of another infection.

Assessment of Nurse Midwives Knowledge Regarding Nursing Care of Post-partum Hemorrhage at Al-Najaf AL-Ashraf City Hospitals

Hanan N. Mohammad¹, Muna A. Khaleel²
¹MSc. Student, Maternity Department, ²Professor, Community Health Nursing Department, College of Nursing, University of Babylon, Hilla City, Iraq

ABSTRACT

A descriptive cross-sectional study design was conducted from 30/July/2018 to 29/July/2019 to meet the previously mentioned objectives. All nurse midwives (n=150) were included who works at the hospital of AL-Najaf AL-Ashraf Province. The result of the study revealed that the mean overall knowledge score of the study participants for all domains was (1.91) which indicated that the overall knowledge of nurse-midwives in Al- Najaf AL- Ashraf city hospitals regarding nursing care of PPH was (fair). the overall knowledge score about prevention of PPH was (1.87) which is also considered (fair). The result of the current study also revealed that there is a significant positive correlation had been found between age of participants and their overall knowledge score (R = 0.412, p. value = 0.004). Other significant positive correlation was found between duration of experience in delivery room (R = 0.575, P. value = 0.001) and a significant direct (positive) correlation was found with receiving training courses or workshops (R = 0.243, P. value = 0.043).

Keywords: nurse-midwives, knowledge, postpartum hemorrhage, prevention

Introduction

Postpartum hemorrhage (PPH) is being designated as the most substantial yet inevitable source of death and maternal illness all over the world (1). Being the utmost prevailing 5th maternal mortality cause, PPH instigate 140,000 demises each year worldwide (2). Rendering the WHO, the distinct PPH definition is being stated by way of 500ml minimum blood loss after childbirth within 24 hours. However, the severe PPH is termed as 1000ml least blood loss in 24 hours of birth (3). Another definition is that PPH the sufficient loss of blood causing hypovolemia, a (10%) decrease in the hematocrit or a situation necessitating the transfusion of blood products irrespective of the delivery route (3). PPH has been categorized into two types: primary and secondary PPH (2). Primary (immediate) PPH is typified by a blood loss of more than 500ml owning to vaginal delivery and blood loss of 1500 ml owning to caesarean section within first 24 hrs of delivery (2). Practically uterine atony is considered to be the root of 70% of immediate PPH. Inadequate contraction of the uterus after a child is born referred to as atony of the uterus. The prevalence of immediate PPH is (5%) of all deliveries (4). An approximated 14 million cases of PPH are registered every year globally with a (1%) case-fatality rate (5). According to an assessment, about 2% of the women childbirths are associated to PPH. Although, another approximation indicates the ratio of 25% global maternal deaths while marking the PPH as a widely held prime reason of demise in low wages countries. Economically well developed countries has overall less decease risk than the developing nations. In the high-income countries, the total death risk is approximated to be 1:100,000 deliveries as compared to 1:1000 in low-income countries (5).

According to Rath (2011), a recent WHO analysis showed that in high-income countries, hemorrhage as a result of PPH accounts for (13.4%) of maternal mortality, (30.8%) for Asia, and 34% for Africa (5). With
a broad difference globally, the incidence of minor PPH and severe PPH is estimated to be (6%) and (1.86%) of all deliveries (4,5). Morbidity resulting from severe PPH is approximated at 4.5-6.7/1000 deliveries with nearly 20 million women globally every year suffering from an acute or chronic disability due to PPH (6). Midwives play a crucial role in effective prevention, diagnosis and treatment of PPH. They are required to be familiar with all the risk factors associated with PPH, and well-trained to manage them to avoid PPH and complications associated with it. Life-saving skills as a part of the training of the midwives enable them to make a substantial contribution to the reduction of PPH (7). The technical know-how, attitudes, and practices of midwives are very crucial for the prevention and treatment of PPH (8).

Methodology

A study aims: The purpose of the current study was to investigate the nurse midwives knowledge regarding nursing care of PPH. The current study also aims to find out the relationship between nurse midwives knowledge regarding nursing care of post-partum hemorrhage with their socio demo-graphic and personal characteristics such as (age, marital status, economic status, educational level, etc……).

Design of the study: A descriptive cross-sectional study design was conducted from 30/July/2018 to 29/July/2019 to meet the previously mentioned objectives

Study Sample: All nurse midwives (n=150) were included who works at the hospital of AL-Najaf AL-Ashraf Province, 53 of them from AL-Zahra Teaching Hospital, 25 nurse midwives from AL-Forat Teaching Hospital, 17 nurse midwives from AL-Hayderia General Hospital, 22 nurse midwives from AL-Manathera General Hospital, 17 nurse midwives from AL-Hakim General Hospital, 16 nurse midwives from AL-Sajad General Hospital.

Study instrument: A constructed questionnaire was prepared and modified after a thorough review of the relevant literature. This questionnaire covers two parts:

Part 1: Socio- demographic and personal characteristics: This part included the following (age, level of education, duration of experience in delivery room, receiving training courses or workshop about postpartum hemorrhage, accommodation, type of accommodation, marital status, economic status, others) which included (8) items.

Part 2: Knowledge of nurse midwives about prevention of postpartum hemorrhage which included (18) items.

Validity and Reliability: The content validity of the instrument was established through a panel of (12) experts, the reliability of the items was based on the internal consistency of the checklist was assessed by calculating Cronbach Alpha which was= 0.765

Data Collection and Data Analysis: A structured questionnaire used to collect data by direct interview. The approximate interview time of 25-30 minutes was provided for the questionnaire completion. Data collection is performed from 2 Jan.2019 to. To determine whether the objectives of the study were met, the current study data were analyzed by using SPSS, version 25.

*Nurse-Midwives Mentioned more than One Choice

Table 1 illustrates the distribution of duration of experience in delivery room together with history of training about postpartum hemorrhage where 20 participants (13.3%) had a duration of experience in delivery room for less than one year, 73 (48.7%) had a duration of one to ten years, 31 (20.7%) for 11 – 20 years, 18 (12%) for 21-30 years and 8 nurse-midwives (5.4%) had a duration of experience in delivery room of more than 30 years. Regarding the training about postpartum hemorrhage, 109 nurse-midwives (40%) had received training courses, 90 (33.1%) had participated
in workshops and 73 (26.8%) nurse-midwives received other types of training.

Good knowledge was about observe the signs of placenta delivery, delivery of the placenta after completely separated and uterus contract is a preventive measure of PPH, Instruct the mother not to push prematurely, proper suturing of episiotomy.

Poor knowledge was reported about Register time of placenta delivery, give an oxytocic drug as ordered, inspection of perineum after delivery provide instruction about episiotomy, uterine tone prevention of infection, make sure bladder is empty, delivery of the baby slowly with contractions.

</tbody>
</table>

Table 3, shows Spearman’s bivariate correlation analysis. A significant direct (positive) correlation had been found between age of participants and their overall knowledge score (R = 0.412, p. value = 0.004). Other significant direct (positive) correlation was found with duration of experience in delivery room (R = 0.575, P. value = 0.001). Moreover, a significant direct (positive) correlation was found with receiving training courses or workshops (R = 0.243, P. value = 0.043). No significant association had been found between overall knowledge scores and other variables including level of education, accommodation, type of accommodation and economic status, (in all of these variables correlation was not significant, P. value > 0.05). All through the progression of current study, the research outcomes indicated age distribution of the participants while revealing that the major age group is between (20 – 29) years which constitutes (44.7%), followed by age group (30-39) years (22%). This data may slightly differ from that obtained by (40) who found that the major age group is (47-55) years (32.5%), followed by (20-28) years (24.7%). The results of the current study indicate the target population from which the sample is drawn; it also indicates that younger nurses midwives constitute the majority among their groups. Table (3) reveals that some of the midwives’ responses about prevention of PPH are categorized as poor (correct responses equal or less than 33.33%), they include : support perineum area by towel, checking membrane and parts of the placenta, prohibition of fundal pressure, assessment of locia, follow up of contraction every 5 minutes, avoid the routine episiotomy, episiotomy should be timely with crowing of fetal head and support flexion point during labor to prevent perineum laceration. This result greatly differs from the results observed by Faiza, (2015), who found that most items related to prevention have high scores and good knowledge (10). The same table shows that some responses are considered (fair), these include : give an oxytocic drug as ordered, inspection of perineum after delivery, provide instruction about episiotomy, uterine tone prevention of infection and make sure bladder is empty. These result disagrees with Onasoga et al. (2012) who found that about (78.8%) of the midwives have correct responses about the question of using oxytocin to prevent PPH(10); while Faiza (2015) observed about (93.9%) have correct answers (10); Elfaki (2015) noticed that (94.8%) of the investigated midwives have correct answers for the same question (9). It is well known that oxytocin is a hormone secreted by the posterior pituitary.
gland and tend to increase the uterine contraction during delivery\(^{(12)}\); so it is unexpected result in the current study to find that (21.3%) of the studied sample to give wrong answers about the question related to oxytocin, and (30%) of them do not know the correct answer.

Regarding the item of bladder emptying, previous studies found the following correct responses; Faiza (2015) found about (79.6%); Elfaki (2015) found that (90.9); Onasoga et al. (2012) found that (93.8%)\(^{(9,11)}\); while Bulndi et al. (2017) found a lower score (only 60%). Their studies that have previously recorded high scores of correct answers related to the other questions (inspection of perineum after delivery, provide instruction about episiotomy, uterine tone prevention of infection)\(^{(13)}\). The present study found good knowledge (correct answer above 66.66%) regarding the following items: (observe the signs of placenta delivery, delivery of the placenta after completely separated and uterus contract, instruct the mother not to push prematurely). It means that knowledge and awareness increases with age, this result is in agreement with Jaber and Abbas (2012) who found a significant association (p=0.02) between midwives’ age and their knowledge\(^{(14)}\). This may be due to increased practice and experience by increasing age resulting in accumulation of information so that the same table (4.17) shows a high significant positive correlation (p=0.001) between overall knowledge and duration of experience in delivery room; this result agrees with that obtained by Bulndi et al. (2017) who observed that high levels of knowledge about PPH is found in midwives with years of experience more than 15 years\(^{(13)}\). However, Jaber and Abbas (2012) did not find a significant relationship between knowledge and experience\(^{(14)}\). Unexpectedly, this results did not reveal any significant relationship (p=0.495) between overall knowledge of nurse-midwives and their level of education, this result agrees with the result obtained by Onasoga et al.\(^{(11)}\). However, disagrees with the study conducted by Jaber and Abbas (2012) who pointed a significant relationship with educational status\(^{(14)}\); another study found that doctors have better scores than midwives\(^{(15)}\). The unexpected result in the present study may be explained by what is mentioned in this chapter that most of the study sample (74%) are graduated from secondary school of midwifery, so that there is no great difference in the level of education of respondents participated in this study. Concerning training, the current study found a significant correlation (p=0.043) between overall knowledge of nurse-midwives and receiving training courses or workshops, this result agrees with the work obtained by Benedict et al. who found that midwives who completed the training courses named “Essential Steps in the Management of Obstetric Emergencies” ESMOE had better knowledge and performance\(^{(16)}\). However, another study conducted in Baghdad did not find a significant correspondence of about p=0.05 amongst the training and inclusive understanding of nurse midwives\(^{(14)}\). While, no noteworthy correlation has been perceived among nurse midwives’ complete knowledge & their marital status, the p value in table (4.17) is (0.06) which is very close to the significant cutoff level (0.05). This result agrees with the study of Jaber and Abbas (2012) who did find a significant relationship (p=0.584)\(^{(14)}\).

**Conclusions**

It was concluded that the nurse-midwives have a moderate level of knowledge about the overall concepts, information and skills related to the prevention of postpartum hemorrhage. Generally, the knowledge of nurse-midwives about postpartum hemorrhage increases with age and years of experience. Training of nurse-midwives by training courses and workshops have an effect on their overall knowledge about postpartum hemorrhage.

Measurement & Evaluation of the Method of Quantitative Correlation Related to the Development of Some Types of Volleyball Reception Skill

Ali Khalif Ali¹, Imad Kadem Yasser²
¹Directorate of Education Thi- Qar; ²Physical Education and Sports Sciences, Thi- Qar University

ABSTRACT

The methods and methods are important in the development of different skills in learning as the path that leads to the achievement of motor duty and through it to reach the requirements of success and these methods which are modern is the interdependence in the performance that allows the learner to shorten the teaching period and at the same time of exciting ways In learning and that the skill of reception of the most important skills in volleyball and mastering the success of the overall performance and that the imbalance in the reception of the ball, which is the first stages lead to a defect in the construction of a correct attack, and the skill of reception of different forms that the player can perform according to the nature of the transmission For the transmitter player, the player must master all forms of volleyball reception.

Keywords: Measurement, quantitative correlation, skill

Introduction

The scientific development is taking great strides through solving the scientific problems that have the greatest impact in achieving the mathematical achievement. This development is not confined to one area ¹, but encompasses all areas of life. The field of physical education is one of these areas that develop very rapidly. The methods and methods of the most important areas that have a great interest in the development of physical activities because of their specificities in this area, and these methods are the method of quantitative interdependence, which reflects the application of the interconnected between the parts of one skill and the field is interesting in the process of learning in addition to the Volleyball is one of those games that are characterized by basic skills and the task that most of the parts of those skills are based on scientific grounds and accurate form of performance determines the player’s special situations in the skill of receiving the defense and defense of the stadium, that basic skill is as important as ² The position of the moment of mastery touching the ball is one of the most important requirements of the correct performance is based on the first situation (readiness) and that the construction of this important situation requires proper timing through the interconnection of a group of The kinetic capabilities such as balance and flexibility as well as agility as well as skill mastery. The importance of research is reflected in the researcher’s attempt to contribute to IGAD or the real knowledge of the level of performance of this important skill, which contributes directly to the win and also to know which of these forms are more used during matches within the actual performance through the application of this type of methods, so that Our trainers who train youth teams have an active interest in this skill. As for the problem of research, through the researcher’s follow-up to many local games ³, the researcher noticed there is a failure in the defensive side at the moment of receiving the ball from the sending of the opposing team as well as the lack of use of performance by modern means that have the appropriate impact in learning this skill in its desired form, As well as the lack of interest of most players with this skill, which is the first pillar to build a successful

attack and its success works to deliver the ball to the player prepared without errors, in addition to the lack of applications in the types of modern methods, In this sense, the researcher was asked to study this problem in order to know the strengths and weaknesses in the forms of receiving the transmission among the members of the research sample, And the goals in this research are based on Identification of the most common forms of reception among members of the research sample. Identifying the differences for each form of receiving reception in the research sample. The percentage comparison according to the use of the different forms of transmission among the members of the research sample.

**Methodology**

**Research Methodology:** The choice of the curriculum usually depends on the exact and objective solutions through which the problem is solved, so the researcher adopted the descriptive method in the survey method with the nature of the research.

The research community and its design: The good choice of the sample is the part that represents the community of origin or model that the researcher is conducting all the research axes. The research community therefore defines the specialized school in the Dhi Qar volleyball for the 2016-2017 sports season, (100%). The researcher conducted a homogeneity of the sample as shown in Table (1).

It is clear that the value of the difference coefficient in all the search variables in Table (1) is between (+ 3, -3). This means that the sample in the research has been distributed closer to normal in all the research variables.

**Search Tools:**

- Arab and foreign sources
- Volleyball court
- Volleyball
- Record of documentation.

**Tests used:**

- Ball reception accuracy test
- Test Name: Accuracy of reception.
- Purpose of the test: Measure the reception accuracy of the ball.
- Gadgets: volleyball court, five plane balls, adhesive tape.
- Mode of performance: The laboratory stands in the right place in the center (6) and awaits the ball sent from the opposing team and receives the ball with the arms from the bottom and try as far as possible to deliver the ball to the player in the center (3) directly towards the area (A) (2) towards area (B) or center (1) in point (C) and give the player five attempts.

- Calculation of scores:
- Five attempts to give the player the total score of the test (25) degree
- A score of (5) for region (A) is given when the successful attempt is made.
- (2) scores are given to Area B when the successful attempt is made.
- (1) scores for Area C are given when the successful attempt is performed.

**Figure 1: Shows the accuracy of the defense of the pitch with arms**

**Main experience:** The work of the actual researcher began the main experiment on 15/3/2017 until 15/5/2017,
ie a period of two months, the special exercises were applied according to this method through the adoption of each form of reception used with no score points. For other forms of reception not recorded in the current study in the special form prepared for this purpose and with the assistance of a dedicated staff of the game. As in some of the following exercises: The number of exercises was different and varied for 4 weeks and three units per week. The total number of units (12 units) included exercises according to the related performance of the type of skill to be learned and according to the type of transmission. The researcher also took care of the method of repetition and diversity in the performance of the exercises during each unit according to the performance of each type of transmission in terms of increase and gradation during the inclusion of the type of exercise during the motor as well as in the degree of difficulty, and was intended to develop the type of reception, improve accuracy, and have been careful in the preparation of exercises through the appropriate rest times the player’s possibility.

Different and varied exercises have been applied as in some of the following models:

1. The reception exercise the transmitter facing the jump over the person until the arrival of the ball sent.

2. The reception exercise Wavy transmission (winding) until the arrival of the ball sent.

3. The practice of receiving the overwhelming transmission by jumping in place until the arrival of the ball sent.

4. The reception reception of tennis by running over the rubber ropes until the arrival of the ball.

5. Receiving the transmitter from throwing the ball at a distance of (6) m and play the last stadium.

6. Receiving the wavy transmitter from the jump and the receiver inside the box 1 * 1 and the ball must be directed to the equipment.

7. Receiving the transmitter is forgetting jump on three barriers.

8. The future running winding and then receives the ball rolling transmitter,

9. Receiving the mass transmission by sending six players multiple transmitters and receivers in the defense zone.

10. Receive the overwhelming and receiving receiver in the back zone with the same number of balls sent.

The researcher then conducted a comprehensive survey of all the cases in the observation forms and separated them separately for the purpose of processing them statistically.

**Statistical Methods:** The researcher used the SPSS ver 19 program to process the data.

**Discussion**

**Table 2:** Calculations, standard deviations, calculated T scores, and significance level are calculated for each form of receiver reception

The researcher shows the variation in the forms of receiving the transmission in the sample of the research sample due to a number of reasons. The statistical analysis shows the results of variance differences in each form. The highest variance of the receiver variable Although this form is not one of the most widely used forms in the volleyball game, the researcher finds that this is because this form does not need a great movement of the player when using it as well as most players in this tournament did not rise to the use of forms of strong transmission such as the crushing and In which the speed and strength of the ball so that the player cannot receive the ball of the ball to receive from the position of standing as well as receiving from the stand position as confirmed 4 that the performance requirements reception ball increases with speed and strength and direction. In addition, the researcher believes that the volleyball player has the basics of standing in the stadium and that the stand, which is the center of gravity closer to the ground by flexing the joints of the knees and arms are bent towards the ground and two close of the knee joint so that the whole body ready to respond any form of transmission In full freedom and on the other hand this situation is one of the best forms of standing to respond to the transmission from the bottom, which was and most of the coaches are focused on this form of standing to respond any form of transmission from the bottom to ensure the future player of the ball flow ball to the player prepared and become So the attack And that the amount of variation received from the bottom is less used than the reception from the top This indicates that most of the players did not undergo focused training to stand right and appropriate during the training units and that such an order is not easy because the process of the ball correctly means the construction of an attack It is true that the proper position of the volleyball player in a balanced manner helps him to deliver the ball in its correct form to the prepared player, as well as that the use of the receiver form from the top in high percentages and clear differences through the table is due to the fact that most of the competing players were performing Send the A ripple in which the speed of the ball is slow and also does not have the power so large that the process of connecting the ball to the player and the player in the case of parking and without the usual effort or movement in the delivery, and the law may contribute in one way or another after this form, which reception from the top It is not permissible for the law to be a legal offense, but after allowing the players to use it legally, it helped the players to use this form and the abundance of its ease and lack of movement. The researcher sees the reasons for the low difference in the third form which is the receiver from the frontal fall. Player A For a competitor as well as often the ball is very high speed and that the distance that hit the ball also be close and also requires this form to the possibility of comprehensive performance from the beginning of attention and focus and determine the speed and strength and direction of the ball in order for the defender to send correctly to the player prepared as “The process of concentration, as it is highly, provides the player with sound movement and high flow, and when the researcher observed through the experiment in this research, although the use of this form with very little reason and the success of the performance of this form was not the required level and this means there is a weakness in the players in use Such as this form due to the lack of use during the training modules of the research members, as well as the researcher decreases the differences in the last form of reception is the side reception of the fall of one hand to several reasons, including standing defender player with the possibility of determining the direction of the ball during the transmission because the transmission used in the Most often it is the wavy transmission or transmission from the top and both forms can the future player determine the speed and direction of the ball and connect the ball from the stand position and if required to take a step to the side without reaching the fall or roll to one side and reception and this made the proportion of S Its use is very few.

Conclusions

The appearance of differences is obvious for the reception form from the top. Lower differences The most important form of reception is the reception from the bottom. Low use of other forms of receiving transmissions.

Effect of Gold Nanoparticles and Laser on Platelet, Lymphocytes, and White Blood Cells

Lamees. A. Abdullah
Department of Physics, College of Science, University of Baghdad, Baghdad, Iraq

ABSTRACT
In the present work, the effect of gold nanoparticles (AuNPs) and He-Ne laser on lymphocyte, white blood cell (WBC), and platelet (PLT) have been studied. The number of lymphocytes, WBC, and PLT were measured using Hematology Analyzer for all samples before and after adding AuNPs and irradiation by laser, and the results treated statistically. The results showed that all three blood components decreased when they are exposure to AuNPs and laser, and the highest effect observed when the samples exposure to AuNPs and laser in the same time, in this case the percentage decline in lymphocytes, WBC, and PLT is found to be 44.4%, 33.6%, and 44.6%, respectively.

Keywords: Gold nanoparticles, Platelet, Lymphocytes, White blood cells.

Introduction
Nanotechnology is the science of producing nanosized materials with dimensions less than 100nm. Nanoparticles (NPs) have unique physical, biological and chemical properties that have attracted important attention due to their possibility use in many applications. Gold nanoparticles is wide used in many areas of medicine that include diagnostics, imaging, biosensing, drug delivery cancer therapy. AuNPs can contact with various cells, including platelet (PLT), lymphocytes, and white blood cells (WBC) because of their high penetration capacity. Leukocytes are cells have immune role for protecting the body against all foreign bodies such as bacteria and viruses. All types of leukocytes are produced in bone marrow. And the leukocytes are spread through the body. WBC is little if compared with RBC, but it is very important for the body. It number is ranged (4000-11.000) cell in millimeter cube, and it represent 1% of whole total blood volume. Leukocytes have real nuclei and organelles. It have distinguish defense role. Lymphocytes are 20-25% of the total white blood cells in the bloodstream. The lymphoid cells are spherical in shape, and have a nucleus spherical dense dyeing, occupy most of the space cell relatively small amount of cytoplasm baseline weak pigment. Lymphocytes have immune functions, such as cytotoxicity, antibody production and delayed hypersensitivity. Platelets, also called as thrombocytes are a tiny important blood cells that prevent blood loss at the site of injury. They are sticky cells, they need to be in constant motion after they are donated or they will clump and cannot be transfused. The platelet count is an important diagnostic parameter in hematology. Automated blood cell counters have largely replaced the manual method. In health there are about 150-400 x 10^9 platelets/liter of blood. Moreover, laser technology has been studied for decades and used in medical applications. Several studied have been performed on the effect of AuNPs and laser on human blood components. Zeng He et al. founded function of citric acid-coated AuNPs (CT-AuNPs) and polyethylene glycol-coated AuNPs (PEG@AuNPs) in RBC function and spreading of the nanoparticles in platelets, leukocytes and erythrocytes. The immunomodulatory potential of silver nanoparticles and gold nanoparticles was investigated by Devanabanda M. et al. using murine splenic and human peripheral blood lymphocytes (PBL) in terms of effects on viability and mitogen-induced proliferation. V. Wiwanitkit et al. evaluated of gold nanoparticle effects on WBC. Mitochondria structure was examined after exposure to He-Ne laser (, dose, 56 J m-2, wavelength, 632.8 nanometer) by Manteifel V. examined by electron microscopy one hour after the irradiation exposure. P.Grešner et al. used flow cytometry for studing effects of a Nd-YAG laser on platelet cell activation and studying activation of glycoprotein of the platelets cell which stained with fluorolabelled monoclonal antibody PAC-1. In this paper, the effect of AuNPs and He-Ne laser on platelet,
WBC, and lymphocyte have been studied by measuring the number of these component using Hematology Analyzer before and after exposure to AuNPs and laser.

**Method and Materials**

**AuNPs Preparation:** The chemical synthesis used to prepare AuNPs by water (85) with HAuCl₄ (5) ml were added together and heated. Then sodium citrate (5) ml was added to the solution during heating and heated for (30) minutes even the solution colour changed to wine red. Fig. 1 shows the UV-visible absorption spectra of AuNPs. The concentration of AuNPs was measured using atomic absorption spectroscopy (AAS) and found to be 387µg/ml as shown in Fig. 2.

![Absorption spectra of AuNPs](image)

**Human Blood Samples:** Blood samples (18-20) ml withdrawn from a vein using syringe size (20) ml for more than (20 donors). These samples are divided into two parts: (2) ml for each part, put in the laboratory tubes containing the anti-clotting. First part considered as control and the second part treated by adding 40µl of AuNPs/2ml blood. Lymphocytes, WBC, and PLT number (for all blood samples) have been measured using Hematology Analyzer by shaking blood samples for 15 min., in Analyzer shaker, then by press on start an automatically metallic needle will step down inside the tube and draw out about 2µml from a blood sample, after a few seconds, all blood data will appear on Analyzer screen, which denoted to lymphocyte, WBC, and PLT account. The blood components (lymphocytes, WBC, and PLT) were measured before and after adding of AuNPs and after irradiation with laser, then they are measured after adding AuNPs and irradiation with laser in the same time. The samples were placed vertically under the source of He-Ne laser at 632.8 nm wavelength for 15 min.

**Results and Discussion**

**Effect of AuNPs and Laser on Lymphocytes:** The number of lymphocytes *10⁹/L, before and after adding AuNPs and irradiating laser, have been measured using
hematology analyzer. It is observed that the number of lymphocytes are no more affect by adding AuNPs or by irradiating laser, the effect is clearly observed when adding AuNPs and irradiating laser in the same time. The results are statistically treated and arranged with SD and P-value in a table 1, then plotted as in fig.3.

Effect of AuNPS and Laser on PLT: The number of PLT is affected by adding AuNPs and irradiation with laser as shown in fig. 5, PLT decreases after adding AuNPs and irradiation with laser, and this decreasing is highly observed after adding AuNPs and irradiation laser in the same time. These results with SD and P value.

Conclusion

The results of the present work indicate that AuNPs and laser impact on lymphocyte, WBC, and PLT. We found that AuNPs and laser have no had apparent effects when samples exposure to either AuNPs or laser, while this effect is clearly observed when the samples exposure to AuNPs and laser in the same time. The percentage decline in lymphocyte, WBC, PLT after irradiation by laser is found to be 8.5%, 5.1%, and 9.4%, respectively. While the percentage decline in lymphocyte, WBC, PLT after adding AuNPs is 10.2%, 12.6%, and 4.6%, respectively. As for the percentage decline in lymphocyte, WBC, PLT after adding AuNPs and irradiation laser in the same time is 44.4%, 33.6%, and 44.6%, respectively. All the results are significant where P-value for all samples less than 0.005.

Study the Levels of Thyroid Hormones in Graves’ Disease and Impact on Leptin and Resistin Levels

Sara J. Kadhim1, Raghda Alsayed1, Alaa Hussein J. Al-Qaisi1
1Department of Chemistry, College of Science, Al-Nahrain University, Baghdad, Iraq

ABSTRACT

Objective: The objective of the study is to assess the clinical execution in Graves’ disease. We tested sera of patients with thyroid diseases and estimated (TSH), free thyroxine (FT4), thyroperoxidase antibodies (TPOAb), thyroglobulin antibodies (TgAb) also Leptin and Resistin. A total sera of 40 successive patients (25 females and 15 males) and 35 healthy subjects (20 females and 15 males) with aged between 30–65 years were assessed. The result of this study showed the increase in serum level of resistin in patients with thyroid dysfunction. The results showed that serum leptin levels were significantly low (P<0.004) in hyperthyroid patient groups as compared to control. Resistin hormones levels increased non-significantly (P˃0.05) than control levels. They affects each other in their physiological function in the human body. We concluded that (TgAb)) and (FT4) high this leads to changes in levels of thyroid hormones and the result of this study showed the increase in serum levels of resistin in patients with thyroid dysfunction.

Keywords: Graves ’Disease, TSH, Tg-Ab, TPOAb, FT4, hyperthyroidism. Leptin and Resistin.

Introduction

Graves’ disease (GD) is the most well-known immune system pathology with a rate in individuals of approximately 14/100000. GD is the reason for the 70-80% of thyrotoxicosis, despite the fact that its predominance can shift among various populaces, as indicated by iodine exposure. 1 Resistin as a hormones has an endocrine effects including effects on insulin resistances, obesity and also play a role in energy homeostasis. Resistin gene an expression is major in white adipose tissues, and especially in abdominal fat. 2 (GD) is caused by thyroid stimulating hormone receptor activating antibodies that imitative the activity of TSH and deliver hyperthyroidism. Substantial changes in charge of poisonous adenoma and germline changes causing familial hyperthyroidism. 3 Leptin is an adipocytes-derived, 167-amino acid an-orexigenic hormones which is a product of obese gene located on chromosomes seven. Major sites of leptin production is white adipose tissue, but it can be produced by others tissues such as ovary, mammary epithelial cell, liver, stomach, also placenta as well 4 The physiologic agonist, thyrotropin, is discharged by the anterior pituitary gland and goes about as the primary regulator of thyroid function, animating thyroid development and function and secretion of thyroid hormones. 5 A study with different results on resistin concentrations in patients with hypothyroidism also hyperthyroidism has been reported. 6 A study has also shown that resistin levels are increased in patients with hyperthyroidism also its concentrations decreased with equalizing thyroid hormones status following treatments 7. Also, leptin increases the thyroid hormones levels. 8 Leptin organizes peripheral and central iodo-thyronine de-iodinase activity also conversion of T4 to T3. Leptin management has been shown to inhibit the fasting produced changes in serum T3 also T4 concentrations. 9 The point of our work was to assess the clinical execution in Graves’ disease. We tested sera of patients with thyroid diseases. We additionally estimated Thyroid stimulating hormone, free tetraiodothyronine (FT4), thyroperoxidase antibody (TPOAb), thyroglobulin antibiotics (TgAb) also Leptin and Resistin.

Materials and Method

Patients: We assessed the sera of 40 successive patients (25 females and 15 males) and 35 healthy subjects (HS) (20 females and 15 male). Aged between 30–65 years. All subjects experienced finish physical examination and endocrinological assessment TSH, thyroglobulin antibodies (TgAb), thyroperoxidase antibodies (TPOAb) and free thyroxine (FT4) were measured using by (ELISA) an enzyme-linked- immune-sorbent assay kit (Sandwich) technologies using commercially available kits (Human, Germany).

Samples Treatment: Blood was drawn by venipuncture into 2 serum tubes and centrifuged at [4000 rpm] for 10 minutes at room temperature. The 2 sera were utilized as takes after the primary aliquot was quickly used to test TSH, FT4 and TPOAb; the second was stored at - 20°C, until used for measuring Tg-Ab.

Data Analysis

The Statistical Analysis System- SAS (2012) was used to determine of different factors in studied parameters, \( p-value < 0.05 \) was expressed as significant. Results were considered as mean (standard deviation).

Results and Discussion

Comparison between Grave’s disease (GD) and Healthy subjects (HS) was done using one-way ANOVA (Table 1 and 2)

The general point of our investigations was to examine at the levels of thyroid stimulating hormone (TSH), free tetraiodothyronine (FT4), thyroperoxidase antibody (TPOAb) also thyroglobulin antibody (TgAb) for each group selected in the examination. Auto-immune thyroid disease, consist of Graves’ diseases(GD) also Hashimoto’s thyroiditis (HT). The Thyrotropin receptor is exceptional among these susceptibility genes since it encodes for a protein that is both in charge of the clinical signs of the disease and is the immediate focus of autoimmune response in (GD). 10 Many patients of Graves diseases can be performance in clinical setting of diffuses goiter, exo-phthalmos, thyrotoxicosis, also dermopathy (pretibial myxedema). The diagnosis is effectively affirmed in many patients with an elevated free thyroxine concentration and a low thyrotropin concentration. In early Graves’ disease, Separating GD from different types on hyperthyroidism consider basic for best possible managements of patients, particularly with references to recognition of related immune system. Our results were aged with a study. 11 On the off chance that the clinical finding of Graves’s infection versus a non-autoimmune causes (eg, poisonous.

Figure 1: Comparison of leptin and resistin between patients and healthy groups
multi-nodular goiter) on hyperthyroidism is being referred to, inspiration for thyroperoxidase antibodies also thyroglobulin antibodies would recognize an immune system. A positive thyroperoxidase antibody helps separate auto-immune diseases (GD) from poisonous nodular hyper-thyroidism. 12 Thyrotropin levels positively balance thyroid-stimulating hormone receptor in typical cells up to a specific breaking point, while down regulating thyrotropin receptor at high concentrations. 13 Thyroid-stimulating hormone (TSH) motioning through its receptor intervenes the paracrine control of thyroid function. 14 The mechanisms by which thyroid dysfunction intervenes these impacts on bone development are yet to be fully explained. It had beforehand been viewed as that the thyroid hormones T4 and tri-iodothyronine (T3) were the key role between of bone rebuilding. 15 Excess thyroid-stimulating hormone receptors activation happens in 2 common stipulations, (GD) in that TSH-ab mimic thyrotropin causing primary hypothyroidism also hyperthyroidism when increased thyroid-stimulating hormone recompense to low thyroid hormones (T4/T3) level results from failure thyroid. 16 However, some study found that serum resistin levels of hyperthyroid patients group were higher than those of control group, where these levels decreased after normalization of thyroid hormones in hyperthyroid patients. Our results were aged with other study 17

Conclusion

In the end we concluded that thyroglobulin antibodies (TgAb)) and free thyroxine (FT4) high this leads to changes in levels of thyroid hormones and the result of this study showed the increase in serum levels of resistin in patients with thyroid dysfunction.

Effect of Plant Alkaloids on Some Pathogens

Aseel Mohammad Omran\textsuperscript{1}, Heyam G.Al Mousawi\textsuperscript{1}, Rasha hadi Salih\textsuperscript{1}

\textsuperscript{1}College of Pharmacy, University of Babylon, Iraq

ABSTRACT

This study aimed to evaluate the antimicrobial activity of Rosmarinus officinalis, Origanum vulgare L. and Cressa cretica L. alkaloids on Staphylococcus aureus, Escherichia coli and Candida albicans. The results showed a prominent inhibitory effect of all alkaloid extracts on all the microbial isolates, noted by the large bacterial growth inhibition zones (0.2-6.8 mm), four concentration were used in this study (10, 20, 30 and 40)\%, all these concentrations appeared inhibition effect. C. cretica had more inhibitory effect on the growth of all microbes than other tested plants.

Keywords: Effect, alkaloids, pathogens

Introduction

Alkaloids are the largest group of secondary metabolites, building from ammonia molecules comprising of nitrogen bases synthesized from amino acid building blocks with various radicals and replacing one or more of the hydrogen atoms in the peptide rings and most of them containing oxygen, alkaloids differ in the basicity according to the structure of molecule groups \textsuperscript{1}. Alkaloids had so numerous and involve such a variety of molecular structure that lead to difficult in theme classification. So, the best solve to this problem is to group them into families, depending on the type of heterocyclic ring system present in the molecule \textsuperscript{2}. Alkaloids are significant for the protecting and survival of plant because of their activity against micro-organisms (antibacterial and antifungal activities), insects and herbivores (feeding deterrence) and also against other plants by means of allelopathically active chemicals \textsuperscript{3}. Many of alkaloids containing plants as dyes, spices, drugs or poisons can be traced back to the beginning of civilization. There are many medical activities of alkaloids including antihypertensive effects like indole alkaloids, antiarrhythmic like quinidine, antimalarial activity like quinine, and anticancer actions like dimeric indoles, vincristine, vinblastine. These are just a few example of the great economic importance of this group of plant constituents \textsuperscript{4}. Rosemary (Rosmarinus officinalis L.) originally grows in southern Europe. Its herb and oil are commonly used as spice and flavoring agents in food processing for its desirable flavor, high antioxidant activity and lately as antimicrobial agent \textsuperscript{6-8}. Furthermore, rosemary extracts have been widely used as a preservative in the food industry due to their inherent high antioxidant activity. In addition, it has been used as a medicinal herb for centuries, due to significant activities against many illnesses. In this sense, many major biological properties have been attributed to this plant, mainly hepatoprotective \textsuperscript{9}, antimicrobial \textsuperscript{10-12}, antithrombotic \textsuperscript{13}, diuretic \textsuperscript{14}, antidiabetic (Bakirel et al., 2008), anti-inflammatory \textsuperscript{15}, antioxidant \textsuperscript{16}, and anticancer \textsuperscript{17}. Origanum (Origanum vulgare L.) grow abundantly on the stony slopes and rocky mountain areas at a wide range of altitudes (0-400m) \textsuperscript{18}. Because of the variability in the chemical and aroma characteristics, different species of origanum ecotypes (biotypes) are widely used in the agricultural, pharmaceutical and cosmetic industries \textsuperscript{19}. In addition, they have been used in the folk medicine to treat several illnesses as spasmodic, antimicrobial, digestive, expectorant and aromatic for the whooping and convulsive coughs. Origanum known for its antifungal and antimicrobial properties, its Leaves are traditionally used as antiseptics and disinfectants. This is the very aromatic plant \textsuperscript{20}. Cressa. cretica L. is a small, erect dwarf shrub \textsuperscript{21} the height of it is 38 cm. Roots appear horizontal, with lateral branches. It is a perennial sub shrub or herb, usually much-branched. Stems are at first erect and then

become decumbent, apparently short-lived. Leaves sessile, ovate to lanceolate. *C. cretica* used in all parts as a paste and decoction to treated fungus infection, asthma, blood purifier and eczema treatment. Aqueous and alcoholic extracts of leaves of this plant have a very good activity against some microbial pathogens such as gram – positive, gram negative bacteria and some fungi species, such as *Candida albicans*, *Aspergillus niger*, and *Penicillium chrysogenum*. The plant can be used as anti-tubercular, and expectorant. Ethanolic extract of cholesterol in rats. Whole plant methanolic extract as a paste and decoction to treated fungus infection, sessile, ovate to lanceolate. Good activity against some microbial pathogens such as *B. Tannic acid reagent:

1. **Dragendorff’s reagent:** 20 g from Bismuth Nitrate in 40 ml distilled water and 16 g from sodium Iodide in 40 ml distilled water, mixed together and added 1-2 ml from this reagent to 5 ml from the extract, a prominent orange color was indicated the test as positive.

2. **Tannic acid reagent:** 2 ml from 10% Tannic acid solution was added to 5 ml from extract, Alkaloids give orange color precipitate.

**Materials and Method**

**Alkaloids extract preparation:** 100 g from dried plant powder was putted in a flask (500 ml), added 350 ml methanol: distilled water (1:4), putted in a horizontal shaker for 24 h, filtered throw filter paper (whatman No1), concentrated in a rotary evaporator, added drops from sulfuric acid (2%) until PH become 1-2, placed in a separatory funnel and extracted with chloroform (three times), mixed and shaken for about five times and allowed to separate into two layers. The lower layer of chloroform contained the alkaloids and the upper layer the aqueous portion, then added ammonium hydroxide (NH₄OH) until PH become 9, transferred to a separatory funnel and another extracted with chloroform: methanol (3:1) for two times, the lower layer was taken, concentrated and dried at 40-45°C, then kept in refrigerator.

**Test for alkaloids:**

- **A. Dragendorff’s reagent:** after added a few drops from this this reagent appear yellow color precipitate, that’s positive indicator to the presence of alkaloids.

**Microorganisms tested:** Microbial cultures of three different species of microorganisms were used for determination of the antimicrobial activity, they were *Staphylococcus aureus*, *Eschrichia coli* and *Candida albicans*. All the test cultures were maintained on nutrient agar media with regular sub-culturing.

**Test antifungal activity of the plant extracts**

**Preparation of Inoculum:** Suspended isolated colonies from nutrients agar was added to 5 ml from 0.85% sterile normal saline to achieve 0.5 McFarland turbidity to form a yeast stock suspension of 1 × 10⁶ to 5 × 10⁶ cells/mL, which should produce semi confluent growth with most microorganisms isolates.

**Preparation of the 0.5 McFarland standards:** 0.5 ml of 0.048 M from BaCl₂ (1.17% w/v BaCl₂.2H₂O) was added to 99.5 ml of 0.18 M H₂SO₄ (1% v/v) with constant stirring. Distribute the standard into screw cap tubes of the same size and with the same volume as those used in growing the broth cultures. Seal the tubes tightly to prevent loss by evaporation. Store protected from light at room temperature. Vigorously agitate the turbidity standard on a vortex mixer before use.

