2. Rumen Fermentation: Rumen liquor samples were collected at the end of period feeding trial using a stomach tube and filtered through double layers of cheese cloth. Samples were withdrawn from the same lambs in all sampling time, using a smooth stomach tube which connected to 50 ml syringe as described by8. The concentration of total volatile fatty acid (VFA) was determined in rumen liquor samples by the steam distillation method10 using Markham micro-distillation, whereas analyzed ruminal NH3-N by the method of steam distillation with MgO using a Kjeltec (Gerhardt - Germany) distillate unit9.

3. Blood Parameters: During the last week of the experiment and within one day. Blood samples (10 ml) were withdrawn from the same lambs that assigned to digestibility's characteristics of nutrients in experimental diets and rumen fermentation, Samples were withdrawn via jugular vein puncture into vacationer tubes, which were immediately placed in refrigerator, before morning feeding to determine Serum glucose (SG) according to11, Serum total protein (STP) and Serum urea nitrogen (SUN) according to12 concentration Serum albumin according to13, Serum globulin according to14.

Result and Dictation

1. Digestion Coefficient: Table 2. Shows that the addition of two levels of coriander (0 and 6 g/h/day) significantly increased the digestion of dry and organic matter and total protein 67.17, 68.18 and 71.50 respectively. The increases in the digestion factor may be due to improved rumen environment and increased utilization of the diet taken as a result of adding coriander powder containing some volatile oils and flavonoids are found in coriander seeds by increasing the efficiency of digestion and absorption as well as increasing enzymatic digestion of carbohydrate and protein this is consistent with15. Whereas, there were no significant differences in the digestion coefficient of crude fiber, ether extract and nitrogen free extract 64.56, 55.62 And 74.63, respectively. The addition of coriander powder under the active compounds in the composition led to improved fermentation processes in addition to synchronize of energy and protein, which led to the formation of microbial protein. Khamisabadi, et. al.,16 pointed out that in field experiment of fattening Sanjabi lambs no significant differences in digestion coefficient In a subsequent study17 feeding Holstein’s calves two levels, (0and 4g) of flavonoids increased the digestion coefficient of dry and organic matter and the ether extract 84.7, 86.4,and 53.5%, respectively. on the other hand, 18added four levels 0, 2.5, 5and 7.5g fenugreek seeds/head/day to digestibility of DM, OM, CP, NDF and ADF were not affected significantly (P<0.05) by increasing levels of fenugreek seeds as well as19 pointed that in his study no significant differences were noticed in vitro
digestion coefficient of dry and organic matter when adding two levels of concentrate: roughage 70:30 and 30:70 with and without coriander seed powder (0 and 6 g).

2. Rumen Fermentation: Table 3. Shows that the addition of two levels of coriander (0 and 6 g/h/day) resulted in decreases ammonia-N and increases acetic proportion, whereas no significant with propionic and butyric. The results obtained from this study showed that herb coriander could improve the ration fermentation and volatile fatty acids production increase. Cieslak, et.al20 added essential oils to the diet of ruminants changed microbial fermentation society and methane gas production. Hashemi21 demonstrate that using medicine plants effects positively rumen performance and reduction ammoniac nitrogen concentration, protein metabolism and improvement of volatile fatty acids production increase. GÜMÜŞ and IMIK22 reported that while serum NH3 levels were significantly increased in group 100ppm (P < 0.05) and slightly increased in group 200 ppm when Yucca schidigera powder added to lamb feed. Mohammed, et.al.19 revealed that no significant differences in NH3-N and TVFA, when adding two levels of concentrate: roughage70:30 and 30:70 with and without coriander seed powder in A wissa ewe.

3. Blood Parameters: Table 4. Shows the concentrations of blood serum metabolites of these lambs. Addition of two levels of coriander (0 and 6 g/h/day) to the basal diet no significant differences were noticed in serum total protein, albumin, globulin, glucose and urea values of lambs serum among all treatments they were within normal range. Saffa23 found that supplemented the basal diet by either chamomile flowers or Nigella sativa seeds into three dietary treatments (0, 10 and 10 g/ewe/day) respectively. While, increased total protein and globulin concentration of these ewes and no significant differences were observed in albumin, glucose and urea concentrations. Mohan, et. al. 24 noted that feeding Murrah buffalo calves three levels of garlic powder at the dose rate of (0, 250 and 300) mg per kg body weight, respectively increase in the total protein, albumin, globulin. In addition to this, no significant difference was observed between the garlic supplemented blood urinary nitrogen (BUN) values (8) added to lamb feed three levels (0, 100 and 200 ppm) Yucca schidigera powder (YSP) serum glucose, urea, and BUN levels were also found to be similar in the all groups.

Knowledge and Attitude Regarding Disaster and Emergency Preparedness among Hospital Health Care Workers in West Java Province, Indonesia

Suparni1, Fatma Lestari2, Ede Surya Darmawan3, Robiana Modjo2
1Public Health Program Study, STIKes Dharma Husada Bandung; 2Occupational Health & Safety Department, 3Health Administration & Policy Department, Faculty of Public Health, Universitas Indonesia

ABSTRACT

Objective: To assess the knowledge and attitude regarding disaster and emergency preparedness among health care workers.

Method: This cross-sectional descriptive analytical study was conducted in several public hospitals in West Java province, Indonesia. A self-administered questionnaire using modified Emergency Preparedness Information Questionnaire (EPIQ) was used for data collection. This questionnaire consists of 3 components, i.e. respondent sociodemographic data, basic knowledge on emergency preparedness, and attitude towards emergency and disaster preparedness.

Results: Health care workers from 9 public hospitals participated in this study by completing the questionnaire. Female comprised the majority of the respondents (70%). More than a half of the total respondents (53.2%, n=115) showed good knowledge on emergency and disaster preparedness. However, slightly less than a half of the respondents (46.8%, n=101) still had poor knowledge. The respondents’ attitude toward emergency preparedness was generally positive as most of them (75.9%, n=164) expressed a positive attitude although some still reflected negative attitudes towards it (24.1%, n=42).

Conclusion: There is a need to improve the overall knowledge on emergency preparedness among the respondents in order to achieve good hospital disaster preparedness. The positive attitude reflects the acceptability of emergency preparedness among health care workers. Therefore, routine emergency planning and drills should be integrated into the emergency and disaster management program in hospital as investments to achieve good hospital emergency and disaster management.

Keywords: Attitude, Disaster, Health Care Worker, Knowledge, Preparedness

Introduction

A disaster is one of the most difficult events healthcare personnel can face. They must be able to provide needed medical care while performing emergency plan tasks, communicating with incident command, managing supplies and resources, and facilitating patient flow. These tasks differ greatly from what normally is expected of hospital personnel on a daily basis. Unfortunately, most hospital personnel are unprepared to cope with a disaster. It has been shown that hospital staff like healthcare workers that practice for disaster situations must well prepare during these events.

West Java province is an area that is considered as a disaster-prone area in Indonesia based on the Indonesian Disaster Risk Index (IDRI) issued by the National Agency for Disaster Management (BNPB) in 2014 that puts West Java province in the High classification.

In September 2016, a flash flood in Garut district, which is one of the districts in West Java province, caused...
damages to health care facilities. Public health care facilities in the district suffered a substantial financial loss, which was estimated to reach 19 trillion Rupiahs. Almost all wards and rooms on the first floor were inundated with one meter of water. As the result, all equipment and devices in the wards and room were submerged and severely damaged. This situation forced the hospitals to transfer their patients to the 2nd floor and other hospitals that were still able to provide proper care. (8)

Health care facilities play an important role in the effort to reduce or minimize the number of victims in the event of a disaster and accelerate post-disaster recovery process (9). Health care workers, consisting of medical doctors, nurses, midwives, pharmacists, public health officers, and medical engineers, comprise the majority of workers in a hospital. Patient outcome and recovery during emergency situations in a hospital are largely dependent on the initial responses from the health care workers and the quality of care delivered. This means that the knowledge and attitude of these workers regarding emergency and emergency preparedness become a major factor that determines the patient outcome and recovery of. In addition to working towards patient survival, preparedness also encompasses planning, training, equipment provision, and drills or exercises (10).

With the high mortality rate due to disasters in Indonesia and worldwide, there is a need for assessing the responsiveness of emergency health care workers towards emergency and disaster situations, where their knowledge and attitude become one of the dominant factors. The World Health Organization (WHO) recommends that a periodic assessment of the capability of health care facilities to respond to emergencies should be implemented. Hospital preparedness assessment is a mean for the hospital to test and evaluate its capabilities and/or recovering from an event that placed a significant strain on its patient care and operating systems. Hence, this study aimed to assess public hospitals in West Java with regards to emergency management and preparedness and to determine the level of knowledge of emergency workers on emergency preparedness, attitudes of emergency workers towards emergency cases presenting to the hospital, current practices of emergency workers regarding emergency preparedness, and the availability of hospital-specific emergency plans. (11)

Material and Method

This study was performed in 9 public hospitals located in disaster high risk areas in West Java province. This cross-sectional descriptive study was carried out during the period of March-May 2018. Respondents for this study were 216 health care workers that included nurses and midwives.