**Agar well diffusion method:** Determine the antimicrobial activity of plant extracts was followed by agar well diffusion method. Nutrient agar plates were swabbed (sterile cotton swabs), wells in about 10 mm in diameter were made in each plate using sterile cork borer. Stock solution of each extract was prepared at a concentration 40 % in different plant extract (aqueous and alcoholic), about 100 µl of different concentration of extract were added using micropipette into the well and allowed to diffuse at room temperature for 2 hrs. The plates incubated at 28°C for 24 -48 hrs. After that measured the diameter of inhibition zone (mm), The experiment were maintained triplicates, for each replicate the reading were taken in three different fixed directions and recorded the average values.
**Results and Discussion**

Table (1) represent the alkaloids constituents that present in the plants under the study. Hager and Tannic acid reagents appear a positive result, while Dragndrof reagent appear a negative result. There was a significant differentiation between the extracts and the microbes according to Pv. Test by using Anova. figure (1) appear the diameter of inhibition zone of *S. aureous* at concentrations 10, 20, 30 and 40 % for all plant alkaloid extracts, it was appear that the inhibitory effect increase with the concentration increasing. figure (2,3) appear the diameter of inhibition zone of *E. coli* and *C. albicans* at concentrations 10, 20, 30 and 40 % for all plant alkaloid extracts, it was appear that the inhibitory effect increase with the concentration increasing. *C. cretica* alkaid appear most inhibitory effect on microorganisms growth, which the diameter of inhibition zone reach to 6.8 mm on *C. albicans*, followed by *R. officinalis* (4.6 mm) then *O. vulgare* (3.2 mm), on *E. coli* as appear in table (2). *S. aureous* was the most affected by alkaloids, followed by *E. coli*, then *C. albicans* as shown in table (2). Plants have ability to synthesize chemical products. These products are secondary metabolites and serve as plant defense mechanisms against microorganisms, like alkaloids. This study agreed with the study of Ivanovska *et al.* (1999) which showed that the alkaloid berberine expresses a protective effect on *C. albicans* infection induced in arthritic mice, Alkaloids targeting cell wall and ergosterol biosynthesis leading to cell death. 25-30, also alkaloids lead to inhibition of extracellular enzyme activity of *Candida* and that might be related to decreased pathogenicity 26. Issabeagloo1 *et al.* (2012) found that extract of rosemary inhibit the growth of *S.aureous* and this inhibitory effect increase with the increasing concentration. Oliveira *et al.* (2009) evaluate the antimicrobial activity of *O. majorana* essential oils on the growth of *S. aureous* and they found that this inhibitory effect increase with increasing concentration.

Conclusion

Results revealed a strong activity of plant alkaloid extracts on the growth of the microorganisms, C. cretica was most inhibitory effect on microorganisms than R. officinalis and O. vulgare, and this effect increase with concentration increasing. S. aureus was most affected than E. coli and C. albicans.

Bacterial Contamination of the Local Available Ice Cream in Hila City

Sura I. A. Jabuk1, Dhurgham A.A. Al-Sultany2, Kadhim Kh. Hashim3
1Department of Biology, College of Science, University of Babylon, Iraq; 2College of Water Resources Engineering, 3College of Environmental Science, Al-Qasim Qreen University, Iraq

ABSTRACT

Ice cream is a frozen food which is usually consumed during summer. It is considered as good food which may provide refuge for many microorganisms that can cause many diseases. Also, it is considered important because it is associated with consumers health. This research investigates the contamination of ice creams available in markets by microbes. Ten types of Ice cream were gathered from the market(Behtak, Jawaad Azburi, Core Dor, AL-Fakma ice cream, KDD silver, Fistachio, AL-Furat, Solero, KDD White), The samples were transported to the laboratory to conduct the necessary tests using a clean and sterilized container with a temperature of zero Celsius. One gram of each specimen was taken and diluted. afterwards, each sample was cultivated on different cultivation mediums under 37 degree Celsius for 24 hr. Also, other biochemical tests were conducted in this research to determine the type of bacteria. The results shown the type of bacterial isolated was (Staphylococcus aureus, Escherichia coli, Klebsiella pneumonia, salmonella enteritidis) this types of bacteria caused of many type of human diseases and food poisonings. Keywords: Ice cream, Bacterial contamination, Food poisonings

Introduction

It is not known exactly when ice cream was began synthesis, but it is believed that the Chinese were the first to use a mix of ice and fruit juice to make dishes after food nearly 3,000 years ago 1. The Romans also used ice to cool drinks in the summer and believed that this idea came from the Pharaonic civilization or the Babylonian civilization 2. Marco Polo, the Italian traveler, is said to have brought with him from Beijing to Venice in 1292 a complete recipe to make frozen milk, believed to be the origin of the frozen beverage industry. However, until the mid-nineteenth century, the frozen confectionery industry and its production were very primitive and limited, In 1851 Jacob Fussell was able to establish the first ice cream factory in Baltimore, and since then the ice cream industry has developed a very large development. Ice cream can be defined as the products obtained by freezing a mixture of different ingredients (pasteurized milk, sugar cream, eggs, flavors, natural and artificial dyes, stabilizers, emulsifiers and other additives). This mixture keeps it frozen until consumed. 3. The main ingredient of ice cream is milk, which contains a large amount of saturated fat, protein and calcium, as well as vitamin C and because of it is considered ice cream of nutritious food 4. The composition of ice cream is different according to its type. Ice cream is generally composed of 5-15% milk fat, milk protein 4-5%, lactose 5-6%, milk ash 1%, sugar 15%, stabilizers 0.1- 0.4% And emulsifying materials 0.2%. 5. The high percentage of nutrient material found in ice cream, such as lactose and proteins, as well as the neutral pH, can make it a good growth medium for many microorganisms that cause many serious and infectious human diseases such as cholera, typhoid and chronic intestinal diarrhea. There are many types of microorganisms that cause disease in ice cream such as Listeria monocytogenes, Staphylococcus aureus, Bacillus species, Salmonella species, Shigella species, Streptococcus spp., Pseudomonas spp., Campylobacter spp., Brucellaspp. As well as the presence of E. coli in general 6, 7. The presence of such living, accurate and pathogenic organisms in pasteurized ice cream is evidence of their ability to survive after pasteurization in the case of Spor 8. This spor stage may continue to survive under the freezing process in an inhibitory state, unless appropriate conditions are available for growth to start again, causing many diseases. The sources of
microorganisms contamination the ice cream from, the raw materials used in the manufacture of ice cream, especially milk in the case of being a result of a sick animal or the residue of antibiotics or pesticides, pollution from people involved in the process of manufacturing and selling, which add a large germ load at Not following the sanitary conditions in terms of clothing and hygiene in their work, manufacturing machinery and tools. The present research aims at studying the type of bacteria contamination of some types of ice cream in local markets to evaluate and determine the quality of ice cream and to allow the treatment of species that are within The accepted limits set by the World Health Organization because of their association with the health of consumers.

Materials and Method

Collection of Samples: 10 types of ice cream (Behtak, Jawaad Azburi, Core Dor, AL-Fakma ice cream, KDD silver, Fistachio, AL-Furat, Solero, KDDWhite). Industry in Turkish Iraq, Iran and Kuwait. The collected samples were carried in a clean, sterile and 0 °C container directly to the laboratory for high resolution results and then microbial tests were performed.

Preparation of serial dilution: 1 ml of each sample of ice cream collected by a sterilized and disinfectant pipette and transferred to a sterile test tube containing 9 ml of peptone for dilution 1:10. In this dilution a sequence dilution of 10-3.

Isolation of bacteria from samples: The samples were incubated in nutrient agar at 37 °C for 24-48 hours. After growth, the isolating colony cultured on blood agar plates, MaConkeys agar, Salmonella Shigella agar, Mannitolaalt agar and TCPS agar and purified in the initial assay of the isolating nutrients of each type. Of the types of bacteria developing and stored in the refrigerator at a temperature of (4) m. Bacterial isolates were identified by growing the colony size, color, surface, edge, slope and elevation. As shown by (9,10).

Gram stain: Bacterial cells were observed under the optical microscope and were observed by the oil lens (100 X) after the bacterial isolates were treated with a gram dye.

Biochemical tests: The most important differences between the bacteria observed in the present study were sugar fermentation tests, bile solubility, starch hydrolysis, gelatin digestion, catalase, lecithinase, indole production and nitrate reduction test (9,12,13), which are the most important differences between the bacteria in the current study.

Results

Table (1) shows the types of bacteria isolated according to the type of ice-cream sample, and notes through this table that some bacteria have appeared in more than one type of ice cream.

In recent years, food safety and health have become a point of concern for many communities. The shift to industrial food is producing and causing a lot of foodborne diseases, and these have increased significantly now. Companies’ search for economic efficiency leads to the production of food at low cost on a large scale and such companies do not have the ability to prevent the introduction of bacterial pathogens in their products. Ice-cream is one of many food products that can serve as a means of transmission for a pathogen. The quality and quality of food is the total number of microorganisms detected through total bacterial counts. However, the microbial load or microbial contamination in food products is influenced by a variety of factors, for example the general environment of the food product, raw materials used in manufacturing, manufacturing and processing conditions, as well as sanitary conditions, which are the cleanliness of the tools used, the packaging and, finally, the storage conditions of the food product. Milk is the main component of ice cream, which is more susceptible to infection with pathogenic bacteria. Two types of ice cream, one containing cocoa flavor and the other containing flannel flavor, were found. After examining the samples, they found that the ice cream with three times as much bacteria as the vanilla ice cream. The results of the study showed the emergence of a number of colonies of various types of bacteria, most of which are classified within the bacteria that cause many diseases.

That the number of bacteria that appeared in ice cream is due to several reasons, including inadequate treatment of raw materials in the industry, especially milk and pasteurization process as well as the cooling of the good mixture of ice cream in the first stage of production after the heating process, which may be the main reason for the multiplication of the existing microbes in ice cream after pasteurization. Pasteurization of ice cream components, especially milk, eliminates most of the hazards of the existing microbes, as well as the freezing process. However, at long storage times and containing high nutrient content and neutral pH, ice cream remains susceptible to bacterial growth. The results of the present study show the emergence of coliform bacteria in the collected samples of ice cream, as they appeared in (Jawaad Azberi, AL-Furat, solero and KDD). The presence of this type of bacteria is a clear indication of the presence of microbial contamination in the sample. Colon bacteria are generally a good indicator of food and water contamination. According to BSTI standards for the quality and manufacture of global ice cream and the number of bacteria in it, the number of cacti bacteria should be E. coli contained 10 g/g of ice cream, and in this study found through the results that the total number of colon bacteria exceeded the limits allowed. The contamination of this number of bacteria and their spores may be due to the wrong heating and freezing of all ice-cream manufacturing stages, the poor quality of water used in the industry, which may be contaminated, the lack of personal hygiene of the manufacturer and its personnel, and the tools used in industry. Large E. coli contamination occurred in ice cream in Mangalore, India, where E. coli was isolated from the IMVIC test and a report was written stating that E. coli should not be present in 1 g of ice cream. The number of E. coli colony colonies in 100 ml of water used in the ice cream industry is 640-683). Therefore, water is considered the main source of ice-cream contamination when used in its manufacture. In this study, the number of colonies of E. coli has exceeded permissible limits (Table 3). Staph. aureus has been observed in most of the studied samples. These bacteria cease to grow at 7 °C. Some studies have shown that in the case of a mixture of ingredients Staphylococcus aureus is kept alive for 7 months at -18 °C and resistance may increase at this level. According to FSSAI, sta. aureus should be 10 g/d of ice cream. The results of the present research indicate that the number of bacteria in the cluster of gold has exceeded the limits (Table 3).
Conclusions

The results of the study showed that the presence of microorganisms that cause possible and serious diseases in the samples of ice cream that have been analyzed and examined should be considered because they cause concern for many people. The presence of *Staphylococcus aureus*, *Escherichia coli*, *Klebsiella pneumonia* and *salmonella enteritidis* An important threat to human health is caused by many dangerous diseases. Milk pasteurization may destroy most pathogens, but the presence of non-lethal spores and pollution during the manufacturing process, as well as the use of contaminated tools, the lack of cleanliness of the workers, the workplace and the poor storage of the products cause these pollutants to appear. Therefore, in particular, to follow the good and sound steps in the industry through the use of sterile raw materials, automatic and clean in the best pollution-free product in microorganisms

ABSTRACT

The research problem is an attempt to answer the following questions; is there any effect of training loads under the maximum in Serotonin level? And does increasing serotonin level leads to increase happiness? While the aims of the research were to prepare the happiness measure, and the preparation of training exercises without the maximum. The sample of the research contained the players of Al-Qasim Sports Club, the youth of volleyball, through the research sample, the differences of the test of the experimental and control groups have been known with the variables of the research that has studied, this study ended with some conclusions and recommendations.

Keywords: Preparation, exercises, physical variables, happiness and Serotonin

Introduction

Volleyball is a team sport that requires understanding, agreement and coordination among the players. It is different from the other games in the style of play, so, Any mistake during the game leads to a loss of points and this requires special preparation for the physical and psychological abilities of volleyball players. The happiness sense is considered a human aim that the player always seeks for 1. It is a symbol that the player accepts his/her abilities and enjoys his/her relationship with his/her teammates. It also gives the player self-confidence. That is more patience and is not affected by suffering 2. The training load exercises under the maximum is a cooperative factor used for preparing the players well through which we try to develop the level of Serotonin that is responsible for the state of happiness of the player, through the high level of happiness there will be positive results achieved by the player with his/her teammates, increasing the level of happiness of the players can be through the development of positive variables and can be perceived 3 as reflecting some of the feelings such as joyment, positive sense, friendship and this is exactly what the team needs to achieve positive results. The significance of the research is to preparing the training loads exercises under the maximum, to learn about the level of happiness and to recognize the effect of exercises in develop the level of Serotonin that is responsible of happiness case for the players. One of the most important things in sports training (coaching) is to recognize the variables that happen in physical and physiological aspects that are related 4 to the performance of a volleyball player. The researchers found out that there is a problem in using the training loads under the maximum because of the lack of use of the trainer for exercises suitable for this type of training, so the researchers saw that the use of special exercises taking into account the intensity and frequency and rest time in training loads under the maximum in order to change the physical capabilities in addition to a change the enzyme of serotonin which will increase 5-7 the level of happiness for volleyball players. The research aims at the following:

1. To recognize the numbers of training loads under the maximum for the players of Al-Qasim Sports Youth Volleyball
2. To Recognize the level of happiness for the players of Al-Qasim Sports Youth Volleyball.
3. To Recognize the effect of exercises in physical ability and serotonin for the players of Al-Qasim Sports Youth Volleyball.
4. To recognize the relationship between the level of happiness and the enzyme of serotonin for the players of Al-Qasim Sports Youth Volleyball.
Methodology

The researchers used the experimental approach to design the two groups of pre-test and post-test combinations for their suitability of the research as shown in the table below.

Table 1: shows the Experimental Design for the Two Samples of the Research

The Community and the Sample of the Research:
The research community was identified by the players of Al-Qasim Youth Sports Club for the academic year (2018 - 2019). The total number of players (32) was divided into two groups: a control group consisting of (12) players dealt with the traditional approach and an experimental group consisting of (12) players dealt with the semi-parametric training loads and (8) players as a survey sample.

Methods, Instruments Devices Used in the Research:
Sources and references, observation, testing and measurement, questionnaire, volleyball stadium, volleyballs, serotonin measuring.

Methods of Practical Research

Identify the Research Variables: The researchers determined physical properties, namely, explosive capacity, velocity, speed, agility, and serotonin.

Identify the physical ability tests: The following tests were identified for each physical susceptibility as presented to the jury that consists of four members, as shown in the table below

Table 2: Shows the physical abilities and its tests which have chosen to be applied to the two groups of the research

</tbody>
</table>

Measure of serotonin: The serum serotonin was measured before starting by 15 minutes and after 5 minutes by the lactic stress test of Cungham and Folkens.

Preparing the measurement of happiness: The researchers studied many studies that dealt with happiness as a study (6-12), it was agreed to choose the study (Wahid Mohammed Ali 2015) for the suitability and objectives of the study where the items of the measurement on (4) of the experts may be the scale of (29) items that distributed to (8) dimensions, as in the table below:

Table 3: Shows the measurements of happiness items according to its fields

</tbody>
</table>

Fifth Likert Scale has been used to give (5 points with very agree), (4 agree), (3 sometimes agree), (2 no agree) (1 never agree).

Experimental Survey: The experience was conducted on a sample of (8) players on (15/11/2018) through which the researchers applied the tests of physical fitness and happiness measure. The purpose of the experience was to identify the possibilities of the sample and to ease applying the tests and extracting the scientific bases.

The scientific basis of the tests used:

Validity: The tests validity was verified by presenting it to a jury of experts.
Stability: Stability of the tests was obtained through applying the test and re-applying the test. The tests were carried out at the Youth Forum of Al-Qassim on 21/11/2018 and were re-applied after 7 days.

Objectivity Tests: The objective degree of the test was obtained by finding the correlation between Pearson and the first and second grades. The validity of the tests for the research sample was confirmed as shown in the table below.

Significance be random if the value of Sig is greater than (0.05) with freedom degree (22)

Conduct training loads under the maximum: The researchers prepared and ordered exercises with (80-89%), the exercises was carried out on the experimental sample taking into account (hard work, frequency and suitable rest) while the control group was training according to the traditional approach, the number of units was (24) per week was (4) units, for six weeks, whereas time for each unit was (40-5-) minutes of the main part only, with frequency arrange between (4-6) times, the aim was to develop the physical abilities and to develop the serotonin enzyme and correlates the training load between (3: 1).

Post-Tests: After complete the aim of the exercise, the tests were carried out on the days (12 - 13/1/2019) and the same sequence of pre-tests that were conducted previously.

Statistical Methods: The SPSS program was used in order to find out the research statistics.

Results and Discussion

In order to recognize the impact of endurance training exercises under the maximum, the researchers do the following:
The Results of the Experimental Group

Through the table below, we will recognize the differences between the pre and post-tests for the experimental group.

The researchers attributed that the training programme on the basis of scientific use of pregnancy less than the maximum have an impact in the development of performance and development of the ability of the nervous system to support the pathways, which help the correct performance and the quality of exercises, which were similar to performance, and these differences emerged as the enzyme is serotonin is a chemical compound and natural proportions at rest but affected when exposed to physical effort and this led to the high level of happiness that this enzyme is responsible for happiness and this is what we see in the teams in the computation level in the level of happiness between the test of the two groups control and Follicular. In order for the researchers to recognize the relationship between happiness and serotonin, the simple correlation coefficient (Pearson) was used. The correlation coefficient was 0.87 with a significance level of 0.05. Thus providing a better level of physical and skillful performance for youth volleyball players.

Conclusions

In the end, and after complete, show and discussion the procedures of the research, the researchers concluded the following: The training loads exercises under the maximum impact on some of the physical capabilities of the club players Al-Qasim young volleyball. The measure of happiness that has been set is able to determine the level of happiness for the players of Al Qasim young volleyball club. The positive relationship between the level of happiness and serotonin was confirmed by the significant correlation between them.

Risk Assessment and Heavy Metal (Cu and Ni) Contamination in Sediments of Shatt Al-Arab Canals, Iraq

Abeer Ghazie Al-Sawafi

Medical Laboratory Department, Health and Medical Technical College, Southern Technical University, Basrah, Iraq

ABSTRACT

The present study aims at investigating the relationships between physico-chemical and seasons to determine heavy metals (copper Cu and Nickel Ni) contaminated of sediments of Shat Al-Arab canals. The pH, Electrical Conductivity (EC), Total Organic Carbon (TOC), Oil and grease were measured. The study investigated the effects of season on the sediment characteristics of Shat Al-Arab canals. Data analyses were done using analysis of variance, Tukey’s multiple range, Pearson correlation coefficient and descriptive statistics. pH, EC and TOC were significantly higher at dry season (7.44 ± 0.129), (544.212 ± 133.8 µcm/cm²) and (13.94 ± 2.157 %) respectively, than at wet season (P<0.05). However, hydrocarbons (Oil and grease) was significantly higher at wet season (4360 ± 1129 mg/l) than at dry season (1920 ± 638.3) (P<0.05). The presence of high levels of organic pollutants indicates organic pollution and stress. Positive and negative Pearson correlation relationship between both heavy metals and physico-chemical parameters were found. Contamination of sediments was assessed on basis of contamination factor (CF), geo-accumulation index (Igeo), pollution load index (PLI) Potential Ecological Risk (Ei) and Potential Ecological Risk Index (RI). Results of geo- accumulation index (Igeo) indicated that sediments were uncontaminated with Cu, uncontaminated to moderately pollution with Ni.

Keywords: sediments; physic-chemical parameter; oil and grease; heavy metals, Geo-accumulation index, Ecological risk assessment.

Introduction

In the past decades, a significant increase in agricultural and industrial development has been witnessed with attended population growth. These activities caused water pollution after release of pollutants. The main sources of pollution are wastewater, and industrial, agricultural discharges, production, refinery and transportation of crude oil 1-3. Sediments are important environmental components of the aquatic habitat, which play an important role in maintaining the trophic status of any water body 4. Sediments near urban areas have high levels of pollutants, which constitute a major environmental problem faced by many anthropogenically impacted aquatic environments 5. The rivers’ sediments do not only play important roles at influencing the contamination, they also record the history of their pollution. Sediments act as both carrier and sources of pollutants in aquatic environment 6-7. Sediments are important sinks for different pollutants like heavy metals and are usually regarded as indicator of water quality 6-9-11. However, the sediments contamination with heavy metals, may lead to serious problem of environment 12. Heavy metals are hazardous substances of considerable environmental interest and the pollution of aquatic systems by heavy metals has been known as one of the most difficult contamination issues, due to their toxicity, abundance, persistence, and subsequent sediment and bioaccumulation 13-14-7. Heavy metals such as copper and nickel are essential metals since their play a considerable role in biological systems 8. Therefore, continuous monitoring is necessary to avoid further pollution, as well as to protect water bodies
in future. In Basrah city, the environmental pollution problem has been exacerbated because of the large quantities of industrial wastes, waste water, fertilizers and pesticides, which find their way into the side branches, hence to the Shatt Al-Arab river and then up to the various living objects (2,13,15). Moreover, the Shatt Al-Arab is the main source for fresh water in south of Iraq. The purpose of this paper is the following:

1. To assess seasonal variations and relationships between the metal levels and physic-chemical parameters at Shatt al Arab sediments.
2. To assess the ecological risk due to sediment pollution of heavy metal.

**Experimental**

**Study Site and Method:** Shatt Al-Arab River is consisted of the confluence of Tigris and Euphrates Rivers at Qurnah City about 90 Km northern of Basrah City (Fig.1). However, the length of Shatt Al-Arab River from Qurnah to its estuary is 175 km with width of 0.4 km at Basrah and 1.5 km at its estuary. It drains into Arabian Gulf and affected by the tides from the Gulf (2).

Shatt Arab River is characterized by its large number of lateral branches. Some of these branches extend into the center of Basra province. The extension of these branches into the center of Basrah transforms them to locations for the disposal of sanitary sewage and solid waste. Sampling stations: A total of five stations were chosen. They were: Al- Najibiyah (S1), Al- Robat (S2), Al-Khandek (S3), Al- Ashar (S4), and Al-Kurnish (S5)

**Samples Collections and Analyses:** Sediment samples with grab sampler once a month from each sampling station were collected for (December, January, April and June, 2015) mostly during the low tides. They were stored in a labeled polythene bags and kept in an ice-chest box before transferring to the laboratory. The sediment properties were determined according to the standard methods (17-22).

**Heavy Metals Analysis:** After frozen other part of sediment were dried by oven for 24 hours at 105°C. Then grinding and sieving. Trace metals analysis was performed on the 63µm fraction of sediment in which exchangeable trace metals extracted according to Chester and Voutsinon (19). The residual fraction according to procedure of Barak and Mason (20) were extracted. Atomic absorption spectrophotometer was used for the determination of the heavy metals including nickel (Ni) and copper (Cu).

**Results and Discussion**

The results of physic-chemical parameters are shown in Table 1. pH is an important parameter for describing the state of chemical processes. Metal Concentrations in the river, decrease with increasing pH, because the binding abilities of metal are decreased with decreasing pH due to proton binding. However, Electrical Conductivity (EC) of sediment samples varied between higher values 544.2 ± 133.8μScm⁻¹ in dry season and lower values 534.4 ± 208.7μScm⁻¹ in wet season. As well, the EC sediment was range from 30.5 μScm⁻¹ in S1 at wet season and higher values in S2 for both seasons (993.2 -859.4) μScm⁻¹.

| Table 1: Variations of sediment parameters in relation to season in Shatt al Arab canals |

|                                         | S4     | 7.1 | 777.2     | 20.3  | 3600            |
|                                         | S5     | 7.9 | 153.4     | 9.7   | 3000            |
| Average ± SEM                          |        | 7.4 | 544.2 ± 133.8 | 13.9 ± 2.2 | 1920 ± 638.3        |
The dry season percentage of total organic matter (TOC) content (13.94 ± 2.157%) was significantly greater than the wet season (4.82 ± 1.31%) (P< 0.05) (Table 1), could be due to the relative high temperature and dilution effect (rains and runoff). Due to The climate of the Iraq southern, including the study area is characterized by dry hot summer, cold winter, and rainy spring. This region also receives brief violent rainstorms in the spring. The results indicated unusually high oil and grease of sediments in wet season (4360 ± 1129) mg/g is higher than dry season (1920 ± 638.3) mg/g (Table 1) for all stations. However, to the petroleum hydrocarbons that reach the water environment from the atmosphere with rain is usually a product of combustion of fuel, oil and its derivatives (15).

The analytic results of exchange and residual phases of heavy metals (Ni and Cu) are given in Table (2). In wet season, the exchangeable phase of sediment of Ni (106.74 ± 16.11)μg/g dry weight was significantly higher than dry season (28.04 ± 11.05)μg/g dry weight. The range values of Ni in residual phase of sediment were (0.42-50.35)μg/g dry weight. Seasonal variation was insignificant (P>0.01) in the concentrations of Ni, the values followed the order wet > dry seasons for more stations of Shatt Al-Arab River sediments. The relatively higher Cu concentration of sediment (61.24- 53.63) μg/g dry weight was detected in S2 at both season than that other stations (Table 2), due to located at the major commercial area with high vehicular activities.

Indices for assessment of sediment contamination and ecological risk: As well the sediment metal pollution is major concern due to metal toxicity even at low concentrations on aquatic objects (4). A well-known and widely used index to assess the heavy metal contamination in sediments is the geo-accumulation index (Igeo), which was originally defined by Müller, as show Table (4). In Fig. 2, the Igeo values for Cu at the sampling sites of Shatt al Arab canals sediments were negative according to Müller’s geoaccumulation index.

The contamination factor (Cf) and the degree of contamination (DC) are used to determine the contamination status of sediments (Table 4, 6). The CF and DC values for Cu and Ni inferred that it comes low polluted to moderately polluted category in Shatt al Arab canals, much in agreement with the finding from I<sub>geo</sub> value. The ecological risk assessment results of heavy metals in study sediments of Shatt al Arab canals are summarized in Table 4, 7. The risk indices of heavy metals were ranked in the order of Ni > Cu at both season (wet and dry). According to values of E<sub>i</sub> or RI for Cu and Ni the sediments had a Blow^ potential ecological risk. The potential ecological risk factors are below 40, and the extent of potential ecological hazards is slight for indicated metals at all the sampling sites.

The difference between potential ecological risk index and contamination/background enrichment indices is reflected on the results of Cu and Ni contamination. Potential ecological risk index shows that there is a low pollution of these metals while the values of Cf and I<sub>geo</sub> indicate a moderate contamination. The main reason is that the I<sub>geo</sub> assessment method focuses on the comparative evaluation of heavy metals contents in sediments, while the potential ecological risk index confirms the differences in toxicity of various heavy metal ions and a comparison is made to examine the heavy metal contents.

The pollution load index (PLI) and the Geoaccumulation Index (Igeo) have been used extensively in the assessment of sediment pollution by heavy metals. Consequently, the implication of this, that these heavy metals may pose risk of contamination of the sediments and overlying surface water. Studies have shown that the concentrations of physico-chemical parameters in sediments are positively correlated with the concentration levels in the overlying water. In hence, particular attention should be paid to this problem. And to minimize the probability health hazards of the inhabitants in the catchment areas who depend on the river water for domestic, agricultural and fishing purposes.

Conclusions

The calculated results of Igeo and Cf values indicate that the study area is unpolluted to moderately pollute. Various anthropogenic sources may be the main reasons contributing insignificant heavy metal to the canals sediment. Therefore, Potential ecological risk index and pollution load index show that there is low contamination of these metals in Shatt al Arab canals. If the aim of work is to assess the overall contamination of a study area, the indices are highly appropriate and no serious heavy metal contaminations in Shatt Al Arab River. In sometimes, this kind of studies provides some early warning signals about heavy metal contamination in aquatic and sediment environments. As a result, continuous assessment is highly essential, improving ecological risk assessment, trace elements management in sediment samples, the calculation of pollution indices, the application of statistical methods is recognized as a useful tool to reduce emission the contaminates.

Mean Shift and Enhancement Contrast Based Technique to Extract Lung Abnormalities in CT Scan Images

Hussein Saadi Kareem¹, Rabab Saadoon Abdoon¹
¹Department of Physics, College of Science, University of Babylon, Hilla, Iraq

ABSTRACT

Medical image processing techniques are utilized to obtain easier and faster abnormalities diagnosis. In this work two proposed techniques are presented to detect and extract lung abnormalities in four CT scan images. Enhancement contrast based technique and mean shift clustering methods were implemented with aid of many morphological operations. The results indicate that the proposed techniques have good performance and were in good agreement with the radiologist delineation. The percent relative differences were ranged from 0 to 7.2 % for the first method and ranged from 1.9 to 7.2 % for the second method.

Keywords: CT Scan Images, Lung Abnormality, Contrast, Mean shift, Morphological Operations.

Introduction

Computed Tomography (CT) utilizes X-ray to generate cross-sectional images of human’s body. To acquire images, the X-ray tube rotates 360° around the part to be examined, and the transmitted radiation is measured by a ring of detectors located on the gantry around it. The resultant data can be plausible as a three dimensional model to display spatial information or surface characteristics, using the basic principle that the internal structure of the human’s body can be reconstructed from multiple X-ray estimates ¹. CT is utilized to visualize anatomy and to originate quantitative information about the volume or attenuation of structures being imaged. CT scan is an increasingly valuable outcome measure that can be utilized to assess the success of therapies in diffuse lung disease; image measurement accuracy, cogency is dependent on optimal and reproducible imaging methods ². CT images demonstrate pathological variations in the lung parenchyma and it is more sensitive than the plain X-ray lung images in detecting alterations in lung parenchyma, the survival from lung diseases is straight linked to with early awareness at the time of detection where the chances of treatment success at detected early ³. There are several studies to process CT scan images of the lung for the detection abnormalities, including (⁴⁻⁸). In this study, mean shift clustering method and enhancement contrast based technique are proposed to extract and isolate the lung abnormalities regions of the infected lung in four adopted CT scan images.

Image Enhancement: Image enhancement techniques divided into two categories: Spatial domain methods and Frequency domain methods, enhancement technique can be expressed as ¹:

\[ g(x, y) = T [f(x, y)] \]  \hspace{1cm} (1)

Where: \( f(x, y) \) is the input image, \( g(x, y) \) is the processed image and \( T \) is an operate acting on \( f \).

The aim from contrast based technique is increase the dynamic range of the gray levels in the image being processed which is adjusted by passing the value of each pixel that a certain range to be a whole range at the image [0 1].

Image segmentation: Image segmentation is an essential procedure for image analysis consequent task ¹⁰. Mean-shift clustering method involved clustering a cloud of N-dimensional points by means of a bottom-up algorithm. Mean-shift technique consists of two stages:
the first, estimation of the points’ probability density function and the second, using the previous of the results to form clusters.

\[ \hat{f}(x) = \frac{1}{nh^d} \sum_{i=1}^{n} k\left( \frac{x - x_i}{h} \right) \]  

(1)

Where \( h \) is the window radius (bandwidth parameter) of the used kernel.

\( K(x) \): the estimate of the density gradient which is defined as the gradient of the kernel density estimate:

\[ \nabla \hat{f}(x) = \nabla \hat{f}(x) = \frac{1}{nh^d} \sum_{i=1}^{n} \nabla k\left( \frac{x - x_i}{h} \right) \]  

(2)

The kernel \( K(x) \) is a function of \( \|x\|^2 \): \( K = c_k \delta_k (\|x\|^2) \). \( K(x) \) is called the profile of \( K(x) \) and \( c_k \delta_k \) is a normalization constant, which makes \( K(x) \) integrate to one. This class of kernels is called radially symmetric kernels. The density estimator can be rewritten as (12, 13):

\[ \hat{f}_{k,h}(x) = \sum_{i=1}^{n} k\left( \frac{x - x_i}{h} \right) \]  

(3)

The two commonly used kernels are the multivariate Gaussian kernel:

\[ k_o(x) = \left( 2\pi \right)^{-d/2} \|x\|^2 \]  

(4)

and the Epanechnikov kernel:

\[ k_E(X) = \begin{cases} 
\frac{1}{2} & d = 1, 2 \backslash 
0 & d \neq 1, 2 
\end{cases} \]  

(5)

Morphological operations: Morphological operators are utilized in image processing and are favored for their robust performance in preserving the form of a signal, whereas suppressing the noise, image morphology offers a way to incorporate neighborhood and distance information into algorithms, the aim of mathematical morphology is to convolve an image with a given mask structuring element and to binarize the result of the convolution utilizing a given function. The morphological operators include dilation; erosion; opening and closing, for more details see 1, 11-13.

Materials & Method

The procedure of this study can be summarized as shown in the block diagram of Figure (1):

**Input Dataset:** The input dataset are four CT scan images of lung, these images are acquired from internet websites. Figure (2) first row shows these input images.
Results and Discussion

The results of the proposed techniques are presented as follows:

**Background cutting:** The first stage of this work is background cutting and removing any extra part. Figure (2) second row shows the results of this stage.

![Image of input lung CT scan images before and after background cutting](image1)

**Figure 2: Input lung CT scan images before and after background cutting**

In Figure (2), the first row represents input dataset and the second row represents the images after background cutting and removing any extra part.

**Enhancement contrast based technique:** In this stage, different ranges of intensity were selected for testing. The utilized gray level ranges were [0.6-0.9], [0.3-0.9], [0.6-0.8] and [0.6-0.7] to be the whole range [0 1]. Morphological operations are implemented on the resulting images. The resultant images are converted to B/W images using thresholding process by extract and isolate the lung abnormal regions. The last step is extra operation to select the proper area in order to converting the resultant image to gray. The results of implementing this method are illustrated in Figure (3a).

**Mean shift clustering method:** Mean shift is a clustering algorithm; it was implemented here to segment images by partition data into certain number of clusters. It is an iterative algorithm that is utilized to split an image into eight segments or clusters. After getting the clusters of the abnormalities, different morphological operations were applied to get the abnormal regions without extra pixels and convert the final extracted regions to gray form. The results of this method are illustrated in Figure (3b).

**Extraction of the infected lung regions:** Many histogram based processes and morphological operations were implemented to extract the infected lung regions only and the results of this stage are illustrated in Figure (3c).
In Figure (3a), represents enhancement contrast based technique; Figure (3b) represents mean shift clustering method and Figure (3c) represents isolating infected lung.

In order to calculate the percent relative surface area of the abnormal regions with respect to the whole lung region, the surface area of the whole infected lungs were calculated. The percent relative surface area of the extracted abnormal regions are calculated and presented in Table (1).

Conclusions

In this study, four lung CT scan images, contain lung abnormalities, were adopted to test the performance of two proposed segmentation methods to isolate and extract abnormal regions. Enhancement contrast based technique and mean shift clustering method, the results showed that, the proposed methods adequately succeeded to isolate and extract lung abnormalities. The resulted extracted tumor regions were in good agreement with the radiologist delineation of the of the abnormal regions in the adopted CT scan lung. The percent relative differences were ranges from 0 to 7.2% for the first method and ranged from 1.9 to 7.2% for the second. The high values of the percent relative differences belong to the utilized structure element radius which affected the shape of the extracted regions.

Medical Applications and Role of Stability on Quantum Dot Semiconductor Lasers with Positive and Negative Optoelectronics

Rajaa Hussein Abd Ali¹, Basim Abdullatif Ghalib², Rabab Saadoon Abdoon³
¹Physics Department, Science College, University of Kerbala, Karbala, Iraq; ²Laser Physics Department, Science College for Women, ³Physics Department, Science College, University of Babylon, Babylon, Iraq

ABSTRACT

Many applications are depending on the nonlinear dynamics of quantum dot semiconductor laser QDSL. In this study, the QDSL dynamics of a theoretical model including positive and negative optoelectronic feedback (OEF) are studied. Then deal with the density of photons and parameters affecting on OEF by using rate equations at constant value of time delay with positive and negative Optoelectronic feedback parts at. A series of stable pulses are obtained in the majority of the results with some mutations or spike during periods of time and the appearance of the chaos. This stable behavior only emerged with a time of \( t = 110 \text{ps} \) and that results are importance significant in applications of medical lasers.

Keywords: stability of quantum dot, Quantum Dot, optoelectronics feedback

Introduction

The ability to the direct magnified formation that made Injection stream in a state of confusion has been one of the features of Semiconductors laser ¹. That features has helped in the optical vibration measurement ². And that forced us to study Nonlinearity dynamics ³. The Optical Communication has been used the light as a channel of transmission, it has been distinguished by exhibited with an available transmission bandwidth on a wider range because of the height of frequency carriers and the large drop in the size of the components Because of very small optical waves ⁴. Due to the rapid development, nanotechnology with semiconductors has been an advanced field in many medical fields ⁵. By combining semiconductor laser with punctiform nano particle technology, which has a higher density than the electronic levels near the edges of the connection and equivalence beams so the higher concentration on the carriers can contribute to emission from the beam edge ⁶⁻⁷. And the theoretical model of quantum pointers of the semiconductors laser (QDSL) shows stable pulses of importance in the medical field ⁸⁻⁹. All of these advantages arise from the quantitative limitation. These lasers have been characterized by high energy and high density. The presence of feedback with these lasers has been played an important role in stability. Optoelectronic feedback has been able to obtain stable and unstable pulses ¹⁰. (Hussein B. AlHusseini) has been able to design the light-emitting diode model with the Equations System pattern and was able to examine the first model during the front alignment without confusion and then the dynamic behavior in (QD-LED) was controlled ¹¹.

In addition, (Lajaurique 2016) and his group have studied the effect of Binary cavity of optical feedback on emission dynamics and stability timing for passive pattern corroboration (passively mode. Locked) for semiconductor laser using the model of differential equation and achieving stability results in an initial experiment ¹². (Huyet 2011) has studied the automatic resonance for confirm of the pattern with the single-type pattern of for the quantitative punctiform lasers in the presence of optical feedback and studied the effect of feedback on increasing the number of pulses and this affects the chaotic output ¹³. (Nada.et. al. 2018)

has studied the quantum dot semiconductor lasers and the success of this model of lasers by integrating the optical feedback with a quantity of nonlinear dynamics and studying the relationship between photons density and probability under the effect of delay time on the amplitude and frequency model 14.

In this research there is a study of the dynamics of the quantum dot semiconductor laser, the laser output which represented as photon density, the density of the charge carriers in the presence of Optoelectronic feedback, the study of the stability of pulse and its importance in the special medical applications of the laser the quantum dot semiconductor

**Optoelectronic feedback:** Optoelectronic feedback involves nonlinear dynamics, whether theoretical or empirical 15. After doing some studies of these non-stationary dynamics, Optoelectronic feedback behaviors were observed that it was these non-stationary 16. These behaviors are useful in many areas, whether they are stable or unstable, the stable has applications in the medical fields and non-stable has applications in communications field 17. The Equations of average used to explore the effects of system parameters 18 in the stability zone and the delay rate numerical simulation show that the region is stable and shrinks with increasing time. In a semiconductor laser with an Optoelectronic reverse feed consisting of a combination of the detector and amplifier to convert the optical output of the laser to an electrical signal it is returned to the laser again by adding it to the inverter stream because the detector responds only to the laser output intensity. In optoelectronic feedback, chaotic pulses can be generated by positive and negative feedback. 19 The laser is controlled flexibly and efficiently through the injection current and the optoelectronic reaction is present on both positive and negative types 20.

**Positive optoelectronic feedback:** It has been a light source for periodic pulses with a short period of time (pico second) compared to short pulses generation by a passive model with absorption saturation. Stable and fast pulses can be obtained with a variable pulse width easily by determining the external parameters appropriately for the system 21. The extent of the anarchic points in the different space parameters of the pulses appear high and the sequence of regular pulses of high density and constant 22. Areas of clutter appear in the chain. This depends on the delay time and generates semi-periodic pulses at three frequencies. The role of the injection affects the laser output through automatic emission and having saturation. The instability that emerges is a thorny behavior of photons density 23.

**Negative optoelectronic feedback:** The number of carriers in this type of nutrition is reduced in the case of free operation. Therefore, the laser threshold increases and the result requires a high injection current with greater bias 24 Pulse fluctuation depends on the high-aligned feeding gain of the injection current and increasing the number of photons that led to an unstable shrinkage region. Regular pulse states and chaotic pulse states appear depending on the output power of the laser, with lockings in the external injection cavity. The intensity of anarchic pulses decreases by separating the frequencies with the number of different rotations 25.