A self-administered questionnaire using modified Emergency Preparedness Information Questionnaire (EPIQ) (12) was used for data collection. This questionnaire consists of 3 components, i.e. respondent sociodemographic data, basic knowledge on emergency preparedness, and attitude towards emergency and disaster preparedness. A correct response to the item of the questionnaire was given a “1” score while the incorrect response received “0” score. All scores were then combined to get the overall score for each respondent. Respondents with an aggregate score of 50-58 or higher were designated as “good” while those with a score between 30-48 or less were graded “poor.”. For attitude, 10 core questions about expected attitudes toward emergency preparedness were used to determine the respondents’ attitudes. The attitude was said to be positive if the respondent achieved a score of ≥15 and said to be negative when the score was <15. Results were presented in tabular and graphical forms using Microsoft Word.

Findings

Deficient hospital disaster planning and preparedness is more pronounced in developing countries as compared to developed countries (13). Majority who are injured and killed by natural disasters reside in developing countries (14). Thus, the impact of poor disaster planning is more pronounced for developing countries. Prior studies have shown that the socioeconomic level of a community influences the vulnerability of its inhabitants and their medical requirements in the event of a disaster (13).

The findings of this study revealed that only 115 (53.2%) of the respondents had good knowledge of emergency and disaster preparedness while the remaining 101 (46.8%) had poor knowledge. The respondents in this study had different levels of cognitive domain that result in various understanding of the concept of disaster. Each individual will have his or her own interpretation on knowledge about the definition of natural disaster, disaster
risk, disaster rescue technique, and means of saving lives. An overall deficiency in the knowledge of emergency preparedness was found in this study, which is in contrast to the finding in a study in Johannesburg study where 70% of the respondents show good knowledge on emergency preparedness and 90% had above-average knowledge on emergency plan as a logistic structure to ensure the optimal use of resources. (15),(16)

Respondents’ attitude toward emergency preparedness was generally positive as most of them, i.e. 164 (75.9%), believed that emergency plan should be regularly updated, emergency simulations should be performed routinely in the hospital, and staff should be adequately trained because emergency preparedness and management is important for all health workers in the hospital. They also believed that hospital management should adequately be prepared should an upsurge in emergency occur in the hospital and that every staff member should be involved actively, not only nurses and doctors alone. They also agreed that emergency drills should be conducted in the hospital. These findings are similar to those of a study in a Johannesburg hospital in South Africa. (15) Only a small number of respondents (24.1%, n=54) had a negative attitude towards emergency and disaster preparedness.

Individual/group capacity to deal with disasters can be seen from the community’s potentials in resolving the negative impacts of disasters, including taking concrete steps to reduce risks. In addition to being prepared at the individual level, disaster preparedness at the community level is also needed as a form of preparedness in a more structural and systemic manner. Disaster education should not only given in schools, but also needs to be promoted to families and communities. Students who have received disaster education are expected to be able to teach their family members at home and the surrounding community so that disaster preparedness at the community level is formed. (12) It is implicated that disaster preparedness for health care worker should be embedded in the curriculum starting from the diploma level.

In this study, most of the health care workers have a Diploma and only a small number has a bachelor degree (75.9% and 24.1%, respectively). Education can influence someone’s behavior, which is also reflected in disaster preparedness. In general, the higher the education level is, the easier it is for individual to receive information. The establishment of a high level of disaster preparedness requires full attention on the educational programs to ensure that the community will take appropriate actions to reduce vulnerability, especially during the critical phase (72 hours) after the disaster. (17)

More than half of the total respondents never attended disaster training (57%) and less than half attended disaster-related training (42%) such as Fire Extinguisher Use training, Integrated Emergency Management System training, and First Aid training. The average knowledge score of respondents who had attended the training was higher than the respondents who had never attended any disaster training. This might be due to the fact that training participants are given relevant information about the concept of emergencies that enable them to answer the related items in the questionnaire correctly.

The results of this study are in line with the findings in Duong’s study on 152 emergency nurses in Adelaide, Australia, that shows 95% of the respondents want to receive disaster-related training with 45% of respondents feel less confident with their disaster preparedness knowledge due to the lack of training and experience in facing disasters. Duong concluded that disaster education and training can increase nurses’ alertness to emergency conditions during disasters. These education and training sessions should include theories, case studies, and disaster simulations that are provided through a multi-profession collaborative approach. Duong also explained that it is very potential to start disaster preparedness education at the higher education level. The goal is that the higher education institutions will produce graduates with good self-confidence when facing emergencies. (18)

Conclusions

There is a need to improve the overall knowledge of emergency preparedness of health care workers to support the hospital disaster preparedness. Despite good attitude and acceptability of emergency preparedness, routine emergency drills are needed to be able to meet the existing demands of emergency care in the country and worldwide. Basic knowledge on emergency preparedness should be owned by all hospital staff members, both new and existing staff, especially among those who are involved in the management of emergencies. Emergency planning and drills should be done regularly and continuously as a part of the emergency and disaster management program in hospital, which will be good investments for good emergency and disaster hospital preparedness of the hospital.

ABSTRACT

Important in the formation of scoliosis are violations of the supporting, spring and elastic properties of the skeleton, ligamentous and muscular system, contributing to the formation of spinal deformity. As a result, the deformation of the musculoskeletal system, which can cause various dysfunctions in the body, develops. Moreover, all forms of scoliosis are divided into two main groups - congenital and acquired. Often in the pathogenesis of scoliosis, there are two main points. The first is a violation of the growth of the vertebra due to local damage or general disorders, the second is the neurological disorders that disorganize the balancing system of muscle groups. These common disturbances can often take on the nature of irreversible. Arrested from the concave side, normal or even accelerated growth from the convex side contributes to the bending of the spine, and the premature soldering of the germ cartilage of the arches from the convex side leads to the appearance of torsion.

Keywords: scoliosis, dysfunctions, pathology of internal organs, spine, intervertebral disks.

Introduction

In recent years, the world has seen a significant increase in various pathological manifestations in the human body¹,². In their structure, an important place besides cardiovascular pathology³ is occupied by disorders of the musculoskeletal system⁴, including spinal curvature⁵. The prevalence in the world of scoliosis tends to increase in different age groups⁶.

Important in the formation of scoliosis are violations of the supporting, spring and elastic properties of the skeleton, ligaments and muscular system, contributing to the formation of spinal deformity⁷. As a result, the deformation of the musculoskeletal system develops, which can cause various dysfunctions in the body⁸,⁹.

Timely detection of disorders of the musculoskeletal system, including scoliosis with early effective complex correction, prevents the progression of dysfunctions, helping to improve the morphological and functional state of organs and systems¹⁰,¹¹.

Currently, scoliosis is considered as one of the most frequently encountered conditions, leading to various dysfunctions of internal organs¹². Consequently, scoliosis is manifested not only by curvature of the spine, but also leads to a number of common pronounced changes in the body, causing deterioration of the functions of internal organs and disturbing the metabolism in tissues, which reduces the overall resistance of the body¹³.

Objective: to consider dysfunction in the body in the presence of scoliosis.

Issues of the Etiopathogenesis of Scoliosis: For a number of years, observing a large group of patients...
with scoliotic disease and subjecting them to the most thorough clinical, laboratory, special spondylographic and neurological examination, it was not possible to say that idiopathic scoliosis is based on only neurological changes, that they are the main cause for the occurrence of scoliotic disease. The first group is represented by various neurological microsymptoms that do not change during the course of the disease, do not progress and do not disappear regardless of the progression of the disease or the medical manipulations undertaken. Many of them are similar to the status described by some authors. The second group includes neurological symptoms, which supposedly have a tendency to more clearly manifest themselves and worsen with the progression of the disease. In the process of treatment, some of them regress, and some remain. And finally, there is a group of the most pronounced neurological disorders (very severe and deep paresis or paralysis) that are absent in the early stages of the development of the disease and appear with the progression of the disease.

It has been suggested that the idiopathic scoliosis renewal consists of congenital mucopolysaccharide metabolic disorders. Developing this assumption about the value of mucopolysaccharides in the genesis of scoliosis, it was suggested that the rotation of vertebrae in scoliosis depends on the weakness of the fibrous ring and the increase in intradiscal pressure caused by changes in the mucopolysaccharides of intervertebral disc collagen. However, there are still no unambiguous judgments on this score.

A morphological and histochemical study of intervertebral discs, hyaline plates, sprout zones and vertebral bodies seized during surgery for a scoliotic disease from a large number of adolescents was carried out. Four spinal preparations were also investigated, which were withdrawn from patients who died of other causes at the age of 9 months, 12 and 15 years with scoliotic disease. As a result of the conducted research, it was established that in case of a second-degree scoliotic disease, the germ zone has a different structure depending on its location. On the convex side, it is predominantly four-layer, although the zone of proliferation is somewhat narrower than normal. Somewhat closer to the center, when passing to the concave side, the germ zone narrows considerably and is represented by two layers of cells, and the proliferation zone is absent. On the convex side of the curvature, there are quite a few dystrophy zones. Chondrocytes are predominantly dual-core and oriented perpendicular to the long axis of the spine or at some angle to it. A large number of clumps of an amylase-resistant substance are found in most cells of the proliferative zone. The cytoplasm of the cells of the fibrous ring of the disk contains a fairly large amount of an amylase-resistant substance and gives intense reactions to acid mucopolysaccharides. The pulposus nucleus of the disk shifts to the convex side of the curvature and reveals gross dystrophy in fibrous structures in the form of a glitchy disintegration, fragmentation and decollagenization. Bone beams are atrophic in places with jagged edges, indicating a restructuring of the bone structures. Bone marrow is predominantly fibrous and only in some areas myeloid. Hemorrhages and forming tissue cysts are visible, and in some cases plasma lakes, which confirms the impaired blood circulation.

On preparations withdrawn from patients with scoliosis of the third degree, dystrophic changes in the elements of the spine are aggravated. The germ zone is deformed, in places sharply narrowed and poor in cells. There are many zones of dystrophy in it, which go beyond the limits of the actual growth zone and penetrate into the hyaline plate.

Closer to the center, the growth zone is represented by fibrous cartilage, and in some places by connective tissue. Cells with basophilic nucleus and light cytoplasm. Dystrophy zones are painted rather intensively. In some areas, the germ zone was fragmented. Observed areas of osteoclastic resorption and along with this pronounced activation of the endosteum. The bone marrow spaces are made with fibrous fat marrow with tissue cysts and plasma lakes.

There are even more pronounced dystrophic changes on the drugs seized from patients with fourth-degree scoliotic disease. The germinal zone on the concave surface is almost not detected, on the convex - deformed and narrowed. Acid mucopolysaccharides in it are found in small quantities. Hyaline plates are fragmented with the presence of calcification and bone formation in them. The number of acid mucopolysaccharides in the hyaline plate is significantly reduced. Some pale colored foci of sulfated mucopolysaccharides are visible. Bone beams undergo pronounced adjustment. Characterized for them is the loss of osseomucoid and the exposure of the mesh structure of the beams. Expression of
endosteum is expressed with the growth of connective tissue elements in bone marrow spaces. Intervertebral disc tissue undergoes calcification. Zones of dystrophy alternate with zones of cell proliferation. There are extensive areas in which acidic mucopolysaccharides and glycogen are not detected.

A change in carbohydrate metabolism in cartilage is evidenced by a decrease in the amount of glycogen in cartilage cells. The appearance of calcifications in the zone of enchondral growth and in the intervertebral disk indicates a pronounced shift in metabolism.

In the pathogenesis of scoliosis, there are two important points. The first is a violation of the growth of the vertebra due to local damage or general disorders, the second is the neurological disorders that disorganize the balancing system of muscle groups. These initial or general “lesions” must be sufficiently heavy, irreversible, must neutralize the possibility of spinal adaptation and extend into 3-4 segments. Growth processes under adverse conditions contribute to the development of scoliosis. Arrested from the concave side, normal or even accelerated growth from the convex side contributes to the bending of the spine, and the premature soldering of the germ cartilage of the arches from the convex side leads to the appearance of torsion. Thus, a combination of two factors plays a role in the development of scoliosis — the initial pathogenic mechanism and growth processes.

**Morphofunctional features of the body with scoliosis:**
In children with signs of scoliosis, there is a deterioration in general physical development and functional capabilities of internal organs. They have registered a decrease in the growth and size of individual parts of the body, a deterioration in the functional capabilities of the body, stress in the work of the cardiovascular and respiratory systems.

In the blood of children with scoliosis, the level of androgenic hormones dehydroepiandrosterone and testosterone increases. An earlier activation of the pituitary gonadotropic function is noted, which inevitably affects their physical development.

Scoliosis causes skeletal deformity. The load on the joints, ligaments, muscular system of the trunk and limbs is increasing. Violations of the spring function of the spine leads to microtraumas of the spinal cord and brain when running, jumping, with significant deformities - and when walking. In these conditions, functional disorders in the activity of the internal organs also occur.

With scoliosis, as a rule, the excursion of the chest and diaphragm is reduced, the vital capacity of the lungs is reduced, and fluctuations in the intrathoracic pressure are reduced. These changes adversely affect the activity of the cardiovascular and respiratory systems, leading to a decrease in physiological reserves, disrupting the adaptive abilities of the organism. The weakness of the abdominal muscles leads to disruption of the normal activity of the abdominal organs, in particular - to dysfunctions of the gastrointestinal tract.

The decrease in the spring function of the spine contributes to permanent microtraumas of the brain during walking, running and other movements, accompanied by a rapid onset of fatigue and headaches.

With scoliosis, there is a delay in the development of motor skills and abilities, impaired bone formation, weakness of the ligamentous-muscular system and related lack of development of the muscular system, exacerbation of associated diseases that reduce the level of physical and somatic health of the child.

With scoliosis, the vegetative regulation of the cardiovascular system: in 55%, the activity of the parasympathetic division prevails, in 36% of sympathetic influences and only 9% of their balance is recorded. It is believed that with dysplastic scoliosis, dystrophic changes in the muscles of the trunk and limbs are apparently associated with damage to the spinal cord motor neuron apparatus.

**Conclusion**

Scoliosis is one of the most common diseases in modern society. Currently, it is recognized as polyetiologic. Moreover, all forms of scoliosis are divided into two main groups - congenital and acquired. Often in the pathogenesis of scoliosis, there are two main points. The first is a violation of the growth of the vertebra due to local damage or general disorders, the second is the neurological disorders that disorganize the balancing system of muscle groups. These common disturbances can often take on the nature of irreversible. Arrested from the concave side, normal or even...
accelerated growth from the convex side contributes to the bending of the spine, and the premature soldering of the germ cartilage of the arches from the convex side leads to the appearance of torsion.

ABSTRACT

Beta-lactamase was purified from local isolate of Acinetobacter baumannii by several steps included ion-exchange chromatography by using DEAE-Cellulose and gel filtration on Sephacryl S-200 column. The obtained purification fold and recovery were 11.72, 55.12% respectively. The characterization of the purified Beta-lactamase showed that the molecular weight was about 44,668 KD as determined by gel filtration. The Acinetobacter baumannii gene (blaTEM) responsible for β-lactamases detection was by PCR. They recorded positive results reaching 39 (86.66%), from the isolates.

Keywords: β-Lactamase, Acinetobacter baumannii, Molecular weight, genotyping

Introduction

Beta-Lactams are the most widely used class of antibiotics. Since the discovery of benzyl penicillin in the 1920s, thousands of new penicillin derivatives and related β-Lactam classes of cephalosporins, cephamycin, monobactams and carbapenems have been discovered. All these antimicrobial agents have a common a Beta-lactam ring which acts as an analog of D-alanyl-D-alanine. The main component in the bacterial cell wall that ensures its integrity is peptidoglycan layer, especially in Gram-positive organisms. These antimicrobial agents inhibit the synthesis of the bacterial peptidoglycan layer by binding with varying affinities to DD-transpeptidases, otherwise known as penicillin binding proteins (PBPs). This, in turn, inhibits the cross-linking of the nascent peptidoglycan layer, which disrupts the synthesis of the cell wall. Moreover, due to the production of enzyme that hydrolyze β-lactams several β-lactamase inhibitor are being combined with β-lactams, produced by many of gram negative bacteria, like Acinetobacter baumannii 1,2,3. Main challenge in A. baumannii pathogenesis is unity, connection, expression and regulation of genetic elements that contribute to the Multi Drug Resistant phenotype, for example, the presence of OXA and ESBLs genes such as TEM and SHV. Extended spectrum beta-lactamase have altered enzymatic activity from their progenitors. Furthermore, they have the ability to hydrolyze4. Chromatography is an important biophysical technique that enables the separation, identification, and purification of the components of a mixture for qualitative and quantitative analysis. Ion chromatography plays a predominant role in ion determinations with the instrumental methods. It offers several advantages over the conventional methods, such as simultaneous determinations of alkali and alkaline earth cations and ammonia. Ion chromatography has been accepted world-wide as a reference method for analyzing anions and cations in water and wastewater due to the fact that it enables the replacement of several individual wet chemistry methods for common ions with one instrumental technique5. Arun et al.6 was made to characterize and optimize the production of this enzyme by ion exchange chromatographic purification. Poirel et al.7 were purified from extracts of E. coli DH10B(pOXA-58), the specific activity of β-lactamase (OXA-58) against benzylpenicillin was 2.3 U per mg of protein and its purification factor was 70-fold.