**Theoretical Model:** The operational properties of the punctiform semiconductor laser have been well described by a set of the equations of average that describe the interaction of photons and electrons within the active or effective area of obtaining a single-signal laser or solo laser. A single-signal semiconductor laser through reverse feedback is an external mirror. At this stage, optoelectronic feedback plays a key role in determining laser dynamics. The complex electric field is used with amplitude and phase with the density of photons or carriers in the equations of average because they have the same properties of light 26.

The equations of average for the lasers model of the quantum dot Semiconductor are given in the following relationships 27.

\[
\frac{dE}{dt} = E \left[ \frac{1}{2t_s} + \text{g}_0 \text{S} \right] (2\rho - 1) + \text{g}_0 E (t - \tau) + R_{sp} \ldots (1)
\]

\[
\frac{d\rho}{dt} = -t_s \rho - \text{g}_0 (2\rho - 1) |E|^2 + \text{CN}^2 (1 - \rho) \ldots (2)
\]

\[
\frac{dN}{dt} = J - \frac{N}{t_{sd}} - 2n_d \text{CN}^2 (1 - \rho) \ldots (3)
\]

\( \rho \) is the occupation probability in a dot. \( N_d \) is the two-dimensional density of dots; and \( J \) is the pump. \( N \) is the carrier density in the well, \( c \) is Auger carrier capture rate. Equations (1-3) which are derived from Huyet are utilized this study with a modification to study the dynamics of the (QDSL).

In the Optical feedback, the electric field component exists while in Optoelectronic feedback the intensity
equation of the photons or transducers exists as shown in the following equations.

\[
\frac{dS}{dt} = S \left( -\frac{1}{2\tau_g} + \frac{g_{\nu}\nu}{2} (2\rho - 1) \right) + R_{sp} \quad \ldots (4)
\]

\[
\frac{dP}{dt} = -t_g \rho - g_{\sigma} (2\rho - 1)|S|^2 + CN^2(1 - \rho) \quad \ldots (5)
\]

\[
\frac{dN}{dt} = J - N - 2n_g CN^2(1 - \rho) \quad \ldots (6)
\]

\(G_0\) Effective gain factor, \(v_g\) Group velocity.

This found. \(R_{esc}\) is a temperature-dependent function controlling escape from the dots.

In this study, the behavior of the optoelectronic feedback (positive and negative) it was stable for the majority of the values (Optoelectronic feedback strength = \(\zeta\)) using Matlab program.

**Results and Discussion**

The study of the optoelectronic feedback (positive and negative) on the output of the quantum dot semiconductor laser at a fixed delay time (\(\tau = 110\) ps) to identify the most stable areas and areas of confusion and at the value (\(\zeta = + 0.2, + 0.6\) and \(\zeta = -0.2, -0.6\)).

There is several areas including stable and confusion (SPIKE) In the fig (1), to study the relationship between photon density and time, we observe that the laser output of the optoelectronic feedback is positive and negative when the delay time is proved (\(\tau = 110\) ps). It was found that there are two areas of stability of the first (3.2-14.9 ns) and the second (15.2-25 ns) separated by an area (SPIKE) at (15 ns) as in fig (1-a,b). This corresponds exactly to what is in the figure (4) Note that (feedback strength \(\zeta = \pm 0.5\))

**Figure 1:** Shows the exact congruence between the positive part and the negative part of the values (feedback strength \(\zeta\)).

Either in case (\(\zeta = -0.3\)) it identical with (\(\zeta = \pm 0.2\)), either in case (\(\tau = 110\) ps and \(\zeta = 0.3\)) they are quite different from what is in the case (\(\zeta = -0.3\)) here we find two areas of stability first and the second (3.4-25) in addition (3.4-14.7) to the area of (spike) in both positive and negative parts (15ns) and the area of chaos. In positive part at (16.6-25ns) as in the fig (2-a,b).

**Figure 2:** Match in the negative part only at a value (feedback strength \(\zeta = -0.3\))
Figer (3) match the positive part at value ($\zeta = 0.4$) in case ($\zeta = \pm 0.2$) with the appearance of two areas of stability first (3.1-14.6ns) and the second (15.3-25ns) and the area of (spike=15ns) This positive part accordance with the negative part of the figure (2b) While we find the negative part ($\zeta = -0.4$) has three areas of stabilities (ns3.1-14.6ns, 15.4-16.2ns, 19-25) with area of (spike=15ps) with confusion area (15.5-18.9ns) this behavior does not match any value of other values (feedback strength $\zeta$, and the fig (3,a-b) explain that.

![Figure 3](image)

**Figure 3:** Match in the positive part and mismatch in the negative part at this value (feedback strength $\zeta = \pm 0.4$).

In fig (4) we found that ($\zeta = \pm 0.5$), there is two areas of stability first (3.1-14.6ns) and second (15.4-25ns) Separated by an area (SPIKE) at (15ns) as in fig (4-a,b).

![Figure 4](image)

**Figure 4:** Accordance is clear in the positive and negative part (feedback strength $\zeta = \pm 0.5$).

Figure 5 There are two areas of stability at the positive and negative part of the value ($\zeta = \pm 0.6$) and area of (SPIKE =15ns) and area of (Chaos =16.6-25ns) as in fig (5-a,b).

![Figure 5](image)

**Figure 5:** Shows the accordance in the positive and negative part (feedback strength $\zeta = \pm 0.6$).
Table 1: Shows areas of stability and areas of confusion (chaos) and (spike) at the values ($\zeta = +0.2$ and $\zeta = +0.6$).

Table (1) represent the stability areas, spike areas, and chaos areas for both positive and negative optoelectronic feedback. Here, spike areas are equal for both types of optoelectronic feedback. The first stability areas are approximately equal and the difference between them is 0.2 ns. There are no confusion areas in the case of (0.2, 0.3, 0.5) and the shortest stability in the case of 0.2 positive. In the second table we find a clear correlation with positive feeding in the spike and two areas of stability except for -0.4. There are no third regions added to chaos in areas, (-0.5,-0.2,-0.3), that mean they are not consistent with the positive state.

Conclusion

The accordance of the quantum dot laser output was investigated with the presence of both negative and positive Optoelectronic feedback. In addition to, knowing the areas of stability and areas of (spike) and (chaos). There was a significant accordance between positive and negative feeding in two cases (0.2, 0.5) and used this results on medical applications.. There is a difference in the other areas. In addition, all negative and positive (feedback strength $\zeta$) values have a spike at 15ns for both positive and negative. Stability areas are two areas for all values feedback strength $\zeta$ positive and negative except off(-0.4) with three stability areas.

Source of Funding: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Kerbala/Science College/Physics department/Karbala, Iraq and all experiments were carried out in accordance with approved guidelines.

Serum Zinc Level in Children with Relapsing Nephrotic Syndrome

Jasim Mohammed Hashim, Khadum Abd Alhussein Jabur

1Al-Sadder and AL-Zahra Teaching Hospitals, The Ministry of Health and Environment of Iraq, Iraq

ABSTRACT

Zinc as a second trace element of human body plays an important role in numerous function. Abnormality in the metabolism of zinc in renal problem especially nephrotic syndrome is well documented. We aim in this study to measure the serum zinc level in children with relapsing nephrotic syndrome. A hospital based case control study that conducted at nephrology clinic at Al-Sadder and AL-Zahra teaching Hospitals for period between 1st January 2013 to end of October 2013. A total of 60 pediatric patients with relapsing nephrotic syndrome were included in this study. They were divided in two groups, (30) patients constituent of group A (patients with infrequent relapsing) and (30) patients constituent group B (patients with frequent relapsing). Control group consist of 32 healthy children. Serum zinc was measured by atomic absorption spectrophotometry. patients aged 2-14 years, boys were 40 and girls were 20. The mean age of patients was 7.5 years. The Mean serum zinc level in group B (frequent relapse) (58.45 µg/dl) that was significantly lower than that of group A (infrequent relapse) (61.58 µg/dl) and control group (89.64 µg/dl) respectively

Keywords; Frequent relapses. Nephrotic syndrome. Zinc

Introduction

Nephrotic syndrome was primarily a pediatric disorder and was 15 times more common in children than adults. The incidence was 2-3/100,000 children per year; and the majority of affected children will have steroid-sensitive minimal change disease. The nephrotic syndrome was caused by renal diseases that increase the permeability across the glomerular filtration barrier. It was classically characterized by four clinical features, but the first two are used diagnostically because the last two may not be seen in all patients:

1. Nephrotic range proteinuria (Urinary protein excretion greater than 50mg/kg per day) or 40 mg/ m² per hour.

2. Hypoalbuminemia(Serum albumin concentration less than 2.5 g/dL(25g/L))

3. Edema

4. Hyperlipidemia

Risk Factors for Relapse in Childhood Nephrotic Syndrome

1. Cold and infections. Cold and infections are the most common cause of relapse of nephrotic syndrome. If left untreated, illness conditions will become even worse. Children and adolescents are still in the growth period and many of their tissues and organs are still immature. Compared with adults, children patients have weak immune system and they are more susceptible to be attacked by various viruses, bacteria which often cause the proteinuria, hematuria, swelling to reoccur.

2. Poor compliance. Different from adult patients, small children usually do not understand why they need to take so many bitter drugs and the importance to have the right dosage on schedule. Often the reduction of dosage or stopping taking the prescribed medicines often cause relapse of illness. Therefore it is very important that parents should supervise the children to have medicines at the right time and with the right dosage.

Proper treatment is very important to prevent relapse of nephrotic syndrome in children. Hormones and immunosuppressant are effective at relieving symptoms but cannot solve the root problems, that is why patients often become dependent on these drugs and illness often relapse when the dosage is reduced or the drug is stopped. Often these drugs have some side effects and harms to the kidneys if taken for long time, that is why nephrotic syndrome will continue to become worse after each relapse.
Infection is an important cause of morbidity and mortality in nephrotic children. Patients with steroid sensitive nephrotic syndrome (SSNS) have increased susceptibility to bacterial infections and various infections may result in relapses or steroid resistance or may trigger the onset of disease. Relapses in SSNS often follow infections of upper airway or gastrointestinal tract and cellulitis. It is estimated that 52–70% of relapses among children in developing countries chiefly follow the upper respiratory tract infection. Common infections associated with either onset of disease or in the course of disease are acute upper and lower respiratory infections (ARI) including pneumonia with or without empyema, skin infections including impetigo and cellulitis, acute watery or invasive diarrhea, urinary tract infections (UTI) and primary peritonitis. Studies have shown that use of prophylactic antibiotics, immunoglobulins, replacement therapy, vaccination against streptococci pneumoniae, thymosin as immuno-modulating agent, use of Chinese medicinal herb (TIAOJINING) and zinc supplements may have a role in prevention of these infections. However, in a recent Cochrane Database of Systemic Review, it has been concluded that there is no strong evidence for any of above interventions for prevention of infection in nephrotic syndrome. Though pneumococcal peritonitis and cellulitis are decreased with use of pneumococcal vaccine and antibiotics but these infections are still responsible for 1.4-10% of mortality and repeated relapses in more than 80% of cases, requiring high dose steroids and hospitalization. A high frequency of infections in children with nephrotic syndrome (38–83%) has been reported from developing countries like India, Pakistan & Bangladesh in different studies. Studies from developing countries have also suggested that increasing the maintenance dose of steroid from alternate day in a child with remission to daily during the episode of mild infections can prevent relapse. Thus a strong suspicion regarding infections in a nephrotic child is important not only for treatment but also to prevent infection associated relapse.

Zinc was an essential trace element. Zinc intake was closely related to protein intake; where diet rich in proteins stimulate zinc absorption as a result, it was an important component of nutritionally related morbidity worldwide.

The usual oral intake of zinc was approximately 4 to 14 mg/day; the recommended dietary allowance (RDA) was 8 mg/day for children ages 9 to 11 years; Primary dietary sources of zinc include animal products such as meat, seafood, and milk. Ready-to-eat cereal contains the greatest amount of zinc consumed from plant products.

Approximately 10 to 40 percent of dietary zinc was absorbed in the small bowel; absorption was inhibited by the presence of phytates and fiber in the diet that bind zinc, as well as dietary iron, cadmium, calcium, copper and phosphorus in high amounts. Approximately 0.5 to 1.0 mg/day was secreted in the biliary tract and excreted in the stool. Zinc circulates at a concentration of 70 to 120 mcg/dL with 60 percent loosely bound to albumin and 30 percent tightly bound to macroglobulin. Urinary excretion typically ranges from 0.5 to 0.8 mg/day. The primary stores of zinc include the liver and kidney. Most of the body zinc stores are intracellular where zinc was bound to metalloproteins.

Relapses in steroid-sensitive nephrotic syndrome (SSNS) often follow infections of the respiratory or gastrointestinal tract. Based on data that zinc supplements reduce the risk of infections, we examined the efficacy of such supplements in reducing relapse rates in the patient.

**Materials and Method**

This was a hospital based case control study on samples at nephrology clinic at Al-Sadder and Al-Zahra teaching Hospitals for period between January 2013 to end of October 2013 as following.

**Sample Size:** A total of 60 pediatric patients age 2-14 years with relapsing nephrotic syndrome were included in this study, male were 40 and female were 20. They were separated into two groups: Group A (infrequent relapsing), 30 children, where there were 20 males and 10 females (relapse once time during 6 months since diagnosis of disease). Group B (frequent relapsing), 30 children, where there were 20 males and 10 females (relapse two or more during 6 months since diagnosis of disease). These patients were compared with 32 healthy children called "control group", where there were 17 males and 15 females.

For both groups and control, blood samples were collected to measure the serum zinc concentration level by using Spectrophotometer.

**Zinc Measurement:** This occur by spectrophotometry where zinc reacts with chromogen present in reagent forming coloured compound which colour intensity proportional to the zinc concentration present in sample.
In fasting state 3 ml of blood was drawn with plastic syringe from each nephrotic and control subject. After centrifugation at 3000 rpm for 10 minutes, separated sera were kept frozen at -70°C. Haemolysed sera were taken out of the study. Serum zinc was measured by atomic absorption device model Carl Zeiss Jena (Jena, Germany) Model AAS3 flame atomic absorption spectrometer. A cut-off value of 70 μg/dl - 115 mg/dl was used for serum zinc, samples below 70μg/dl was regarded as low (hypozincemia). After collecting data, statistical analysis was performed by SPSS 16.0.2. Values were presented as means ± 2 SD. Differences were considered significant at P <0.05. Laboratory observer and data analyzer had not any idea about the relationship of samples to patients or normal subjects. The study was approved by the local research and the ethics committee in the hospital and the college, parents consent was taken.

Results

We made the statistical analyses to correlate the different conditions groups (Control, A, and B). These different conditions were divided according to the historical background of the patients (frequent and infrequent relapsing) in the mentioned hospitals during the lifetime of the disease (nephrotic syndrome).

In this study The Mean serum zinc level in group B (frequent relapse) (58.45 μg/dl) that was significantly lower than that of group A (infrequent relapse) (61.58/ dl) and control group (89.64 μg/dl) respectively. P-value <0.001 these finding can be explained by Mild zinc deficiency is believed to result in a reduced production of Th1 cytokines, resulting in Th2 cytokine bias(13, 14). In contrast, zinc supplementation is proposed to augment gene expression for IL-2 and IFN-γ, thereby restoring the Th1 immune response (15). Since the Th1–Th2 cytokine imbalance is also believed to result in relapses of SSNS. So this results support the findings that suggest the patients with SSNS receiving supplementation with RDA of zinc show a trend towards fewer relapses and higher likelihood of remission. The response was better in the frequent relapers(16, 17). The Mean serum zinc level of group A (infrequent relapse) is also low (61.58/dl), this finding can explained by The increase urinary zinc excretion in children with NS (whether in relapse or in remission) was attributed as a cause for low serum zinc level by many...
authors who reported a positive correlation between urinary zinc and protein excretion in their studies,\(^{18,19,20,21}\). Also, several studies demonstrated low blood or serum zinc levels among children with NS compared to that of the control groups.\(^{16,18}\) This study certifies insignificant difference corresponding to sex in all groups of patients studied. This result was also stated by \(^{22}\).

**Conclusion**

Hypozincemia can occur in chronic renal problem like nephrotic syndrome. The low level of serum zinc mainly found in those with frequent relapses there is no effect of sex on mean serum level in all group studied.

**Source of Funding:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

The Impact of the Strategy of Lists Focused on the Achievement of Second-Grade Students in Science

Iman Abbas Rasool¹, Saeed Hussein Ali Thalab¹, Sana Salem Najm¹
¹Faculty of Basic Education, University of Babylon, Iraq

ABSTRACT

The study aims to identify the effect of the strategy of the concentrated lists in the achievement of second grade students in science. The researcher adopted the experimental method as the appropriate method for the research procedures. The research community consisted of middle schools for girls in Karbala governorate, (32), and the second was a control group that was studied in the usual manner. The number of female students was 34, and the researcher rewarded between the two research groups in some variables, For students measured in months and the collection of parents and students degrees in science at the end of the first semester (first course) And the degrees of testing the previous information in the science and intelligence test), (The test of two independent samples, the square of Kai, the coefficient of difficulty and ease of paragraphs, the coefficient of discrimination, the effectiveness of alternatives and the equivalence of Kyodar_ Richardson 20) and the magnitude of the effect) Students of the control group in the achievement test, ie, there is a difference of statistical significance at the level of significance (0,05) and for the benefit of the experimental group.

Keywords: Strategy of Focused Lists - Achievement - Second Grade Students – Science

Introduction

The scientific development and the rapid explosion of knowledge in the world has become the hallmark of this age in various fields, especially in the field of communication, which has greatly helped to support the use of theories (models of philosophies and methods of teaching). All this is done in order to improve and develop educational learning process ¹. Education is an effective means of achieving the strategic goals of the society because of its importance in adapting and interacting with the local environment, which create the conditions for the formation of citizens and prepare them able to promote the community and adapt to changes in the environment and society. ². He noted ³ Scientific education is a system whose aim and purpose is to provide the learner with the necessary knowledge and scientific knowledge to become a scientific educator. The purpose of the scientific education is to provide the learner with information, customs and scientific values and to activate the kinetic role in order to be educated scientifically, socially and physically. Understanding scientific facts and knowledge and applying them to reality from the scientific, social, and motor aspects ⁴. The curriculum is very important in education and its importance is reflected in the fact that it is the main tool that achieves the goals of education, which are at the heart of the educational process and its means The importance of curricula is great because it is concerned with human numbers and their construction ⁶. Al-Janahi (2018) pointed out that the curriculum has a close relationship to the teaching methods because it is a corner of its structure, or as Klepatric describes it: “The method is one of the legs of education and the other leg is the curriculum. Education cannot walk on one leg.” ⁷ does not focus on specific teaching methods, but the challenge facing other researchers clearly shows that educational curricula should be centered around students and beyond the role of the educational teacher on the transfer of his teaching function ⁸. The teaching of any branch of science and knowledge must reflect its nature and processes. Thus, the teaching methods of science must reflect the nature of science that deals with natural phenomena of all kinds. ⁹ The study of physics helps students to understand and think in the age of science and technology Which has become difficult for students to live in the twenty-first century without understanding the nature of science and knowledge of basic physical information and the use of scientific thinking methods to solve the problems of life and make good decisions under the innovations of science and technology ¹⁰-¹³.

Branches of Medical Physics

Medical Physics is divided into four main branches:

1. Therapeutic Radiological Physics
2. Nuclear Medicine Physics
3. Diagnostic Imaging Physics
4. Medical Health Physics

In the large hospitals, there is a department called Medical Physics, under which people are divided into these four branches. The Division of Radiotherapy Physics is often the largest. Physicists provide support services for the department of oncology at the hospital, such as radiation dose planning and accurate access to tumor patients and diagnostic imaging devices Ray, radiography, magnetic resonance imaging, ultrasound, etc. The presence of diagnostic imaging physicists is necessary to ensure that these devices conform to international standards and standards when used in patients. Radiation at the hospital or facility? If there are healthy physicists make sure that the patients or employees are not exposed to unnecessary radiation and are communicating with the competent authorities in the protection of radiation in the State and in the case of the presence of nuclear medicine devices in the hospital there is at least one medical physicist services for that section, Ensure the safety of the work environment as well as radiation training and education.

Methodology

The research procedures include research methodology, experimental design, identification of the research community and its sample, the equivalence of experimental and control groups, preparation of research requirements and tools, procedures for applying the experiment and presentation of the statistical means used, which will be presented as follows:

Experimental design of the research: The independent variable includes the strategy of the concentrated lists, the usual method and the variable of the collection. Therefore the researcher used experimental design with partial control of two equal groups, one experimental and the other control as in the following table:

<table>
<thead>
<tr>

<tr>
<td>Control</td>
<td>The usual method</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Search community and design: The current research community is represented by second grade middle school students, all in the public schools of the Directorate General of Education in the province of Karbala, the province of Hindia for the academic year (2018-2019). The researcher chose (medium Omaima for girls) randomly to apply the experiment, as it includes three people for the second grade (A, B, C), the researcher chose (A) random sampling method to represent the experimental group and the number of female students (32) students who studied their students according to the strategy (concentrated strength), in the same way was chosen Division B to represent the control group and the number of female students (34) students who studied their students on (The normal method).

Equivalence of the two groups of research: The researcher conducted the equivalence of the two groups of research in the following variables (the age of the students, the grades of students in the science of the first chapter, the IQ test) The following table shows the equivalence between the two groups:

<table>
<thead>
<tr>
<th>I am equal</th>

<td>64</td>
</tr>
</tbody>
</table>
Adjusting the Exogenous Variables: The variables related to the experiment have been set.

Determination of the course material: The course material was determined in the second part of the book of science, 2018, i1, which is to be taught for the second intermediate grade for the year by the Iraqi Ministry of Education (2018-2019) Of the teaching plans and the behavioral goals of the two research groups according to the content of the book of science part II (2018, i), which is to be taught to the second grade students for the academic year 2018-2019. 32 teaching plans were prepared with (16) In accordance with the strategy (focused lists) and (16) the group’s teaching plan According to an officer (the usual way).

Search Tool:

Steps have been prepared for the research tool (test collection) which is as follows:

To determine the purpose of the achievement test: The requirements of applying the current research to prepare an achievement test used to measure the academic achievement of the sample of research in the science (Part II), so the researcher prepared an achievement test related to the subject matter taught and behavioral purposes related to them and appropriate to the level of sample search.

Believe the test: The results showed that the apparent honesty obtained the proportion of agreement (80%) by the arbitrators and specialists. The results showed that all the clauses of the achievement test are statistically significant, so The achievement test is honest in measuring the comprehension and comprehension of second graders in science.

The pilot application for the test of achievement: It includes the following:

The first pilot application: To determine the clarity of the test instructions, the clarity of the paragraphs and their formulation, and the time it took to answer the test. The test was carried out on a non-sample sample of 30 students from the second grade in Mustansiriyah High School on Monday, 2/2019). After completing the answer it became clear that the instructions for the answer and the test paragraphs were clear and that the average response time for the students was (40) minutes.

The second test application: After confirming the veracity of the test paragraphs and instructions and the time taken to answer, the test was repeated again on a sample of (100) students of the second grade intermediate in the middle of the cities on Wednesday (27/2/2019) After informing the students of the test date several days ago, and supervised the researcher herself to apply the test, and the purpose of this application is the statistical analysis of the test paragraphs.

Statistical analysis of the test paragraphs: The analysis of the test paragraphs of the basic processes that can be used by the researcher in the examination of vocabulary, and determine the quality and effectiveness, each of the paragraphs of the test characteristics of the distinctive, the purpose of analyzing the paragraphs of the test is to know the degree of difficulty of each paragraph (difficulty coefficient), And the possibility of distinguishing between the different levels of female students (coefficient of discrimination) and the effectiveness of the wrong alternatives to the test, so correct the answers of the students of the second survey sample (the number of 100) students and found their grades and rank descending, in order to conduct the following statistical analyzes:

Difficulty factor for paragraphs: Any paragraph whose coefficient of difficulty is between 0.25-0.75 is acceptable. The researcher applied the coefficient of difficulty of the substantive paragraphs on each paragraph of the test and found that the value ranged between (0.35-0.72), which means that it is suitable in terms of difficulty and ease, and thus counted all paragraphs with a coefficient of difficulty acceptable.

The coefficient of discrimination for the paragraphs: The researcher applied the coefficient of discrimination coefficient on each of the test paragraphs and found that the value ranged from (0.26-0.70). Thus, all the paragraphs were considered to have an acceptable coefficient of discrimination. The paragraphs with a coefficient of distinction between (0.25-0.75).

Half way split: The researcher adopted the answers of the sample of the second exploratory application, which amounted to (100) answer sheets, as the individual paragraphs of each student were grouped on one side and the matrices on the other hand (ie the grades were divided into two groups, one representing the degrees of the individual paragraphs and the other representing the vertebrates) Pearson’s correlation between the two test levels was (0.85) and corrected with the Spearman-Brown equation of (0.92). It is a good stability factor that can be trusted. The stability coefficient is good if it is (0.80) and above.
Method (Kyoder-Richardson 20): The researcher used this equation because the test is a multi-choice type. This equation is suitable for this kind of tests with one specific answer that corrects its paragraphs by giving one score for the correct answer and zero for the wrong or abandoned answer or if choosing more than one alternative. Stability was 0.83, indicating that it was a good and acceptable stability factor.

Application of the experiment:

The researcher followed the following steps in applying the experiment: The experiment was implemented on Monday (4/3/2019) of the second semester. The researcher studied the experimental and control groups by herself. The researcher prepared teaching plans for the experimental and control groups. And (16) plan of the control group according to the usual method, the trial ended on Thursday (25/4/2019), the researcher applied the test of achievement on Sunday (28/4/2019) on the two sets of research at one time, And the students’ grades were obtained.

Search results and interpretation: In the experimental group, the students of the experimental group studied the control group students who studied according to the traditional method in the achievement test. This indicates that there was a statistically significant difference at the level of (0.05) between the average of the students of the experimental group and the average score of the students of the control group. In the test of the collection of science and this is consistent with the studies that confirmed the superiority of the experimental group on the control group in the achievement test, and Table (3) shows that

<table>

Note from the table above, we note that teaching according to the strategy of concentrated lists has contributed to raising the academic achievement of second-grade students in science is better than the usual method of teaching

Conclusion

The focused list strategy has the positive effect of increasing the average second graders’ achievement in science and increasing their ability to understand information, facts and knowledge and raise their academic level. The focused lists strategy plays a role in making female students the focus of the educational process through their active participation in the educational situation, which will increase their confidence in themselves and encourage them to persevere to raise their scientific level.

Reliability of Salivary Alpha Amylase as a Biomarker of Obesity

Zainab Hadi Kamil1, Kareem Hameed Rashid2
1Assistant Professor, Basic Science Dept., College of Dentistry, 2Professor, Biology Dept., College of Science, Babylon University, Iraq

ABSTRACT

Obesity is generally defined as a condition of body fat accumulation in adipose tissue in excessive manner that may lead to impaired health. Saliva is an easy collected noninvasive biofluid, which contains various components like hormones and enzymes. The researches correlated to salivary α-amylase (sAA) and obesity are quite limited and not fully examined. This study aimed at finding out the reliability of salivary amylase as a biomarker to obesity. The study results showed a significant increase in anthropometric measurements (BMI, NC, WC, HC and WHR) and salivary α-amylase concentration and activity in obese subjects when compared with normal ones. In conclusion, salivary α-amylase activity was increased in obese subjects and could be an indicator to obesity. Further studies should be carried out to confirm that the salivary amylase to be a biomarker of obesity.

Keywords: obesity, salivary amylase, BMI, NC, WC, HC, WHR

Introduction

Obesity is a common but undervalued condition of public health and clinical importance all over the world, and is a result of fat accumulation in adipose tissue in excessive manner that may lead to impaired health 1. The total amount of fat is not the only important issue in the risks of obesity but where it is distributed in the body 2. Peripheral or abdominal obesity is supposed to be more risky and related morbidity and mortality because it involves more of the visceral organs 3. Commonly Body Mass Index (BMI), is the mostly used parameter to express what is considered as an “excess” of body fat 4. It is easy to measure by calculating the weight in kilograms divided by height in squared meters (kg/m2) in adults 5. For children and adolescents, the BMI ranges is considered according to their sex and age and expressed as gender-specific BMI percentiles in the growth charts 6. Waist circumference (WC) is used as simple anthropometric measurements of central obesity 7. Neck circumference (NC) is a measurement of upper body obesity and could be a significant indicator of central adiposity and maybe of visceral adiposity and a significant risk sign of metabolic conditions 8. Saliva is an easy collected noninvasive biofluid secretion primarily from the three pairs of major salivary glands: parotid, submandibular and sublingual, which contains hormones, enzymes, antibodies, antimicrobial component, and cytokines 9. Salivary amylase is one of the first enzymes recognized with several mysteries remain about the molecular mechanisms contribute to amylolysis of starch and the physiological role of the salivary amylase itself. The most important function of the salivary α-amylase enzyme is to catalyze the first stage in starch digestion into dextrin and maltose 10. The studies on salivary α-amylase (sAA) and obesity are quite limited and not fully examined. Moreover the study results that have been informed are mostly contradictory in many aspects. Limited studies have been done on sAA and its role in diabetes, proposing a close association between the salivary amylase activity and glucose homeostasis (11,12). Studies found a positive correlation between sAA activity and obesity expressed by increased BMI in adolescent (13,14), and a significant positive association between sAA and waist to hips ratio (WHR) in women 15. While another study revealed that average morning sAA was negatively associated with BMI 16.

Materials and Method

Study Population: This study was carried in the laboratories of Biology Department, College of Science,
Babylon University, Iraq. The volunteers were recruited from October to December 2018 in the clinics of College of Dentistry, Babylon University. The study was performed on 89 subjects (56 obese subjects and 33 normal subjects) aged from 6 to 50 for both genders (40 males and 49 females). Each subject was given a questionnaire included age, gender, diseases, family history and last medical check. According to the World Health Organization \(^5\), normal weight subjects were with BMI 18.5-24.9 kg/m\(^2\) and obese subjects were with BMI of ≥30 kg/m\(^2\). Children (aged 6-10 years) and adolescents (aged 11-18 years) were also grouped into normal weight group and obese group depending on their BMI percentile. Subjects with BMI of <85\(^{th}\) % for age and gender were included in the normal group and subjects with BMI of ≥95\(^{th}\) % for age and gender were considered obese subjects \(^7\). Subjects with diabetes, hypertension, or other diseases, or having any medicine during the last three months were excluded from the study. Smokers, alcohol abusers, pregnant and nursing women were not involved in the study.

**Anthropometric measurements:** Height was measured by meters and weight was measured in kilograms by a digital weight scale. BMI were obtained as the weight in kilograms divided by the square of the height in meters (kg/m\(^2\)) according to WHO \(^5\). The WC, HC and NC were measured by centimeter according to the protocol of WHO \(^8\).

**Collection of saliva:** Unstimulated whole saliva (4 ml) was collected by draining method in the morning at 8:30 to 11am after fasting for at least 8 hours. Before that subjects were told to rinse their mouth with 10 ml of water (preferably distilled) for 30 seconds to remove debris and moisturize the mucosa \(^9\). Immediately after saliva collection the samples were centrifuged at 3000 rpm for 15 minutes. The supernatant were removed and transferred to the eppendorf tubes and stored at -20°C until analysis (not for more than one month).

**Salivary α-amylase measurements:** Salivary alpha amylase concentration was measured according to ELISA kit procedure supplied by Elabsclone - China company. The activity of sAA was determined according to Sahu et al. \(^20\)

**Statistical Analysis:** Statistical analysis was performed by using SPSS version 23. All data were analyzed using descriptive statistics for normal distribution and homogeneity of variance by the Kolmogorov–Smirnov tests before statistical analyses were managed. For comparison between obese and normal weight groups, independent t-test or Mann-Whitney U test was performed. Data were expressed as the means ± standard error. P value (P≤0.05) was considered statistically significant. Bivariate correlations were performed using the Pearson correlation coefficient between the anthropometric measurements and sAA measurements \(^21\).

**Results and Discussion**

**Anthropometric measurements in normal weight and obese subjects:** In the comparison between the obese and control groups, there was a highly significant (p≤0.01) increase in the means of BMI, NC, WC, HC and WHR (31.17 ± 0.7 kg/cm\(^2\), 35.09 ± .67 cm, 93.21 ± 2.21cm, 101.85 ± 2.42 cm and 0.93 ± .023 respectively) in obese group as compared to the means of (18 ± 0.69 kg/cm\(^2\), 30.00 ± .84 cm, 65.58 ± 2.59cm 80.48 ± 2.78 cm and 0.82 ± .02 respectively) in normal weight group (table 1).

The correlations between anthropometric measurements in obese subjects (table 2) revealed that BMI has highly significant (p≤0.01) positive correlation (R\(^2\)= 0.77, 0.78 and 0.65) with NC, WC and HC respectively. NC measurement was high significant (p≤0.01) positively correlated (R\(^2\)=0.85, 0.58) with WC and HC respectively, and significant (p≤0.05) positively correlated (R\(^2\)=0.33) with WHR. Furthermore WC as a measurement to central obesity had highly significant (p≤0.01) positive correlation (R\(^2\)= 0.71) with HC and positively significant (p≤0.05) correlated (R\(^2\)=0.33) with WHR (table 2).

Salivary α-amylase measurements in normal weight and obese subjects: The analysis of results showed no significant difference in the concentration of the enzyme α-amylase in saliva of both groups of this study (37.67 ± 5.62 ng/ml in normal weight subjects and 38.61 ± 4.14 ng/ml in obese subjects) as shown in figure (1), while the α-amylase enzyme activity revealed significant (p≤0.05) elevation (figure 2) in obese subjects (335.85 ± 34.58 U/ml) as compared to normal weight subjects (285.78 ± 35.47 U/ml).

As shown in table (3), α-amylase concentration was significant (p≤0.05) positively correlated (R²=0.37 and 0.36) with BMI and NC respectively. Meanwhile the α-amylase activity was significant (p≤0.05) negatively correlated (R²=-0.43 and 0.38) with NC and WC of obese subjects.

Discussion

Anthropometric measurements in normal weight and obese subjects: The present anthropometric study object was to recognize the most appropriate anthropometric measurement that best correlates with obesity in the population of this study. From table (1) all the anthropometric measurement involved in the current study were high significantly elevated in obese subjects, and correlated with each other (table 2). The BMI was strongly associated with body fat, but abdominal obesity is a distinct predictor of mortality and morbidity, even in people with a normal BMI.

The recent study showed high significant increasing in WC in obese subjects comparing to normal weight subjects. WC is used as simple anthropometric measurements for abdominal obesity. WC than 102cm in men and 88cm in women is a risk factor for diabetes mellitus, insulin resistance and cardiovascular disease.

NC was highly elevated in obese group of this study, it could be a significant indicator of central or visceral adiposity and a significant risk sign of metabolic conditions. Also it could be considered an important measurement in health care clinics especially pregnant women where classical measures are not meaningful. NC can be used as a primary test for the prediction of obesity.

WHR was highly raised in obese group of this study. WHR has lately been proposed as a useful alternate method of percentage body fat assessment. But BMI is still the most commonly used method for identifying obesity in most epidemiological studies.

Salivary α-amylase measurements in normal weight and obese subjects: From this study (figure 1&2), sAA concentration and activity were increased in obese subjects. The concentration of enzyme in obese saliva was not significantly increased as compared with the activity of the enzyme in obese saliva. sAA catalyzes starch digestion into dextrin and maltose. One study revealed a positive association between salivary α-amylase activity and increased BMI in adolescent. Another study found that BMI was negatively associated with average morning sAA. Lamy et al. mentioned that sAA activity increased in obese women as compared with normal weight women. Hossain et al. found that sAA activity to be positively linked with BMI. Most studies linked salivary amylase with diabetes and insulin and cardiovascular risks. A recent study proposed the association between sAA concentration and sweet taste marks in children. The favoring of sweet and high-fat foods is often described as being related to obesity occurrence. Salivary amylase may increase glucose levels in saliva. A relationship between salivary glucose levels and low-sensitivity to sweet taste was studied and explained as a higher continual stimulation of taste receptors to glucose which may lead to a desensitization of these receptors, causing the need for higher concentrations of sweet stimuli to be recognized. Desensitization of taste receptors because of the constant stimulation has earlier been described.

Conclusion

In conclusion salivary α-amylase activity was increased in obese subjects and could be used as an indicator of obesity. Further studies should be carried out to confirm its use as a biomarker of obesity.

Source of Funding: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Dentistry, Babylon University, Iraq and all experiments were carried out in accordance with approved guidelines.

Infertile Women’s Knowledge Regarding Adverse Effect of Invitro Fertilization Treatment

Zainab Saddam Humadi¹, Iqbal M Abbas²
¹Academic Nurse, at Al Emamain Al Kadhamain Medical City, Iraq; ²Professor, Maternal and Child Health Nursing Department, College of Nursing, University of Baghdad, Iraq

ABSTRACT

Objective: To identify Infertile Women’s Knowledge about adverse effect & to find out association between these infertile women’s knowledge & sociodemographic characteristic, reproductive variables. The present study employs a descriptive comparative design held at the Um El Banin Center for Infertility & In-Vitro Fertilization Treatment at Al-Emamain Al-Kadhemain Medical City. Data collection was initiated on 2nd January to end of March/2018. Purposive sample consisted of (100) infertile women. An assessment tool was constructed for the purpose of the study, it was comprised of socio-demographic data, information about women age at marriage, number of years of marriage, age at puberty (menopause), regularity of menstruation, suffering from dysmenorrhea. Previous medical history. The main results of the study show that participants’ knowledge about the adverse effects of IVF are of low-mean scores with low R.S. and their assessment is low in the pretest time. In the posttest time, all items of participants’ knowledge about the adverse effects of IVF are of high-mean scores with high R.S. There is a statistically significant difference in the scores of knowledge about adverse effects of IVF for women in the study group between the pretest time and posttest I (p-value = .000). On the other hand.

Keywords: Contributing Factors of infertility, Invitro fertilization.

Introduction

The definitions of infertility vary according World Health Organization infertility as “a disease of the reproductive system defined by the failure to achieve a clinical pregnancy after 12 months or more of regular unprotected sexual intercourse” (Zegers-Hochschild et al., 2009). Population studies differ on infertility from one country to another, according to the area in which the study was conducted. Knowing the prevalence of infertility among the population is of great importance, to identify the potential needs and adapt health care for each particular community (Young, 2013). The infertile couple suffer from enormous psychological burdens, especially for woman. Knowledge about the factors that affect reproduction or fertilization may help couples reduce infertility by avoiding certain dangerous factors that lead to infertility ¹.

Methodology

The present study employs a descriptive comparative design held at Um El Banin Center for Infertility & In-Vitro Fertilization Treatment at Al-Emamain Al-Kadhemain Medical City. Data collection was initiated on 2nd January to end of March/2018. Purposive sample consisted of (100) infertile women. An assessment tool was constructed for the purpose of the study, it was comprised of socio-demographic data, information about women age at marriage, number of years of marriage, age at puberty (menopause), regularity of menstruation, suffering from dysmenorrhea. Previous medical history. include: urinary tract infection, thyroid diseases, diabetes mellitus, hypertension, and cardiovascular diseases. Gynecological History, do you have history of Inflammation of the reproductive system, fallopian tube, Congenital malformations, ovarian dysfunction, previously artificial insemination if found number of trials, ovarian cyst and fibroids and Women’s Knowledge about Diseases and Factors Contributing to Infertility Multiple choice items (Three alternatives) scale was used to measure the knowledge of women about infertility and its contributing factors, these include (11) items. The instrument was constructed through the use of (2) level type of scale, and scored, yes (2) and No (1). The pilot
study conducted on (10) mothers and their neonate to test the, reliability of questionnaire, from 2nd January to 10th February 2018, the actual value is (0.764), in study post I and study post II respectively, this means that the items of the questionnaire were clear and understood and the questionnaire was adequately reliable. To make instrument valid, it was presented to a panel of expert in different medical and nursing specialties. Data were collected through, application, observation, assessment, and interview techniques as a mean of data collection process. Data were analyzed through application of descriptive and inferential statistical data analysis approach through the use of SPSS Version 24.

Results and Discussion

With respect to wife’s level of education, more than a quarter in the study group hold a bachelor’s degree (n = 30; 30.0%), followed by those who are high school graduates (n = 20; 20.0%), those who are intermediate school graduates (n = 13; 13.0%) and those who hold a diploma degree (n = 20; 20.0%) for each of them, those who are unable to read and write (n = 10; 10.0%), those who are primary school graduates (n = 5; 5.0%), and one who reads and writes (n = 2; 2.0%).

Concerning husband’s level of education, more than a quarter in the study group are high school graduates (n = 26; 26.0%), followed by those who hold a bachelor’s degree (n = 24; 24.0%), those who hold a diploma degree (n = 11; 11.0%), those who are unable to read and write (n = 11; 11.0%) and those who are intermediate school graduates (n = 11; 11.0%), and those who reads and writes (n = 9; 9.0%) and those who are primary school graduates (n = 8; 8.0%). Regarding wife’s occupation, most in the study group are housewives (n = 64; 64.0%), followed by those who are freelancers (n = 22; 22.0%), and those who are governmental employees (n = 10; 10.0%). With respect to husband’s occupation, most in the study group are freelancers (n = 54; 54.0%), followed by those who governmental (n = 36; 36.0%), and those who are do not work (n = 10; 10.0%).