The aim of this study is dealing with extraction and purification of β–Lactamase from local isolates A. baumannii, then genotyping for β–Lactamase has been studied.
Material and Method

Extraction and partial purification of crude β-lactamase: The β-lactamase was isolated from local isolate of A. baumannii isolated in 100 ml nutrient broth at 37°C, diluted 10-fold with the fresh nutrient broth; the culture was incubated with shaking at 37°C. After 1.5 hr. of incubation, the penicillin-G was added to the final concentration of (6g/l) as the inducing agent, the incubation continued for 3 hr. The bacterial cells were harvested by centrifugation at 10000 g for 30 min at 4°C, washed once with (0.05M) Na2HPO4/KH2PO4, (pH 7.0), suspended in 4 ml of the same buffer, and disrupted by ultra-sonicater for 30 min in an ice-water bath. The disrupted cells suspension was centrifuged at 10000g for 15 min at 4°C, and the crude enzyme extract (the supernatant) was lyophilized by freeze dryer, then stored at -20ºC until use8.

Detection of β-lactamase activity: Beta-lactamase activity was determined by a micro-iodometric assay according to modification method described by8,9. The reaction mixture (total volume (2225µl)) consisted of:

a. Starch-iodine reagent 1000 µl was added to.

c. Crude or pure enzyme1000 µl.

d. Starch solution 200 µl.

These components were mixed in small test tubes, blue color developed immediately due to the reaction of iodine with starch. Rapid decolorization indicated β-lactamase production. Control solution was made up by replacing the enzyme in phosphate buffer solution, and the absorbance was read spectrophotometrically at 620 nm.

Determination of Protein Concentration: Protein concentration was determined according to the method of10. A 20µl of β-lactamase crude was mixed with 50µl of 1 M NaOH with shaking for 2-3 minutes then 1 ml of Bradford solution, was added with shaking. The absorbance was measured at 595 nm by spectrophotometer.

Purification of β-Lactamase:

A. Cells harvest and disruption

B. Separation with ionic exchange by using diethyl Aminoethyl- cellulose (DEAE-cellulose): Ten ml of solution was loaded on ion exchange column, the separated fractions were collected at flow rate 60 ml/hour (approximately, 5ml for each fraction), the wash was obtained by use of phosphate buffer solution. (the same buffer used in equilibration), the elution was achieved by the same buffer with gradual increase in concentration of sodium chloride, the flow rate was 60 ml/hour too, the protein concentration of the fractions was measured at wavelength 280 nm to the washed and eluted fractions, protein concentration then was calculated and the enzymatic activity was assayed.

C. Gel filtration Sephacryl–S200: Sephacryl – S200 column (87 x1.5cm) was prepared and packed according to the instructions of the manufacturing company (pharmica Sweden). The column was equilibrated with (20mM) phosphate buffer solution (pH 7.0) . A (5ml) sample of each concentrated partially purified β- Lactamase enzyme was added to the column, carefully using pastur pipette. Elution of Tris- base A (5ml) fraction was collected of each enzyme activity then protein concentration was estimated by measuring the absorbance at (280nm).

Determination of Molecular Weight of β-Lactamase by Gel Filtration Chromatography: The method of gel filtration on a column Sephacryl S-200 was followed to estimate the molecular weight of the β- Lactamase enzyme, using a standard protein by drawing the relationship between the logarithm of a standard protein molecular weight and size of recovery volume size of Void volume (Ve/V0).

Genotyping study: DNA was extracted from all (61) A. baumannii clinical isolates using a commercial purification system (Genomic DNA Mini Kit (Geneaid, Taiwan). DNA was stored at - 4°C until used for molecular detection. Conventional PCR was used for detection of blaTEM gene. Forward primer 5-CATTTTTCGTGTCGCCCTTAT-3, and reverse primer 5-CATCCATAGTTGCCTGACTCC - 3. Concerning the conventional PCR reaction, designed primers were used for gene detection. The condition of PCR blaTEM gene of 796 bp PCR prduct were: initial denaturation 94 °C for 5 min, cycling condition (32) included denaturation 94 °C for 45 sce, annealing 57 °C for 40 sce, extension 72 °C for 45 sce, and the final extension 72 °C for6 min.
Results and Discussion

Extraction and purification of β-lactamase enzyme: Beta-lactamase isolated from local isolate of *A. baumannii*, was isolated in ml nutrient broth at 37°C, and washed with (0.05M) Na₂HPO₄/KH₂PO₄ (pH 7.0), then lysis, breaking the cell wall of bacteria according to procedure. After that estimate the enzyme activity was in crude supernatant. The enzyme activity was 1.56 unit/ml, and specific activity 1.07 unit/mg protein.

Ionic Exchange Chromatography: This is one of the most useful methods for protein purification. Depending on the surface molecule charge, the protein and the buffer conditions, the protein will have net a positive or negative charge. β-lactamase enzyme was obtained by using buffer solution (0.05M) Na₂HPO₄/KH₂PO₄. Absorbance of eluted fractions were measured at 280 nm upon the arrival of absorbance to the line of zero (line base), then same buffer with the NaCl gradient (0-2M) was used to elute the bounded protein. Ionic exchange chromatography patterns showed one protein peak in wash and two peaks in gradient elution, represented enzymic activity (tubes 40-43). Those fractions were pooled and tested for specific activity (6.36U/mg) a fold purification of (5.94) and enzymic yield of (78%) in parts. figure (1). and this result is in agreement with that reported by

![Figure 1: Ionic exchange chromatography for β-lactamase enzyme activity from *A. baumannii* through DEAE cellulose column (1.5X7) cm. The column was calibrated with buffer solution(0.05M) Na2HPO4/KH2PO4, PH (7), flow rate 60 ml/hrs and 5ml fraction](image)

Purification of β-lactamase enzyme by gel filtration chromatography: Purification of β-lactamase enzyme by gel filtration chromatography was done by passing the sample through Sephacryl S-200. Enzymes fraction from DEAE cellulose were pooled and passed through gel filtration column. Column was washed by buffer solution (0.05M) Na2HPO4/KH2PO4 and then sample passed, fractions were collected up to 30 fractions. The fractionation yielded two protein peaks as absorbance reading at 280nm (wave length), only one peak appeared when reading absorbance at wavelength of 280 nm and when determined for enzyme activity in resulting parts enzyme activity recorded in, the specific activity reached (12.54U/mg), fold of (11.72) and a yield (55.12%) as mentioned in table (1) and Figure (2) and this result is in the finding of agreement with...
Determination of molecular weight of β-lactamase: The molecular weight (MW) was determined by S-200 gel filtration depending on the size of the separate molecules with their charge\(^{11}\). Sephacryl S-200 (1.5 x 87) cm was used for estimation of the molecular weight of purified β-lactamase enzyme from *A. baumannii* illustrated in figure (3). According to the logarithm molecular weight and elution volume/void volume (Ve/Vo) Table (2) standard curve the calculated molecular weight of the β-lactamase found to be 44,668 KD.

Detection of β-lactamases using (bla$_{TEM}$): The prevalence of β-lactamases producing genes (bla$_{TEM}$) was detected and determined for each *A. baumannii* clinical isolates and the results were illustrated as follows: 39 (86.66%) for positive isolates, 6 (13.33%) for negative isolates, and the Sample Total number 45 (100%).

The Figure (4) indicated the PCR product of blaTEM gene which was 793pb.

The production of β-lactamases, a family of enzymes that hydrolyze the β-lactam ring, thereby inactivating the antibiotic molecule prior to binding with penicillin binding proteins (PBP’s), is the principal mechanism of resistance to β-lactam antibiotics. They also play a major role in intrinsic and acquire resistance of bacteria, mainly in gram-negative.¹⁴
Conclusion

This study concluded that the obtained purification fold and recovery were 11.72, 55.12% respectively, and the characterization of the purified Beta-lactamase showed that the molecular weight was about 44,668 KD as determined by gel filtration. The molecular detection for Acinetobacter baumannii gene (blaTEM) responsible for β-lactamases was recorded that the positive results reaching 39(86.66%), from the isolates.