Concerning consanguinity, the majority in the study group reported that there a second-degree consanguinity (n = 86; 86.0%), followed by first-degree consanguinity (n = 11; 11.0%), and third-degree consanguinity (n = 3; 3.0).

Regarding wife’s marital status, the majority in the study group reported that they are the first wives (n = 89; 89.0%), followed by second wives (n = 8; 8.0%), and married previously (n = 3; 3.0%).

Finally, Socio-Economic Status through applying of WHO instrument shows that the highest percentage of the study groups are within low category and accounted 62(62.0 %),33 (33%), and 5(5.0%), in women infertility in study group.

Respo. = Response, F = Frequency, % = Percentage, MS = Mean Score, R.S = Relative Sufficiency, Ass. = Assessment, n= Number of sample, L = Low (R.S = less than 75%), M = Moderate (R.S = 75% - 87.5%), H = High (R.S = 87.6% – 100%), n= Total sample

Adverse effects of IVF for the study sample shows that, (excessive ovarian response, increase weight in a few days, change in mood, damage in the bowel or bladder during the extraction process, collection fluid inside the abdomen or lungs, difficult of breathing, low rate of urination, congenital malformations, nausea to vomiting, general anesthesia complications, high temperature and infections in the upper genital canal) as shows all items of participants’ knowledge about the adverse effects of IVF are of low-mean scores with low R.S. and their assessment is low all items of participants’ knowledge about the adverse effects of IVF.

Distribution of study sample according to sociodemographic characteristics: Wife’s age, the mean age for women in the study group is 27.88 ± 5.18; less than a half age 27-33-years-old (n = 46; 46.0%), followed by those who age 20-26-years-old (n = 40; 40.0%), and those who age 34-40 years old (n = 14; 14.0%). Regarding husband’s age, the mean age for husbands in the study group is 31.52 ± 4.81; more than a half age 29-35-years-old (n = 56; 56.0%), followed by those who age 36-42-years-old (n = 22; 22.0%), and those who age 22-28-years-old (n = 20; 20.0%). No significant differences were found between both groups (p= 0.161).

The current study agreed with Atuahene & others (2016) who reported mean age with standard deviation of participant (30.05 ± 5.18). There were no significant
A cross-sectional survey was conducted from July to September 2011 by married women, 18 to 45 years old, seeking infertility care from clinics in Jakarta, Surabaya and Denpasar reproductive knowledge and patient education needs among Indonesian women infertility patients attending three fertility clinics age groups 18–29 years 34% 30–35 years 40% 36+ years 25% Participants were literate, the sample was highly educated, predominantly urban and primarily middle class or elite. Results: Infertility consultants were cited as the most useful source of information by 65% of respondents, 94% understood that infertility results from female factors, further knowledge of reproduction and infertility was expressed by 87%. Patients’ knowledge of the causes and treatment of infertility was extremely poor. Two key causes of infertility, advanced age and untreated sexually transmissible infections, were not named. Only 19% of patients had received written information.

**Educational Level & Occupation:** With respect to wife’s level of education, more than a quarter in the study group hold a bachelor’s degree (n = 30; 30.0%), followed by those who are high school graduates (n = 20; 20.0%), those who are intermediate school graduates (n = 13; 13.0%) and those who hold a diploma degree (n = 20; 20.0%) for each of them, those who are unable to read and write (n = 10; 10.0%), those who are primary school graduates (n = 5; 5.0%), and one who reads and writes (n = 2; 2.0%).

"show that the educational status, 3.6% had finished primary school, 31.8% had finished high school, 56.4% were University graduates and 8.2% were graduates of another school. no statistical significant differences between all groups in socio demographic characteristic.

14. This study was conducted in April 2012 among obstetricians and gynecologists. How do Egyptian gynecologists manage infertility? Cross-sectional study (66.3%) of the participants had a master’s degree or diploma and 33.7% had a medical degree (MD) or doctorate (PhD). Both groups were matched regarding age, gender, and work affiliation significant differences were identified between clinicians with Master degree/ Diploma and those with higher degrees (MD or PhD) with regard to knowledge as well as management options of different causes of infertility.

15. present the demographic and study data of the subjects showed that the majority of the subjects was low levels of education such as illiterate, read and write, primary and intermediate schools, high significant differences were found between all groups (p= 0.006). Also they found in their study that mother’s occupation (housewives) present highest percentages for all groups (87.5%) (80%) respectively. There were no statistical significant differences between all groups in socio demographic characteristic.

Regarding wife’s occupation, most in the study group are housewives (n = 64; 64.0%), followed by those who are freelancers (n = 22; 22.0%), and those who are governmental employees (n = 10; 10.0%).

Concerning husband’s level of education, more than a quarter in the study group are high school graduates (n = 26; 26.0%), followed by those who hold a bachelor’s degree (n = 24; 24.0%), those who hold a diploma degree (n = 11; 11.0%), those who are unable to read and write (n = 11; 11.0%) and those who are intermediate school graduates (n = 11; 11.0%), and those reads and writes (n = 9; 9.0%) and those who are primary school graduates (n = 8; 8.0%).

Concerning consanguinity, the majority in the study group reported that there a second-degree consanguinity (n = 86; 86.0%), followed by first-degree consanguinity (n = 11; 11.0%), and third-degree consanguinity (n = 3; 3.0).

**Distribution of study sample according to Reproductive Profile:** Wives’ age on marriage, the mean age for wives in the study group is 22.88 ± 5.66; less than a half got married on the age between 20-26-years-old (n = 48; 48.0%), followed by those who got married on the age between 13-19-years-old (n = 31; 31.0%), and those who got married on the age between 27-33-years-old (n = 21; 21.0%).

2. Age at marriage for female (18.0%) sexual experience at age 15-20 years compare to (22.0%) females who got married on the age between 21-26 years. (10%) females who got married on the age between age between 27 -32 years. No statistical significant differences were found between all groups.

**Duration of marriage,** the duration mean for couples in the study group is 7.8 ± 3.44; a half got married for 6-9 years ago (n = 49; 49.0%), followed by those who got married for 10-13 years ago (n = 30; 30.0%), and those who got married for 2-5 years ago (n = 21; 21.0%).
Conclusion

The study concluded that the women’s knowledge about adverse effects of IVF and assisted reproduction were few have been improved through the study.

The Impact of Science Knowledge and Program for Developing the Predictive Skill

Ameer Abdulhussein Jameel Shaban¹, Mushrig Mahammad Mujweal¹, Asaad Mohamed Ali ALNajjar¹
¹College of Basic Education, Babylon University, Iraq

ABSTRACT

The study was conducted in Iraq and aims to define the effect of the strategy of predicting the correct answer in the collection of Arabic grammar among the students of the first-grade intermediate. The researcher followed the experimental method as the appropriate method for the current research. The research community was the middle schools for boys in Hilla city center in Babylon province. A middle school chose 78 students, 40 students for the experimental group and 38 students for the control group. The research tool was an achievement test for Arabic grammar. The research experiment was carried out by the researcher himself for a full semester of the academic year 2018-2019. The researcher used the SPSS statistical method to use the T-test, chi-square, and Pearson correlation in the study procedures and to reach the results. The results showed that the experimental group was superior to the control group. The researcher had produced a set of conclusions, recommendations, and proposals that had complement the current study.

Keywords: Impact, development the Skills of Students

Introduction

The sons of the Arabic language in this time do not have them what helps them to read sound or accurate writing or visual expression has become a mistake written by verbal errors, grammatical, grammatical, linguistic and spelling problem students suffer in the possession of the skill of writing sound without subject to the laws of correct writing in the language of our students complain crisis At the same time, the language of the language has become sober, that it has become problematic, which is reflected every day in the level of rhetoric ⁴. There are those who say that the Arabic Language is difficult and that dealing with it is difficult and that its rules are not affordable and that its communication is not understood and the answer to this is simple ⁵. The defect is not in the Arabic language itself, nor in its rules, its meaning and its rhetoric, and not in anything related to language ⁶. Grammar rules have become subjects and sciences that alienate students from them. Grammar rules are difficult because of the complexities that have been developed by the authors in advance, and rely on the development and the budget and the infractions and division and the rules taught in schools do not achieve the goals of career in the lives of learners and the phenomenon of conservation The rule cannot be applied by the learner in his daily life, and this is far from the purpose for which the grammatical rules have been laid ⁴. The impact of education on the life of societies, nations and peoples is the foundation of their social, cultural, economic and political development and their basic means of survival and continuity and facing the challenges and developments that face them and represent a major part of the global strategies, no less important than health and defense if not the basis of progress. It monitors the funds and sets plans for the near, medium and long term and prepares the human cadres crisis and works well to organize and develop them ⁵. In order for educational institutions to achieve their objectives, they must rely on curricula when they are successful. The curriculum in the educational field is a system that is interrelated with all its components so that the vocabulary in the curriculum cannot be separated by teaching, activity, means or tests ⁶. And that the success of education is linked to the success of the method because the good way to deal with much of the development of the curriculum, and the weaknesses of the learner and the difficulty of the...
curriculum and can contribute significantly to stimulate the learner’s motivation towards the material and the substance of the subject to learners. It is to identify the “impact of the strategy of predicting the correct answer in the achievement of Arabic grammar language among the students at the first intermediate”

To investigate the aim, the researcher put the following null hypotheses: There was no statistically significant difference at the level of (05.0) between the average achievement of students in the experimental group who study Arabic grammar language with a correct answer predicting strategy and the average score of students in the control group who study Arabic grammar in the traditional way. This is the result of the teacher in the behavior of the students of the first grade intermediate in the course of applying his experience of the research sample or object already achieved, which leads to achieving the goal.

Strategy: Hiella defined it as (A set of rules involving means that lead to a certain goal, it is a plan directed towards a particular goal).

Procedural definition: A set of measures, methods, and practices that the researcher adopts in teaching the students of the experimental group the subjects of rules that have been set in advance to enable them to acquire the planned educational experiences and achieve the goals set by them.

Predicate the correct answer: Predicating the correct answer is one of mind-based mental strategies and anticipating the correct answer based on what the learner has of prior knowledge. It is a mental strategy that aims to stimulate the mind of the learner to reach the answer to the question at hand.

Achievement:

A. In linguistics: Achievement of everything is what remains and is proven and gone, and everything else is obtained, and the thing gets earned, and the achievement of the distinction takes place and the name proceeds and the thing gets achieved and proven. (Ibn Masur, article).

B. The term: Defined as worship that: “The level reached by the student in the collection of the subject matter”

Procedural Definition: It is the result of the students of the experimental and control groups (the research sample) of the degrees in the achievement test conducted by the researcher for the purposes of the research, which is the subject of the topics they study during the duration of the experiment.

Fifth: Arabic Grammar:

A. In linguistics: Rule: The origin of the rule, the basic rules, the rules of the house and the foundation, and the download ((And Abraham raises the rules of the house and Ismail 000)) (Baqarah/148).

B. (Khatib) as: “A general term that accommodates the rules of Arabic and its rules, all the rules of the vote, the writing, the drainage, the grammar, the eloquence, and the significance.” (Al-Khatib: 2009, 293).

Procedural definition: It is a set of grammatical and grammatical rules that are included in the subjects studied by the experimental group and the control group (the research sample) during the duration of the experiment.

First intermediate: It is the first the intermediate stage, as the duration of study in the intermediate stage three years, knowing that this stage comes after the primary stage and precedes the preparatory stage.

The researcher did not find any previous study on the independent variable (predicate of the correct answer). The dependent variable (students’ achievement in Arabic grammar language)

Othman study 1995: The effect of cooperative learning on the achievement of ninth grade students in Arabic grammar; This study was conducted at Yarmouk University, Faculty of Education, Jordan; The aim of the study is to identify the effect of cooperative learning methods in the achievement of the ninth grade students in Arabic grammar.

To achieve the study aim, the researcher put the following null hypotheses: There was no statistically significant difference at the level of significance (0.05) between the average achievement of students who study Arabic grammar in a cooperative manner and the average achievement of students who study Arabic grammar in the usual way.

In this study, the researcher did not mention the experimental design and merely indicated that he had followed the experimental and post-test methods.
The sample consisted of (12) departments, the number of students (331) students from (6) schools in the Directorate of Education in the Bani Kenana in Jordan for the academic year 1994-1995. (6) Experimental people taught according to the method of cooperative learning and (6) the people of the officer taught in the usual way, divided the experimental people into small groups of each group of (4-6) students and learning strategy together. The researcher was rewarded between the groups (experimental and control) in terms of tribal achievement and social and economic variables.

Methodology
The experimental approach is followed to achieve the aim of the study because it is an appropriate method for the procedures of searching and reaching the results. The experimental term is intended to change something and observe the effect of the change in something else. Intent on the situation within specific conditions, and follows the change that may result from these conditions.9

Research Community: Middle schools in Hilla city center in Babylon province Middle schools located in Babil province

Research Sample: A sample is students at first intermediate school in the center of Babylon province.

Fourth: The equivalence of the two research groups: in terms of
1. The student’s age is calculated in months.
2. Educational achievement of parents.
3. Educational achievement of mothers.
5. Grades of Arabic grammar in the half-year test for the current year 2018-2019.
6. The marks of testing the previous information in Arabic grammar language.

Fifth: Control of external variables:
1. Experimental and incident conditions.
2. Experimental extinction.
3. Processes related to maturity.
4. Differences in the selection of the two groups (statistical regression).

Sixth: study requirements:
1. Determining the educational material.
2. Formulation of behavioral objective.
3. Preparation of the lesson plan.

Seventh: instrument of study: Achievement test is structured method which determine the level of learner’s achievement of information and skills in a previously learned subject, from the learner’s answers to a sample of questions or paragraphs representing the academic content.10

The test may pass the stage of construction steps, notably:
1. Preparing the specifications table.
2. Determine the type of test item.
3. Formulation of test item.
4. Validity of test is the test that measures what has been prepared to measure it.”
5. The pilot study of the test of achievement.
6. Statistical analysis of test item. It includes:
   A. The difficulty of test item.
   B. Calculation of the distinction of test item.
   C. The effectiveness of the wrong alternatives.
   D. Stability of the test: It is intended to “give the test the same results if it is applied to the individuals themselves in the same circumstances”

Eighth: Application of the experiment: The experiment was implemented in the academic year 2018-2019 and for a period of a full semester and applied the same researcher experience.

Ninth: Statistical Means: The researcher adopted the following statistical means in the research procedures and access to the results
1. TEST for two independent samples
2. Chi-square for independence.
3. Pearson correlation coefficient

Results and Discussion

This chapter includes the review and interpretation of the results, and the conclusions, recommendations, and proposals. The results of the null hypothesis: The hypothesis stated that (There is no statistical difference at the level of (0.05) between the average achievement of students in the experimental group who study the Arabic grammar by the strategy of expecting the correct answer and the average grades of students in the control group who study Article Arabic grammar in the traditional way). To verify the validity of this hypothesis, the researcher calculated the arithmetic mean, variance and T value for both experimental and control groups, as shown in table 1.

Table 1: Calculation the arithmetic mean, variance and T value for both experimental and control groups

<table>
<thead>
<tr>
<th>Group</th>
<th>Sample size</th>
<th>SMA</th>
<th>Standard deviation</th>
<th>T value</th>
<th>Statistical significance at Level (0.05)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Experimental</td>
<td>40</td>
<td>26.3</td>
<td>11.77</td>
<td>3.71</td>
<td>Calculated: 3.71 Tabular: 2</td>
</tr>
<tr>
<td>Control</td>
<td>38</td>
<td>23.03</td>
<td>8</td>
<td></td>
<td>significance</td>
</tr>
</tbody>
</table>

Table (1) above shows that the experimental mean of the experimental group’s students is 26.28, while the mean of the students in the control group is 23.03 and the calculated T is 3.71, which is greater than the T (2) at the degree of freedom (76) and the level of significance (0.05), which means that there are differences of statistical significance for the benefit of the experimental group in the achievement test, thus rejecting the first zero hypothesis.

Interpretation of the results:

1. The results showed rejection of the null hypothesis and acceptance of the alternative hypothesis. This means that there is a statistically significant difference between the two research groups in the achievement of the students in favor of the experimental group. The researcher finds that this difference is due to the efficiency and effect of the strategy of predicting the correct answer, by teaching this strategy, students are accustomed to following steps that require them to think by looking for the right answers that are appropriate for the subject.

2. The researcher believes that the students exceeded the achievement in the experimental group that the strategy of predicting the correct answer gives a large capacity in thinking and skills to answer the questions studied by students, which contributed to the increase in achievement. In light of the research results, the researcher concluded the following: Teaching Arabic grammar with the strategy of predicting the right answer develops the reasoning skills of middle school students. The level of achievement improved among students who study the strategy to expect the correct answer in the middle stage.

Conclusion

The researcher used the SPSS statistical method to use the T-test, chi-square, and Pearson correlation in the study procedures and to reach the results. The results showed that the experimental group was superior to the control group. The researcher had produced a set of conclusions, recommendations, and proposals that had complement the current study.

The Impact of Reading Strategy Knowledge and Science Knowledge on Developing Reading Skills of School Students

Rana Kadhim Rahoomi1, Sabeeha Hamza Dehham1, Muhataram Abid Al-Wahid1

1College of Basic Education, University of Babylon, Iraq

ABSTRACT

The samples of the study were randomly selected from the second intermediate school students. The study adopted a pretest treatment-post-test design. The first hypothesis was accepted and was concluded that picture strip story activity was better than the recommended teaching in both the overall achievement and reading comprehension items. Both English teachers and students need to improve and to master the four important language skills, i.e. listening, speaking, reading, and writing. Reading is one of the four language skills required when the students learn the target. The presented study aims at investigating the effects of picture strip story on reading comprehension of Iraqi EFL students. The study uses quantitative research method. By reading texts which is categorized as a receptive skill, the students are able to get a lot of information.

Keywords: Picture Strips, developing, Reading Skills.

Introduction

Reading comprehension (RC), basically, contains a variety of cognitive strategies that can facilitate learners’ comprehension (e.g., posing questions about the text, monitoring one’s comprehension, summarizing and activating one’s background knowledge)1. RC skills, together with other linguistic skills, are supposed to be improved by the syllabus adopted in Iraqi schools by the Ministry of Education. For that purpose, plenty of reading passages are given; yet many students experience comprehension problems. They show little sign of developing these skills when finishing their intermediate school study. According to Wigfield and Lutz, reading comprehension is the process that includes elicitation and building meaning from texts. Most of reading investigators now assume that comprehension implies active construction of meaning rather than passive receiving of information from a text.1. A Strip Story technique is a story which has been separated into smaller segments from beginning to end.2 These story segments do not have to contain much or many text at all in fact, a strip story could consist entirely of pictures similar to what one would find in a comic book. A picture strip story is divided into separate picture. One picture is handed to each member of group. Without seeing each other picture, the learner in group must decide on original sequence and reconstruct the story.3 This activity gives a fun and provides a useful way of introducing new texts and/or new vocabulary and grammatical items. There are several parts to a Strip Story activity including pre-, during, and post-reading activities. This is not purely a reading activity however, and there are several supplemental activities that can be done to enhance a Strip Story which will lead students having a greater command of the vocabulary, as well as improving their reading, writing, and oral skill. Previous studies exploring the impact of clickers on the process of learning are talked about with a particular ultimate objective and that is to decide how students and instructors have reacted to the use of new procedures and strategies in their standard teaching designs. A couple of studies proposed that picture strip story enhance understudies’ outcomes, for instance, tests marks, succeeding rates, learners’ observation and perception, and furthermore, that students appear to like picture strip story. The First research was conducted by Wulandari (2004), this thesis is The Use of Picture To Improve The Students’ Speaking Ability. The similarity
of the research with this research is; (1) the researchers use pictures. The differences of the research are; (1) this thesis uses picture without a story to emphasize student ability, (2) the place of the study is different.4 The English language is viewed as the most broadly utilized language on the planet. It is used in both the social life and business savvy. Its use is building up every day by occupying more prominent roles of our lives. The mastery of English requires good teachers and dynamic pupils who are eager to collaborate to grow their ability and enhance their capability. There are various factors that could discourage language learning which Iraqi understudies experience.5

The basic premise of English for Iraq course is that primary school pupils learn English for the purpose of communication. “The process of communication requires a clear and explicit focus on the actual development of all four skills: listening, speaking, reading and writing”.6 The researcher found that through her modest experiences as a teacher the students have difficulties to comprehend the transcript when they read the story, from this point the researcher tries to identify some subskills such as skimming, scanning, and intensive reading) to treat them through Story. Picture Strip Technique is supposed to reinforce the ability of the students to comprehend the meaning of words, sentences, general meaning, and events through pictures. Pupils face difficulties in making prediction while reading these texts without picture strip story. Also, only very few of them could draw conclusions about the events, characters and setting. These findings are discouraging; therefore, such texts require explicit technique to enhance comprehension.

Methodology

This section includes a presentation of the procedures used to achieve the objectives of the study, starting from selecting the population and samples, neutralizing the variables of both samples, designing the instruments and tools of the study, conducting the experiment and analyzing data and the results.

Experimental Research Design: The experimental design includes one independent variable (picture strip) and a dependent variable (reading comprehension), thus the experimental design was adopted on two equivalent groups one experimental and the other is controlled.

Sample of the Study: The sample of the presented study is represented by the second-grade intermediate school students in the province of Babylon for the educational year (2018-2019). Al Huda intermediate school which lies at the heart of the province was chosen to sample both the control and the experimental groups. We randomly selected class (A, 37 students) to represent the experimental group that received picture strip story based instruction and class (B, 39 students) to represent the control group which was taught by conventional method of teaching.

Samples Equivalence: The researcher conducted a statistical equivalence between the experimental and control sets in some variables that could affect the results of the experiment. The researcher has chosen the two groups randomly, the students of the research sample from similar social and economic status and study in the same school. These variables are: age measured by months, first course scores, and parents academic achievement.7

The statistical results demonstrated that the two sets were equivalent in all the aforementioned variables.

Extraneous Variables: Despite the fact that the researcher verified the equivalence of the two sets of research in some variables that are believed to affect the course of the experiment, she also tried to avoid the effect of some extraneous variables in the course of the experiment. Some of these variables and how to control them are as follows:

1- Accidents associated with the experiment. There were no accidents during the execution of the experiment. No students left the school or got transported to another one. The sample was chosen intentionally and the two sets were equalized accordingly.

2- The maturity factor: Since the duration of the experiment was unified between the two research groups As well as the age of the students in the two groups so all the growth that occurred will be unified between all the students because they are on the same level. So, this factor did not have an impact on the research.

3- the impact of experimental procedures: the researcher worked on reducing the impact of experimental procedures that can affect the dependent variable during the course of the experiment.8

Preparing the Material: The teaching materials that were used for conducting the experiment were represented by the ”English for Iraq”- syllabus and the
content that was taught during the second semester of the academic year (2018-2019) (Unit 5- Unit 8). The researcher set a number of behavioral objectives to be expected from the test sample. As for the lesson plans, the researcher prepared a total of (30) lesson plan for each tested group based on the second intermediate grade book –“English for Iraq”.

Research Instruments

The Performance Test: It is defined as the assessment of the knowledge of an individual in a particular area content area, skill or accomplishment in a particular curriculum, time frame, and material. They can also help in diagnosing the level of students and what they need to develop and work on (Brown.2003).

The performance test was constructed by following these steps:

1. The purpose of the test: the desire of constructing the test was to measure students’ reading skill aptitude in the English language by depending on the behavioral objectives specified by the teachers’ guide.

2. Determining test items: the test items were determined by the researcher to be 25 test items and prepared a scoring scheme for the test.

3. The test was designed by depending on the revised Bloom’s Taxonomy of educational objectives.

Pilot Test: The researcher chose the students of two schools that are located near the main school on which the experiment was conducted. The two schools were Babylon intermediate school and Al-Rahman. Fifty student from each school for the pilot test. The test items were statistically analyzed and found that the item difficulty ranged from (0.76- 0.31) by which the test items were considered valid as regards the level of difficulty. The item discrimination ranged from (0.82-0.33) which is also accepted.

Conducting the main test

The Pre-test Final Administration: Both the experimental and control groups were pre-tested on the 20th of February 2019. This pre-test aimed at comparing the scores of the students’ achievement in the pre-test with those in the post-test.

The Post-test: Students of both groups (the experimental and control ones) were post-tested on the 20th of April 2019. The same pre-test procedures were followed in conducting the post-test, namely scoring scheme, validity, pilot study, item difficulty, item discrimination, and reliability. It is worth mentioning that the post-test was also approved by a jury of fifteen specialists in linguistics and TEFL methodology.

Results and Discussion

The students of the experimental group who studied according to the picture strip story had a better comprehension language (English) in the performance test to the control group, who studied according to the guided method. Thus, the first null hypothesis is rejected and the alternative null hypothesis is accepted: (There is a statistically significant difference at the level of 0.7) and the average score of students in the control group). Roschelle confirmed that the superiority of the experimental group which studied according to picture strip story to the control group, which was taught according to the recommended way.9

Conclusion

The samples of the study were randomly selected from the second intermediate school students. The study adopted a pretest treatment- post-test design. The first hypothesis was accepted and was concluded that picture strip story activity was better than the recommended teaching in both the overall achievement and reading comprehension items.

Aluminum Chloride Administration Induced Behavioral and Physiological Changes in Adult Male Rats

Halla Abdul–Hadi CHabuk1, Hussein Jasim Al-Harbi2, Haider Kamil Zaidan Al-Saadi2

1College of Science, University of Babylon, Hilla, Iraq; 2Department of Scholarships and Cultural Relations, Ministry of Higher Education and Scientific Research, Baghdad, Iraq

ABSTRACT

Introduction: Aluminium chloride is a neurotoxic metal that induce several neurodegenerative diseases such as anxiety, depression and Alzheimer diseases. The aim of this study designed to investigate the effects of aluminium chloride on some behavioral and physiological parameters of male rats.

Material and Method: Twenty one male rats were used in this study and divided to three groups with seven rats for each group, included untreated control group received distilled water and two treated groups that received aluminium chloride at the doses 300 mg/kg and 400 mg/kg of body weight orally and daily for 60 days, the following behavioral parameters measured by using Elevated Plus – Maze test.

The Results: Administration two different dose of Al for eight weeks of rats in group II and group III causing significantly reduced in brain monoamine oxidase A and neurotransmitters levels (serotonin and dopamine), In addition, Al causing also significantly decreased in serum hormones (testosterone, corticosterone and LH) compared to control group I. The results showed significantly suppressed of the sexual behavior and memory disorders of rats that exposure to aluminium compared to control group. In conclusion, Aluminum enhances depression and anxiety parameters and cognitive disorders characterized by the affection of memory.

Keywords: Aluminum, Depression, Anxiety, Memory, Rat, serotonin, dopamine.

Introduction

Humans are exposed to heavy metals because their ubiquity in environment and wide use in industry and long-term persistence in the nature causing contaminated soil, air, food and water. therefore, the excessive amount of these pollutants such as (barium, cadmium, mercury, thallium, lead, Aluminium and boron) causing dangerous to most human body organ. Accumulation of metals produces damaging effects in the nervous and reproductive system. Aluminium (Al) is the most widely distributed metal in the nature. Al can reach circulation system and rapidly transferred to the brain across the blood brain barrier. The toxicity of Aluminium induce a wide range of behavioral, physiological and biochemical dysfunctions in lab animals and humans. Evidence suggests that the neurotoxic effects of aluminum may be mediated through impairment the brain neurotransmission system and alteration neurotransmitters may precede neurological, cognitive deficiency and neurobehavioral conditions such as Alzheimer’s disease when it enters the brain. Therefore, impairment of this system may be associated with the behavioral disturbances and enhances depression and anxiety by deficit in learning and memory observed in humans and animals however.

Material and Method

Experimental design: Twenty one male rats were used for this experiment, the ages of rats were between eight and ten weeks. The animals put in the cages and fed ad libitum and they were exposed to a 12 h light: 12 h dark cycle. Animals were divided into three groups each group contain seven rats.

- **Group 1:** Normal Control group, **Group 2:** (Aluminum treated group) rats were oral administered 300 mg/kg/day aluminum chloride for 60 days.
- **Group 3:** (Aluminum treated group) rats were oral administered 400 mg/kg/day aluminum chloride for 60 days. Blood samples and brain tissue were collected and stored in micro tubes.
at −20°C until analysis for serum hormones (testosterone, corticosterone and LH) and analysis neurotransmitters (serotonin, dopamine), monoamine oxidase A in brain by using particular ELISA kits.

**Behavioral Studies:** The behavioral tests were conducted after the end period of treatment for evaluate effect of aluminum on rats memory by Elevated Plus Maze test.

**Elevated Plus Maze test:** This test was made of wood consisted of two opposite enclosed (10 cm wide and 50 cm long) and two opposite arms open (10 cm wide and 50 cm long) by 40 cm high walls. Rats put in the end of the enclosed arms and the time (latency) was recorded to withdraw from the arm. After that this step was repeated two successive times at about 30 min of intervals between all attempts and the get out times from the closed arms were recorded for 5 min and called Inhibitory Avoidances (Inhibitory Avoidance 1, Inhibitory Avoidance 2). The Escape test was performed after the IAL 2 and it was represented by the time used for animal to withdraw from the open arms. For assess long-term memory tests (IAL3 and ESL2) measured again after 72 h. later.

**Sexual Behavior Testing:** Sexual behavior testing was performed in a test room. Female was introduced into the male in home cage and behavior tests were recorded for 10 min.

**Statistical Analysis:** All statistical analysis for serum hormones and brain neurotransmitters results represent a mean ± S.E. and behavior results represent a mean ± S.D. by using the one-way analysis of Variance (ANOVA) test with post hoc LSD test under a probability significant level (p< 0.05).

**Results**

**Physiological study:**

**Effect of aluminium chloride administration on brain of Neurotransmitters and Monoamine Oxidase A levels in rats:** The result were showed that levels of brain serotonin non–significantly different (p>0.05) in rats group II (277.24 ± 18.62), compared to control group (1296.39 ± 7.27), while it showed a significantly decreased (p<0.05) in rats group III (186.62 ± 9.48) compared to group II and control group I. Brain dopamine were showed a significantly decreased (p < 0.05) (469.15 ± 28.50) in rats group II compared to group I (763.21 ± 13.25) and group III. At the 400 mg/kg/day dose of aluminum group III recorded further a significantly decreased (p < 0.05) levels of dopamine (388.46 ± 32.61) when compared to both the control group I and the group II. On the contrary, brain monoamine oxidase level recorded non–significant different (0.584 ± 0.11) of rat group III compared to rats in group II (0.844 ± 0.15), there are significant decrease in brain monoamine oxidase levels in rats of group II and group III compared to control group I (1.644 ± 0.26).

**Effect of aluminium chloride administration on hormones levels in rats:** The testosterone, corticosterone and LH hormones levels were dramatically decreased with the increase of the aluminum chloride dose compared to control group I. Testosterone recorded a significant decrease (P<0.05) at the 300 and 400 mg/kg/day dose of aluminum chloride of rats group II and group III (8.54 ± 0.99, 2.73 ± 0.79 respectively) compared to control group I (21.95 ± 2.85). Whereas, corticosterone and LH hormones levels in serum showed non–significant decrease between group II and group III 11.53 ± 0.85, 9.78 ± 0.94 respectively for corticosterone and 1.58 ± 0.43, 0.82 ± 0.19 respectively for LH and these hormones were showed significant decrease (p< 0.05) of rats group II and group III when compared with control group I 17.72 ± 1.70, 3.39 ± 0.74 respectively.

**Behavioral study**

**Effect Aluminum on Memory measured by the Elevated Plus Maze (Test EPM):** The inhibitory avoidance latency (sec.) (IAL) and escape latency (sec.) (ESL) of the elevated plus maze test for 5 min. The IAL1 was significantly higher (P< 0.05) in intoxicated animals groups (228.79 ± 10.76) and (252.84 ± 13.70) respectively, compared to control group (87.23 ± 7.47), this rats stayed time (sec.) (IAL1) in enclosed arms were much longer compared to control. In the next attempt IAL2 after 30 min. the results showed a significant decrease in latencies (sec.) in the enclosed arms (162.64 ± 9.59) and (149.90 ± 15.85) respectively, by intoxicated rats when controls stayed there (288.05 ± 8.13). For the first escape 1 experience, rats joined to the closed arms of the apparatus within (sec.) (27.12 ± 6.75) for control group showed a significant decrease in latencies (sec.) compared to intoxicated animals groups (43.59 ± 9.19).
and (55.28 ± 8.45) respectively. The long-term memory tests 3 (IAL3) and (ESL2) were performed at three days (72 h) after avoidance 2 and escape 1 tests. The result showed highly a significant decrease in latencies IAL3 in the enclosed arms (67.23 ± 14.77) and (75.98 ± 11.12) respectively, by rats that exposure to Al compared to control group (184.19 ± 9.21) that showed a significant increase latencies. Whereas in escape 2 showed a significant increase latencies (73.23 ± 14.46) and (84.14 ± 12.44) by rats that exposure to Al compared to control groups (9.40 ± 2.22). when those of Al intoxicated group indicated an impairment in long-term memory process through a highly significant decrease in IAL3 compared to controls.

**Effect of oral aluminium chloride administration on sexual behavior test for 10 min. of rats:** The results showed a significant decrease in Sexual behavior of all parameters (latency of mounting, Intromissions (sec.) and number of mounting, intromissions, anogenital snifing of the female, nosing and Grooming of the female and self-grooming) in rats group that treated with aluminium compared to control group. Where observed also a significant decrease in latency of mounting, Intromissions (sec.) and number of anogenital snifing of the female, nosing and Grooming of the female in rats group II compared to group III. Whereas non- a significant in number of mounting, intromissions and self-grooming between group II and group III table (1).

### Discussion

Aluminum chloride is neurotoxic and its behavioral toxicity in experimental animals can be easily accumulates in the brain of human and animal, Aluminum is causing several neurodegenerative disorders such as Alzheimer’s disease (4,12). This result agreement with (3,13,14,15). The exposure to AlCl₃ produced also a significantly decreased in serotonin, dopamine and monoamine oxidase (A) enzyme, these agreement with (16,17,18,19). Aluminum may be causing an inhibitory effect on 5-HT due to the withdrawal of cholinergic input outcome in decreased levels of 5-HT in different regions or it can interfere with cellular energy status and bring about changes in cholinergic neurotransmitter and destruction of BBB function to cause dementia or other degenerative diseases. Another important resulting of the presence of Aluminium at the synapse could be the reduction of effective neurotransmitters concentrations with biological activity due to Aluminium binding to neurotransmitter molecules receptors (15). Aluminum may be impairs different enzymes that associated with neurotransmitters biosynthesis, Al is also act as non-competitive inhibitor for MAO-A enzyme (12). The decrease in dopamine levels may be due to increase in cerebral noradrenalin that showed in rats exposed to Al causing the activation of its synthetic pathway, particularly the step which involves the conversion of dopamine to noradrenalin via hydroxylation and explain the decreased level of dopamine (18). High Al concentrations cause oxidative stress is one of the major contributing factors to male brain disorders (20). Studies were found that accumulated heavy metals in the body alterations as plasma corticosterone, LH and testosterone hormones levels and these agreement with our results. In contrast, this result disagreement with (21) they showed increase in LH levels in rat that exposure to AL. Aluminum alteration in spermatogenesis as well as in steroidogenesis of rats with increasing of damage of testicular tissue and a disturbance in pituitary gonadotrophic activity that lead
to a significant adverse effect on the steroidogenesis and inhibit release of testosterone \(^{22}\). Exposure to AlCl\(_3\) lead to negative effects on rats behavior, increased anxiety rate \(^{23}\). Elevated Plus Maze test is behavioral task which reflects memory and learning abilities by measuring inhibitory avoidance (IAL) and escape. Rodents are keeping a vivid memory through measuring the time spent in the open arms during the test showed that Aluminium intoxicated animals presented differences in IAL compared to control animals. This Indicates to oral AI administrations of rodents lead to learning process failures and memory deficits \(^{10}\).

Physiological and Behavioral Changes of Male Rats Following Social Isolation Stress During Early-Adolescence and Fluoxetine Exposure

Halla Abdul–Hadi CHabuk1, Haider Kamil Zaidan Al-Saadi2, Hussein Jasim Al-Harbi1
1College of Science, University of Babylon, Hilla, Iraq; 2Department of scholarships and cultural Relations, Ministry of Higher Education and Scientific Research, Baghdad, Iraq

ABSTRACT

Stress experiences during youth lead to abnormal behavior profile in adulthood, including an increase in aggression, depression and anxiety disorders in humans. The animals during early- adolescent period (PD 35) were divided into the following groups: Group 1 - Control. Group II– social isolation stress for 42 days – Negative control. Group III – The animals were treated with 10 mg/kg of the fluoxetine for 21 days in combination with isolation stress for 21 days, all groups followed by behavioral studies, and assessed the biochemical effects of exposure to stress and stress with drug. The results showed there was significantly improvement in the open field test including significantly increased locomotor and exploratory activity with decreased anxiety and aggressive behavior after treatment with fluoxetine compared to stress group. The results were also noted significant increase in the levels of brain serotonin in stress with fluoxetine group compared to stress group, The results showed significantly decreased in levels of dopamine and monoamine oxidase A in brain tissue of rats treated with fluoxetine compared to stress group. While corticosterone, testosterone and LH levels in stress rats showed significantly increased compared to stress with fluoxetine group.

Keywords: Fluoxetine; isolation stress; Serotonin; Dopamine; Testosterone; Aggressive behavior

Introduction

In the modern environment, many peoples are exposed to different chronic stressful conditions. Exposure to stress triggers a cascade of hormonal and behavioral changes 1. However, the stress response is exaggerated a series of pathophysiological changes occur in the brain and immune system that may ultimately result in disease. Stress also alters brain neurotransmitters and enzymes responsible for metabolism of monoamine neurotransmitters such as Monoamine oxidase A2. Social stress is a common psychological stressor, especially during early and mid-adolescent (PD 21 – 34) rats 3, lead to increased rats behavior for anxiety and depression in adulthood and occur changes in neuron morphology, HPA axis, endocrine and neurotransmitters functions 4,6.

Antidepressants (Fluoxetine) are consider as efficient treatments for several psychiatric disorders including depression and anxiety disorder which specially inhibit neuronal reuptake of serotonin and correct chemical imbalances of neurotransmitters inside the brain4.
Preparation of fluoxetine hydrochloride solution: Each fluoxetine capsule containing 20 mg/kg was dissolved in distilled water to obtain on 10.0 mg/ml concentration and it was given daily to animals stress orally for three weeks.

Behavioral Study: For evaluate efficiency of Fluoxetine on social isolation stress of the rats by using the open field test

The open field test: This test provides measures of locomotion, exploration and anxiety, sizes of the open field box (70 x 70 cm with 30 cm walls), blue lines were drawn on the thick paper floor, these lines divided the floor into sixteen squares. In this test, rat was individually placed in one of the four corners of the box, then it allowed to explore for 5 minutes.

Aggressive behavior measured by (Resident-intruder test): In this model, One of the rats (intruders) are allowed to establish a territory (the resident) in its home cage, another animal is placed into the residents’ home cage and two animals are allowed to interact with each other for 10 minutes.

Statistical Analysis: All statistical analysis for results represent a mean ± S.E.M. and behavior results represent a mean ± S.D. by using the one-way analysis of Variance (ANOVA) test with post hoc LSD test by using IBM SPSS Statistic software version (23) under a significant level (p<0.05).

Results

Physiological study:

Effect of isolation stress and isolation stress with Fluoxetine treatment on Neurotransmitters and Monoamine Oxidase A levels in brain of rats: The results were showed a significant decreased (p<0.05) in brain serotonin level (152.48 ± 11.88) and a significant increase in dopamine level (873.71 ± 64.51) in rats group II compare to control group I (281.00 ± 20.73, 703.44 ± 42.52 respectively) and group III(317.86 ± 23.16, 589.16 ± 36.08 respectively).

Effect of isolation stress and isolation stress with Fluoxetine treatment on Corticosterone, Testosterone and LH hormones levels in serum of adult rats: A significant increase (p<0.05) of corticosterone and testosterone levels in serum (45.94 ± 4.71, 32.98 ± 2.43 respectively) in rats of stress group II compared to group III (23.27 ± 1.86, 4.99 ± 0.83 respectively) and control group I (24.60 ± 1.77, 19.32 ± 1.68 respectively). Rats in the group III were showed a significant decrease in testosterone level compared to control group I and group II. The results showed also a significant decrease in corticosterone level in group III compared to group II and did not show significant(p>0.05) in corticosterone level in group III compared to group I. on the other hand rats of the group II did not show significant(p>0.05) in serum LH level (1.29 ± 0.14) compared to control group I (1.39 ± 0.33). While in stress with Fluoxetine group III showed a significant decrease serum LH level (0.70 ± 0.17) compare to stress group II and control group I

Behavioral study:

Behavioral Changes of male rat that exposure to isolation stress following Fluoxetine treatment: For assessment the efficiency and effectiveness of the Fluoxetine treatment on the behavioral activity of male rat that exposure to isolation stress by using the open field test.
III in the central square (sec) were showed significant increase in duration (sec) compared to stress group II. Whereas. There was not significant between group I and group III. Furthermore, the time spent rats of group II in the Peripheral square (sec) showed significant increase in duration (sec) compared to group and group III and there was not significant between group I and group III, table (1).