ABSTRACT

The goal of search determine the effect of use commercially chewing gums on fluoride kinetics in saliva. Using of three commercially chewing gums with fluoride from local markets, contains 3.38 mg of fluoride as marketed sodium mono fluorophosphates (NaMFP), Stannous fluoride (SnF2) and sodium fluoride (NaF) which are the three most common sources of fluoride used in currently fluoride dentifrices. Fifteen 7-9 year-old volunteers were instructed to chew the fluoridated gums. After starting chewing saliva collected at 0, 3, 6, 9 and 15 minutes. The Salivary fluoride analyzed by using of fluoride- specific electrode (201Fluoride E. Hanna instruments) after acid hydrolysis. The fluoride amount in the saliva samples after the use of chewing gum which contains Sodium mono-fluorophosphates (NaMFP) and Stanous fluoride (SnF2) , were 0.328 mg and 0.258 mg respectively which higher than after the use of chewing gum contains sodium fluoride (NaF) which was 0.041mg in all experimental periods. The high fluoride presence in saliva after the use of chewing gum of (NaMFP) and (SnF2), are significant to prevent dental caries and this should be evaluated in clinical researches.

Keywords: chewing fluoride gum, fluoride kinetics, Stannous fluoride, Sodium mono fluorophosphates, sodium fluoride, fluorosis

Introduction

Cavities, technically called dental caries caused by a bacteria called Streptococcus mutan, this bacteria lives in the mouth and thrives on Sugar and other carbohydrates. The presence of carbohydrates, S. mutans produces acids that dissolve the enamel of eeth, causing cavities. Dental caries is one of public health diseases and have multifactorial causes. As a result of several studies carried out to understand the dental caries process as well as its risk factors, dental treatment emphasis has been moved from corrective to preventive methods. Fluoride is an extensively proven effective agent for the control of dental caries. Its cariostatic effect is related to its presence in the aqueous phase of the apatite crystals Which inhibits demineralization and activates remineralization. There are many studies supporting the frequent and repetitive use of low concentration and self-applied fluoride agents. Stimulating the search for alternative devices to apply it in the mouth, such as professional products, at high fluoride concentrations (solutions, gels, pastes and varnishes) or through home care products, like toothpastes, mouth washes fluoridated mucoadhesive tablets, and more recently fluoridated chewing gums. The use of chewing gum increases the salivary flow, which helps to clean the oral cavity, and introduced as useful vehicles for fluoride, calcium, phosphate and chlorhexidine delivery. Fluoride-containing chewing gums increase salivary and dental plaque pH, calcium and phosphate concentration and also act on enamel remineralization. The chewing gums of (NaMFP) , (SnF2) and (NaF) were introduced in the marketplace as an additional agent to prevent dental caries. Each piece of the product contains (3.38 mg) of fluoride as mono-fluorophosphates, Stannous fluoride or sodium fluoride. Despite the possibility of helping to prevent dental caries, a concern arises about its contribution as an additional source of fluoride intake when consumed by children in the age of risk for dental fluorosis. Dental fluorosis is a health condition caused by a child receiving too much fluoride during tooth development. The critical period of exposure is between 1 and 4 years old is more risky than children over 8 years old. In its mild form, which is the most common, fluorosis appears as tiny white streaks or specks that are often unnoticeable. In its severe form, it characterized by black and brown stains, as well as cracking and pitting.
of the teeth. The severity of dental fluorosis depends on the amount of fluoride exposure, the age of the child, individual response, and nutritional and other factors. Although water fluoridation can cause fluorosis, most of this is mild (0.7-1.2 mg of fluoride/L) and not usually of aesthetic concern. Severe cases can be caused by exposure to water that is naturally fluoridated to levels well above the recommended levels, or by exposure to other fluoride sources such as brick tea or pollution from high fluoride coal. According to the centers for diseases control, 32% of American children now have some form of dental fluorosis, with 2 to 4% of the children having the moderate to severe stage (CDC 2005 USA). Thus, the aim of the present study was to analyze the amount of fluoride released in saliva after chewing the gums of (NaMFP), (SnF2) and (NaF) in Iraqi subjects.

![Chemical Structure of Sodium mono-fluorophosphates](image)

**Materials & Method**

**Experimental design:** The study was carried out with fifteen 7-12 year-old children. All of them had good general health, the children chewed the fluoridated gum, each piece containing (3.38) mg of fluoride as mono-fluorophosphates, Stannous fluoride and sodium fluoride. The saliva was collected in cooled plastic containers at (0, 3, 6, 9, and 15) min after 3 minutes starting chewing gum. During this period, the volunteers remained seated were not allowed to have any food or drink. The samples obtained were stored in freeze at -5°C until fluoride analysis.

**Fluoride Analysis**

**Acid hydrolysis:** The acid hydrolysis of fluoride was done because the samples of chewing gums contain fluoride as mono-fluorophosphates, Stannous fluoride and sodium fluoride which form complex with some of saliva components. The method used was adapted from the method proposed by [13] modified by [14] for the analysis of mono-fluorophosphates and sodium fluoride in saliva after using a dentifrice containing these fluoridated compounds. To 0.25 ml of each saliva sample, 0.25 ml of 2 mol L⁻¹ hydrochloric acid (Analytical reagent, Gainland chemical company, UK) was added, and the samples were kept for 1 hour at 45°C under agitation in water bath. Then, neutralization was accomplished with 0.5 ml of 1 mol L⁻¹ sodium hydroxide (Analytical reagent, Gainland chemical company, UK).

**Fluoride measurement:** Fluoride was analyzed by the direct method, using a fluoride specific Electrode (201 Fluoride E. HANNA instrument, China) and an ion analyzer. Prior to the samples analysis, a set of standards (ranging between 0.025-3.2 ppm F) was prepared in triplicate, using serial dilution from a 100 ppm NaF stock solution (E. Merck, Darmstadt, Germany). The millivoltage potentials converted to µg F using a standard curve.

**Graph 1:** showed the kinetic released of fluoride (mg/g) in saliva from chewing gum of NaMFP and NaF respectively at different periods (min).

**Results**

Graph 1 shows the mean total fluoride released (mg) with time. The comparisons showed that the chewing gums which contains (NaMFP) and (SnF2) released significantly higher amounts of fluoride when compared to chewing gum which contains (NaF), up to the 15 min collection time. The amount released decreased with time. Table (1): represents the total amount of fluoride released in saliva (mg), during the whole experiment, for the two gums, a significantly higher amount of fluoride was released when chewing gums which contains (NaMFP) and (SnF2) were chewed (0.328) mg and (0.258) of fluoride respectively when compared to chewing gum which contains NaF (0.041) mg of fluoride.

Fig. 1: Shows the relation between fluoride released in saliva & collection period

**Discussion**

It is known that the frequent and repeated use of low fluoride concentration products, which promote low and constant salivary fluoride levels, is the most efficient way to prevent dental caries \textsuperscript{[11],[16],[10]}. Levels between 1 and 10 ppm of fluoride reduce the enamel solubility and increase the remineralization rate, facilitating the precipitation of minerals on the enamel surface \textsuperscript{[11],[16],[10]}. found the greatest fluoride values in saliva between 5 and 10 minutes after the use of a fluoridated chewing gum. The subsequent periods, the fluoride concentration in saliva decreased gradually. In this study, the fluoride release was significantly higher at 0, 3 min compared to 6, 9 and 15 min when the fluoridated gum was chewed.

Although \textsuperscript{[10]} also suggest that the salivary flow stimulation may have a negative effect on the fluoride retention in the mouth, \textsuperscript{[13]} demonstrated that a single chewing gum tablet with 0.5 mg of fluoride can maintain high fluoride levels in saliva for at least 60 min.