Stress has a wide range of affects behavior. These effects differ by gender and age and also affects endocrine function, brain chemically and physiologically function. Social isolation is enhance to the effects of social defeat stress. post- weaning isolation for 6 weeks from postnatal day (PD 35) has dangerous consequences for brain development, causing alterations in neurotransmission and behavioral abnormalities (aggression, anxiety and depression) in rodents (9, 10). One of the major mechanisms of adaptation to stress is activation of the hypothalamic-pituitary-adrenal system and increased stress hormones secretion, especially, corticosterone which regulate biochemical and physiological processes in the body, On the other hand, the increase level of corticosterone causing by prolonged stress leads to negative results effect on morphological and functional brain regions 11. Several studies have showed that chronic stress during adolescence results in a dysfunctional serotonin and dopamine system., social isolation of rats lead to activates the HPA axis which causes imbalances in 5-HT turnover in rats, decreases the number of 5-HT neurons because of stress and glucocorticoids modulate the serotonin system in the brain 12. This results showed increase in MAO-A enzyme levels in stress group because of Corticosterone is an important regulator of MAO-A expression and activity. During stress, increased brain MAO activity.
due to increased glucocorticoids and decreased brain levels of serotonin. Whereas administration of fluoxetine after chronic social stress developed showed decrease serum levels of Corticosterone, Testosterone, LH and caused remarkable increases Serotonin levels in brain this result disagreement with because of the action of Fluoxetine is preventing neurotransmitter reuptake like serotonin by neuron after it released by inhibit the serotonin transporter protein lead to increase in the extra-synaptic (extracellular) levels of serotonin that stimulates nerve cells in the brain. The secondary mechanisms of the antidepressant therapy are blocked monoamine oxidase activity in mitochondrial brain tissue that degrades monoamine neurotransmitters. This result showed increased in serum testosterone levels. may be due to catecholamines activation that consider as one of the major mechanisms that stimulate secretion of testosteron during stress or may be due to 5-HT can modulate GnIH neuronal activity following post-weaning social isolation. On the other hand, Some experiments showed an increase in testosterone level during stress without altering LH values in both humans and rodents. FLX-treated rats showed lower levels of behavioral despair when exposed to open field test, these results agreement with. Rats that exposure to isolation stress showed increased in aggressive behavior compared to the control group I and stress with FLX may be due to altered DA and 5-HT levels in the prefrontal cortex, low 5-HT level and high testosterone/cortisol (T/CRT) ratio acts on facilitates aggression.

Conclusion

The results were also noted significant increase in the levels of brain serotonin in stress with fluoxetine group compared to stress group. The results showed significantly decreased in levels of dopamine and monoamine oxidase A in brain tissue of rats treated with fluoxetine compared to stress group. While corticosterone, testosterone and LH levels in stress rats showed significantly increased compared to stress with fluoxetine group.

Effect of Competitive Exercises and Hospitalization with Salt Lipson to Develop Performance Tolerance and Some Biochemical Variables for Young Handball Players

Baha Mohammed Taqi Al-Musawi¹, Ali Basim Al-Fadhli²
¹Asst. Prof., ²Asst.Lecturer, College of Physical Education and Sports Science, Wasit University, Iraq

ABSTRACT

The study aimed to prepare competitive exercises with Hospitalization In the water medium with the salts of the Lipson to develop the performance tolerance and the concentration of lactic acid, magnesium and serotonin in the blood and identify the differences In the measurements of pre and post-tests performance tolerance and the concentration of lactic acid and magnesium and serotonin in the blood of young handball players. The researcher conducted his study on the players of the Wasit province youth handball team, where the number (14) players were selected (6) players The tests used in the research were measured by the ratio of the variables (manganese and serotonin) in the blood and the researcher used a measure of the concentration of lactic acid manually type (Lactate Pro 2) at rest time as well as after effort (Walk test). After (5 days) of the walking test (for Cunningham and Folkens) and concluded that the competitive exercises applied to the sample research contributed to the development of bearing performance, found that hospitalization water medium with Lipson salt has a positive effect on the variants (lactic acid, manganese and serotonin) resulting in improvement the functional status of the players.

Keywords: Salt Lipson, performance tolerance, biochemical variables

Introduction

The level of performance in handball depends mainly on the training and physiological factor, where these factors come first to influence the physical and skill level in the handball game ¹, all closely related to the training process and its vocabulary through which adaptation occurs to the body’s vital organs. Almost all sport activities and events are of great importance for the development of the level of achievement during training and competition through the ability of the individual to perform physical duties and skill as well as the schematic ². Due to the lack of consistency in the performance of the handball game, the player’s performance and movements vary according to the game’s position and change So the player becomes more important to meet these requirements through Great physical effort to increase its physical and technical ability through the use of various competitive exercises which is working ³ to develop the performance, where competitive exercises are the main means to develop the physical requirements of the handball player in addition to the quality of competitive exercises and formations. Those efforts or training stimuli, And athletes are naturally tired after physical exertion the higher the fatigue level, the greater the side effects after training It appears that in contemporary training trainers must work to find ways and means to ensure that athletes overcome the limiting factors of training as much as possible and also help them to achieve continuous achievement ⁴-⁶. The most effective way to achieve such goals is to use different recovery methods.

Methodology

The researcher used the experimental method of one experimental group for pre- and post-tests for the nature of the research.

Society and sample research: The researcher’s task is to identify the research community and its vocabulary. The researcher conducted his study on the players of the Wasit governorate, where the number of players was (14) players and (6) players were selected in a deliberate manner representing the sample of the research. Variables with effect on the results of the study as shown in Table (1).

**Means, tools and devices used in research:**
- Arab and foreign sources.
- The Internet
- The exams
- Handball field
- Hand balls number 15
- Diagnosing number 15
- Medical balls 4
- Stopwatch number 2
- Lactate Pro 2 (Japan)
- Laptop (Lenovo) Chinese origin.
- American Treadmill.
- Medical injection, gel tube, Chinese capsule and box to save blood samples.
- Centrifuge, Universal 16A, Germany for sealing.
- Different grades for measuring (manganese and serotonin).
- Cobas e411 Roche.
- Cobas c111 Roche.

**Tests used in research:** Walking test (for Cunningham and Folkens) this test requires that the laboratory run at full speed on the treadmill at a 20% angle and at 8 mph, and record the working time until fatigue. This test may also include a specific concentration of lactic acid in the venous blood at the fifth and twelfth minutes after work.

**Measurement of lactic acid in the blood:** The researcher used a device to measure the concentration of lactic acid (Lactate Pro 2) is the second generation at the time of rest and also after the effort (5 minutes) of blood «being suitable to ensure the transfer of lactic acid from muscle to blood». The measurement method was chosen by selecting one of the fingers of the hand to be pricked and showing the first drop of blood and then wipe it after the emergence of a drop of blood a second time is placed on the measurement tape connected to the device to draw blood towards the tape and then show the result of measuring the proportion of lactic acid in (15) seconds.

**Measurement of research variables (manganese and serotonin):** After the withdrawal of blood from the research sample and put it in special tubules (gel Tube), after which the separation of the serums by the centrifuge because the measurement of variables (and manganese and serotonin) depends on the blood serum where it is by placing a certain amount of the serum on the relevant pieces to give the final result of Through the device used (Cobas).

**Exploratory experiment:** The researcher carried out the exploratory experiment on (25/6/2017) at 5:00 pm in the stadium of the College of Physical Education and Sports Sciences. The purpose of the exploratory experiment was as follows:
- Fit the exercises set for the research sample.
- Identify some of the obstacles or difficulties that may face work during the exercise of exercises.
- Determine the maximum time for each exercise.
- Know the rate of pulse during the time of rest (recovery time) between the frequencies and the time of rest between groups.

**Field research procedures**

**Pre-tests:** The tests were carried out by intravenous blood withdrawal (5cc) to measure the variables (manganese and serotonin) and then the walking test to measure the concentration of lactic acid in the blood and then give the convenience and implementation of performance test on (30/6/2017) 5 p.m. at the Handball Stadium Faculty of Physical Education and Sports Sciences.
Competitive exercises: The competitive exercises were started on Saturday (2/7/2017) in the stadiums of the Faculty of Physical Education and Sports Sciences.

The vocabulary of competitive exercises was as follows:

This period was characterized by the use of competitive exercises suitable to the nature of the game, characterized by repeated performance and continuity as well as the component of diversification so that the continuation of periods of unity without boredom and gradually allows to benefit from these exercises.

1. The researcher used high-intensity fetal pregnancy, and requires the formation of a good pregnancy test predetermined the intensity of the exercise and the number of times or exercise time and the number of groups and the rest period and the number of weekly training.

2. The use of tools lists - hand balls - the figures in the exercises and others of the exercises without handballs.

3. Rotation and diversification in the exercise different muscle groups

4. Using the element of competition between two people or more in one exercise, which increases the thrill.

5. Use exercises in half the pitch and length of the stadium and in the goal area to become aerobic competitive exercises to develop the ability of players.

6. Competitive exercises were included in the main part of the training dose, which was between 30 minutes and 45 minutes.

7. The intensity of the exercises used were (80-90%) of the best achievement of the player and the fact that the intensity of appropriate fit with the period of special endurance.

Statistical Means: The data obtained by the researcher were processed using the SPSS program where the following statistical methods were extracted.

1. The arithmetic mean
2. Standard Deviation
3. T test for interrelated samples
4. Coefficient of variation and coefficient of torsion

Degree of freedom (6-1) = 5 below confidence level (0.05).

The results showed a positive effect on the development of performance. The researcher attributed this development to the nature of the various competitive exercises that developed the performance of the performance. The exercises were of a physical and skilled nature and this requires the performance of the handball game. The correct order and quality of exercises through Involve all muscle groups needed by a ball player as well as (temporary training) to develop the performance of the performance, including the rest periods as well as
the intensity and size of loads used to match the nature of the game, as well as the work of muscle groups, which ensures the development of players under a certain level without stress on the player’s physical ability and access to exhaustion, but was working within a certain level of fatigue, which showed the results on the development of carrying the performance required by handball player. The nature and quality of the exercises that were applied were suitable for the sample of the research, especially its intensity and diversity, the difference in its distances and frequencies, as well as the element of competition and suspense, so that they are close to the requirements of the game of handball through the use of balls or without balls and the presence of scoring or handling short, medium or long or exchange sites or moves In the field of handball, which contributed to the harmony of players and away from boredom because of the nature of the various competitive exercises that contributed to the activity of players, The performance in ball games requires an increase in the anaerobic ability of the body. The more the nature of the game requires the speed of the moves in the stadium, the more the body is equipped with the anaerobic power system. Therefore, the player cannot continue to perform very efficiently all the time. Players in the game and to achieve access to high levels in such games, along with the development of anaerobic ability must pay attention to the development of the aerobic ability of the player must also develop general endurance for games that need to develop the element of strength, speed Fitness and private endurance. One of the basic principles for the development of a performance component through the concept of modern sports training is to repeat the performance of the largest possible number and with appropriate and incomplete rest periods. This is what the researcher did so that the exercises were consistent with the nature of the sample in addition to maintaining the rate of performance during the continuation and the number of exercises During the course of the training unit and the difference, as well as the number of training sessions during the one week, which does not exceed three units with a period of hospitalization between them, which have achieved positive results on the development of performance of the performance of the research sample. The lactic acid system relies on the construction of aerobic ATP by the process of anaerobic glycolysis, where the sugar is broken in the absence of oxygen, which leads to the formation of lactic acid in the muscle and blood, which in turn leads to muscle fatigue when increased. The action requires anaerobic muscle action, which increases the accumulation of lactic acid in the muscle as a result of the anaerobic synthesis, which leads to fatigue and slow performance of the player and low abilities. Abu Alaa and Shaalan (1994) mentioned that with the continued development of anaerobic endurance of the player improves the ability of muscles to tolerate lactic acid as follows:

1. Reduce the rate of the accumulation of lactic acid by reducing the rate of production in the muscles with an increased rate of disposal in the same muscles.

2. Increase the ability of the muscle to bear the pain caused by the accumulation of lactic acid and maintains a high level of speed of motor performance.

The researcher attributed the change in the measurement of the ratio of manganese to hospitalization in the water medium, which contains the esophagus salt after exercise, which increases the feeling of rest and relaxation. Although magnesium can be absorbed through the digestive system, through many foods, drugs and medical materials, but salt bath Epsom Is one of the most effective means of making magnesium penetrate the body of an athlete easily, “Epsom salt, or magnesium sulfate, is a commonly used product known as al Ipsum in relation to the mineral-rich area of the ipsum. The ipsum bath is very useful especially for the players after hard work.

Adding a little water to it and lying down for a while helps to get rid of Detoxification and Sediment After High Physical Effort. The body’s absorption of salt helps calm the central nervous system, as well as its natural laxative, which helps relax muscles and relieve post-exercise pain. The serotonin is one of the neurotransmitters and through the exercise increases levels of serotonin. And then we feel comfort and relaxation because the body gets rid of mental stress and muscle and works to balance the levels of hormones in the body, and increases the secretion of serotonin. We feel comfortable and calm, The athlete can resist all the new stresses during exercise in the training modules. All of these positive effects on the body make the athlete more prepared for the training modules. Magnesium is necessary for serotonin absorption, which improves mood and relieves fatigue and stress due to...
high stress exercises, especially high-intensity anaerobic exercises “The magnesium is necessary for the body (to bind *) sufficient amounts of serotonin, A chemical to raise the mood within the brain that creates a sense of well-being and relaxation and many functions as magnesium has the ability to regulate more than 325 enzymes. The researcher finds that the use of the sessions of water basins as well as ipsum salt in the hospital have different effects through reflexes that occur in the skin, the circulatory system, the nervous system and 14 the musculoskeletal system, and all the products of metabolic processes, metabolism and oxidation resulting from various exercises and effort spent for varying periods during the implementation of training doses. During the sessions of the treatment of water reaches the cerebral cortex sensory signals of the sensory receptors of the skin and blood vessels and internal organs of the body and can affect these sensory receptors of the body through the temperature of water at different levels between cold and heat as well as when adding some chemicals to water, Water and its friction or collision with the body lead to excitation Sensory nerve endings.

Conclusions

The competitive exercises that applied to the research sample contributed to the development of performance tolerance. It was found that the hospital in the water medium with the salt of the ipsum has a positive effect on the variables (lactic acid, manganese and serotonin), which improved the functional status of the players.

ABSTRACT

A 120 middle-aged adults and elderly were enrolled in this case–control study, including 48 type 2 diabetes without foot infection patients, 36 diabetic foot patients and 36 apparently healthy individuals matched as control group. The current study was carried out to evaluate the immunological status displayed by antimicrobial peptide and their role in diabetes mellitus patients and diabetic foot infection patients. The results of demographic data examination among patients with diabetes mellitus in this work revealed that out of all 84 diabetic patients, 78% had their first signs of diabetes during their forties. Otherwise, the most common age interval for acquisition of diabetic foot infection among diabetic patients were in 50s-60s leading to 60% of diabetic foot patients underwent foot amputation at that age interval. Regarding gender as a demographic factor among diabetes patients in this study, the results showed that the gender of females and males were equal in frequency among diabetes patients without foot ulcers. On the other hand, the results demonstrate that the gender of male was found to have susceptibility to get diabetic foot infection more than the female gender (63.89% versus 36.11%). In this study, biochemical test and hematological parameters that affected on foot amputation were random blood sugar (RBS), hemoglobin A1c, neutrophils (high-significant difference between the groups in the study (P=0.0001)) and neutrophil-lymphocyte ratio (high statistical significant difference between the study groups (P>0.003)). Regarding the evaluation of immune parameters reflected by antimicrobial peptides in present study, serum HNP1-3 and DEF-β2 levels were non-significant difference between the study groups (P>0.05). Otherwise, LL-37 level was significant difference between the study groups (p<0.05). These results suggest that although most AMPs are expressed in DFU, this production is not appropriate to promote wound healing and contain secondary infections but present decrease in human LL-37 can be cause in don’t wound healing in diabetic foot patients.

Keywords: Diabetes mellitus; Diabetic foot ulcer; HNP1-3; LL-37; DEF-β2

Introduction

Diabetes is widely recognized as an emerging epidemic that has a cumulative impact on almost every country, age group, and economy across the world. Type 2 diabetes mellitus (DM) is a chronic metabolic disorder in which prevalence has been increasing steadily all over the world. As a result of this trend, it is fast becoming an epidemic in some countries of the world with the number of people affected expected to double in the next decade due to increase in ageing population, thereby adding to the already existing burden for healthcare providers, especially in poorly developed countries. Diabetes complications are common among patients with type 1 or type 2 diabetes but, at the same time, are responsible for significant morbidity and mortality. The chronic complications of diabetes are broadly divided into microvascular and macrovascular. Microvascular complications include neuropathy, nephropathy, and retinopathy, while macrovascular complications consist of cardiovascular disease, stroke, and peripheral artery disease (PAD). Diabetic foot syndrome has been defined as the presence of foot ulcer associated with neuropathy, PAD, and infection, and it is a major cause of lower limb amputation. For a long time, alterations of immune defences have been implicated in the susceptibility
Materials and Method

Patients group: This study was conducted in the department of Microbiology of Medicine College/Babylon University. A hundred and twenty middle-aged adults and elderly were enrolled in this case-control study, including forty-eight diabetes mellitus only, thirty-six diabetic foot and thirty-six healthy individuals matched as control group. All patients in the study were referred and diagnosed in the Diabetes Center at Marjan hospital Teaching Hospital during the period from November 2018 to February 2019. A full questionnaire including demographic information’s set, residence, history of diabetes mellitus, taking medication subjects. All were matched regarding the age & set to the patients group.

Specimens collection: Blood samples were taken from all subjects in the study for biochemical, hematological and immunological parameters. Blood samples were collected by drawing 3ml of blood from each subject included in this study using sterile 5ml syringes with sterile needle G-22. Blood samples of study groups were collected in sterile 10ml capacity sterile gel tubes and labeled with name, age, gender as well as date of their collection. After blood clot formation at room temperature within 30minutes, clot blood sample were centrifuged at 2500 r.p.m. for 5 minutes. Separated sera samples were collected, distributed in 0.5ml quantities in sterile containers, labeled and stored at -20°C until used. Two ml of venous blood was collected by disposable syringe then withdrawn in EDTA container and mixed with the anticoagulant to avoid clot formation.

Complete blood count: Complete blood count (HB, RBCs, WBC (neutrophil and lymphocyte), MCV, MCH, MCHC, HCT, platelet indices) was tested by automated method (Sysmex).

Biochemical tests: Random blood sugar (RBS) was detected by Glucose kit {Company: Biomaghreb, France, Lot number (20121)}. HbA1c was perceived by Finecare HbA1c kit {Company: Wondf, China, Lot number (F20712420AD)}. Test should be performed at room temperature.

Serological Markers: HNP1-3, Human DEFβ2/DEFB2 and Human LL-37 detected by enzyme linked immunosorbent assay {Human HNP1-3(Neutrophil Peptide 1-3), Human DEFβ2/DEFB2 (Defensin Beta 2) and Human LL-37 (Antibacterial Protein LL-37) ELISA Kit, Elabscience, U.S.A., Lot number(E-EL-H2299, E-EL-H0996 and E-EL-H2438 respectively)}. Parameters were measured according to instruction of the manufacturing company.

Statistical Analysis: This done by using statistical package for social sciences (SPSS) version 22, in which the researcher used analysis of difference (ANOVA) and independent sample T-test for measuring the data and chi square ($X^2$) for a categorical data. Set p value < 0.05 as significant (95%).

Results and Discussion

This result was supported by the recommendation of the American Diabetes Association (ADA) that doing annual diabetes screening tests after the age of 45. But the age at which someone develops the condition depends on too many differing factors to accurately predict. Many people have diabetes for years before being diagnosed, causing a large variation between the age of onset and age of diagnosis. Coming in line with this study data about the age distribution among diabetic patients, according to the CDC, the majority of new diabetes diagnoses were among adults aged between 45 and 64. While there might not be a set age for onset for type 2 diabetes, age greatly increases the chances of developing diabetes complications most importantly diabetic foot infection 9. Otherwise, the most common age interval for acquirement of diabetic foot infection among diabetic patients were in 50s-60s leading to 60% of diabetic foot patients underwent foot amputation at that age interval (Table: 1)

In this study, blood sugar was studied as a biochemical diagnostic parameter for diabetic patients. Random blood sugar level among the three groups through the current study established that there was a high-significant difference between their serum levels. While Hba1c in the diabetic foot group were significantly higher than diabetes and control groups, and there was a high-significant difference between the groups in the study (P=0.0001) (Table: 3). In recent studies about the distribution of random blood sugar mean value among diabetic patients, the risk factors of foot ulceration varied in studies, loss of glycemic control for any reason may lead with time to diabetes become progressed and less responsive to treatment and resultant increase in DFU risk. Improving ability to predict and prevent diabetic foot ulceration is imperative because of the high personal and financial costs of this complication. Furthermore the better glycemic control the fewer complications from hyperglycemic attacks (12, 13). The results regarding HbA1c reached through this study were in consistence with pervious study which reported that higher HbA1c levels were positively correlated with future diabetes complications such as risks of stroke, coronary heart disease, and all-cause death. The risks of ischemic stroke increased by 1% increment of HbA1c regardless of diabetes diagnosis. In addition, HbA1c levels 7.5% (58.5 mmol/mol) incrementally and significantly increased future risks of ischemic stroke, coronary heart disease, and all-cause death compared to the reference group of HbA1c levels <5.5% (36.5 mmol/mol) (Chen et al., 2015). Likewise, these results about HbA1c were agreed with earlier study which found that Hba1c in diabetic foot ulcer was 9.76 ± 2.5, diabetic control group 7.93 ± 2, statistically high significant differences were also observed according to HbA1c (P = 0.000). Short-term glycemic control as measured by HbA1C was variable
in regression models among patients with diabetic foot ulcers in the study; however, the association between poor glycemic control and development of diabetes complications demonstrated that health-related quality of life was not identified in the diabetic patient group. These findings have implications for clinical and policy decisions, as well as for the design for future studies with larger sample sizes. In particular, the findings underscore the importance of quality of life in the management of diabetic patients with or at risk of foot disease 36.

Likewise in the present study neutrophil count was studied as a hematological parameter for diabetic patients, the results showed that neutrophils count in the diabetic foot group were significantly higher than diabetes patients and control group and there was high significant difference between the study groups ($P = 0.001$) (Table: 3). In the present study we hypothesized that the phagocytic activity disturbances in patients with poorly controlled diabetes may play an important role in the pathogenesis of infectious complications in these patients and may augment the progression of immune dysfunction to increased morbidity and mortality rates. These results regarding neutrophils count among diabetic foot patients identified in the present study was in agreement with earlier study who found a higher mean laboratory result for neutrophils count than control. Among laboratory finding neutrophils had a significant impact on extremity amputation, the presence of coronary artery disease, duration of hospital stay, presence of osteomyelitis, decreased levels of neutrophil are crucial for predicting amputation in patients referring to emergency units with DFU 10. While the neutrophil-lymphocyte ratio in the diabetic foot were higher than both the diabetes patients and control groups, also the healthy control group had high ratio than diabetes mellitus group and there was high statistical significant difference between the study groups ($P > 0.003$) (Table: 3). The NLR is a result of dividing the number of neutrophils to lymphocytes acquired by the differential blood cell count test. It is an inexpensive and more accessible way of evaluating immune system activity compared with many other wound-specific markers. These results in the existing study were confirmed with a prior study which mentioned that there was a statistically significant differences observed groups according to NLR ($P = 0.001$). Patient with diabetic foot ulcers and non-ulcer has been analyzed regarding NLR level as inflammatory marker. Determining NLR in the presence of high levels of diabetic foot ulcers is not a local inflammation alone but also showed that there is a systemic inflammatory response. In patients with diabetic foot other macrovascular complications of diabetes can be seen much more and using NLR has been suggested as cheap and accessible inflammatory markers for developing and following of macrovascular complication 19.

**Conclusions**

In this work foot ulcer of type 2 diabetes mellitus is fairly common. Lack of awareness of foot care and delayed treatment request will increase the extent of tissue destruction. Neutrophils are themain source of antimicrobial peptides which are expressed in DFU, although their expression levels are not appropriate to promote wound healing and contain secondary infections. Administration of antimicrobial peptides may be recommended to be used as augmentation therapy to fasten diabetic foot infection.

The Infection of Child with (Dysgraphia Dyspraxia Problems Related to Language, Perception and Thought, and Affect Fine Motor Activities, Such as Pen-Holding Disease Related to Language, Perception and Thought, and Affect Fine Kinetic Activities

Safaa Ataar Habeb¹, Imad Hussein Obed¹, Aqeel Khaleel¹
¹Department of Educational and Human Sciences, Iraq

ABSTRACT

The purpose of this study is to discuss the concept of Dysgraphia with the view to shed some more light on the difficulty in writing for pupils at primary school. In this attempt, we focus on three factors from developmental learning disabilities grounds, mainly: Visual perception disabilities, language and memory difficulties. In so doing, we refer to some particular tests. The result of this study comes about to reinforce and emphasize the existing known relationship between Dysgraphia and the other types of developmental learning disabilities.

Keywords: Dysgraphia Dyspraxia Problems related to language, perception and thought, and affect fine motor activities, such as pen-holding disease, affect fine kinetic activities

Introduction

Before recognizing Dysgraphia, we have a look at Species learning difficulties. There are many types of learning difficulties, probably the most common. The difficulty of developmental kinetic synergy is a particular learning disability that affects the individual’s ability to synergize the movement and regulate precise and inaccurate movements. The difficulty of developmental kinetic synergy affects the child’s acquisition of handwriting skills, leading to problems in the learning process and in acquiring literacy skills and spelling. The term expresses the disorder of sensory integration and includes problems. Balance is the compatibility between hand and look, no failure enables the student to coordinate and control simple movements such as writing and cutting, or more complex movements such as running and jumping. Dysgraphia is basically a difficulty in kinetic synergy. The child has a disability or immaturity in organizing the movement, leading to problems related to language, perception and thought, making the tasks associated with the learning process difficult. This imbalance in the completion of the movement results from a problem in the way the brain sends the information and receives it from a specific organ in the body. The person can be infected with Dysgraphia at any stage of his life due to shock, stroke, accident or illness. It can also be caused by myself. The boys suffer more than girls Baldesberaxia, they begin to have several symptoms of the form, such as:

- Difficulty in eating, sitting, walking, completing movement and standing, in the sense of all that relates to his kinetic development, and the patient needs help from all around him in clothes, eating or washing.
- He cannot organize his objects or even his thoughts.
- He does not like games that need to be analyzed like cubes.
- It is difficult to grasp objects such as writing tools.
- He suffers from difficulty concentrating.
- Also suffers from muscle dysfunction.

Dysgraphia is Difficulties Kinetics which is due to cognitive problems, especially visual kinetic difficulties and other kinetic difficulties. The definition of Dysgraphia according to the British Dysgraphia Association in England. It is immobility or immaturity in organizing the movement leads to problems related to language, perception and thought (Disparaxia Association, 2001). These difficulties are in processing the above information seems to relate to the skills necessary for many of the tasks associated with the learning process, and will affect focus, memory and reading. Kinetic difficulties which is due to cognitive problems, especially visual kinetic difficulties. That is, difficulties in the voluntary kinetic system, or sensory integration disorder and include problems of balance - compatibility between hand performance and consideration. 

Control minute motion: Difficulties in coordinating fine movement lead to handwriting problems, which can be due to intellectual or intellectual difficulties. They can be problems associated with this area include the following:

- Learn basic movement patterns.
- Develop desirable typing speed.
- Learn the language characters - for example, Latin alphabet, plus numbers.
- Hold the pen correctly
- Pain in the hand while writing.

Precise traffic problems can also cause difficulties in a wide range of other tasks, such as the use of knife and fork, hook studs, shoelaces, cooking, tooth washing, putting beauty tools, hairdressing, opening jars and bags, opening and closing doors, shaving, doing household chores. There are many labels for Dysgraphia the most important of which: Developmental coordination disorder (DCD) Developmental Dyspraxia and Clumsy Child Syndrome Developmental coordination disorder (DCD) Developmental Dysgraphia and Clumsy Child Syndrome.

Symptoms and reasons of Dysgraphia: It has the impact on the student’s performance and behavioral and social. As of the age of 3 years, it is possible to observe the child’s injury when he is late in walking, and when he has difficulty in not specifying the square and triangle. Here we need to use a doctor or psychologist to distinguish whether there is any intellectual problem or only a kinetic problem and can be surer than injury at the age of 7 years. The cause of Dysgraphia is not known today. Researchers believe that nerve cells that control muscles do not develop properly. Since they are not able to establish a proper connection, the brain will need more time to analyze the information. Dysgraphia can be infected at any stage of his life by shock, stroke, accident or illness. Undoubtedly, Dysgraphia has negative consequences. The first is independence. The child will not be able to feel his independence, such as wearing his clothes alone or managing his own affairs, in addition to the difficulties that can result in school performance. There is also dictation, especially as the spelling difficulties are associated with a transcription disorder, so the student makes mistakes in copying when he moves from the board to the book. In this case it is very useful to use the “computer”.

All these problems cause delays in school performance. As well as losing the student confidence, making him isolated from his colleagues, if accompanied by a disorder of lack of concentration and frequent movement. It is possible for a child to attend a regular school or need a specialized school.

He can enter a normal school, but to a certain stage then he will have to become a specialized school with specialized classes. It is possible to detect the infection as soon as the child enters school. Certainly, on condition that the teacher has experience, and thus be able to distinguish between the normal development of the student and abnormal development. One of the most noticeable aspects of a child’s difficulty in dealing with situations that require group work is the difficulty in calculating, writing and copying from the board. There are specific skills or difficulties faced by the student in which the teacher in the nursery can discover a problem.

The consequences of Dysgraphia on student performance: Dysgraphia has negative effects on school performance. And directly affect:

- Movement and trends: low maturity of movement, organization and spatial structures. For example, it is difficult for the child to determine the orientation of the lines on the paper.
- Line: The writing is automatic and thus the result appears to be scribble, as the letters are written in a remarkably uneven size.
Articulation: Difficult to apply the rules of addition and subtraction, despite his familiarity with it.

Reading: Be hesitant and slow and tends to confuse similar characters in the form and has difficulty spelling.

Research writing: The student does not know the search for suitable information for the subject for the impossibility of the structure of the text.

Dictation: Spelling difficulties are associated with a transcription disorder. So, the student makes mistakes in copying when he moves from the board to the book.

Singing and imitation: The student cannot reproduce the movements, and also finds it difficult to follow the rhythm of the song correctly.

**Problem statement:** As well as other disorders that result in learning difficulties such as autism, hyperactivity disorder and activity. Dysgraphia difficulty Kinetic synergy, Dyspraxia Dysgraphia. This problem is a silent disability that impairs the child’s learning and life. He needs the help of parents and everyone around him to overcome them.

**Dysgraphia diagnosis:** The first stage is the evaluation of physical development, that is to build a clear and detailed picture from the beginning of the stages of pregnancy through birth to physical development and the accompanying stages. This development is compared to peers who are children of the same biological age. So, such as sitting, walking, talking, toilet training and the like. And make sure that the child did not suffer from any diseases have similar symptoms.

The second stage is the assessment of mental abilities, i.e. the level of intelligence in the child. We then perform a kinetic sensory assessment to identify difficulties and their degree in the functions of the trunk muscles (e.g. jumping, throwing, walking, jogging, balance) and fine muscles (e.g. lacing, decoding, studying, shearing, writing). Finally, we seek to evaluate kinetic theory Motor Visual Perception Kinetic Visual Perception. The speed in kinetic performance after looking at the object is an important indicator that develops with age.

**The treatment of Dysgraphia:** Dysgraphia has been associated with the patient throughout his life, and his condition can improve with early detection and correct treatment. Some of the specialists who should work with people with Dysgraphia are:

- **Therapist Occupational therapist Occupational:** Therapist to help the child organize and develop his movement to facilitate daily tasks.

- **Speech and Language:** SpecialistSpeech therapistSpeech helps him to develop spoken language, written language, thinking and analysis skills.

**The effects that may weaken the child’s fine kinetic abilities:** Some children may notice that they are unable to use their hands properly during activities, which in turn can frustrate them. This frustration may appear to be resistant or reluctant to perform activities that may require high coordination in the use of small muscles in their hands and fingers. As a result of their refusal, they cannot properly exercise those skills and miss the opportunity to develop those muscles. This in turn may affect the development of more precise kinetic skills such as typing. It will be easy for the teacher or educator to identify the problem by observing the child’s behavior or reactions when asked to perform some of those skills, for example, we will review some of the expected responses from the child:

1. Techniques of evasion or avoidance of participation:
   - a. Rapid refusal to participate in some activities.
   - b. evade participation by asking to go to the water cycle or drink water.
   - c. Flicks may appear as shredding paper.
   - d. Sadness and crying.

2. The techniques of defeatism:
   - a. It may appear in the phrases used by the child such as: I do not know - I am not good - or I appreciate her parents!

**Better times to train children on fine kinetic skills:** It is preferable to start training on these skills after exposing the child to activities that stimulate his or her large muscles. The time that follows the time of the break or play time is one of the best times for training, because the activities or movements that the child during his play help to move the big muscles such as shoulders and muscles of the forearm and pelvis and thigh, these muscles in turn are in readiness and readiness to act as an assistant and essential stabilizer and necessary for the muscles of the smallest or minute. If it is not possible to create a suitable timing for training at some times, light
warm-up exercises help stimulate the muscles before starting the training, preferably in a different form, in the sense that they make the teacher in the form of a race to escape from place to place, for example Inventory, and not take a boring and repetitive.

Teacher helps the child: One of the most important roles of the teacher is to observe children in the performance of activities and the ability to recognize or discriminate children who show signs of weakness in the performance of some skills and activities. The teacher also has a great role in creating the child’s motivation to practice the skills they create challenging, as well as working on developing those skills by focusing on the child’s weaknesses through classroom activities or through play. The teacher’s positive attitude to the child and encourages him not to show a sense of failure, which reduces the fear of the exercise of those skills in the future. It is also necessary to adapt, modify or compartmentalize those skills to suit the level and abilities of the child, which helps him to achieve a simple success, which in turn can positively support the child. It also helps to reduce the high expectations of the child towards his fear of failure, as well as to increase the child’s self-confidence and help to show a marked improvement in performance.

Conclusion

We mentioned earlier that basic skills begin to develop in the child at the age of breastfeeding and in the following years, and these skills are ready to use school tools. Although the majority of children at this stage are fascinated by the use of school tools from pencils and scissors, emphasis should not be placed on writing and cutting skills, especially in the three to four year period, because it would be useful for them to use that time to develop and increase their readiness to find a solid foundation for those skills in the future. We conclude from the above that working to support and support the child to develop these skills at an early age helps him to achieve success and a sense of satisfaction with his performance both at home and school.

ABSTRACT

The present study was aimed at exploring the prevalence of multiple health risk behaviors and determine their relationship with socio-demographic characteristics among adolescent high school students. The present investigation was a cross-sectional study that was carried out in the public high schools located in Erbil, the Kurdistan Region of Iraq. The study sample consisted of 1000 students who were selected using a multi-stage cluster sampling method from 32 high schools in 6 municipalities of Erbil. The required data were collected using a self-reported close-ended questionnaire. The present study was participated by 1000 adolescent high school students whose mean age was 16.7 years with a standard deviation of 1.2 and a median of 17 years. Over half of the students (57.4%) belonged to the age group 16-17 years. Regarding their gender, 57.4% were females, and the male: female ratio was 0.74: 1. With regard to their grades, about 43% of them studied in the 11th grade. In terms of their socio-economic status (SES), more than half of them (54%) had a low status and 12.8% a high SES. It was observed that their mean risk was 3.38 with an SD of 2.15 and a median of 3.

Keywords: Multiple health risk behavior, smoking, adolescent, violence, alcohol drinking, safety, suicide, physical activity

Introduction

As a transition from childhood to adulthood, adolescence is accompanied with an increase in autonomy and independence and tendency for risky behaviors in different milieus. Few research studies have focused on the relationship between living conditions and health risk behaviors, which is a critical issue. Developing effective youth health policies requires a deep understanding of how social and physical environment can influence risk behaviors conducted by individuals. Adolescence is characterized by psychological and physical changes including puberty, stress, and family- or school-related challenges which can cause adolescents to conduct negative behaviors like smoking, drinking alcohol, suicide, and violence. Such adolescents are typically prone to continue such risky behaviors right into their later life, i.e. adulthood and old age period. It also pointed out that such behaviors can lead to or increase mortality and morbidity. Unequal distribution of socioeconomic resources has been reported to play a role in health disparities in different communities. In fact, given its potential great impact on school-aged adolescents, socio-economic status should be taken into special attention. To the authors’ best knowledge, no survey in Iraq has ever focused on multiple health risk behaviors among adolescents in Kurdistan Region except for a single study that was conducted on health risk behaviors among male students in the secondary schools located in Erbil.

Materials and Method

The present investigation was a cross-sectional study that was carried out on 10th, 11th, and 12th students who were 14 to 19 years old, of both genders, and studying in public high schools in Erbil, the Kurdistan Region of Iraq. A multistage cluster sampling method was employed to select the study sample. In order to collect the required data from the students in each school and grade, the researchers referred to the Directorate General of Education of Erbil. In order to include all quarters of the city, the schools were divided into 6 groups based on the municipalities of Erbil, and a simple random
sampling method was utilized to select the target schools from each municipality. Based on the teaching language (i.e. Kurdish, Arabic, Turkish, or English), the schools in Erbil are categorized into 4 types. The first three types (i.e. Kurdish, Arabic, and Turkish schools) are either male or female schools, while English schools are mixed. In most of the schools (67 out of 78), Kurdish is the language of teaching. The proportion of the students in each municipality was used in order to select a certain number of schools in each municipality. Moreover, during the selection of the target schools, at least 1 and at most 3 schools were selected for each gender in each municipality. A total of 11 males and 15 female Kurdish schools were chosen. There are four Arabic schools out of which 1 female school and 1 male school were chosen. Also, 2 Turkish schools were selected. And from among the English schools, two were randomly chosen. Therefore, a total number of 32 schools were selected from 6 municipalities of Erbil. After the schools were selected, a single class was randomly selected from each school. Afterwards, a minimum 30 students were chosen from each grade. After that, the counseling specialists of the schools collected the required data by attending the classes. Moreover, the students were provided with information on the nature of the research and the definition of multiple health risk behavior. In addition, written informed consents were obtained from the students by giving them a consent form and asking them to have it signed by their parents and return it back the day after. On the next day, the participating students were required to complete the questionnaires. They were asked to complete the questionnaires anonymously and not to include their names in order to ensure confidentiality and the highest possible honesty in their answers. The total population of the 10th, 11th, and 12th graders (i.e. 36777, according to the statistics retrieved from the Ministry of Education for the academic year 2016-17), confidence interval (CI) of 95%, 5% allowed error, and a prevalence rate of multiple health risk behavior of 50% were utilized to determine the sample size, which led to a sample size of 381. Moreover, according to the rules in cluster sampling method, a larger target sample size was considered in order to achieve the required precision, which led to multiplying the calculated sample by the design effect of 2, resulting in a sample size of 762. In addition, 10% more students were included so as to account for non-response or recording error, leading to a sample size of 839 students. Finally, the sample size was considered as 1000 in order to cover all schools and classes.

In order to collect the required data from the chosen study sample, a closed-ended questionnaire designed by the Centres for Disease Control and Prevention (CDC) was modified and employed. This questionnaire is composed of three parts. The 1st part aims to collect data on the respondents’ demographic characteristics including age, gender, grade, ethnicity, and religion. The 2nd part gathers data on their socio-economic status (educational level and occupation of father, house ownership, car ownership, and age of father). The 3rd part focuses on the respondents’ habits and lifestyle such as wearing helmet and seat belt, riding with a drunk driver, drinking alcohol, physical inactivity, less sleeping hours, smoking cigarette, physical fighting, bullying at school, electronic bullying, suicide, and other health-related topics. The questionnaire was translated into Kurdish and Arabic by expert translators in an English language center in Sulaimania to assure it was properly understood by all students.

Results and Discussion

There was no significant association between the students’ age and the prevalence of risky behaviors (p=0.081). However, the 10th graders had a significantly higher prevalence of risk behaviors than among those of than the 11th and 12th grades (p<0.001). Moreover, the male students were found out to be twice more prone to conduct risk behaviors than the females (p<0.001). Also, it was concluded that prevalence of risk behaviors increase with a rise in the students’ SES (p<0.027) (See Table 1).

</table>
According to the results, it was observed that 90% and 86% did not wear a helmet while cycling and skateboarding, respectively. Moreover, wearing a seatbelt was reported by 58% of them, while sitting in a car, while riding a car with a drunken driver was mentioned by only 5.4% of them. It was also reported that about 14% of them carried a weapon, 28.4% got involved in physical fighting, and 27.4% got hurt and treated by a doctor or a nurse. Moreover, 3.4% of the students referred to bullying at school, while electronic bullying was reported by 3.7% of them. Serious attempt to commit suicide was reported by 12.5% of the students, 17.4% reported smoking, and drinking alcohol was reported by 2.2% of them. Taking steroid pills or shots without a doctor’s prescription was reported by only 1.7% of the students. Also, participation in physical activities was reported by 36% of them, and 58% of them reported that they slept for less than 8 hours per night (Table 2). Compared with the 11th grade students, the 10th and 12th grade students (with respectively OR=1.98; 95% CI=1.43-2.75 and OR=2.01; 95% CI=1.40-2.88) were significantly associated with developing risky behavior. Male gender was found as another factor that was associated with risky behavior (OR=3.58; 95% CI=2.65-4.82). Moreover, the students with a medium SES were more likely to develop risky behaviors than those with low SES (OR=1.37; 95% CI=1.04-1.85) (Table 3). Since median is the value that shows the middle position when all observations are arranged in an ascending or descending order, and it is also known as positional average, it has been suggested to be employed to determine the prevalence of multiple health risk behavior among the high school adolescent students.”

Based on median, the frequency distribution is divided into two equal halves. The results of the present study showed that multiple health risk behaviors were 35.5% prevalent. This finding is in agreement with the one reported by a study carried out in Ontario, Canada (35.1%) \(^\text{11}\). It is also in line with the results of a study conducted on adolescents of 11-15 years old in the UK in 2008 which revealed that about 33% of the adolescents had risky behaviors \(^\text{12}\). However, this prevalence rate is higher than what was reported in studies carried out in Luangnamtha Province, Lao (8.1%) \(^\text{13}\), Australia (9.8%) \(^\text{14}\), Northeast of Brazil (9.0%) \(^\text{15}\); and Pernambuco, Brazil (17%) \(^\text{16}\). As reported by the Australian Bureau of Statistics’ National Health Survey, 14.0% of Australians aged 15-18 years smoked daily \(^\text{18,19}\). The results of a study conducted in Ibadan, south-western Nigeria in 2010 revealed a prevalence rate of 0.8% of risky behaviors among adolescents, which is much lower than the findings of the present study \(^\text{20}\). The results of the present study also showed that 43% of the students with a high SES practiced multiple risk behaviors, which is a significantly higher prevalence rate than other SES categories. This finding is in agreement with the findings of a study carried out in the UK in 2015 which showed that the prevalence of multiple health risky behavior was more among the adolescents with high socioeconomic status \(^\text{21}\). On the contrary, Lawlor et al. concluded that low SES was associated with the risky behavior \(^\text{18}\). It is also stated that social pattern of behavior can change over time, as illustrated by the history of smoking behavior that started in higher SES groups but its prevalence declined in these groups \(^\text{20}\). The results of the present study made it evident that 57.9% of the students did not wear seatbelts while they are in a car, which is higher than the results of the studies conducted in the USA in 2010, 2012, 2013, and 2014 \(^\text{20,24,41,31}\) which respectively reported 9.7%, 7.7%, 7%, and 7.6%.

Conclusion

According to the results of the present study, there was an association between demographic characteristics like gender, grade, and socio-economic status factors and multiple health risk behaviors among high school adolescents in Erbil, the Kurdistan Region of Iraq. The 10th and 12th grade students were significantly more prone to develop risky behaviors compared with the 11th graders. Moreover, male gender was another factor that was associated with risky behavior. Finally, it was observed that those of medium SES background were more likely to have risky behaviors than those of low SES.

Evaluation of Knowledges, Attitudes, and Practices of Breast Self-Examination of High School Female Students in Al-Diwaniyha City

Zainab Jaber Abed1, Wissam Jabbar Qassim1
1Community Health Nursing Department, College of Nursing, Baghdad University, Iraq

ABSTRACT

Objectives: To evaluate the breast self-examination knowledge, attitude, and practice for female students. To determine the relationship between female students knowledge, attitudes, and practices of breast self-Examination in high school and socio-demographic characteristics. Two-hundred and twenty female sample Cross sectional study was used to assess high schools females about knowledge, attitudes, and practices related to breast self-examination among high schools female students in AL-Diwaniyha City. A Cluster “probability” sample of (220) female students were selected. These female students study at school, (220) female students from Al-Diwaniyha directorates Female students were assigned to the study according to the following criteria: 1- Female student 2- High school female students who are of the fourth, fifth, and sixth classes. The overall number of items included in the questionnaire is (77) items. Scored assess high school females about are rated on three levels type Likert scale range from 1 to 3; of Always =3, Sometimes =2 and Never=1 Validity refers to the extent to which an instrument measures what it intends to measure (Polit and Hungler, 2013). There is no statistically significant difference in students’ knowledges, attitudes, and practices related to breast self-examination among father’s level of education.

Keywords: Evauation, knowledges, Attitudes, Practices, Breast self-examination

Introduction

Breast cancer is the most common form of cancer in females, with over 1.38 million females diagnosed globally in 2008, accounting for 23% of all different cancer cases 1 Bray,F. etal; 2004) reported that most cancer diagnosis is related to cancer of breast, the most commonly diagnosed cancer among females worldwide. Breast cancer is the most common cancer and leading cause of deaths among females universal 2. Breast cancer is the most commonly happening cancer in females and it is second most common cancer overall. There were above 2 million new cases in 2018. Breast cancer affects primarily women, but a small number of men are also diagnosed each year. It is estimated that the lifetime risk for men is 0.11%, whilst the risk is 13% for women. The Continuous Update Project Panel made a decision about that there was solid proof that utilization of mixed beverages, more noteworthy body bloatedness all through adulthood, grown-up weight increase and grown-up achieved tallness are reasons for postmenopausal breast malignancy. The Panel additionally made a decision there is solid proof that physical movement (counting enthusiastic physical action) and more prominent body bloatedness in youthful adulthood ensure against postmenopausal breast disease 4.

Moreover, the Panel made a decision there was solid proof that lactation secures against breast cancer growth (undefined menopausal status) National Cancer Registry records, and now India has turned into the nation with the most elevated evaluated number of breast cancers. Cancer growth passings around the world. An ongoing investigation of breast malignancy chance in India recognized one of every 28 ladies create breast disease during their lifetime. An expanding pattern in occurrence
is accounted for from assorted libraries of national cancer growth library task and now India is a nation with biggest evaluated number of breast disease passings around the world. Absence of mindfulness with respect to screening strategies, chance components and social taboos that make Indian ladies humiliated to discuss their real issues prompts late discovery of disease and demise. In India the occurrence/mortality proportion is 0.48 contrasted and 0.25 in North America. 11 The American Cancer Society guidelines for early detection of breast cancer recommend yearly mammogram starting at the age of forty, clinical breast examination (CBE) about every three years for women in their twenties and thirties, and every year for women at age forty and over and also recommends Breast Self-Examination (BSE) for women starting their twenties

**Methodology**

The aims of the study1- To evaluate the “breast self-examination knowledges, attitudes, and practices for female students.

2- To define the relationship between female students knowledges, attitudes, and practices of breast self-Examination in high school and socio-demographic characteristics.

The Design of the Study: Cross sectional study was used to assess high schools females about knowledge, attitudes, and practices related to breast self-examination among high schools female students in AL-Diwaniyha City. This study was started from 15 October 2018 to Jon 2019.

Study Sample: A Cluster “probability” sample of (220) female students were selected. These female students study at school, (220) female students from Al-Diwaniyha directorates

Study Instrument: The study instrument includes the socio-demographic sheet, The triple scale was measured by a scale that was adopted from 11. 9 The overall number of items included in the questionnaire is (77) items. Scored assess high school females about are rated on three levels type Likert scale range from 1 to 3; of Always =3, Sometimes =2 and Never=1.

Part I: Which composed of demographical characteristics.

Part II: This part is related to evaluation of student’s knowledge toward Breast self -examination.

Part III: This part is related to evaluation of student’s Attitudes toward Breast self –examination

Part IV: This part is related to evaluation of student’s practices toward Breast self -examination

Data Collection the Methods Data were collected through the utilization of the self-reported questionnaire for the period from March 11th, 2019 to April 10th, 2019.

**Statistical Analysis:** The data were analyzed through the application of statistical package for social science IBM-SPSS version 24.0 and by applying of descriptive and inferential statistical tests that are: Frequencies, Percentages, and Standard deviation.

**Results and Discussion**

Regarding father’s level of education, less than a third are intermediate school graduates (n = 70; 31.8%), followed by those who are high school graduates (n = 58; 26.4%), those who are high school graduates (n = 58; 26.4%), those who hold a bachelor’s degree (n = 39; 17.7%), those who are primary school graduates (n = 22; 10.0%), those who read and write (n = 19; 8.6%), those who hold a graduate degree (n = 9; 4.1%), and those who are unable to read and write (n = 3; 1.4%) With respect to family’s monthly income, the monthly income for less than two-fifth is more than 901.000 I.D. (n = 84; 38.2%), followed by those whose monthly income ranges between 301.000-600.000 I.D. (n = 50; 22.7%), those whose monthly income is less than 300.000 I.D. (n = 45;

Comparison of the Cyclic Fatigue of Protaper Next, 2Shape and Hyflex EDM Using Glyde

Noor Salman Nadhum1, Shatha Abdul-Kareem2, Omar Bakr Hazm3, Shatha Al-Hamrany4

1Lecturer Assistant, 2Lecturer, Department of Conservative and Cosmetic Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq; 3Lecturer, Department of Conservative, Al-Bayan University, Baghdad, Iraq; 4Dentist, General Practitioner, Ministry of Health, Baghdad, Iraq

ABSTRACT

This study aimed to compare the resistance to cyclic fatigue of Protaper Next, 2Shape and HyFlex EDM and assess the effect of glyde. A total of 30 new Protaper Next, 2Shape and HyFlex EDM were tested. From each brand 10 files were tested with glyde. The cyclic fatigue test was performed using a specially designed endodontic motor. Resistance to fracture was determined by recording the time. The study concluded that HyFlex EDM recorded the highest value of resistance to cyclic fatigue than 2Shape and Protaper Next respectively. Glyde may reduce the resistance to cyclic fatigue in all brands of files also was concluded in this study.

Keywords: Cyclic fatigue, Glyde, Reciprocating instruments.

Introduction

Instrument separation is a serious concern in endodontics. Because stainless-steel instruments usually deform before they separate, dentists can inspect them for visible signs of instrument deformation. A deformed instrument usually shows severe bending or unwinding of the flutes, indicating that the elastic limit of the metal has been exceeded and that the instrument should be discarded. Nickel-titanium (NiTi) endodontic instruments were introduced to facilitate instrumentation of curved canals. Ni-Ti instruments are super elastic and will flex far more than stainless-steel instruments before exceeding their elastic limit1,2. This flexibility is an important property that allows preparation of curved canals while minimizing transportation. Despite this increased flexibility separation is still a concern with NiTi instruments and they have been reported to undergo unexpected fracture3. Separation can occur without any visible signs of previous permanent deformation, apparently within the elastic limit of the instrument. Cyclic fatigue of nickel-titanium engine-driven instruments was studied by determining the effect of canal curvature and operating speed on the breakage of Light-speed instruments. Multivariable analysis of variance indicated that cycles to failure significantly decreased as the radius of curvature decreased from 5 mm to 2 mm and as the angle of curvature increased greater than 30 degree. Scanning electron microscopic evaluation revealed ductile fracture as the fatigue failure mode. These results indicate that for nickel-titanium, engine-driven rotary instruments the radius of curvature, angle of curvature and the instrument size are more important than operating speed for predicting separation.

Materials and Method

Three brands of rotary instrument with tip size 0.25 were used. 10 instruments for each type were tested within the artificial canal. These instruments were tested with glyde.

Group 1 Protaper Next (NiTi rotary instrument tip size 0.25)

Group 2 2Shape (NiTi rotary instrument tip size 0.25)

Group 3 HyFlex EDM (NiTi rotary instrument tip size 0.25)

Each instrument of these groups were subjected to cyclic fatigue testing device specially designed for the purpose that allowed a reproducible placement of the instrument in artificial canal. The instrument rotates freely in a curvature generating tension, compression cycles at the point of maximum flexure until the fracture occurs.

Instruments were tested within the canal (60° angle of curvature) with radius of curvature for all canals was 5 mm and the width of canal was 1.5 mm within a block made from stainless steel with a swiveling glass cover allowed for visualization of the file rotating in the canal and the removal of broken instrument among test. All the instruments were activated with endodontic motor that was connected to a cyclic fatigue test device using (Recipro All) program design. The instance of fracture was based on visual observation of the fracture occurring in the instrument. The time (T) of fracture recorded in second (from starting reciprocating within a canal until fracture occur). An independent t-test was used to compare the cyclic fatigue resistance of Protaper Next, 2Shape and HyFlex in all groups.

Results

Descriptive statistic for each file are summarized in Table 1. The mean of cycle to fracture of all HyFlex EDM was greater than 2Shape and Protaper Next (p<0.00). There was a significant difference between Hyflex EDM and Protaper Next also there was a significant difference between Hyflex EDM and 2Shape, but there was no significant difference between Protaper Next and 2Shape when considering the irrigating media (Glyde) as the independent variable.

Discussion

Fracturing of rotary nickel-titanium (NiTi) instruments occurs due to torsion or flexural fatigue(5). Cyclic fatigue failure is reported to occur unexpectedly without any sign of previous permanent deformation. This occurs because of the alternating tension/compression cycles that instruments are subjected to when flexed in the region of maximum curvature of the canal(6,7).

Several strategies have been incorporated in the manufacturing process to reduce the incidence of separation of NiTi instruments. These methods include (a) advanced surface treatment or electropolishing that finishes the surface and prevent crack propagation (b) varying the taper within one file and modifying the cross-section, thus reducing the contact area of the instrument with the canal walls (c) heat treatment or thermal processing the optimizes the microstructure of NiTi alloys(8,9,10,11,12) Using NiTi instruments in reciprocating motion can enhance the cyclic fatigue resistance(13). Prptaper Next files (Dentsply Maillefer, Ballaigues, Switzerland) which have been recently launched are designed in such a way that the center of mass or center of rotation is offset. This offset design minimizes the contact between file and dentine in addition it enhances augering debris out of the canal(14). They are manufactured using M-Wire technology which in combination with the offset design improves the flexibility along the active portion of the file(14,15) with considerably less iatrogenic error(16,17).

The 2Shape file system consist of 2 shaping instruments in continuous rotation increased resistance to instrument fracture. Data from research reported that the resistance of 2shape to cyclic fatigue was 40%. The HyFlex EDM OneFile (HEDM; Coltene/Whaledent AG, Altstatten, Switzerland) is a novel instrument designed and marketed to shape root canals using a single file technique in continuous rotation.

HEDM is manufactured using the technique of electrical discharge machining (EDM). EDM can be used to manufacture all types of conductive materials (eg, metals, alloys, graphite, ceramics and so on) of any hardness with high precision.
The shape of a workpiece is changed by building a potential between the workpiece and the tools. The sparks initiated in this process are melting and vaporizing the material of the workpiece in its top layer.

From the result of the present study it’s clear that the mean cycle to fracture of HyFlex EDM is greater than that of 2Shape and Protaper Next, and that was due to it’s properties as:

1. HyFlex EDM files are produced using an innovative manufacturing process called Electrical Discharge Machining. The EDM process results in a file that is extremely flexible and fracture resistant. In fact HyFles EDM files are up to 700% more resistant to cyclic fatigue compared to traditional NiTi files (18). While 2Shape files are up to 40% resistant to cyclic fatigue.

2. HyFlex EDM files follow the anatomy of the canal which can significantly reduce the risk of ledging, transportation and perforation.

3. The combination of flexibility, fracture resistance and cutting efficiency of the HyFlex EDM make it possible to reduce the number of files required for cleaning while preserving anatomy.

Finally, HyFlex EDM owes its unique properties to a breakthrough technology called “Electrical Discharge Machining”. This innovative manufacturing process uses spark erosion to harden the surface of the NiTi file resulting in superior fracture resistance and improved cutting efficiency. HyFlex EDM files offer trusted controlled memory effect and regenerative properties.

**Conclusion**

Cyclic fatigue resistance of HyFlex EDM was higher than that of 2Shape and Protaper Next respectively with the use of Glyde as irrigant solution.

Assessment of Knowledge and Practices of Pregnant Women Toward Antenatal Care Services at Primary Health Care Centers in AL Hila-City

Noor Al-Huda S. Skel¹, Muna A. Khaleel²
¹MSc. Student, Maternity and child health Department, ²Professor, Community Health Nursing Department, College of Nursing, University of Babylon, Hilla City, Iraq

ABSTRACT

Today, it is well-known that knowledge and practices of pregnant mothers about prenatal care are essential for the health of women and fetuses and also through pregnancy, breastfeeding and childbirth. Interventions, education and information, for pregnant mothers is a catalytic process. A descriptive, cross-sectional study design at (10) PHC centers selected randomly from total (48) PHC centers affiliated to first and second health care sector in Al Hilla City from 30/July/2018 to 29/July/2019. A constructed questionnaire was prepared and adopted by the researcher direct (face to face) interview to meet the objectives of the study, it contains : socio-demographic data, reproductive history of the sample, knowledge of pregnant women about importance of antenatal care services and practices of pregnant women toward antenatal care services. Findings of the study revealed that the mean overall knowledge score of the study participants for all domain (2.08) which indicated that the overall knowledge of mothers regarding antenatal care was fair, and the current study also showed that the mean overall practices score of the study responses for all domain (1.93) which indicated that the overall practices of mothers regarding antenatal care was fair.

Keywords: antenatal care, knowledge, practices, pregnant women

Introduction

Pregnancy is a unique and powerful feminine experience. It is a normal process that leads to a series of both psychological and physiological changes in expectant mothers. (1) Pregnant women should receive special care and attention from the health care community and the family. Therefore, Pregnancy is a very important social and medical event (2). The normal gestation period is nine months during this period of external and internal changes in the body of the pregnant mother. The mother is prepared during this period for her new role in motherhood. Gradually move to attend to another object of life (3). Antenatal care services are not just interventions; they are a series of interventions and assessments of expectant mothers by health care providers. However, some developing countries can not apply these services uniformly and effectively (4). Prenatal care means that care during pregnancy by a caregiver at a medical facility or at home, and the need for ANC services by explaining its many benefits, which may include monitoring child mother during pregnancy, anticipating difficulties in birth and pregnancy through first management to reduce maternal and child risk, facilitating better use of emergency obstetric care, and disseminating information health and education (5). In a large number of studies done among pregnant mothers, it was found that mothers who did not receive good care from ANC were more likely to have premature birth, and there was a clear correlation between the quality of poor ANC and infant mortality (6). The World Health Organization (WHO) is advice the mother to take blood, urine, weight, height and blood pressure tests on each visit. The World Health Organization (WHO) urged women to be their first visit within eight to twelve weeks after pregnancy and the second visit between twenty-
four and twenty-six weeks of gestation, the third visit between thirty-two weeks and the fourth visit between thirty-six and thirty-eight weeks (7). In Iraq, according to (Dawood, 2017), it was reported that the antenatal care visits up to 28 weeks every four weeks, (28-36) weeks every two weeks, and from 36 to delivery every week. In addition, the Iraqi Ministry of Health has confirmed the same instructions for visits during pregnancy. (8)

Methodology

Objectives: The purpose of the current study was to assess the knowledge and practices of pregnant mothers regarding antenatal care services at primary health care centers in Al-Hilla – City. The current study also aims to determine the association between the knowledge and practices of pregnant mothers toward the antenatal care services with their socio-demographic and personal characteristic such as (age, level of education, economic level)…..etc

Design of the Study: A descriptive cross-sectional study design was conducted from 30/July/2018 to 29/July/2019 to meet the previously mentioned objectives

Study Sample: The study included a non-purposive sample of (432) pregnant mothers who attended PHCCs in Al-Hilla City.

Study instrument: A constructed questionnaire was prepared and modified after a thorough review of the relevant literature. This questionnaire covers four parts:

Part 1: Socio-demographic and personal characteristics which is contained of seven items, that consist of the level of education, age, occupation of pregnant women, husband’s education, husband’s occupation residency and economic status.

Part 2: Reproductive history of the sample which is consisted of (12) items gravidity, age at marriage, parity, age at the first child, number of abortion, gestational age of pregnancy, place of delivery of the last baby, smoking status, smoking status of husband, health problems, obstetric problem and previous mode of delivery.

Part 3: Knowledge of pregnant women about the importance of antenatal care services which is consisted of (19) items.

Part 4: Practices of pregnant women toward antenatal care services which is consist of (13) items

Validity and Reliability: The content validity of the instrument was established through a panel of (12) experts, the reliability of the items was based on the internal consistency of the checklist was assessed by calculating Cronbach Alpha which was= 0.78

Data Collection and Data Analysis: A structured questionnaire used to collect data by direct interview. The approximate interview time was (25-30) minutes was provided for the questionnaire completion. Data collection is performed from Jan.2nd, 2019 to Feb.2nd, 2019 to determine whether the objectives of the study were met, the current study data were analyzed by using SPSS, version 25.

</table>
represented 54 (12.5%), primary school level 70 (16.2%),
intermediate 69 (16%), high school 64 (14.8%), institutes
57 (13.2%) and college and above were 118 (27.3%),
this result similar to study done by Habib et al (2017) in
Saudi Arabia, the result of their sample was 678 (41.9%)
graduated from college and above, this also reflects that
the husband education level for studied sample is good.
(10) as shown in (Table 1).
Results of this study reveal that the smoking history of almost the participated
women (95.1%) were non-smokers, the finding of this
study go along with study that conduct by Jiee (2018) in
Malaysia, who found that the majority of their studied
sample were non-smokers 78 (28.2) (12)
In regard to smoking history of husbands (75.0%) were non-smokers. The result of under hand study
supported by study titled “Assessments of knowledge
and attitudes of pregnant women of antenatal care - and post
natal care, Al- Seef primary health care center, in Basra
city (2017)” that conducted by dawood, who stated
that majority of (88%) were non –smokers. (9) Result
of the present study reveals that there is no significant
relationship between knowledge with (maternal age,
residence, economic status, and having health problem)
at p-value ≤ 0.05 as evidenced by not significant
difference were found among overall knowledge and its
subdomains. While, the current study that indicates there
is relationship of knowledge with their level (education)
at p-value P<0.001. This is may be due to their low level
of education as we found that high percentage of them
were attended primary school only. The finding is similar
to a study done by Patel et. al., in Maharashtra, (2018)
who found statistically relationship of level education and
maternal level of their knowledge about antenatal care
services in (p- value = 0.001) (13). Moreover, the finding of
this study go along with another cross-sectional study that
carried out by Laishram et al.,(2013), who found that there
was statistically significant association between maternal
knowledge and their education at status at (p-value <0.05). (9) In regard to husband’s education, the current
study indicates significant relationship of husband’s
ingelligence and knowledge of pregnant women (R = 0.130,
P = 0.007). This means the well-educated husbands have
an important role in encouraging their wives to learn and
to increase their knowledge about antenatal care services.
This result is consistent with a study entitled done by
Ahirwar (2018) who found that husband’s education have
statistically significant association with antenatal women
knowledge at (p-value = 0.0001). (15)

All through the progression of current study, the
research outcomes indicated a total of 432 pregnant
mothers were enrolled in this present study, the age of
majority of the studied group ranged from (20 to 39)
years where 69 women (16%) aged less than 20 years,
173 (40%) aged from (20 – 29) years, 182 (42.1%) aged
from (30 – 39) years while only 8 women (1.9%) aged 40
years or above, this finding is supported by Laishram et
al. (2013) in India who found that the ages of their study
participants ranged from (20-29) years old (9). Regarding
the level of education, not able to read and write
represented (5.1%), those who able to read and write
were 68 (15.7%), primary school level 103 (23.8%),
intermediate 69 (16%), high school 44 (10.2%), institutes
36 (8.3%) and college and above were 90 (20.8%).This
result corresponding with a study that carried out by
Abdul-ALHusain (2015) in AL-Hilla city, among the
total study participants 96 (43.6 %) were educational
class level attended primary schools only. (10) Concerning
maternal occupation distribution revealed that women
192 (44.4%) were housewives, 148 (34.3%) private
sector employee 74 (17.1%) government employee and
18 (4.2%) students. this result is supported by the study
conducted by Dawood (2017) in Basra city who showed
89 (89%) of his studied sample were housewives. The
result of the present study may be associated with their
educational level, in which highest percentage of them
were graduated from primary schools, accordingly,
having job opportunities for them is less. (9). In relation
to level of husband education, able to read and write

Conclusions

It was concluded that the pregnant women have a moderate level of knowledge and practices about antenatal care services. They have a moderate level of knowledge about benefit of tetanus toxoid injection, time of given folic acid during antenatal care and information given to participants about smoking, also moderate level of practice related to: registration during first trimester, breast statues during pregnancy and consult others. They have weak knowledge about many items of antenatal care services such as first antenatal care check-up, time of given Iron during antenatal care and gestational diabetes higher risk of big babies.

ABSTRACT

The aim of this study was to assess the echocardiographic changes in patients who have masked hypertension (MH) and white coat hypertension (WCH) depending on monitoring of blood pressure by ambulatory method. This study was conducted on (66) subjects in a private clinic in Al-Hilla city; the subjects underwent a (24 hours) ABPM in addition to a transthoracic echocardiography. Based on the readings of ABP measurements, average and maximum (24 hours) diastolic and systolic blood pressures (BP) were analyzed during mean nighttime (from 10 p.m. to 6 a.m.) and during mean daytime (from 6 a.m. to 10 p.m.). The echocardiographic parameters included the measurement of left atrial size, left atrial diameter (LAD), posterior cardiac wall thickness (PWT), anterior cardiac wall thickness (AWT), E/A ratio, left ventricular end-diastolic diameter (LVEDD), and isovolumic relaxation time (IVRT). The percentage of patients having WCH was higher than MH 41:66 (62%) vs. (38%) (25:66). Regarding WCH, there were few patients had personal history of hypertension 5 (12%) and most of them had family history of hypertension 36 (88%), while in case of MH, all patients had negative personal history of hypertension and most of them had negative family history 21 (84%) of hypertension.

Keywords: Echocardiographic parameters, ABPMs, white coat hypertension, masked hypertension.

Introduction

Ambulatory blood pressure monitoring (ABPM) was described for the first time since 40 years 1. The ambulatory monitoring tools record blood pressure automatically for (24 hours) duration or more while patients perform the daily activities normally 2. Oscillometric Technique Share used in most monitors. They are tied on a belt and are connected by a plastic tube to the sphygmomanometer cuff on the upper arm 3. The arm of subjects should remain still during inflation of the cuff in addition to avoiding severe physical activities during monitoring 4. The monitor program takes readings every quarter to half hour during the night and the day, the readings then are downloaded into a computer at the end of the recording period 5, 6. White coat hypertension (WCH) can be defined as the clinic blood pressure of (140/90 mmHg) or more on at least three visits, with measurements of less than (140/90 mmHg) at least two occasions in non-clinic settings with no target-organ damage 7. The importance of this diagnosis comes from general acceptance that WCH patients have low risk and weekly benefit from antihypertensive drugs [8]. Some WCH patients may develop sustained hypertension, with increased risk of stroke after sixyears, so the continuous follow-up with ABPM is important [9]. Masked hypertension (MH) is defined as a clinic blood pressure less than (140/90 mmHg) at least three visits and more than (140/90 mmHg) at least two occasions in non-clinic settings by ABPMs 10. The risk of cardiovascular complications of patients with MH is under estimate during the clinic blood pressure measurements 11. This study is aimed to assess the echocardiographic parameters in patients with WCH and MH as determined by ABPMs.

Methodology

This is a cross-sectional study was done in a private clinic in the period from November 2018 to May 2019, it included 66 subjects with no history of hypertension, chronic heart diseases, diabetes mellitus or other chronic diseases. Demographic data were taken from each subject that included age, gender, personal and family history of
hypertension, and the type of hypertension whether MH or WCH, body mass index (BMI) was measured by the dividing the weight (in kg) to height (in square meters). The (24 hours) ABPM was performed during day and night at home, during working days, when the subjects performing their usual activities. It was performed by Medset system (Korea) according to current guidelines. The program of the device was as the following: the readings of BP was obtained at (20-minute) intervals during the day (starting from 6 a.m. to 10 p.m.) with (30-minute) intervals during the night (starting from 11 p.m to 7 a.m), the readings of recordings were then analyzed to give us a (24 hours), nighttime and daytime average diastolic BP (DBP), systolic BP (SBP), and cardiac rate which then down loaded to a personal computer (PC) to be processed with specialized software to obtain the values of nighttime and daytime average diastolic BP (DBP) and systolic BP (SBP).

The echocardiographic parameters were done by using a commercially available ultrasound system (Philips, USA, Clearvue 350 with harmonic probe S 4-1). Left atrial diameter (LAD), LA size, left ventricular end-diastolic diameter (LVED, posterior wall thickness (PWT), anterior wall thickness (AWT), EA ratio and iso-volumic relaxation time (IVRT) were measured by M-mode, a transthoracic echocardiogram were done for all study subjects.

**Statistical Analysis:** The statistical analysis for all results in this study was performed by using the SPSS version 18. Some continuous variables expressed as number and percentage while others variables were expressed as mean ± standard deviation (SD) by using descriptive and frequency analysis. Cross-tabulation and T-test was used to analyze some categorical and continuous data. The level of p values< 0.05 was regarded as statistically significant.

**Results and Discussion**

This study enrolled 66 patients, (41 males and 25 females) and the mean age was 44.48 ± 11.147.

**Relation between gender and types of hypertension:** There was no significant relation between gender and types of hypertension as illustrated in table (1).

ASBP= average systolic blood pressure, ADBP= average diastolic blood pressure, MSBP= maximum systolic blood pressure, MDBP= maximum diastolic blood pressure.
In this study, we provided the new insight to cardiac mechanical dysfunction in WCH and masked hypertensive patients. The highly increased risk of occurrence of cardiovascular events lies behind the clinical importance of MH and WCH. Our study reassured the unfavorable effect of WCH and MH on left ventricular function and structure. The percentage of patients with WCH was larger than MH patients (62% versus 38). There are many mechanisms that illustrate the effect of WCH on cardiac remodeling. One of them is the humoral mechanisms that include increased stimulation and interactions of the renin-angiotensin-aldosterone system and sympathetic system which can lead to pulmonary vascular hyper-reactivity. There are no definitive cause and mechanisms for MH, some studies revealed that there is correlation between MH and young age, male gender and smoking. Our study showed that subjects who had MH have larger target organ damage than WCH, and this agrees with some longitudinal studies like one of them that revealed patients with MH had more cardiovascular morbidity. In addition to a study performed by Ohasama which revealed that the cardiovascular mortality risk was larger for patients with MH and sustained hypertension than for those patients with established normal blood pressure and WCH patients. The explanation for this finding might be related to the fact that patients with masked hypertension remain for long duration without diagnosis and treatment.

**Conclusion**

This study showed the impairment of LV mechanical function in white coat hypertension and masked hypertension and the effect of MH was greater than WCH in addition to the great benefit of using ambulatory blood pressure monitoring to evaluate those patients which is clinically more superior than traditional blood pressure measurements.

**REFERENCE**

Hypothalamic-pituitary-adrenal system release salivary cortisol hormone, which may encourage the proliferation of Mutans Streptococci. The aim of this study was to assess the impact of salivary cortisol and Mutans streptococci on the development of early childhood caries. Eighty children aged 4-5 years old were selected randomly were divided into two groups (forty for each), early childhood caries group and caries free group. Dental caries was determined by measuring the dmfs according to WHO (1987), collection of unstimulated saliva was done and laboratory investigations was carried out to measure the viable count of Mutans Streptococci. Salivary cortisol was measured using cortisol kit (electrochemiluminescence immunoassay “ECLIA”). Statistical analysis was done using SPSS version 23. The statistical analysis showed that salivary cortisol and the viable count of Mutans Streptococci were significantly higher among the early childhood caries group than that found among the caries free group. Moreover, a significant positive association was found between salivary cortisol and the viable count of Mutans Streptococci. Salivary cortisol level was increased in children with early childhood caries so as the viable count of Mutans Streptococci, so it may play a role and has an impact on the bacterial proliferation in those children.

Keywords: Cortisol, early childhood caries (ECC), Mutans Streptococci (MS).

Introduction

Early childhood caries (ECC) is a critical widespread health problem in both industrialized and developing countries. It is defined as the “presence of one or more, decayed non cavitated or cavitated lesions, missing teeth due to caries, or filled tooth surfaces in any primary tooth in a child 71 of months age or younger” 2. The process of caries initiation in ECC is the same as that found in other type of dental caries. Several etiological factors were identified in the development of ECC e.g., cariogenic microorganisms (flora), susceptible tooth (host), fermentable carbohydrate (diet) and time 3. Feeding practice, stress and socioeconomic status were recognized also to be risk factors 4-9. ECC is a fast-growing form of tooth decay, in which there is intensive infection with Mutans streptococci (MS), which sometimes surpass 30 % of the cultivable “plaque-biofilm flora” 10. Mutans Streptococci are the main cariogenic microorganisms associated with this type of disease 11. It had been detected that the level of Streptococcus mutans (in plaque and saliva) was higher significantly among children with severe ECC than those who were caries-free 12. On other hand, it had been reported that highly anxious children had more proximal dental caries in contrast to the low anxious group 13. The levels of salivary cortisol give a precise, dependable, and non-invasive evaluation of stress together in children and adult 14-16, and used appropriately to observe the systemic “adrenocortical-response” to stress 17. In dentistry, salivary cortisol had been used to measure the role of stress in a variety of settings such as, anxiety from dental treatment, dental caries and periodontal disease 18-22. In Iraq, there is no previous study concerning the relationship between ECC and stress. In addition, there is scarcity of literature on this relationship, so, the current study was designed to assess whether there was any association between salivary cortisol level and Mutans Streptococci bacteria in children with ECC in an attempt to evaluate the effect of the stress as a risk indicator for early childhood caries among Iraqi children.
Materials and Method

An approval was gained from the Scientific and the Ethical Committee in College of Dentistry/University of Baghdad/Iraq, after the submission and the reviewing of the study protocol. The study last for 4 months from January until the end of April 2019. Several public kindergartens from (Al-Karkh sector) were visited after getting the permission and an approval from the Directorate of General Education in Baghdad city in order to conduct the study at these kindergartens without any obstacles. Objectives of this study were explained to the kindergartens authority to get their cooperation as much as possible and that was done by a formal documents. Prior to children enrolment, the study design, purposes and probable benefits were explained to the children’s parents, ensuring them for their right to withdraw (if they wanted) from this study at any time they want and a written signed consent was obtained from them regarding their acceptance for the involvement of their children in the current study. Two hundred and fifty child aged between 4 to 5 years old were examined visually and dental caries measurement (dmfs) was recorded according to WHO. Forty child (the study group) were categorized as ECC according to Wyne. Another 40 child had been selected who were free of dental caries (the control group who were matching the study group by age, gender and they were from the same geographical area). A questionnaire was designed concerning the general health of the selected children to ensure that they were free from any systematic disease and did not take any medications for at least the last fifteen days, which could affect the hormone level and MS count.

In the morning between 9–11 AM, unstimulated saliva collection was carried out, in which part of it was used for serial dilution and the other part centrifuged at 3000 rpm/10min and the supernatant stored in deep freeze to be used later for the determination of salivary cortisol. Serial dilution from $10^1-10^6$ was done using (PBS) and then were cultured in the Mitis Salivaris Bacitracin agar (MSB). Simple identification to MS by gram stain, colony morphology, catalase test and mannitol fermentation test was taken place, then counting of the MS was done according to Al-Mizaqqchi 1998 (25) and the result was represented in colony forming unit (cfu/ml).

Salivary cortisol level was determined using a cortisol kit (electrohemiluminescence immunoassay “ECLIA” which were intended for use on Elecsys and cobase immunoassay analyzer) by following the manufacturer’s instructions and the results were expressed in μg/dL. The impact of salivary cortisol and Mutans streptococci was demonstrated using statistical test (student’s t-test and simple linear regression) relies on SPSS program version 23, if the p value was <0.05 it was considered as statistically significant.

Results

According to the findings of the present study, salivary cortisol level was significantly differed between the two groups (p = 0.002), the lower mean was found among children who were caries free (0.67) compared to the ECC group (0.68). With regard to the viable count of Mutans Streptococci (CFU/ml) ×10⁵ among the two groups, the mean value was found to be higher among the ECC group (160.15 CFU/ml) than that found among the caries free group (41.75 CFU/ml). The statistical analysis showed that there was a highly significant difference between the two groups, p value was (0.000), Table (1).

</tbody>
</table>

By using simple linear regression, a positive significant association was found between the salivary cortisol level (μg/dl) and Mutans Streptococci (CFU/ml×10⁵) (Fig.1)
Many etiological and associated risk factors are responsible for the development of ECC. Therefore, it is considered as multifactorial disease and these factors include, biological (26), psychological and behavioral risk factors (27). Stress my influence the relationship between ECC and the psychological factors. Therefore, a considerable attention had been given for the association between early childhood caries and stress in children (28). Many hormones and neurotransmitter released by the hypothalamic-pituitary-adrenal system in response to a stressful situation, this will suppress the activity in the brain and trigger an emotional response of “fear”. After a stressful stimuli, cortisol hormone secreted to the circulation and act as a key event in the activation of hypothalamic-pituitary-adrenal system. Periodontal diseases strongly associated with many psychological variable like stress, depression and anxiety. The oral cavity affected by chronic stress in many ways, the major salivary glands may undergo atrophic changes because of corticosteroids secretion, altering the total volume and the composition of the saliva, stress may cause reduction of the salivary flow rate. Salivary cortisol can be used as a helpful biomarker of adrenocortical function and as an indicator for stress, even its level correspond to 50–60% of plasma cortisol concentrations (30,31). Saliva collection procedure was found to be non-invasive and the children were found to be more comfortable to it. So that in the present study, salivary cortisol level was used which can be achieved without undue discomfort. Results of the present study revealed that salivary cortisol level among the ECC group was significantly higher than that found among the caries free group. This was came in accordance with the other studies (23). While other study (27), stated an opposite result when it found no significant differences in the salivary cortisol levels between the early childhood caries group and the caries free group. This controversial finding might be due to the differences in the sample size, age, method of analysis and time of saliva collection or it could be due to the differences in the socioeconomic status. Dental caries was increased in children with stressful emotional states; this is because of that stress may cause immunosuppression, which might make those children more susceptible to infection with S. mutans or other...
types of bacteria. In the present study, the results demonstrated an increase in the mean value of Mutans streptococci (MS) among children with ECC, which was significantly higher than its value among the caries free group. This result was in agreement with other studies. The cariogenicity of Mutans streptococci result from its acidogenic and aciduric properties. There is a strong correlation between the amount of MS and the presence of the decayed teeth. Mutans streptococci amount reduced when the decayed surfaces treated with the filling materials. So, it is important to monitor the child’s oral hygiene during early childhood. Concerning the impact of salivary cortisol level on the viable count of Mutans streptococci, there was a positive significant association between these two variables among the study and the control group. No available data was found from previous studies concerning the relation between the salivary cortisol level and the viable count of mutans streptococci in children with ECC and those who were caries free. However, the relation between salivary cortisol level and MS bacteria that contributed to dental caries experience might be explained through several possible reasons like; elevated salivary cortisol level might cause immune suppression in the oral cavity, which induce proliferation of the cariogenic bacteria leading to increase in the incidence of dental caries. There is a positive association between dental caries and basal salivary cortisol secretion, from a theoretical perspective; salivary cortisol could suppress mucosal immunity against cariogenic bacteria. During stress the body’s cortisol level increase producing “acid” which provide suitable medium for these bacteria, also atrophic change of the major salivary glands caused by corticosteroids which lead to decrease the quantity (volume) and composition of the saliva, decreasing salivary secretion will reduce the clearance of cariogenic bacteria.

**Conclusion**

In conclusion, the viable count of Mutans Streptococci increased in children with ECC. The results of the current study highlight a relationship between ECC and the salivary cortisol level in children. ECC was positively associated with increased salivary cortisol levels and the viable count of MS. Within the limitations of this study, it can be concluded that a definite relationship was existed between salivary cortisol levels and ECC among children.

Association between Family Cohesion and Mental Health–Related Quality of Life for Secondary School Students in Amara City

Raad Hashim Zamim al-Maryani¹, Kareem R. Sajit²

¹Msc Student. Academic Nursing Specialist, Ministry of Health, Misan Health Directorate; ²PhD. Assist. Prof., Department of Psychiatric and Mental Health Nursing, College of Nursing, University of Baghdad

ABSTRACT

The aim of the study is to identify the association between students’ age, family’s socioeconomic status, family cohesion, and mental health-related quality of life, and to investigate the differences in students’ mental health-related quality of life between the groups of grade, socioeconomic status, living arrangements, birth order, and academic achievement. A descriptive correlational design. In this study, several variables were examined to determine the association between family cohesion and mental health-related quality of life. The target population for this study was drawn from middle and high school adolescents, aged 11 to 22-years, who were living in Amara City. The Family Relations and Cohesion Scale - Student Survey of Risk and Protective Factors (Social Development Research Group, University of Washington, n.d.) was used to measure family interaction and cohesion, which includes six items. The mean age is 16.08 ± 1.99; more than a half age 17-18-years (n = 202; 33.7%), followed by those who age 15-16-years (n = 176; 29.3%), those who age 13-14-years (n = 142; 23.7%), those who age 19-20-years (n = 68; 11.3%), those who age 11-12-years (n = 8; 1.3%), and those who age 21-22-years (n = 4; 0.7%).

Keywords: Association; Family Cohesion; Mental Health –Related Quality of Life; Secondary School; Students.