\textsuperscript{[11]} sustained in their study that chewing a fluoridated gum with only 0.1 mg of fluoride five times a day favors the remineralization of initial dental caries lesions, and that this frequency could maintain high fluoride levels in saliva during most part of the day. \textsuperscript{[17]} evaluated the effect of two commercially available Chewing gums with fluoride on the cariogenic micro biota of saliva and dental plaque. The gum Fluorite showed a faster pH recovery and a F release to saliva after up to 30 minutes. The potential anticariogenic effect of chewing gums containing fluoride has been proposed by \textsuperscript{[11]} and \textsuperscript{[10]}. However, there are no data regarding the fluorosis risk that this type of product may promote. It has been suggested that the incidence and severity of dental fluorosis have become greater in the last decade in both optimally fluoridated and non-fluoridated areas in many countries, as well as in Brazil\textsuperscript{[18],[19],[20],[21],[22]. This attributed to an increase in the fluoride level of foods and beverages through processing with fluoridated water, inadvertent ingestion of fluoride toothpaste, and the inappropriate use of dietary supplements\textsuperscript{[7]}. Considering that the highest risk factor for the development of dental fluorosis is the total amount of fluoride ingested, and that nowadays there are several available sources, the chewing gum of NaMFP can cause concern for children at the age of risk for dental fluorosis, which comprises 1 to 7 years of age. of NaF. One tablet of NaMFP chewing
gum could represent 47%, (NaMEFP is Easily soluble in water with strong hygroscopy, its solubility is 42gm/100 gm water at 25 °C) and one SnF2 tablet chewing gum could represent 37% only of the maximum daily fluoride ingestion, (solubility 35g/100 gm water at 20 °C), while one NaF tablet chewing gum could represent 5.7% only of the maximum daily fluoride ingestion (the relative constant solubility rate of NaF makes it an ideal source for the fluoride ion in treatment of municipal water supplies, solubility 0.76g/100gm water at 25 °C), This maximum daily ingestion was calculated, based on the literature, as being 0.07 mg of fluoride/kg of body weight (18) and considering the use of a single tablet. Unfortunately, there is no data available on the consumption of chewing gum by children. However, it is possible that children use more than one tablet per day, which increases the risk of dental fluorosis development. Hattab et al. [23] (1989) demonstrated a mild increase of fluoride plasma levels after the use of a fluoridated chewing gum and concluded that this product offers a minimal risk of adverse effects. However, this study was carried out in fluoride deficient areas and with adult subjects, using a chewing gum with smaller amounts of fluoride (0.113 mg) when compared to that used by the present study (approximately 3.38 mg, according to the manufacturer). Therefore, other studies with children living in optimally fluoridated areas are necessary to observe the effect of chewing gum which contains NaMFP on the plasma fluoride levels.

Conclusions

This study indicated that:

1. The fluoride concentration in saliva samples after the use of chewing gum which contains (NaMFP) and (SnF2) were significantly higher than that observed after the use of chewing gum which contains (NaF) in all the experimental times. The fluoride release during the experiment were 0.47and0.37mg for chewing gum which contains (NaMFP) and and (SnF2) respectively, while 0.041 mg for chewing gum which contains (NaF).

2. The high fluoride concentration in saliva after the use of chewing gum which contains (NaMFP) and (SnF2) may be important on dental caries prevention in children or adults, especially for individuals with compromised salivary flow or the ones who live in deficient fluoride areas.

However, further clinical research is necessary to clarify this issue.

3. The use of chewing gum which contains (NaMFP) and (SnF2) should be avoided by children at the age of risk for dental fluorosis because the fluoride release varied from 47% and 37% of the maximum recommended daily intake for children aged 1 and 7 years old, respectively.

4. The use of fluoridated gum should be used to patient with high risk to caries.

“Go360”—A Fall Risk Assessment Smartphone Application for Older Adults

Thirumalaya Balaraman¹, Mohamodhossen Maysoon Hanaa²
¹Senior Lecturer cum Head of Program-Physiotherapy, ²BSc (Hons) in Physiotherapy, Faculty of Health and Life Sciences, INTI International University, Malaysia

ABSTRACT

Background: Globally, falls are the second leading cause of death and early identification of fall risk among older adults is very important to plan preventive measures. The literature has shown that a smartphone (SP) can be used for fall detection and fall risk assessment.

Objective: To develop a smartphone application (SA) for older adults to assess their fall risk based on clinical practice guidelines (CPG) and to pilot test the application.

Material and Method: A SA named “Go360” was developed with three main built-in sensors of the phone to assess the fall risk using Timed Up and Go Test (TUG), 30-Second Chair Stand Test (30SCST), and Four Stage Balance Test (4SBT) along with body sway and gait speed data. The SA was pilot tested with 8 older adults concurrently with standard manual tests.

Results: The results showed that SA overestimated the TUG, 4SBT stage 2 and 4SBT stage 3 test values. Conversely, there was no difference in 30SCST, 4SBT stage 1 and 4SBT stage 4 values. The fall risk matched with the manual test results.

Conclusion: The newly developed Go360 SA detects the fall risk using 3 evidence-based functional tests in agreeable level with the standard manual test and it can be used by older adults for self-checking.

Keywords: fall risk, smartphone application, older adults, Go360, timed up and go test, 30- second chair stand test, 4 stage balance test.

Introduction

Globally, falls are the second leading cause of death due to accidental or unintentional injuries¹. Older adults aged more than 60 years are more prone to death due to fall¹². Nearly one-quarter of the older adults reported to fall every year in developed and developing countries²-⁶. Falls prevalence was reported to be between 4.2% to 61% in the Malaysian community-dwelling older adults⁷. Muscle weakness, impaired balance and gait, side effects of medication, history of previous falls, advancing age, female gender, underlying medical conditions, visual problems, cognitive problems, physical inactivity, and environmental hazards were identified as risk factors for falls¹²,³-⁸. As exercise interventions have shown a reduced risk of fall, early identification of fall risk among older adults is very important to plan the preventive measures¹².

As the risk factors for falls in older adults are multifactorial, International Clinical Practice Guidelines (CPG) recommends that the fall risk assessment should be multifactorial⁸-¹¹. The algorithm commonly recommended in the CPG is to check the fall history in the first step followed by gait and balance assessment if no history of falls. If gait and balance results are abnormal, then a comprehensive multifactorial assessment should be carried out⁹-¹¹. However, these screenings can be possible only when older adults are seeking healthcare for any reasons. In Asian countries like Malaysia, it is very common that the older adults did not consider falls...
as serious and they did not seek medical help. Hence, there are more chances that fall risk assessment may be missed in the community-dwelling older adults. Hence a very simple screening tool to assess the fall risk in the community is needed to tackle this situation. As per a recent scoping review, the tools used to assess fall risk in Malaysia were similar to other countries.

Since the introduction of the first SP to the consumers in 1994, SP has been utilized in many fields for different purposes along with its primary role of telephone calls. Multiple sensors, mobile applications, and advanced features have made the SP one of the famous device in the healthcare industry. The literature has shown that SP can be used for fall detection, fall risk assessment and fall prevention through the function of its various sensors and Internet of Things (IoT). However, most of the SA was designed to detect the falls and alert the caregiver or healthcare professional. Out of SA to assess the fall risk, most of them were developed for healthcare professionals use and some also utilize the wearable sensors along with SP for fall risk assessment. Hence this study was aimed to develop a SA for older adults use to assess their fall risk based on CPG. The developed SA was pilot tested among older adults with and without fall history.

**Material and Method**

**SA development:** A SA named “Go360” was developed with the help of an information technology expert to assess the fall risk of older adults based on the initial screening steps mentioned in the CPG and Stopping Elderly Accidents, Deaths & Injuries (STEADI) guidelines. The SA was designed to be simple, so that older adults and their caregivers can use it to assess the fall risk. However, it can also be used by a healthcare provider. The SA will collect fall history as a first step. The next step would be screening tests for gait and balance along with lower limb strength assessment. Based on the results, fall risk will be reported. The SA was developed for Android-based devices to record the information from the tests on a webpage. The SA was hosted at the google play store from Jan 2019 to April 2019 for testing. The details of the tests used in Go360 (TUG, 30SCST, 4SBT, body sway and gait speed) can be found elsewhere. The cutoff scores to detect the fall risk was based on the STEADI guidelines. The body sway and gait speed are not a separate test, nonetheless, it will be collected from the 4SBT and TUG test, respectively from all the participants to identify the normal and abnormal trends. Nevertheless, the SA does not decide fall risk based on these two values. The home page of Go360 SA is given in figure 1.

**Pilot testing:** After getting ethical clearance from INTI International University research ethics committee, a pilot test was conducted with 8 voluntary, community-dwelling older adults from the Nilai and Seremban town using Asus ZenFone 3 (ZE520KL) model. The functionally independent older adults aged 60 and above, irrespective of their fall history were selected by the convenience sampling method. Elderly who had a visual impairment, physical disabilities, mental disorders, mobility problems due to medical diagnosis, those using mobility aids and under regular medications which can affect their balance and gait were excluded. After obtaining the informed consent, an open-ended questionnaire was administered to collect basic demographic data and focused fall and medical history to identify the participants who fit the inclusion criteria. The participants were then requested to use the SA to test their fall risk. The manual tests were also concurrently administered using the STEADI guidelines to check the validity of the SA.

**Statistical Analysis:** The agreement between the SA method and the standard manual method was assessed
using Bland-Altman analysis. A zero bias indicates no difference between SA and standard manual test. Whereas a negative bias point to an underestimation of the SA test data (SA minus the manual test values); and a positive bias related to an overestimation of the SA test data. The Statistical analyses were performed using GraphPad Prism version 8 (GraphPad Software, San Diego, CA, USA).

Results

The participants were 8 older adults and details were given in the Table 1.

Discussion

Fall risk application is a crucial tool for the elderly so that their fall risks can be analyzed as quickly as possible and necessary precautions can be taken. In this pilot test, most of the participants had a history of fall and it is also reflected in the fall risk detection by Go360 SA.

The TUG test results of the SA have shown an acceptable agreement with the manual test considering the bias (0.1313 seconds) reported in this study are lower than the mean difference to detect falls (0.63 seconds) reported in the literature. Previous studies with mobile TUG tests were also shown that SA identifies the fall risk in an acceptable levels. The reason for the difference in scores could be due to delays in the SA’s timer cutoff.
at the end of the TUG when the participant returns to the original position of sitting which needs improvement. The 30SCST values of SA shown agreement with manual tests. Previously published studies also showed a strong correlation on the number of sit to stand repetitions between SA and motion capture system\textsuperscript{19}.

The 4SBT stage 1 and stage 4 values matching with the manual test values since all the participants either completed or did not attempt the test. Conversely, 4SBT stage 2 and stage 3 reported the agreeable amount of bias referring to the STEADI guidelines which consider completion or non-completion of tandem standing for 10 seconds to assess the fall risk rather than the duration of tandem standing\textsuperscript{21}. The difference could be due to sometimes the participant need to manually stop the timer during 4SBT if they break the test less than 10 seconds as the body sway may not be strong enough for the sensor to stop the SA timer. Furthermore, literature reported a correlation between SA and motion capture and force platform systems to detect the anteroposterior and mediolateral displacements during single limb stance test\textsuperscript{19}. Similarly, Go360 app also captures the body displacements during the 4SBT, though, it needs improvement to capture the break of standing at any phase of 4SBT.

Previous studies also reported the gait measurement with SA\textsuperscript{20}. Go360 also captures the gait data in the background during TUG. Nonetheless, the app is not set to calculate the fall risk based on the gait speed, which will be a future enhancement. The pilot test results of this SA shown that the Go360 SA can provide valid results about fall risk and its fall risk detection also matches with the standard manual tests. However, the small sample size is the limitation of this pilot test. Hence a large scale testing for reliability and validating with more gold standard testing like force platform is required. Also, warning about using the Go360 under supervision should be included as there are chances that some of the test components may predispose to fall. Currently, as the tests are conducted by placing the phone in the pocket, the body sway data are not recorded accurately since the phone may be in slanting position. Hence the future plan would be placing the phone at chest during testing using a chest strap and providing voice commands/instructions using the local language. As older adults aren’t necessarily using old fashioned mobiles, we can assume that the older population in Malaysia may be ready for an advanced tool to determine their fall risk\textsuperscript{30}.

**Conclusion**

This study has developed and pilot tested a SA “Go360” to detect fall risk of older adults, which can be used by the older adults, caregivers or by healthcare professionals. Pilot testing indicates that the Go360 SA detects the fall risk using 3 evidence-based functional tests in agreeable level with the standard manual test. Nevertheless, further technical improvement and large scale testing are required for further enhancement.

ABSTRACT

Mercury (Hg) is a liquid metal element, silver at room temperature (25°C) and has a melting and boiling points at -38.87°C and 35.0°C, respectively. In traditional gold mining activities, Mercury (Hg) is used for gold purification (amalgamation). This study aims to determine the level of risk (RQ) in the community of Bulawa District who consume fish and drinking water sourced from the waters around traditional mining activities. This type of research is observational with an environmental health risk analysis design. Sampling was calculated using purposive sampling with the inclusion criteria by the researchers and resulted in 100 citizens. The results of the calculation of the level of Risk (RQ) of Mercury (Hg) consumption of fish and drinking water in the community of Bulawa District was 0.08 and 0.003, respectively, thus, RQ <1, meaning that it does not have an effect on health. However, this value can be used as a reference level of risk level (RQ) of Mercury (Hg) in people who consume fish and drinking water from the waters of traditional mining areas in Indonesia. Control measures can be taken to maintain the level of Risk (RQ) of Mercury (Hg) <1 through limiting the frequency of consumption and the rate of intake of fish and drinking water from surrounding waters. Warning signs of mercury contamination around mining waters can be also provided.

Keywords: Mercury (Hg), Mine, Risk Level (RQ), Society

Introduction

Merkury (Hg) is a liquid metal element in silver at room temperature (25°C), has a melting point of -38.87°C and a boiling point of 35.0°C. Mercury in aquatic environment comes from illegal traditional gold mining activities. Mercury in the mining sector is used for amalgamation process (gold refining). Pollution occurs because Mercury used to purify gold is disposed of freely in the waters. Over time, bioaccumulation of Mercury in water and fish causes increased mercury concentration. If humans consume water and fish, humans will also be exposed to mercury (Lestarisa, 2010)(1).

Mercury causes neurological symptoms, teratogenic effects, and increases the ratio of red blood cells to blood plasma. Methyl mercury has a high affinity for the sulfhidryl group which has a large effect on the dysfunction of the colinasetyl transferase enzyme. The result is acetylcholine deficiency which contributes to signs and symptoms of motor dysfunction (Broussard, 2002)(2).

According to the Food and Drug Administration/FDA (1996), the limit of mercury (Hg) in fish is 1 ppm (ATSDR, 1999)(3). The Food and Drug Administration/FDA (1997) also states that the limit of mercury in fish is ≤ 1 mg/kg (Permenkes, 2016)(4).

According to the Federal State Toxicology and Regulation Alliance Committee (1995), the standard concentration of Mercury in permissible drinking water is 2 μg/kg and based on the World Health Organization/WHO (1984), the limit of mercury concentration is 0,0001 mg/L (ATSDR, 1999)(3).

The results of the Singga study (2013), Mercury concentration in fish samples in Bulawak Subdistrict, Bone Bolango District, Gorontalo Province was 0.0298 mg/kg(5). This shows that Mercury concentration in fish in the area was still below the Threshold Value issued by the Indonesian National Standard (2009) by 0.3 mg/kg(6). In addition, the concentration of Mercury in drinking water is below the Threshold Value issued by the (Permenkes, 2010) by 0.001 mg/L(7).

Based on the previous research on the analysis of mercury exposure health risks in the community of Bulawa Subdistrict, Bone Bolango Regency, Gorontalo Province, the level of risk of exposure to Mercury through consumption of fish and drinking water in the community has not been performed. This makes the community of Bulawa District being exposed to mercury from fish and drinking water consumed. Based on the explanation above, the researchers measured the level of risk (RQ) exposure to Mercury (Hg) through consumption of fish and drinking water in the community of Bulawa District.

**Materials and Method**

This study aims to determine the level of risk (RQ) exposure to Mercury (Hg) through consumption of fish and drinking water in the community of Bulango District, Gorontalo Province with non reactive research using the dose response approach and NOAEL. The number of samples was 100 citizens. Sampling was performed by purposive sampling method; i.e. citizens of Bulawa Subdistrict, Bone Bolango District who consumed fish caught from Bulawa waters and had lived in the area for at least 1 year and used river water and ground water as drinking water.

The study began with a literature study on the calculation formula of the Reference Reference(RfD), non-carcinogenic intakes and the level of non-carcinogenic risk. Secondary data was then obtained; which includes respondent characteristics such as body weight, mercury exposure concentration(Hg), intake of fish and drinking water intake rates, duration of exposure, frequency of exposure and average duration of exposure which causes non-carcinogenic effects.

The variables in this study included the highest dose of toxin without causing effects on experimental animals (NOAEL) from Mercury(Hg), weight of experimental animals (W animals), body surface of experimental animals (BSA of experimental animals), workers’ body weight(W), workers’ height(h), workers’ body surface area (BSA), reference dose of Mercury(Hg) for workers(RfD), as and the rate of consumption of fish and drinking water. Data analysis in this study was carried out using quantitative analysis manually to determine the level of risk(RQ) of Mercury(Hg).

The level of risk(RQ) of Mercury (Hg) uses the following formula (Tualeka, 2019)(8):

\[
RQ = \frac{\text{Intake}}{\text{RfD}}
\]

Where:

- **RQ**: Risk Level
- **Intake**: The amount of risk agent intake received by individuals(mg/kg/day)
- **RfD**: Daily exposure estimation(mg/kg)

**Findings**

**A. Characteristics and Surface Area of Experimental Animal Bodies**: Experimental animals are used as a support in testing a compound toxicity. This is because the response of humans to toxic is qualitatively similar as the response of animals. Therefore, this fact is used as a basis for extrapolating from animal to human data.