Introduction

Family systems theory is one of the main theories in the behavior and sociology disciplines. Family systems theory was advanced by pioneers in family therapy during the fifties of the last century in the wake of perusing deal with general frameworks hypothesis¹. General system and family systems theory hypothesis established the framework for other family speculations. Intergenerational family theories incorporate such hypotheses as Bowen’s family treatment, relevant family treatment, and item relations family treatment². The intergenerational models all conceptualize families inside generational examples and see change occurring because of understanding these examples. Bowen built up his hypothesis all through his vocation in the wake of working with mother–youngster dyads in which the tyke was determined to have schizophrenia and afterward later working with families without mental judgments³. Various researchers have discussed the reasons for making life quality a focal point for mental health evaluation. Some of the reasons are simply negative, dwelling on all the things which are incorrect in the way that we conceptualize mental disorders and treat people with them; others are more positive, focusing on potential gains to the client, the helping professions and the general community of focusing on life quality issues⁴. The contents of the Mental health category of quality of life include e.g., positive affect, negative affect (psychopathology—symptoms), affect balance, stress, happiness and morale, Personality, e.g., self-concept, locus of control, extroversion/introversion, Adjustment, social adaptation and personal growth, subjective quality of life e.g., mastery, independence, values⁵. Inside family frameworks and subsystems, enthusiastic atmospheres create which control how relatives collaborate with one another and how social elements are seen ⁶ There was a positive correlation between adolescents’ report of cohesion and parents’ report of cohesion. However, there was a negative correlation between adolescents’ report of cohesion and parent reports of conflict and impairment. Furthermore, there was a positive correlation between adolescents’ report of conflict and adolescent report of impairment, parents’ reports of conflict and impairment,
and clinician report of impairment. Additionally, there was a negative correlation between parent report of cohesion and parent reports of conflict and impairment and clinician report of impairment. There was a positive correlation between parent report of conflict and parent report of impairment. Consistently, there was a positive correlation between clinician report of impairment and parent report of impairment (7).

Materials and Method

The research design for this study was a descriptive correlational design. In this study, several variables were examined to determine the association between family cohesion and mental health-related quality of life. The study population included middle and high school students. The target population for this study was drawn from middle and high school adolescents, aged 11 to 22-years, who were living in Amara City and met the inclusion criteria mentioned below. The accessible population included middle and high school students in Amarah City, the center Missan Governorate, southwest a large Midwestern city in the United States. Participants were those who met the previously mentioned inclusion criteria and were willing to participate in the study. Data collection took place at those locations. For the purpose of the present study a questionnaire was designed and developed by the researcher. Demographic data were collected using a form that requests the subject’s age, gender, birth order, living situation, grade. The Measurement properties of the Adolescent Quality of Life Mental Health Scale was used to measure the measure mental health-related quality of life. Data were analyzed using the IBM Statistical Package for Social Science (SPSS) version 21 for Windows©. Descriptive statistical measures of frequency, percentage, mean, and standard deviation were used to demonstrate the participants’ sociodemographic characteristics. Inferential statistical measure of Bivariate Spearman correlation was used to measure variables that can predict variables that influence both family cohesion and mental health-related quality of life.

Results and Discussion

The mean age is 16.08 ± 1.99; more than a half age 17-18-years (n = 202; 33.7%), followed by those who age 15-16-years (n = 176; 29.3%), those who age 19-20-years (n = 68; 11.3%), and those who age 21-22-years (n = 4; 0.7%). Concerning father’s level of education, less than a fifth are elementary school graduates (n = 112; 18.7%), Regarding mothers’ level of education, less than a quarter are unable to read and write (n = 134; 22.3%). Concerning household’s monthly income, less than a quarter have an income of less than 300.000 (n = 142; 23.7%), Lastly, less than a third of students came in the first birth order (n = 184; 30.7%), followed by those who came in the second order (n = 132; 22.0%).

There is a statistically significant difference in family cohesion among family’s monthly income groups (p-value = .001). On the other hand, there is no statistically significant difference in students’ mental health-related quality of life among family’s monthly income groups.

There was no statistically significant correlation between student’s age and mental health-related quality of life. There was no statistically significant correlation between student’s birth order, family cohesion and mental health-related quality of life. There was no statistically significant correlation between family cohesion and mental health-related quality of life. There was a statistically significant difference in family cohesion among students’ age group (p-value = .043). On the other hand, there is no statistically significant difference in students’ mental health-related quality of life among students’ age groups. There was no statistically significant difference in family cohesion and students’ mental health-related quality of life between students’ gender groups. There was a statistically significant difference in family cohesion among students’ age group (p-value = .043). On the other hand, there is no statistically significant difference in students’ mental health-related quality of life among students’ level of education groups. There is a statistically significant difference in family cohesion among mother’s level of education groups (p-value = .05). On the other hand, there is no statistically significant difference in students’ mental health-related quality of life among mother’s level of education groups. There was a statistically significant difference in family cohesion among family’s monthly income groups (p-value = .001).

On the other hand, there is no statistically significant difference in students’ mental health-related quality of life among family’s monthly income groups. There was no statistically significant differences both in family cohesion students’ mental health-related quality of life among living arrangements groups.

Conclusions

The findings of the present study conclude that the older the age the student, the better the mental health-related quality of life. The prior the birth order, the better the mental health-related quality of life. The better the family cohesion, the mental health-related quality of life. The higher the father’s level of education, the better the family cohesion. The higher the mother’s level of education, the better the family cohesion. The higher the monthly income, the better the family cohesion.

ABSTRACT

School-based health education is an appropriate approach for improving students’ knowledge, and hence practices regarding multiple risk behaviour. The objective of the study was to examine the impact of an educational intervention on the risky behaviours of the students, which will, in turn, motivate the students to take protective measures against the risky behaviours. This quasi-experimental study was conducted on 190 students selected randomly from three high schools in Erbil city, during the academic school year 2017-2018. A self-administered questionnaire on practices assessment regarding multiple risk behaviours was developed and validated by the experts regarding the relevance of the items. A structured teaching program for imparting knowledge on various aspects of health risk behaviours was developed based on extensive review of literature and experts’ opinions. Of the 190 students, 47.9% were males and 52.1% were females. The study revealed a statistically significant improvement in the mean rank of the practice of students following the implementation of a health education program (p<0.001). Implementing a health education program about multiple risk behaviour on high school students in Erbil city is achievable and valuable.

Introduction

In developing counties, adolescents are the susceptible population in terms of health associated with risk behaviour due to their bio-psycho-social characteristics, and health risk behaviour may appear obviously as potential prominent behaviour with serious results, particularly among adolescents 1,2. Bio-psycho-social changes may lead to unhealthy lifestyles in adolescence, which tend to co-occur and have similar determinants. This has a major impact in terms of disease, disability, death, and high costs to families and the community 3-5. Adolescents are more prone to risk behaviour 6 as it is a critical life-course period during which patterns of health behaviour are formed, before tracking into adulthood, and they experience physical, mental, and social interactional changes during this period 7. Moreover, adolescence is characterized by an increased adventurous tendencies and peer influences. As a result, they are susceptible to new ideas that may lead to risk behaviour 8. Health risk behaviour may also lead to unhealthy lifestyles in adolescence, which tend to co-occur and have comparable determinants. This has the most important impact in phrases of disease, disability, death, and high costs to families and society 9. To avoid unhealthy lifestyles, health promotion programs are performed at schools. These are convenient environments to improve public health that allows contact to higher numbers of adolescents 19,10. Systematic reviews have been performed to evaluate the effect of school-based interventions regarding nutrition and physical activity 10,12, alcohol consumption 10,13, or violence 14, which found some positive effects of variable magnitude. Knowledge is considered as one of the factors that influence adolescent students’ decision to be involved in risk behaviour [8], with insufficient knowledge about the multiple health risk behaviour and

its results, a student will be less likely to make a fact-based and informed decision. Studies have shown that providing adolescence with precise information about negative risk behaviour consequences which may encourage abstinence from health risk behaviour. Hence, providing health education in schools about health risk behaviour can encourage students to make positive decisions on their future lives. Accordingly, the purpose of this survey was to examine the impact of an educational school intervention for high school students intended at improving their knowledge for multiple health risk behaviour and its adverse outcomes, which will, in turn, stimulate students to take protective measures against health risk behaviour.

**Methodology**

**Participants:** This quasi-experimental (one group; pre, and post-test) design was conducted from November 2017 to June 2018 amongst high school students in Erbil city which is the capital of the Kurdistan Region-Iraq, knowing that the high schools include three stages (10, 11, and 12). According to the data obtained from Erbil Directorate of Education, the total number of high schools in Erbil city was 78 during the academic year 2016-2017. The mentioned schools were categorized according to the gender of the students into three categories: males, females, and mixed schools. One school from each category was selected by simple random sampling technique using the Microsoft Excel computer program. Students of grade 11 from these three schools were the target population for the educational program as the prevalence of risky behaviour was the highest among the students of this grade (according to the results of an unpublished study of the researchers which was done just before this study). In addition to that, students of grade 12 had no time to participate in the program as they were busy with the final exams. A random sample of 190 students was collected from these three schools, using the simple random sampling method, which was done by the Microsoft excel computer program. Students aged 14-18 were included in the study.

**The data collection tool:** A self-administered questionnaire was developed by the researchers based on the extensive review of the literature. The questionnaire consisted of two sections. The first section is related to socio-demographic items such as age, gender, and socioeconomic status level. The second section was designed to assess the students’ practices that consisted of 15 main questions about risky behaviours. A score of 1 was given if the student practices a risky act. Accordingly, a risk scale of 15 scores was generated which was divided later into three equal categories (5 in each), and these are low, medium, and high risk. It is worth to mention, that the researchers used the same questionnaire of an unpublished study that they conducted just before this study (mentioned above) involving 1000 students, and the internal validity and reliability had been ascertained before conducting the mentioned study.

**The Educational Program:** A structured educational program for imparting knowledge on various aspects of health risk behaviour especially prevention was developed by the researchers. The content of the educational curriculum was designed based on extensive review of literature and experts’ opinions. The intervention consisted of a series of four educational modules. The module content was created and edited by the researchers; the first module included an introduction to multiple health risk behaviour and historical background, some definitions, side effects, and negative consequences, and causes and risk factors. The second and third modules identified the types of multiple health risk behaviour and the final module described prevention of multiple health risk behaviour. Before the curriculum is finalized, it has been sent to three experts. The three experts have read and edited the content of the curriculum to assure that the program fits local teaching and learning styles.

**The procedure:** After obtaining the informed consent, the students in the three schools were given the pre-test questionnaires one week before the administration of the educational program. The questionnaires were administered in the classrooms by schools’ social workers (Rabers) in the presence of the primary researcher. Each student was given a serial number to be followed in the second assessment (post-test). After administration of the questionnaires, twelve ‘45 minute-sessions’ were presented using lectures, group discussions, and booklets. These sessions were mainly taught by the “Rabers” during a six months’ period. These “Rabers” were trained properly by the primary researcher on the content of the educational program. As a reminder, each student was provided with a copy of a health education booklet prepared and designed by the primary researcher and named “Know some facts about multiple health risk
behaviours among adolescents”. One week later after the end of session, students were asked (for the second time) to complete the same questionnaires (post-test).

**Data Analysis:** The data were coded and entered into the Statistical Package for the Social Sciences (SPSS) software, version 22. Wilcoxon Signed Ranks Test and McNemar tests were conducted as univariate analysis to compare pre-to post-intervention changes in the percentage of students’ knowledge of each level (low, moderate, and high). Chi-square tests were conducted to compare knowledge attainment with some variables. A P value of ≤ 0.05 was considered as the level of significance.

**Results Discussion**

A total of 190 students (47.9% were males and 52.1% were females) completed a pre and post-intervention survey: The mean age ± SD of the participants was 16.59 ± 0.784 years, ranging from 14-18 years. Table 1 shows that 47.4% of the students were practicing moderate and high-risk behavior before the intervention which decreased to 15.8% after the intervention. The table shows also that the behavior of more than two thirds (67.8%) of those who had practiced moderate and high-risk behavior improved, to fall in the low-risk category (p < 0.001). Before implementing the educational program, no significant association was detected between the age and the risk behaviour (p = 0.248) as presented in Table 2. The prevalence of the medium and high-risk behaviour was 65.9% among males, which was significantly higher than the prevalence (30.3%) among females (p = 0.001). No significant association was detected between the socio-economic status and the risky behaviour (p = 0.733). The same pattern can be applied after the implementation of the educational program as presented in Table 3 which shows no significant association between the prevalence of risky behaviour with age (p = 0.394) and the socio-economic status level (p = 0.247). The prevalence among males (23.1%) was significantly higher than the prevalence (9.1%) among females (p = 0.007). It is evident in Table 4 that all the parameters of the risk scale decreased after the implementation of the educational program. There was a significant decrease in the mean ranks of risk score from 77.87 before the program to 21.5 after the program (p < 0.001). The prevalence of the specific items of the risky behaviour before and after the implementation of the educational program are presented in Table 5 which showed a significant decrease in the prevalence of the majority of the items except for wearing the seat belt (p = 0.368), and bullying (p = 0.500).

**Conclusion**

A health education program about multiple health risk behaviours is feasible to be implemented in high schools of Erbil. Thereby, proper implementation of this school-based prevention program is critical to strengthening protection and reducing the prevalence of multiple health risk behaviours amongst this part of the population.

ABSTRACT

Objective: Evaluate and compare the fracture resistance between CAD/CAM interim dental bridges and conventional interim resin dental bridges. Ideal model of full dental arch was used as a pattern to simulate three units dental bridge with (maxillary first molar and maxillary first premolar) as abutments. This model was then duplicated and resulted cast sectioned by separation disc to produce a small cast that limited to the prepared dental bridge area only. This cast was then duplicated and resulted mold poured by molten wax to produce wax pattern that was modified before casting with the use of radial shoulder finishing line design instead of chamfer finishing line that came with the original ideal model. From this wax pattern, metal master model was produced by casting using lost wax technique. Thirty two impressions for master model with two stage putty-wash impression technique were taken and poured with die stone to produce thirty two stone models. The results showed that the highest mean value of fracture resistance was recorded by Group 1 (735.9N) followed by Group 3 (585N), Group 2 (508.8N) and Group 4 (460.8N) respectively. Concerning fracture mode, the connector area showed the weakest and most frequent area of fracture.

Keywords: CAD CAM Interim Dental Bridge, conventional, Fracture Resistance.

Introduction

Interim fixed dental prostheses (FDPs) are important to protect tooth from physical, biological and mechanical effects until the final prosthesis can be cemented. These restorations could be short-term (until the final prostheses has been fabricated) or long-term (in case of a patient requires a longer treatment period, as in full mouth prosthodontic therapy, orthodontic or endodontic treatments, or in oral surgery)¹ Long-term interim FDPs needs materials with mechanical properties that guarantee enough fracture strength and adequate dimensional and marginal accuracy (2-5). Numerous interim materials are used for dental treatment. “Polymethyl-methacrylate (PMMA), a synthetic polymer of methylmethacrylate”, was the most common material due to its high strength and stability of color, and easy repair. On the other hand, PMMA produced significant heat during polymerization, which may lead to polymerization shrinkage and pulpal discomfort (7,8). Using computer-aided design/computer-aided manufacturing (CAD/CAM) to produce interim restoration is of interest for the reason that CAD/CAM interim therapy uses optical impression which eliminates patient’s discomfort. In addition to that, CAD/CAM interim materials are prefabricated with the use of blocks that are industrially polymerized, that prevent polymerization generated shrinkage and heat (9-10). Interim crowns and bridges are important components of fixed Prosthodontics treatment. Interim restorations should have sufficient mechanical property to support functional and removable forces, that maintain tooth position and exhibit marginal integrity and biological properties conductive to periodontal health (12).

Materials & Method

Ideal model of full dental arch made from plastic material prepared by Ivoclar company (figure 1) was used in this study and prepared to act as pattern that simulate three – unit bridge, the maxillary first molar and maxillary first premolar as abutments and the maxillary second premolar is missed.
This model then duplicated resulted mold poured by die stone to make a cast that then sectioned using separation disc to produce a small cast that limited to required work only and as shown in figure (2).

This cast then duplicated to form a mold that poured with molten wax to obtain a wax pattern that modified in its design to make the margins more prominent and shaping from chamfer to radial shoulder finishing line that proved to give more accurate margins. This wax pattern then sprued, invested and casted to obtain the final master model (figure 3).

Thirty two impressions for master model with two stage putty- wash impression technique were taken and poured with die stone to produce thirty two stone models, then divided into four groups with eight models per group, according to the material and fabrication technique used to produce interim dental bridge and as follow:

**Group 1:** Ivoclar CAD CAM (Telio CAD).

**Group 2:** Ivoclar conventional (Telio Lab).

**Group 3:** Vita CAD CAM (Vita CAD-Temp).

**Group 4:** Vita conventional (Vita VM CC).

**Interim dental bridges fabrication by conventional technique:** Group 2 and group 4 samples were fabricated by this technique using Telio lab PMMA and Vita VM CC cold cure acrylic resin materials. First, waxing up for full anatomy to dental bridge was done on every model, and then silicone indexing key was formed on it that registered the fine details of the waxing up. After set, silicone key removed and remaining wax cleaned off, and then separating fluid was applied using fine brush. Mixing powder and liquid in silicone bowl as manufacturer’s instruction was utilized with standard ratio and after reaching dough stage, the silicone key filled with material and seated back on model and placed in polymerizer for about 15 minutes with a pressure of 2 bar and temperature of 40-50°C. After polymerization, finishing and polishing for every dental bridge was made.

**Interim dental bridges fabrication by CAD/CAM technique:** Group 1 and group 3 samples were fabricated by this technique using Telio CAD PMMA blocks and Vita CAD Temp composite resin blanks. First the models were covered with a scan spray and fixed on the dental scanner (Imes-Icore) and bridge design was by Exocad software and the same design was for both types of materials with cement space of 100um, wall thickness in occlusal of 1.5mm and 0.8 mm circumferentially and connector dimensions was set for 12 mm² for both milled materials that used in the current study. The dental bridges were then milled using CORITEC 250i machine. After milling, dental bridge separated and smoothed.

Before fracture resistance testing and for the metal model to be easily fixed between the jaws of testing machine holder and to prevent any movement from master model during testing, metal model was embedded in auto polymerizing acrylic block that prepared by mixing cold cure acrylic resin in a rectangular shaped split mold that specially designed for it with a dimensions of (3cm x5cm) and height of (3cm). The samples were tested for fracture resistance by the use of three point bending test with a “universal testing machine”(Layree, China). Each sample was positioned with a slight pressure on the metal model and gripped on the testing machine. Steel ball with a diameter of 5mm was used to apply load on samples
and this ball positioned on machine arm that loaded in the dental bridge pontic (in central fossa area) (figure 4) with a speed of (1mm/min.) for the crosshead that applied load until sample fracturing taken place. In order to distribute the applied force over a larger area and to avoid loading stress peaks on the pontic surface, i.e., homogenous stress distribution, rubber piece with 1 mm thickness was positioned between the sample and load tip.

On the computer screen the program window displayed and bending test selected. The increasing compression load applied on the sample and the maximum load at the time of fracture recorded and displayed in Newton (N). At the same time the program set and displayed different curves (stress-strain, load- extension) and a sudden load drop was detected on stress strain curve at the time of fracture. Mode of fracture for samples was evaluated to determine fracture patterns in dental bridge that could happen at different points (pontic, abutment, mesial connector, distal connector or both connectors).

### Results and Discussion

A total of 32 measurements of fracture resistance from four groups were recorded for two different techniques and two different manufacturers in Newton (N). Table (1) shows the fracture resistance means, standard deviations, minimum and maximum values for the four groups. The fracture resistance results showed that the lowest mean was for Group 4 (460.8 N) and highest mean was for Group1 (735.9 N).

The highest and lowest fracture resistance means values in Newton of the four groups are shown in Figure (5).

To see whether the difference in the mean value for all groups was statistically significant or not, one way (ANOVA) test was applied. Highly significant difference was founded in fracture resistance among all experimental groups.

LSD test which were applied to know the actual significant levels among all probable pair wiselyed for different groups. There was a statistically significant difference in the fracture resistance mean values between the four groups.

### Modes of Fracture:

The samples were examined under (20x) magnification using light microscope to identify the type of fracture. The frequency of each mode of fracture for all groups was calculated. The identified modes of fracture were (mesial connector, distal connector, both connectors, pontic or in abutment). This analysis indicated
that mesial connector was the most frequent mode of fracture for the tested samples. The improved mechanical properties play an important role when the interim FDPs are expected to function for extended periods of time or when additional therapy is required before completion of definitive treatment like during the prosthetic phase of dental implants and reconstructive procedures, while evaluation of a change in vertical dimension, for orthodontic stabilization, in case of assessing the results of periodontal and endodontic therapies and in cases of bruxism. Interim restorations may fracture throughout construction, functioning, trimming or even after removed from patient’s mouth. This failure often occurs as a result of a crack propagating from a surface flaw, inadequate transverse strength, impact strength, or fatigue resistance. In long span prostheses, connector region subjected to fracture mostly as a result of some functional or para-functional movements that led to localization of stresses inside the prosthesis. Fracture could also happen as a result of voids during construction of prosthesis.

**Master Model:** Natural teeth have a large variation due to size, age, shape, anatomy and storing periods after their extraction causing difficulty in getting standardized abutments and for that, metal models were used in this study. The advantages of using metal model includes; easy reproduction, standardized preparation, more resistant to destruction, wear or scratching under testing procedure.

**Use of Loading Ball and Rubber Foil:** Stainless steel ball with a diameter of 5mm was utilized in this study to represent pontic contact pressure by opposing cusps and those were affected by elastic modulus ratio of the sample to loading ball elastic modulus and radius. Rubber piece was placed between the dental bridge sample and loading ball to be as stress stopper that simulating cushion activity of food between upper and lower teeth and help in avoid cone cracks.

**Fracture Resistance Testing method:** The interim dental bridge samples were subjected to three points bending test (the same test used for bars specimens). Steel ball loaded in pontic at area of central fossa with a speed of (1mm/min.) for the crosshead until dental bridge fracture taken place. Initial fracture was registered as a result of the load application.

**Test Results:** All fracture resistance test mean values for the dental bridges in the current study were exceeding reported maximum biting force in the premolar region (300N) reported by Hagberg in 1987. The current study was in agreement with whom made a comparison of fracture strength and failure modes for CAD/CAM interim crowns (Telio CAD, Vita CAD-Temp and Peek) with that of direct interim crowns (Protemp) and concluded that CAD/CAM crowns showed higher fracture strength than direct one’s.

The present study comes in agreement with a study by whom compared the fracture strength of interim FDP’s constructed by direct method and CAD/CAM fabricated interim FDP’s (Telio CAD material) and reported that the PMMA CAD/CAM restorations showed higher fracture resistance than conventionally fabricated PMMA restorations. The present study was in agreement with whom evaluated the impact of connector cross-sectional area on the fracture load of 3-unit CAD CAM (Telio CAD, Vita CAD-Temp and art Bloc Temp) FDPs and compared this with conventionally fabricated ones and concluded that the CAD/CAM resin FDPs revealed significantly higher fracture load values than conventionally fabricated FDPs and showed a significant increase in fracture load with the increase of the cross sectional area.

**Effect of fabrication technique on fracture resistance:**

CAD/CAM resin blocks exhibit high quality concerning its mechanical characteristics and microstructure for the fact that they were industrially fabricated under constant high pressure and heat (polymerization taken place during these fabrication steps only). This permits prosthesis to be fabricated with high fracture strength when compared with traditionally fabricated materials.

Commonly, interim restorations were fabricated from self-cured resin material either in shape of paste (resin composite) or powder and liquid system (PMMA). Interims that were fabricated by direct method uses self-cured composites and those that were fabricated by indirect method uses PMMA based acrylic resins that their polymerization takes place in a polymerizer device. Parameters for polymerization of interim FDP’s were essential for their mechanical characteristics. When compared with CAD/CAM constructed FDP’s, conventional interim FDP’s were influenced by polymerizing device, operator, polymerization duration and mixing ratio.
PMMA materials fabricated by conventional technique are uneven in shape, size and have grainer consistency and those were as a result of air bubbles incorporation, the way that materials were dispensed in the mold and insufficient mixing of the material which led finally to the lower fracture resistance values. There is important factor that may influencing the conventional technique materials inferior results concerning fracture resistance, which is the incorporated micro cracks and voids that reduce its fracture resistance significantly during mechanical and thermal processes.

Fracture Modes: The most frequent fracture mode in the current study was through connector area. Direction of the propagation was obliquely attaching load point of pontic at occlusal area with gingival embrasure area of the connector. The most area of fracture in all four groups was in mesial connector. This mode has observed clinically and attributed to a cantilever effect as a result of fractured connector in occlusal aspect following the initial fracture from gingival region. Crack propagation line resulted from stress concentration that simulates cracks in way perpendicular to principal tension long axis. When the axial load applied on the pontic, compressive stress were initiated in occlusal embrasure region first, and then followed by tensile stresses at gingival embrasure region. Connectors represent the region of least cross section across the bridge, and thus are at high risk for fracture, because of the concentration of stresses in this region during flexure under occlusal loading. According to Tinschert, fractures of dental bridges typically occur between the abutment and the pontic. In the study of Fischer et al., finite element analysis indicated that the connector between the bridge abutment and the pontic was the critical bridge area.

Conclusions

Cad/Cam groups showed higher fracture resistance than conventional groups. Group 1 (Ivoclar Cad Cam) showed highest fracture resistance than other groups. The weakest and the most frequent fracture point in all groups is the connector. Accordingly, for long span and long term interim treatment; Cad/Cam fabricated interim dental bridges are recommended.

Prevalence and Some Epidemiological Symptoms of Molluscum contagiosum Virus Infection in Al-Najaf Province

Ebtehal Edrees Shubbar1, Huda Jameel AL-Khilkhali1, Nawras Alwan AL-Barqawi1
1Microbiology, Faculty of Science, University of Kufa, Iraq

ABSTRACT
Molluscum contagiosum virus causes awidely spread infection worldwide. Which can affect imunocompetent as well as immunocompromised individuals. Corresponding native studies are still rare. Current study targeted the screening of the mcv infections among patients visited Al-Sadr Teaching Hospital in Al Najaf Province. During the study period a total of 619 patients were clinically diagnosed with the virus from 3699 patients who visited the dermatology clinic, Furthermore histological study was carried out to investigate the age effect on developing the infection. patients with MCV comprised 349 males, and 270 females. According to age patients were divided into six age groups, the 0-5 years age group occupied the first order with 173 patients. Regarding the month of the study, April was the first recording 110 patients. Regarding the histological study the higher the age was the more the inclusion bodies to be noticed. Molluscum contagiosum virus can infect various age groups of both genders. Different samples taken from different ages showed common features of MCV cytopathic effects but with different density of their numbers in each sample.

Keywords: Molluscum Contagiosum, Inclusions bodies, Skin infection, Iraq

Introduction
Molluscum contagiosum, is a DNA virus belongs to the poxvirus family. taxonomically Molluscum contagiosum for now is the only member of the poxvirus family which causes significant disease in humans (1,2), the only known hosts for MCV are Humans. Molluscum contagiosum virus (MCV) causes a superficial infection of the dermis as a lesions in the skin and mucous membranes which represents a benign self-limiting infection observed by the healthy individuals. This condition is characterized by the formation of distinctive, persistent dermal lesions that may disappear within several weeks to several months. Autoinoculation play an important role in prolonging time of infection due to accidental transmission of the virus to other parts of the body that is associated with circumstances involving skin-to-skin contact (e.g., sports such as wrestling, sexual activity, and so on 4). Infection appears on face, arms, legs and anogenital regions as a single or multiple umblicated papules or nodules 5. MCV infects both children as well as adults,6, although children seem to be the most targeted category. In adults most MCV occurs in people with an immunosuppressive immune status, but it can also be seen in immunocompetent adults,8, in the latter cases they are mostly self-liming, while in the earlier cases they are tend to be prolonged and more severe like with patient HIV infection9. Lesion of the virus is typically characterized by the absence of inflammation even though containing high titers of live virus which reflect the remarkable ability of the virus to inhibit the human innate immune response.10. People with dermal allergy, atopic dermititis show more extent lesions and course of the infection as compared with patients suffering from MCV alone 4. Attempts to culture the virus had been failed instead the lesion and the virus particles has been studied extensively by electron microscope.(11,12). Diagnosis of the virus does not depend on laboratory investigations alternatively, it could be done clinically 4, besides other methods like dermoscopy that may resolve diagnosis of misdiagnosed cases within shorter time and with accurate results. Various approaches have been used to treat MCV infections, physical methods: cryotherapy, laser treatment, chemical methods: iodine,
lactic acid, Imiquimod, besides the antiviral drugs like cidofovir. Recent years have witnessed an increase in number of patients suffering from MCV infections. In Al Husseiny teaching hospital the second common dermal disease was the viral diseases including MCV infections. conducting studies on MCV infections in Iraq generally and particularly in Najaf province still insufficient if found at all. This study was planned to achieve the following aims: detection of cases of MCV that are diagnosed clinically by estimating number of MCV patients visited Al Sadr teaching hospital/dermatology clinic during the study period, monitoring common approaches for treating MCV cases, and histological comparison of three randomly selected MCV patients from three different age groups.

Materials and Method

Patients’ Data: During the study period; from beginning of January 2018 to the end of June 2018, regular visits had been made to Al-Sadr teaching Hospital/dermatology clinic in order to collect outpatients data whose clinically diagnosed as MCV patients.

Histological study: From three different age groups, samples (MCV papule) of three patients whose dermatologist recommended proceeding curettage had been collected in sterile tubes containing 10 % neutral-buffered formalin for fixation. The 2-3 mm diameter samples then transported to laboratory of histological preparations in science faculty/university of Kufa, where they were processed and paraffin embedded then cut into sections with 5 µm thickness, finally stained with Hematoxylin and eosin. Diagnosis was done by professional histologist at Al-Sadhr teaching hospital.

Results

MC outpatients Data analysis: During the study period 619 patients were clinically diagnosed as Molluscum contagiosum patients, from 3699 patients visited the dermatology clinic at Al-Sadr Teaching Hospital, comprising 349 males and 270 females with an overall percentage 56.4% and 34.6 % for both respectively.

The following figure shows distribution of patients’ gender according to the study month where April witnessed the highest number of patients, while May recorded the lowest. Obviously no significant differences were observed regarding the month of study between male and female patients.
Regarding age, patients were grouped into six age groups measured in years: (0-5), (6-15), (16-20), (21-30), (31-40), (41≤), ranging from six months age to 65 years. During the study period the highest group was the first one recording 173 (27.9%) patients followed by the second group with 144 (23.3%) patients, next was the fourth one with 111 (17.9%) patients, while the third group represented the lowest number of patients with 50 (8.1%) patients. (figure-2)

![Figure 2: Distribution of patients according to age](image)

**Histological study:** In order to examine the effect of age on development of the histological changes within the infected tissue, three biopsies were surgically removed from three different aged patients (6, 26, 42) years old, and submitted for sectioning and staining to evaluate the differences if found. Grossly, selected viral lesions had the typical appearance specifically the white round shape with central depression. Histologically, the three samples showed the classical appearance of molluscum contagiosum lesion which characterized by the intracytoplasmic acidophilic inclusion bodies the so-called molluscum or Henderson-Paterson bodies as shown below.

Sample 1: taken from a patient of 6 years old
Sample 2: taken from a patient of 26 years old
Sample 3: taken from a patient 42 years old

Discussion

The infection of MC is considered as benign and has little significant clinical manifestations, this made the actual prevalence underestimated. This study spotted a light on the prevalence of MCV in Al-Najaf province where the results were similar to the findings of 4, regarding gender.

Also it revealed that the least aged patients were the highest frequency of infection where MCV infection is said to be one of the three most common skin infections caused by viruses in children 16, while differently showed the highest incidence in the age group of (1-4) years.

The infection among children can be attributed to either of explanations: first it could be due to the relationship between the age and the efficiency of the immune system, where it does not work optimally at both ends of lifetime. Besides researches refer to the ability of the MCV to inhibit the immune system by producing evasion molecules 16, second children could be more potential to internally disseminate the virus because of their relatively poor self-hygiene care. While in progressive age there is weak response to activation and proliferation of T-cells similarly the B- cells show weak response to some of viral infections 17.

We also noticed that different sites of the body could be infected with the virus, but sites more affected than others are traumatic or skin injured8. The biopsy excision is highly beneficial particularly in overlapping cases that may lead to misdiagnosis by the physician, furthermore it provides significant tool in studying histological changes caused by the MCV 18. Skin infection of MCV is characterized with fleshy colored umbilicated dome shaped papule. When microscopically examined typically shows the molluscum bodies (MB), MCV replicates in the stratum spinosum of the epidermis. within the keratinocytes specifically in the cytoplasm, which result in their hypertrophy and increase in numbers producing the formerly mentioned inclusion bodies 19, current study clarified that the density of number of inclusion bodies were varied according to age were we notice that they are more dense in the elderly patient as compared with younger ones

Conclusion

Molluscum contagiosum virus can infect various age groups of both genders. Different samples taken from different ages showed common features of MCV cytopathic effects but with different density of their numbers in each sample.

The Role of Hyperglycemia and Coexisting Hypertension in the Development of Diabetic Nephropathy in Type II Diabetes Mellitus

Kadhim Abbas Al-Hilali, Mosa Jaafar Mosa, Ahmed Ali Hussein

1Dept. of Nursing, Alsafwa University College, Karbala, Iraq

ABSTRACT

Background: Diabetic nephropathy (D.N) is an important cause of morbidity and mortality and now the most common cause of end stage renal failure ESRF worldwide but especially in developed countries.

Objectives: The aim of the study is to know the role of hyperglycemia and co-existing hypertension HTN in the development of D.N. among patients with type II Diabetes Mellitus(DM).

Patients and Method: One hundred and twenty one diabetic patients were enrolled in a prospective observational study. Sixty six patients were females and fifty five were males. Besides full history and physical examination data were collected according to a format. At the end, these data were collected and analyzed statistically. The average age was (54 ± 2.1) year, female to male ratio 66 to 55 (1.2:1) the number of patients with hyperglycemia was 90. Average random blood sugar R.B.S was 259 ± 1.6 mg/dL. number of patients with hypertension was 71, the average of systolic blood pressure BP was 158 ± 6.1mmHg and diastolic was 10.2 ± 1.1, the average duration of D.M. was (10.5 ± 4.2) year, the average of glycosylated hemoglobin HbA1c was 9.8 ± 2.1. the number of patients with D.N was 77.

Keywords: Diabetic Nephropathy, Type II Diabetes Mellitus, Hyperglycemia, Co-Existing Hypertension.

Introduction

Diabetes Mellitus D.M is defined as fasting blood sugar (F.B.S) at or more than 126 mg/dL or a random blood sugar (R.B.S) at or more than 200 mg/dL. Plus signs and symptoms of DM plus glycosuria and recently by estimation of glycosylated hemoglobin (HbA1c) 1. Diabetes Mellitus is a heterogeneous disorder or syndrome because overtime it results in damage or dysfunction of multiple organ-system including the kidney causing diabetic nephropathy 2. Diabetic nephropathy DN is pathologically defined as changes occurring in the kidney as result of DM (3,4) with thickening of basement membrane of glomeruli, widening of the slit membrane of the podocytes, an increased number of mesangial cells, and matrix which invade the glomerular capillaries and eventually produces nodular deposits called kimmelstiel-wilson nodules (5,6). Chemically high blood sugar leads to formation of advanced glycation end products and cytokines which are implicated in the mechanism of development of D.N (7,8). Clinically D.N. is characterized by excretion of abnormal amount of albumin in the urine, Plus at the end stage renal failure other signs and symptoms like; tiredness, edema, frequency of urination, pallor, puffiness of the eyes and ankles, anorexia, nausea, and vomiting etc… Diabetic nephropathy can be monitored by testing urine regularly for urinary albumin, urinary creatinine and serum creatinine (S.Cr). the amount of the protein in the urine reflects the degree of damage to the any still functioning glomeruli. The value of S.cr can be used to estimate the glomerular filtration rate(GFR). The most common cause of (ESRF) specially in the developed countries is D.N., that affect approximately one quarter of adults with D.M in united states(9,10) and also associated with an increased risk of death in general population.
particularly from cardiovascular disease. Diabetes Mellitus with co-existing hypertension HTN induce pathophysiological change in the kidney including inappropriate activation of the renin-angiotension-aldosterone system, inflammation, increased sympathetic nervous system activation, increased oxidation stress and other mechanisms which eventually share in the damage of the kidney. Women with D.M have a higher incidence of HTN than men. The earliest evidence of D.N is a microalbuminuria which means the presence of small quantities of albumin in the urine (30-300)mg per 24hours, this stage is called incipient nephropathy because the patient looks clinically healthy and biochemically the kidney function expressed by glomerular filtration rate GFR is preserved. The disease then progressed with increased excretion of albumin to more than 300mg/24h (macroalbuminemia), and ultimately progressed to renal impairment and failure. this stage is called overt nephropathy, in which the patient feels ill and unwell, looks pale with puffiness of the face and ankles, dry, itchy skin and frequency of urination. Regular examination of albumin is a good monitoring test to discover the disease progress. The use of dipsticks is a useful but insensitive way for quantitative albumin measurement, the efficient way is by radioimmunoassay method. The progress of D.N can be delayed, stopped, or even reversed if early discovered by; strict glycemic control, aggressive blood pressure control (below 130/80 mmHg) with the use of angiotension converting enzyme inhibitors (ACEI) or angiotension receptor blockers (ARBs), quit smoking, life style modification, control of obesity, the use of statins and aspirin etc... Persistent hyperglycemia represented by raised HbA1c the relation between ACR and HbA1c was seen in table 4. The relation of pre-existing HTN and its effect on ACR was shown in table 5, the relation between chronicity of D.M and the development of D.N is shown in table 6 this table shows that in the first five years after diagnoses of D.M one patient would have D.N microalbuminurea but when more than 20 years has passed since diagnoses of D.M 19 patients would have D.N out of 20 (95%). Women are more liable to develop D.M and HTN than men this is probably due to the increase in their waist circumference and body mass index (BMI) compared with men. In addition the no. of patients with D.M increases with age (see table1) which shows the female to male preponderance 1.2:1. Although not classically: in this study hyperglycemia plays a great role in the development of D.N because it induces pathophysiological changes in the glomeruli e.g by inducing activation protein-kinase C and other product.
mentioned earlier which induce mesangial expansion and glomerular basement membrane thickening etc….

The usual story is that patients with DM usually started as normoalbuminuric whether controlled or uncontrolled. By the passage of time(chronicity) especially if remained uncontrolled, some of them will pass to the stage of microalbuminuria. If action would not be taken to control, stop or reverse the risk factors, they would pass to the stage of macroalbuminuria and finally, to the end stage renal disease (ESRD)…Table 2.

Practically at the time of diagnosis about 1 in 8 (12.5%) of people have microalbuminuriea and 1 in 50 (2%) have macroalbuminuriea(22), while in this study for comparison only one patient out of (21) had microalbuminuria at the time of diagnosis(table6), and after 10 years of having DM, 8 patients out of 26(30.7%) had microalbuminuria and 6 out of 26(23.1) had macroalbuminuria. Sixteen to twenty years after diagnosis, 10 patients out of 30(33%) had microalbuminuria and 18 out of 30(60%) had macroalbuminuria, table 6. If DM is poorly controlled for a long period of time, this would be reflected by increased HbA1C, and this would be a risk factor to develop DN. There is good correlation between the level of HbA1C and DN represented by ACR, table 4. Hypertension (HTN) is also an important risk factor if it co-exists with DM…..table.. (5). The association of HTN and DM increases the pathophysiological changes in the kidney which eventually share in the damage of the kidney tissue(22-23-24). In 2008(67%) of American adults aged 20 years & over with DM had BP greater than 140/90mmhg and hence type 2 DM and high BP increase the risk of developing diabetes related diseases such as kidney disease (or DN). In short female sex increasing age, increasing duration of D.M (chronicity) with persistent hyperglycemia and co-existing HTN are the major risk.

Factors which play a great role in the deterioration and damage resulting into ESRD. In addition we have not to forget the role of other factors which contribute or assist in the damage of the kidney such as smoking, obesity, hyperlipidemia, genetic factors and race (26-27-28-29-30-31).

Conclusion

Sixty six patients were females and fifty five were males. Besides full history and physical examination data were collected according to a format. At the end, these data were collected and analyzed statistically. The average age was (54 ± 2.1) year, female to male ratio 66 to 55 (1.2:1) the number of patients with hyperglycemia was 90. Average random blood sugar R.B.S was 259 ± 1.6 mg/dL. number of patients with hypertension was 71, the average of systolic blood pressure BP was 158 ± 6.1mmHg and diastolic was 10.2 ± 1.1, the average duration of D.M. was (10.5 ± 4.2) year, the average of glycosylated hemoglobin HbA1c was 9.8 ± 2.1. the number of patients with D.N was 77.

Emotional Duality in Preparatory School Teachers

Ali Hussein Al-Maamouri¹, Shaimaa Majid Hameed²
¹Prof., ²Asst., Lect., Department of Educational and Psychological Sciences, College of Education for Human Sciences, University of Babylon

ABSTRACT

The current research consists of a fundamental concept: Emotional Duality, which is the contradiction or internal conflict of the individual between what he wishes to express about his feelings of selfishness and fear of the consequences or consequences of such expression. The aim of the research is to identify the emotional duality of the teachers of the preparatory stage and the differences in the emotional duality of the teachers of the preparatory stage according to sex variables (males, females), and specialization (scientific, humanitarian). The researchers followed the descriptive approach. The study is based on a sample of 420 school teachers. After the extraction of honesty, consistency and objectivity, the tool was applied to the basic sample of 520 teachers and schools from the preparatory stage in the center of Babil Governorate. The results of the research show that teachers have a double emotional in the performance of their tasks to correspond with the school climate.

Keywords: individual, preparatory stage, emotional expression.

Introduction

This is consistent with Rogers’ suggestion that the need for positive respect and self-protection is present in every individual, and when the individual gets it he feels satisfied, and if it does not, it leads to frustration ¹. All these behaviors and others have introduced some in conflicts and resort to crooked methods to get rid of the cases of frustration and psychological defeat and the state of oppression or retaliation for what was exposed to the person from the cases of weakness and defeat and crush dignity, which in turn leads to waste his energies ² and his professional giving to the feeling of insecurity and psychological disorder Which may reflect negatively on the performance of the professional and the educational process as the personality of the teacher is an example role after the parents, with the confirmation of many studies on the seriousness of this aspect, as the disorders that may affect the emotional side or the ability to understand emotions and expression commensurate with the Stopping leads to negative outcomes such as loss of social support, disintegration of groups, and failure to achieve mental efficiency ³. This is consistent with the study of E. Baum & A. Becker2010 has reached a correlation between the feelings of contradiction and the increase in the negative impact on the individual and exposure to stressful events, forcing him to resort to methods incompatible, such as emotional duality, especially the groups of actors in society, including junior high school teachers. Because of the difficulties and challenges in their professional work they may resort to duplication in dealing with their peers teachers or students ⁴. When their desires conflict with the constraints of society or when they are drawn by opposing forces and the conflict intensifies and they fail to reach their goals, each individual responds with a particular response of conflict and frustration ⁵. This is what Frum has emphasized that society seeks to make individuals realize their desires in the way society wishes, breaking the will of its members without being aware of it through tyranny, oppression, humiliation, punishment and other ideologies. This makes them follow their wishes and they are unconscious. The theory developed by King and Emmons states that the contradiction in emotional expression can reflect a state of internal conflict between the individual’s need to express emotions and The current situation and the demands ⁶ of this position, and the desire not to show or express emotions or emotions and self-expression where this internal contradiction - in terms of showing emotions or emotions in certain situations or not to show - is exhausting and is a source of abnormal psychological processes, especially if not failure Show fatigue T emotional this is just a modification or short-term
behavior inhibition, but cognitive mechanism unusual or permanent (Emmons, R. A. & King, L. A. 1988: 1040).

King and Emmons assume that individuals who use such abnormal psychosocial mechanisms have difficulties in communicating their emotional needs or express them clearly, and they face more problems in relationships that may lead to harmful social consequences. This, in turn, can increase the level of stress, thus leading to reduced social support and reduced self-esteem. In the view of King and Emmons that the contradiction in emotional expression can show itself in different ways: people who use these mechanisms may wish to express their emotions, but feel that they are unable to do, or may be expressed, but do not want to do so. Or may regret having expressed their emotions later⁷. The main component of emotional expression is the motivation to express it, as any goal coupled with a desire to discourage it is likely to have devastating physical and psychological consequences for the individual. It has been assumed that the emotional dissonance in which the individual is located is a crucial element in distinguishing the healthy and unhealthy way of expressing emotion⁸, so it is not only that the individual expresses emotions or does not express them. Expression of emotions can manifest itself within any of the emotional states of the individual, whether positive or negative, it is the outcome of the expression of emotions. The weakness or lack of expression of emotions is repressed and not shown to others while the contradiction in their expression is seen as an interactive inability in relationships between individuals who suffer from this contradiction in expression because either they cannot express their emotions fully, or They are expressing it but regretting their expression⁹ soon after. Thus, they are in contradiction or internal conflict because of the expression or fear of not expressing their emotions. Emotional expression is thus perceived as socially inappropriate but beneficial in terms of health to the individual. The owners of this theory that each individual goals specific to him may get in some cases that there is a conflict or conflict between these goals with other goals and therefore the discouragement of such goals and not achieve or express it will lead to the effects of chronic involuntary and psychological collapse of the individual in end of the day. When these objectives are incompatible with social norms or other goals, the individual may suffer from the harmful effects of this, whether expressed or meaningless. As such conflict leads to the individual’s sense of contradiction, which can be in direct contact with his physical and psychological well-being, as emotional inhibition undermines the psychological well-being.

**Methodology**

The research methodology followed in this research is the descriptive and associative approach in the process of data collection and analysis to suit this approach, which is the subject of study in the current research. Research Community: The current research community is represented by middle school teachers in the center of Babil governorate for the academic year (2018 - 2019) male and female. (2177) were distributed to (53) schools. The research sample was selected in random stratified manner with a proportional distribution of the teachers of the preparatory stage in the schools of the center of Babil province. The total number of teachers (420) teachers and schools (167), including males and (253) of females and the (197) scientific specialization and (223) humanities. Research tool: the measure of emotional duplication: to achieve the objectives of research and after defining the theoretical definition of the variable of emotional duality based on the theory. The measure of emotional duality was built for the teachers of the preparatory stage consisting of (41) paragraphs. The balance of the response: a balance of response was placed in front of each paragraph consisting of five alternatives (applied to quite, very often, rarely, never applicable) and the score (applied to exactly/5) and the alternative (much/4) 3) The alternative is seldom/2) The alternative does not apply to the first/1) The highest degree that can be obtained by the teacher is 205 and the lowest grade is obtained. Where he asked the members of the sample to answer them honestly and frankly for the purpose of scientific research, and stated that there is no need to mention the name, and that the answer will not be seen by anyone but the researcher This is to reassure individuals of the confidentiality of the answer. Validity of paragraphs: The paragraphs were presented to 30 experts in psychology and psychological measurement to judge their validity in measuring what was put to measure. After taking into account the observations of experts and the validity of each paragraph in measuring emotional duality, Experts and thus became the measure consists of (41) paragraphs. Statistical analysis of the paragraphs of the measure of emotional duplication: For the purpose of statistical analysis of the paragraphs and to find their strength and the degree of internal consistency and to find the validity of the measure and stability and then identify the emotional duality in the teachers of the preparatory stage was applied in the final form on a sample of (420) teachers and schools After collecting the data, The two distinguishing features:
a) The discriminating force of the emotional duality scales: In order to extract the discriminating power of the double-standard clauses, the scale was applied to the statistical analysis sample of (420) teachers and schools. When the significance of the differences between the upper and lower groups was tested, the values of the paragraphs ranged between (2.597 - 24.756), which is greater than the scale value of (1.96). Therefore, they are statistically significant at (0.05) and freedom (218).

The relationship of the degree of the paragraph to the total degree of the measure. The relation of the score of the paragraph to the total score of the emotional duality index using the Pearson correlation coefficient was calculated for the statistical analysis sample of (420) teachers and schools. All correlation coefficients were (0.051) and the degree of freedom (419), ranging between (0.121-0.731) because the degree of correlation is greater than the value of the table (0.098) and thus, the number of paragraphs of the measure of emotional duplication.

The validity of the scale: Two types of honesty have been found for the current measure: Virtual honesty: verifying the apparent honesty by presenting the paragraphs of the scale to (30) of the arbitrators in the educational and psychological sciences and psychological measurement.

**Results and Discussion**

In order to achieve this objective, the emotional duality scale was applied to the sample. After correcting the scale and conducting the statistical analysis of the data, it was found that the mean of the scores was 164.37 and with a standard deviation of (9.184) and the mean (123). To find the difference between the arithmetic average and the arithmetic average, Use the TEST test for one sample. The results showed that the calculated T value was (10.723) degrees. Which is greater than the tabular T value of 1.96. Therefore, it is statistically significant at the significance level (0.05) and the degree of freedom (519). Table (1) shows this.

</tr>
</tbody>
</table>

According to Kink and Emmons (1990), emotional duality is the state of emotional contradiction, as a result of exposure to circumstances or psychological pressures or responsibilities above the possibility of the individual, the solution is duplication, in order to reconcile with the reality and escape from the experience that prevented the individual’s compatibility with himself. Excessive suppression works on duplication, and on the other hand, the characteristics of the organization of independence, is one of the most important factors associated with emotional duality, as independence in the work leads to reduce pressure, as well as to reduce the contradictory feelings, and since independence is positively linked to job satisfaction duplication can exist Teachers have a low rate of job satisfaction which leads them to emotional duality and this is consistent with the study. This is consistent with Van.Di.Bearg’s view that the source of emotional duality is society in its cultural context and also agrees with the study of MICHAEL HARRIS BOND (2005: 67). The mean mean of males (164.28), female (164.34), standard deviation of males (9.061), females (9.264), calculated value (0.069) and comparing them to the tabular value of (1.96) at the significance level (0.05) is statistically insignificant, and Table (2) shows this.

**Table 2: Differences in emotional duality according to gender variable**

<table>
<thead>
<tr>
<th>Gender</th>
<th>Arithmetic mean</th>

<td>9.061</td>
<td>-0.069</td>
</tr>
<tr>
<td>Female</td>
<td>164.34</td>
<td>9.264</td>
<td></td>
</tr>
</tbody>
</table>

Table (2) shows that there are no statistically significant differences in the differences between males and females according to gender. The result is that the environment requires that women be equal to men and bear the same responsibilities. Both teachers and teachers work in the same conditions and for them
roles they do are no different subject to the same laws and lived in the same conditions.

This is consistent with Micheal I. Raulin’s assertion that the degree to which any cohabitation ends in a poetic or unconscious form will affect how the partners deal with the conflict between them if two persons have a relationship that determines their nature according to context.

Objective 3: Differences in emotional duality among middle school teachers (by specialization variable).

Table 3: Differences in emotional duality according to specialization variable

<table>

</tr>
</tbody>
</table>

From Table (3) we find that there are statistically significant differences in the relationship of emotional duplication according to specialization (scientific - human) for the benefit of scientific specialization, and this result is due to the fact that emotional duality is a psychological variables that are much influenced by specialization. It is exposed to the attitudes and frustrations associated with the nature of the materials that teach the scientific specialization in terms of the nature of teaching and the material and the need of mental processes in how to deliver the material, all this puts pressure on the teacher, which raises the contradiction in the behavior.

Results

Teachers have a double emotional in the performance of their tasks to correspond with the school climate. There are no statistically significant differences in the relationship of emotional duality according to sex (male – female). There are statistically significant differences in the relationship of emotional duality according to specialization (scientific – human).

Conclusion

There are no statistically significant differences in emotional duality according to gender. There are statistically significant differences in emotional duality according to specialization (scientific - humanitarian). The researchers came out with a number of recommendations, including the use of the research tool in other studies dealing with the same fields. And the establishment of seminars to highlight the emotional duality and its impact in the educational process. In addition to a number of proposals, including conducting a study similar to the current study on university professors to check their emotional duality, in the light of a number of variables, such as: age, moral thinking, decision-making, and self-organization They are tired of exhaustion, misery and loss of meaning in everything in their lives, because they are always frustrated and despairing.

Malva parviflora and Medicago sativa in vitro Anti-fungal Activity and Bioactive Chemical Compounds of Using FTIR Spectroscopic Technique

Lena Fadhil Hamza1, Sanaa Hasan Abdalakhwa2, Imad Hadi Hameed3
1College of Pharmacy, 2College of Basic Education, 3Biomedical Science Department, College of Nursing, University of Babylon, Hillah city, Iraq

ABSTRACT

The objectives of this study were analysis of the secondary metabolite products and evaluation of Anti-fungal activity. The FTIR analysis of Malva parviflora proved the presence of functional group assignment Alkenes, Alkyl halides, Aromatic, Amide, and Alkane with Intensity 70.282 (Strong), 71.720 (Strong), 77.439 (Strong), 66.259 (Strong), 82.894 (Strong), 85.533 (Strong), 85.135 (Strong), 85.999 (Medium), 85.109 (Medium), 85.991 (Strong), 81.181 (Strong), and Peak (Wave number cm⁻¹) 667.37, 690.52, 788.89, 999.13, 1029.99, 1226.73, 1417.68, 1454.33, 1516.05, 1539.20, 1645.28, 2854.65 and 2924.09. The FTIR analysis of the FTIR analysis of Medicago sativa proved the presence of functional group assignment Alkenes, Alkyl halides, Amide, and Alkane with Intensity 77.367 (Strong), 66.277 (Strong), 72.897 (Strong), 83.166 (Strong), 80.730 (Bending), 87.443 (Strong) and Peak (Wave number cm⁻¹) 717.52, 1020.34, 1093.64, 1234.44, 1604.77, and 2920.23. In the current study, the anti-fungal activity of Malva parviflora and Medicago sativa methanolic extract was evaluated by determining the zone of inhibition against fungi. Malva parviflora was very highly active against Aspergillus terrus (5.012 ± 0.19). Medicago sativa was very highly active against Aspergillus flavus (4.791 ± 0.17).

Keywords: Malva parviflora, Medicago sativa, Anti-fungal Activity, Bioactive Chemical Compounds.

Introduction

Malva parviflora is an annual or perennial herb that is native to Northern Africa, Europe and Asia and is widely naturalised elsewhere. 1 Common names include cheeseweed,1 cheeseweed mallow, Egyptian mallow, 1 least mallow, 2 little mallow, 1 mallow, 3 marshmallow, 3 small-flowered mallow, 4 small-flowered marshmallow 8 and smallflower mallow. 3 M. parviflora leaf extracts possess anti-inflammatory and antioxidant activities. 6 It has a decumbent or erect habit, growing up to 50 cm in height. 4 The broad leaves have 5 to 7 lobes and are 8 to 10 cm in diameter. 4 It has small white or pink flowers with 4 to 6 mm long petals. The whole plant is emollient and pectoral. It can be used as a poultice on swellings, running sores and boils. They are used in the treatment of coughs and ulcers in the bladder. A decoction of the roots or leaves has been used as a hair rinse to remove dandruff and to soften the hair. Malva parviflora L. (Malvaceae) is widely distributed throughout Africa. Traditional healers and herbalists use M. parviflora leaves and roots to clean wounds and sores. A hot poultice made from leaves is used to treat wounds and swelling, and incorporated into a lotion to treat bruised and broken limbs. Screening of medicinal plants used in Lesotho for anti-bacterial and anti-inflammatory activity. Leaves of this plant are used in the treatment of boils. Herbal drugs have received greater attention in recent times because of their diversity of curing diseases, safety and being well tolerated remedies when compared to the conventional medicines. Development of resistance against antibiotics has further emphasized the necessity of research for alternative antimicrobial agents (Bax

and Mullan 2000). Malva parviflora L. and Malvastrum coromandelianum L. belong to the family Malvaceae which has been famous for medicinal properties for many years. The plants of this family are well known for their antibacterial and antifungal activities due to the presence of alkaloids, essential oils and phenolic quinolside. The *Medicago Sativa* known as alfalfa. *Medicago Sativa* is a medicinal plant belonging to Fabaceae family. This herb is rich from substances called saponins. Recent studies have shown that saponins produce many effects in the body that can boost the immune system, have anti-tumor effects, helps detoxification due to the combination with bile acid, as well as antimicrobial effects such as antibacterial, antifungal and also has an antiviral effect (10,11). In most cases, numerous scientific investigations have led to the confirmation of therapeutic value of medicinal plants. *Medicago Sativa* used to be known/named as the Queen of Plants and Green Gold 12. The plant is rich in various proteins, calcium, mineral elements, various vitamins in group B, vitamins A, C, D, E, K and amylase enzyme, emulcer, invertase and pectinase, as well as very small amounts of arsenic and silica (13-17). In the taste of people, there is a greater tendency to use plant compounds instead of chemical drugs. while, many researchers believe that the side effects of taking herbal drugs are much fewer than chemical drugs. Due to the wide distribution of medicinal plants in our country, studies on their antimicrobial properties provide a suitable basis for using the results of these studies to replace the natural drugs to control and treat bacterial infections. It can reduce the use of chemical drugs and their complications. In this research, the antimicrobial effects of alfalfa extract on common bacteria in sinusitis and bronchitis are investigated. *M. sativa* has a long tradition of use as Ayurvedic and homoeopathic medicine in central nervous and digestive system disorders, and for the treatment of various other ailments. However, only limited research has been conducted on this plant species. The present review emphasizes the traditional uses and phytopharmacological potential of *M. sativa*. Additionally, sporadic pharmacological work has so far been carried out to prove its traditional claims. Through this review, the authors hope to attract the attention of natural product researchers throughout the world to focus on the unexplored potential of *M. sativa*.

**Materials and Method**

**Collection and preparation of plant material:** The leaves were purchased from local market in Hilla city, middle of Iraq. After thorough cleaning and removal foreign materials, the leaves were stored in airtight container to avoid the effect of humidity and then stored at room temperature until further use.

**Preparation of sample:** About 20 grams of the plant sample powdered were soaked in 100 ml methanol for 16 hours in a rotatory shaker. Whatman No.1 filter paper was used to separate the extract of plant. The filtrates were used for further phytochemical analysis. It was again filtered through sodium sulphate in order to remove the traces of moisture.

**Fourier transform infrared spectrophotometer (FTIR):** The powdered sample of *Malva parviflora* and *Medicago sativa* was treated for FTIR spectroscopy (Shimadzu, IR Affinity, Japan). The sample was run at infrared region between 400 nm and 4000 nm.

**Determination of antimicrobial activity of crude bioactive compounds of Malva parviflora and Medicago sativa:** The test pathogens were swabbed in Müller-Hinton agar plates. Sixty μL of plant extract was loaded on the bored wells. Antifungal activity was evaluated by measuring the zone of inhibition against the test microorganisms. Methanol was used as solvent control51-55. Amphotericin B and fluconazole were used as reference antifungal agent. The tests were carried out in triplicate. The antifungal activity was evaluated by measuring the inhibition-zone diameter observed after 48 h of incubation.

**Results and Discussion**

**Identification of biochemical compounds:** The FTIR analysis of *Malva parviflora* proved the presence of functional group assignment Alkenes, Alkyl halides, Aromatic, Amide, and Alkane with Intensity 70.282 (Strong), 71.720 (Strong), 77.439 (Strong), 66.259 (Strong), 63.849 (Bending), 82.894 (Strong), 85.533 (Strong), 85.135 (Strong), 85.999 (Medium), 85.109 (Medium), 85.991 (Strong), 81.181 (Strong), and Peak (Wave number cm−1) 667.37, 690.52, 788.89, 999.13, 1029.99, 1226.73, 1417.68, 1454.33, 1516.05, 1539.20, 1645.28, 2854.65 and 2924.09. (Table 1; Figure 1). The FTIR analysis of *Medicago sativa* proved the presence of functional group assignment Alkenes, Alkyl halides, Amide, and Alkane with Intensity 77.367 (Strong), 66.277 (Strong), 72.897 (Strong), 83.166 (Strong), 80.730 (Bending), 87.443 (Strong) and Peak (Wave number cm−1) 717.52, 1020.34, 1093.64, 1234.44, 1604.77, and
In the current study, the anti-fungal activity of *Malva parviflora* and *Medicago sativa* methanolic extract was evaluated by determining the zone of inhibition against fungi. *Malva parviflora* was very highly active against *Aspergillus terrus* (5.012 ± 0.19). *Medicago sativa* was very highly active against *Aspergillus flavus* (4.791 ± 0.17). Malva genus is widespread in tropical and temperate region belongs to the family Malvaceae. They possess efficient role in coughing, intestinal infections, colitis, tonsillitis, gastroenteritis, cholesterol and lipid-lowering, antihypertensive, antioxidant, analgesics, emollient, pectoral girdle and arteriosclerosis treatment [11]. Malva parviflora Linn. is widely distributed in Uttarakhand. It is originated from the Mediterranean region of Europe and temperate Asia. *M. sativa*, produces secondary metabolites, such as coumarins, isoflavones, naphthoquinones, alkaloids and saponins, that have nematocidal, cytotoxic and antimicrobial effects. Infrared spectroscopy provides a useful method for herbal analysis and elucidate the compounds structures as well as for quantitative analysis of drugs. Recently, a number of plants have been reported for antibacterial properties across the world [19-21]. It is hoped that this study would direct to the establishment of some compounds that could be used to invent new and more potent antibacterial drugs of natural origin. Further work will emphasize the isolation and characterization of active principles responsible for bioefficacy and bioactivity.

Figure 2: Fourier-transform infrared spectroscopic profile solid analysis of *Medicago sativa*

**Conclusion**

Medicinal property of *Malva parviflora* and *Medicago sativa* methanolic extract is due to presence of secondary metabolites. Ninety phytoconstituents were identified by (FT-IR) analysis. This plant derived bioactive compounds used as source of antibiotic properties and pharmaceutical industries used for drug formulation. *M. parviflora* fruit extracts have moderate antibacterial properties against selected microorganisms. The bioactivity of fruit extracts was confirmed by the results of phytochemical analysis. This can be utilized in respiratory tract illnesses caused by studied microorganisms.

Pharmacognostical Study and Antibacterial Activity of Cardio
Active Glycoside of Iraqi Yellow Oleander
(Thevetia Peruviana L.)

Hayder Yousif Falih¹, Noor Mohsen Nasser², Thamer Mouhi Jasiem²
¹Department of Basic Sciences, College of Dentistry, ²Department of Pharmacognosy and Medicinal Plants, College of Pharmacy, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

Objective: Thevetia peruviana consider from the toxic plants for all vertebrates because the major active constituents are cardio active glycosides and caused many poisoning for humans the toxins active constituent such as thevetin A and thevetin B. The aim of this study was isolation of the major active compound which found in the leaves of Iraqi plant which cultivated in Iraq environments and investigated the biological activity of it on different pathogenic bacteria. The plant anatomical results were reference to Anomocytic stomata type in the leaves, Unicellular unbranched covering of trichomes, fibers and starch present in the leaves of the T. peruviana plant. Which confirms that isolated compound from preparative TLC is thevetin. According to the results as shown in Pharmacognostical and phytochemical studies. The pathogenic bacteria which used for investigated the bioactivity of leaves extract of yellow oleander were E coli, pseudomonas aeruginosa, Streptococcus spp., Staphylococcus epidermidis, Enterococcus faecalis, Klebsiella pneumoniae and Staphylococcus aureus. The different concentrations of cardioactive glycosides extract from leaves (1000,500,250,125,63.5µg/ml) were found active for all microorganisms strain in concentration 1000 µg/ml while inactive in 63.5 µg/ml concentration exception Enterococcus faecalis effected in this concentration.

Keywords: Thevetia peruviana leaves, phytochemical screening, Antibacterial activity

Introduction

Apocynaceae family is a most important family contain many genera most of them tropics and subtropics. There are two important genera belong this family both of them very close relative Nerium oleander and Thevetia peruviana which called yellow oleander or lucky nut. Yellow oleander is cultivated as ornamental tree in gardens and parks because it’s a evergreen flowering shrub or tree. The major active constituent was found in all parts of plant Nerium oleander and Thevetia peruviana contain cardio active glycoside which effect like digoxin effect on heart muscle its increase the tone of heart muscle as positive inotropic effect. T. peruviana consider from the toxic plants for all vertebrates because the major active constituents are cardio active glycosides and caused many poisoning for humans the toxins active constituents are thevetin A, thevetin B, Peruvoside., Neriifolin, Thevetoxin and Ruvoside. These types of cardenolides are stable to heat and drying and don’t destroyed by drying or heating. These contains found in milky sap. T. peruviana consider as medicinal plant which use for a large pharmacological activity like Antimicrobial activity, antifungal, piscicidal, antispermatogenic and anti-termite. The antibacterial activity of the leaf extract of T. peruviana was more sensitive with pathogenic bacteria which isolated from food borne such as Salmonella typhimurium while the minimum activity was against E.coli bacteria. The seeds oil of T. peruviana act as antimicrobial activity against many pathogenic microbial strain such as Staphylococcus aureus, Bacillus subtilis and Escherichia coli examples of bacteria and Candida albicans as fungi.
Material and Method

Collection of plant material: The leaves of plant *T. peruviana* were collected from Baghdad city and was authenticated by professor Ibrahim S. AL-jubory/Department of Pharmacognosy and Medicinal Plants/College of Pharmacy, Mustansiriyah University.

The plant material was collected during September-October and then washed by tap water to remove the dust and soil and then about two week leave it for drying at room temperature in the shade after drying the leaves were ready for extraction the active constituents and for phytochemical analysis.

Pharmacognostical evaluation: By standard method for investigation of types of trichomes, stomata, phloem, starch, fibers the leaves of plant were immersed in chloral hydrate solution for several minutes for lost its color and pigments. Examine the epidermis and stomata with fresh leaves and another components with dried leaves and finally investigation under microscope.

Preliminary phytochemical investigation: Depending on standard methods of investigation the active compounds. we were investigated the phytochemical profile of leaves of *T. peruviana* plant by used many reagents special for the active compounds dragendroffs andayers for alkaloids, ferric chloride test solution for tannins, foam test for saponins, baljet test for cardio active glycosides, borntragers test for anthraquinone glycoside and Lieberman-burchard test for sterols and triterpenes.

Extraction of glycosides: The leaves powdered of *T. peruviana* (20 g) were extracted by using soxhlet extractor and the solvent used 70% ethanol for about 8 hours until exhaustion. and then under reducing pressure using rotary evaporator concentrated the ethanolic and then the glycosideic linkage broken by 4N HCL and heated under water bath and the hydrolyzed extract partitioned with chloroform (50mL) and allowed to settle over night. The lower organic layer (100mL) was collected which is dried with anhydrous magnesium sulphate, the organic layer was concentrated by rotary evaporator.

Bacterial isolates: The isolated pathogenic bacteria which used in this study from urinary tract infection samples, were patients collected suffered from different problems with UTI and many clinic symptoms. *E. coli*, pseudomonas aeruginosa, *Streptococcus* spp., *Staphylococcus* epidermidis, *Enterococcus faecalis*, *Klebsiella pneumoniae* and *Staphylococcus aureus* were isolated from patients urine.

Culture media: There are different cultures media which used to grown the different pathogenic bacteria such as Blood, mac conkey, chocolate agar media the prepared depended on the instructions of the Hi-media –India company.

Extract dilutions: The dilutions were prepared from yellow oleander ethanolic leaves extract include (1000, 500, 250, 125, 63.5) mg/ml. all those diluted were determined on the different pathogenic strains of UTI bacteria and shown the effect of it and used the DMSO as control.

Antibacterial activity: The effect of ethanolic extract of yellow oleander leaves was determined by well diffusion method. all type of pathogenic bacteria was grown on muller-hinton agar plate and blood agar and then 100µl volume of ethanolic extract of yellow oleander leaves from different diluted submitted in wells into media. Incubated the plates at (37°C for 18-24h.). the inhibition zone determined which surrounding the wells.

Fourier Transform Infrared Spectrometry (FTIR): The method of FTIR was implemented on a spectrophotometer system and registered as KBr disc, which was used to identify the distinguishing peaks values of the thevetin isolated compound.

Results and Discussion

The plant anatomical results were reference to Anomocytic stomata type in the leaves. Unicellular unbranched covering of trichomes, fibers and starch present in the leaves of the *T. peruviana* plant.
The phytochemical profile results of active constituents were referenced to many active compounds were presented such as tannin, saponins, flavonoids, steroid and cardioactive glycoside which isolated and purified Table (1).

The pathogenic bacteria which used for investigated the bioactivity of leaves extract of yellow oleander were *E coli, pseudomonas aeruginosa, Streptococcus spp., Staphylococcus epidermidis, Enterococcus faecalis, Klebsiella pneumoniae* and *Staphylococcus aureus*. The different concentrations of cardioactive glycosides extract from leaves (1000,500,250,125,63.5µg/ml) were found active for all microorganisms strain in concentration 1000 µg/ml while inactive in 63.5 µg/ml concentration exception *Enterococcus faecalis* effected in this concentration. The largest inhibition zone found in *Enterococcus faecalis* in all concentrations while the smallest inhibition zone found in *Staphylococcus epidermidis* bacteria. In obtained results shown that yellow oleander extract effect for all types of bacteria that mean this extract has good potency against all tested bacteria seen in table (2) and figure (2).

The thevetin structure illustration by FT-IR showed the presence of Phenols ArO-H bonded at 3392 cm⁻¹, also Carboxylic acid around the region 2922 cm⁻¹and 2850 cm⁻¹ presence Ester RCOOR 6-ring at 1735 cm⁻¹ and Alkanes RCH2CH3 at1462 cm⁻¹ seen in table (3) and figure (7). The spectral data are agreement with standard of the same compound.

Phylogenetic Profile of *Staphylococcus aureus mec A* and *ica A* genes Associated with UTI Patients

Ahmed A. R. Abbas¹, Saad S. Hamim²

¹Ministry of Health, ²Pathological Analysis Department, Science College, Thi-Qar health office, Iraq

ABSTRACT

The latest years indicated an upsurge in the urinary tract infections (UTIs) occurrence instigated by *Staphylococcus aureus* at the ward of urology. A total of 50 *S. aureus* isolate from UTI patients during the period from August to December 2018 at the AL-Hussein Teaching Hospital in Nassyriah City, Southern Iraq were assayed to find the presence of mec A & ica A genes by Polymerase Chain Reaction technique. Selection of six PCR products of mec A and ica A genes named primarily (No1, No2, and No3 for each gene) was done and further exposed to the partial sequencing of DNA to aid the targeted genes for following up their probable relation amongst the global records of Genbank and local isolates. The phylogenetic tree that was created by MEGA 6.0 version software showed closed different molecular relationships among the local *S. aureus* isolates with similar ones around the world of mec A (No.1-No.3) which were closely related to NCBI-BLAST *S. aureus* strain MRSA 365325 (MH798858.1) at total genetic changes (0.0005-0.0025%). while, ica A gene in local *S. aureus* human urine isolate (No.1-No.3) showed close interrelation to the NCBI-BLAST *S. aureus* strain Pn2301 (FJ004990.1) at the total genetic changes of about 0.2-1.0%.

Keywords: *Staphylococcus aureus*, Urinary tract infections, Gene sequencing, Virulence factors.

Introduction

Urinary tract infections (UTIs) are triggered by microorganisms’ growth and presence anywhere in the urinary tract. This might be the only most communal bacterial infection in humans ¹. In unindustrialized countries, the UTI infections indicates the utmost significant health problem’s effects in the population of all age groups ². Since the pathogens appearance along with the up surging antimicrobial agent’s resistance, it has become challenging to treat the UTI. It occurs much more frequently in females than males due to the proximity of the urethra to the anus ³,⁴. Its yearly global occurrence is of nearly 250 million ⁵. From most common pathogens are associated with UTIs Staphylococcus, particular *S. aureus* which is a major human pathogen and a widespread contaminant in hospitals. Though, in several patients, the *S. aureus* isolation from the sample of urine is frequently subordinate to the escalating Staphylococcal bacteremia somewhere else for example endocarditis cases. Likewise, the ascending colonization of urinary tract and infections are instigated by *S. aureus* ⁶. The foremost *S. aureus* pathogenicity is linked to its capability of a number of virulence factors’ production, most specifically extracellular factors as well as toxins’ synthesis, adherence ability and biofilm formation on host surfaces and lastly causing a resistance to the phagocytosis ⁷. Moreover, the pathogenic bacteria’s molecular typing comprising *S. aureus* can be beneficial to support the controlling measures of infections, for suspected outbreaks’ investigation and nosocomial transmission prevention ⁸. The recent study targeted the investigation of molecular characterization of genes ica A and mec A in various isolates of *S. aureus* from patients of UTI in the city of Nassyriah.

Materials and Method

Samples Collection, Isolation and Identification: Current research utilized 50 total *S. aureus* isolates that were collected from the UTI patients in AL- Hussein Teaching Hospital in Nasiriya City, Southern Iraq from August to December 2018. Identification of all *S. aureus* isolates was done depending on Gram’s stain; Mannitol salt agar (MSA), cultural characteristic and conventional biochemical tests ⁹. API system as well as Vitek2 compact (BioMerieux, France) was used to confirm the diagnosis of bacteria. A latex agglutination test was used as per
the manufacturing (Remel, UK) company’s directions to serologically diagnose the proteins A for all *S. aureus* isolates.

**Antibiotic susceptibility test for *S. aureus* isolates:**

The total isolates of *S. aureus* were exposed to the susceptibility of antibiotics with the help of disc diffusion procedure. Moreover, the interpretation and measurements of diameters of inhibition zone were carried out conferring to.

**Detection of mec A and ica A genes by Polymerase chain reaction:** *S. aureus* isolates were exposed to the identification of methicillin mecA & biofilm icaA genes by conventional PCR technique using specific primer pairs (Table 1). The amplification was conducted in a thermal cycler (BioRad, USA) that has been automated as follows: with one cycle, the initial denaturation stage was done at 95°C for five minutes. Whereas, amplification with 30 cycles was executed by following conditions: 30 seconds denaturation at 95°C, 30 seconds annealing at 58 and 59 °C, one minute extension at 72 °C and lastly five minutes final extension at 72 °C. These conditions were designed by the researcher in this study.

**DNA sequencing:** The *S. aureus* six PCR products were dispersed into three ica A & mec A genes that were selected for further sequencing. The sequencing of each genes’ reverse and forward primers was done in Macrogen, Korea outside of Iraq. While Basic Local Alignment Search Tool analysis (BLAST) led to the algorithm of BLAST by (www.ncbi.nlm.nih.gov/BLAST) site. The sequences of samples labelled as (No1, No2 and No3 for mec A - No1, No2, and No3 for ica A) were further aligned, edited & related with reference sequences by using Unweighted Pair Group Method with Arithmetic Mean (UPGMA tree) with MEGA6 software. Thus, MEGA 6.0 version was used to construct the every gene sequences’ phylogenetic tree.

The PCR primers were designed online and provided by (Macrogen, Korea) using NCBI Gene Bank and primers 3 plus as follows (Table 1).

**Results and Discussion**

**Phenotypic characterization of *S. aureus* isolates:** Six hundred urine samples were collected from complaints of UTI patients at AL-Hussein Teaching Hospital. The finding of the present study showed that 380 (63.67%) isolates recorded positive growth. While 220 samples (36.33%) showed no significant growth. The present results agreed with who reported (57.9%) positive urine culture and (39.3%) were showed no growth. Our study was non compatible with, which showed (41.6%) positive culture. Specimens showed a positive culture as *S. aureus* on MSA, biochemical test and API-20 *Staph*. In addition, Vitek2 system and serological diagnosis were used in the present study to confirm the diagnosis. All isolates gave positive results for all tests which recorded a total percentage of *S. aureus* infection with 13.15%. These results of *S. aureus* agreed with the results of the study of who found *S. aureus* isolate from UTI were (13.71%). The results of the present study were incompatible with where was *S. aureus* accounted for only 0.5% of all isolates.

**Detection of mec A and ica A genes:** The present study tried to shed light on the prevalence of two of *S. aureus* virulence factors while molecularly detecting the biofilm of ica A gene and of methicillin (mec A) gene extracted from the patients of UTI from Nassryrah City, Southern Iraq. The entire fifty *S. aureus* isolates from UTI patients were precisely recognized as per former methodologies utilized for DNA extraction while agarose gel electrophoresis was used to identify
the results. Molecular detection of the two selected genes among all *S. aureus* isolates showed that 95/100 amplified mecA gene, having the molecular weight of roughly 215 bps (Figure 1,2). Amplification of ica A gene showed the positive results by all *S. aureus* isolates for the targeted gene having an approximate 213bp molecular weight (Figure 3). Despite the ongoing debate about the role of different *S. aureus* virulence factors, a lot of reports tends to believe that the resistance mechanism against methicillin includes the acquisition of the mecA gene, a determinant of penicillin-binding protein has lowered affinity for the β-lactams where to play a major role in *S. aureus* pathogenesis 16. Recent results disagree with the result of 17 showing that 68 isolates 75 % of MRSA had mecA gene. While it agreed with local study performed by 18 that recorded a complete percentage of the target gene 100 % in all MRSA isolates. The present results agree with the results of various research works for instance from Iran 19, Iraq 21 and Egypt 28 who revealed that all MRSA isolates had mecA gene. The outcomes of recent study differ with the studies showing a different percentages of mecA gene in *S. aureus* isolates (21,223) showed a percentage of 90.9% and 71.5%, respectively. These variations may be due to many factors, such as the sources and amount of clinical samples used, geographic distribution, and the sensitivity of different techniques used. However, the variability of this gene distribution among *S. aureus*, globally, continue to be dissimilar and this is obviously, reflected by different reports around the world. On the other hand, for identification and confirmation of biofilm producing strains, the present research subjected these strains to PCR for determination of ica A gene. Results confirmed that staphylococcus biofilm-producing strains showed positivity for the gene ica A. These result is in agreement with those of 14,15,16,17 whom reported that all biofilm synthesizing strains contained *S. aureus* which designated a significant ica A genes role as virulence markers for infections of *Staphylococcus* related to the urinary tract infections. In this study, there was a highly significant association between ica A gene presence in *S. aureus* strains and resistance to various antibiotics. The results of our study do not agree with 16 that reported in their study that 72% of the isolated MDR *Staph.* strains carry the ica A. From the previous results, we can conclude the great correlation between biofilm formation and ica A gene presence in *S. aureus*. Furthermore, there is a great correlation between MDR *S. aureus* and ica A gene carriage. MDR isolates of *S. aureus* usually carry ica A gene has the capability for the formation of strong biofilm while giving the higher antibiotic resistance a contribution. Thus, a rapid diagnosis is significant for these strains and to administer prophylactic antibiotic and for eliminating planktonic bacteria before they can form a biofilm.

**Sequencing analysis:** The PCR products of six isolates of *S. aureus* were sequestered from the urine & were further referred to the South Korean Company Macrogen to sequence the partial gene mecA and icaA. While, these were further blasted in contrast to the *S. aureus* standard strains in NCBI to record these bacteria in NCBI data to obtain the accession number of each gene of isolate in the NCBI-Genbank. Moreover, the specific selected three molecular & phenotypic methicillin isolates were exposed to the sequencing of particle DNA for mecA gene.

To discover the potential genotypic variations, the files of FASTA format comprising of local strain sequences were utilized for evaluating the molecular association amongst the Nassyriah City isolates of Southern Iraq and Genbank submitted universal sequences. Thus, the local urine isolates No.1 and No.3 of *S. aureus* strain revealed an association with the NCBI-BLAST *S. aureus* strain MRSA 365325 (MH798858.1). The Phylogenetic tree shows that the study isolates on the mecA gene appeared in the tree as a single tone and the closest genetic group is (MH106551.1, and MH798858.1) from Pakistan, and Italy respectively, at total genetic changes (0.0005-0.0025%) (Figure 4). On the other hand, the present study investigate the phylogeny analysis of other three *S. aureus* icaA sequences. As shown in Fig. 5, the local urine isolate of *S. aureus* Number 1 into Number 3 represented a close relation with the NCBI-BLAST. The icaA gene marker was related to the *S. aureus* local isolate which was further correlated to the *S. aureus* strain of gene Pn2301 and partial gene sequence (FJ0049901) of NCBI-BLAST as well as the *S. aureus* ATCC 6538 *S. aureus* strain (CP020020.1) from India and Germany respectively, at total genetic changes (0.2-1.0%).
Figure 1: Agarose gel electrophoresis image that shows the PCR product analysis of methicillin antibiotics resistance *mec A* gene in positive isolates of *S. aureus*. Where M represents the marker (100-2000bp), lane (1-12) positive *S. aureus mec A* gene at (215bp) PCR product size.

Figure 2: In positive isolates of *S. aureus*, the methicillin antibiotic resistance *mec A* gene PCR product analysis has been shown in image of agarose gel electrophoresis. However, M is the Marker having 100-2000 bp while, 1-32 lanes of positive *S. aureus mec A* gene at (215bp) PCR product size. With the exception, two strain was negative for *mec A* gene (isolate 26,27).

Figure 3: The image of Agarse gel electrophorosis presented the analysis of the product of PCR in isolates of *S. aureus* for formation of *ica A* gene biofilm. M represents the Marker ladder with 100-2000bp while lane 1-12 showed positive *S. aureus* isolates with *ica A* gene having 213bp of product size.
Figure 4: The sequences No. 1-No.3 of urine isolates of local S. aureus’ phylogenetic diversity indicated a closed relatedness with the S. aureus NCBI-BLAST strain MRSA 365325 (MH798858.1) at total genetic changes (0.0005-0.0025%).

Figure 5: Phylogenetic diversity of the locally S. aureus urine isolate sequences (No.1 - No.3) revealed a close relationship with S. aureus strain Pn2301 (FJ004990.1) of NCBI-BLAST at total genetic change of (0.2-1.0%).

Source of Funding: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Ministry of health-Thi-Qar health office, Iraq and all experiments were carried out in accordance with approved guidelines.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialties. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:
- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or background
- Material and Methods
- Findings
- Conclusion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: editor.ijphrd@gmail.com

Send all payment to :

CALL FOR SUBSCRIPTIONS

About the Journal
Print-ISSN: 0976-0245 Electronic - ISSN: 0976-5506, Frequency: Quarterly
Indian Journal of Public Health Research & Development is a double blind peer reviewed international Journal. The frequency is half yearly. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialities concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and south east Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.