<table>
<thead>

</tbody>
</table>
Based on the data of white mice body weight (W), the body surface area was obtained by using the following formula:

\[ BSA = 0.09 W^{0.67} \]

Where:

- BSA: Body Surface area (m²)
- W: Weight (kg)

**B. Characteristics, Surface Area, and Fish and Drinking Water Consumption Rate:** The characteristics of the respondents used in this study included weight and consumption rate of fish and drinking water from 100 people in Bone Bolango District. The weight of the respondents was categorized into 40 kg, 45 kg, 50 kg, 55 kg, 60 kg, 65 kg and 70 kg. For the average height of respondents, the researchers used the average Indonesian height of 159 cm. Data on body weight and average height were used to calculate the surface area of the respondent’s body. The surface area of the respondent’s body uses the following formula (Tualeka, 2013)⁹.

1. **Body surface area**

\[ BSA = \sqrt{W \cdot h / 3600} \]

Where:

- BSA: Body Surface (m²)
- W: Weight (kg)
- h: Height (cm)

The calculation of the respondents’ body surface with body weight of 40 Kg, 45 Kg, 50 Kg, 55 Kg, 60 Kg, 65 Kg and 70 kg are as follows:

<table>
<thead>
<tr>
<th>Respondent</th>
<th>Wb (kg)</th>
<th>h (cm)</th>
<th>BSA (m²)</th>

<td></td>
<td></td>
<td><strong>1.21</strong></td>
</tr>
</tbody>
</table>

The result of the analysis of the calculation of the surface area of the respondents in table 2 show that the average body surface area of the respondents is 1.21 m².

2. **Fish and Drinking Water Consumption Rate**

Rate of fish consumption:

\[ R = 0.2 \text{ kg/day} \]

The rate of drinking water consumption:

\[ R = 2 \text{ Liter/day} \]

<table>
<thead>
<tr>

<tr>
<td><strong>Average</strong></td>
</tr>
</tbody>
</table>

The result of the calculation of the rate of consumption of fish and drinking water in table 3 shows that the average rate is 0.2 kg/day and 2 L/day, respectively.

3. **Merkury Concentration (Hg):** The results of measurements of mercury concentration in Bulawa Subdistrict, Bone Bolango District, Gorontalo were 0.0298 mg/kg (0.0036 ppm). Based on the measurement results, the average concentration of Mercury (Hg) in the respondent’s drinking water in Bulawa District was 0.000478 mg/L (0.0000582 ppm). This concentration is still below the Threshold Value issued by the Minister of Health Regulation (2010)⁷ of 0.001 mg/L.

The highest distribution of Mercury (Hg) concentrations in respondent’s drinking water was
found in the Kaindudu Barat region of 0.00065 mg/L (0.000079 ppm) and the lowest was in drinking water in the village of Mamungaa by 0.000285 mg/L (0.00034 ppm).

D. Animal Km and Human Km: Determination of the reference dosage of toxin for residents of Bulawa Subdistrict of Gorontalo Province was carried out by counting Animal Km and Human Km.

Animal Km

\[ \text{Animal Km} = \frac{W_{\text{animal}}}{BSA_{\text{animal}}} \]

where:
- Animal Km: Km factor on animal
- W: Weight of white mice
- BSA: Body Surface Area of white mice

Table 4: Results of Calculation of Animal Km in Experimental Animals (White Mice)

</tbody>
</table>

The results of the Human Km Calculation in table 5 show the average human Km for respondents in Bulawa District, Gorontalo Province by 45.28. The table of calculation results is as follows:

E. No Observed Adverse Effect Level (NOAEL) of Merkury (Hg): Determination of safe limits of chemical concentration begins with the determination of the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL). According to the World Health Organization/WHO (2005)\(^9\) the value of NOAEL Mercury (Hg) is 0.23 mg/kg, Day.

F. Reference Dose (RfD) of Merkury (Hg) Saridewi and Tualeka (2017)\(^9\) stated that the reference dose (RfD) of toxin exposure is obtained using the formula from Shaw et.al (2007) as follows:

\[ \text{RfD} = \frac{\text{NOAEL}_{\text{Animal Km}} \times \text{Animal Km}}{\text{Human Km}} \]

where:
- RfD: Reference Dose (mg/kg)
- Animal Km: Km factor on animal
- Human Km: Km factor on animal

Based on the above formula, the RfD calculation results obtained from the NOAEL value of Mercury, the average Animal Km, and the Average Human Km are:

\[ \text{RfD} = \frac{0.23 	imes 5.81}{45.28} = 0.295 \text{ mg/kg} \]

C. Merkury Intake(Hg): According to Tualeka (2013)\(^9\), the following formula can be used to calculate intake through fish and drinking water:

\[ \text{Intake} = \frac{C \times R \times f \times E \times Dt}{WB \times t_{\text{avg}}} \]

Intake of Mercury through fish in respondents with a body weight of 40 Kg, 45 Kg, 50 Kg, 55 Kg, 60 Kg, 65 Kg and 70 kg is as follows:

The average intake of Mercury (Hg) in Fish based on table 6 is 000009 mg/kg/day. Calculation result
of the average intake of Mercury (Hg) in drinking water based on table 7 is 0.00008 mg/kg/day.

**H. Risk Level (RQ) of Merkury (Hg):** According to Tualeka (2019)\(^9\), the calculation of Mercury (Hg) level of risk (RQ) can use the following formula:

\[
RQ = \frac{\text{intake}}{\text{RfD}}
\]

Risk Level (RQ) of Mercury (Hg) through fish in respondents with a body weight of 40 Kg, 45 Kg, 50 Kg, 55 Kg, 60 Kg, 65 Kg and 70 kg is as follows:

<table>
<thead>
<tr>
<th>Resp.</th>

</table>

The calculation of the Risk Level (RQ) of Mercury (Hg) average in Fish and Drinking Water based on table 8 is 0.003 and 0.08, respectively.

**Discussion**

Based on the results of this study, the value of the Risk Level (RQ) in the community consuming fish in Bulawa Subdistrict, Bone Bolango Regency, Gorontalo Province, Indonesia the waters surrounding traditional mining was 0.08 for fish and 0.003 for drinking water. The two results of this calculation indicate that the RQ value <1. The value of RQ <1 means that mercury has not affected the health of the community (Tualeka, 2013)\(^8\). The results of this study are smaller than the results of the study by Zolfaghari (2018)\(^12\) showing the Risk Level (RQ) value of fish consumption was 0.2. The results of RQ calculation on the average drinking water consumption in this study are also smaller than that of Hartati’s research\(^11\) by RQ >1 of 1.1.

The value of risk level in the present study is (RQ) <1 which can be used as a guide for consumption of fish and drinking water. With the average fish consumption rate (R) of 0.2 kg/day and drinking water of 2 L day, the community has not been at risk of being affected by health problems due to Mercury. This is because the calculation of RQ uses RfD derived from Indonesian body weight data. In conclusion, this figure can be used as a reference for the Indonesian people in consuming fish and drinking water sourced from the waters around traditional gold mining areas in Indonesia.

**Conclusion**

The Mercury RfD (Hg) is 0.023 mg/kg. The intakes of fish and drinking water are 0,0009 mg/kg and 0,0008 mg/L, respectively. The results of the calculation of risk level (RQ) on fish consumption and drinking water are 0.08 and 0.003, respectively. Value of risk level (RQ) <1 which means it has not caused an effect on health.

**Recommendation**

Control can be performed by local policy holders by guiding the rate of safe consumption of fish and drinking water in the Bulawa Subdistrict area, mapping water territories contaminated by Mercury (Hg) as well as installing warning signs and symbols that waters are contaminated, and providing information about consumption of fish species allowed in the general public and vulnerable groups such as pregnant women and children\(^3\). In addition, it is also necessary to limit the frequency of consumption of fish and drinking water from the waters around the mining site.

**Conflict of Interest:** All authors have no conflicts of interest to declare.

**Source of Funding:** This is an article “Determination of Mercury (Hg) Risk Level (RQ) with Exposure
through Fish and Drinking Water Consumption in Bulawa Sub-district, Bone Bolango District, Gorontalo Province, Indonesia” of Occupational Safety and Health Department that was supported by Activity Budget Plans 2019, Faculty of Public Health, Universitas Airlangga.

Factor Affecting of the Diphtheria in East Java: Scoping Review

Vema Aisya Rahma¹, Windhu Purnomo², Soenarnatalina Melaniani²
¹Student Master, Public Health, ²Department of Biostatistics, Faculty of Public Health, Airlangga University Surabaya, Indonesia

ABSTRACT

Diphtheria is an acute infectious disease caused by the Corynebacterium diphteriae bacteria. This bacterium will produce a toxin that spreads systemically and attacks the upper respiratory system and can cause damage to the respiratory epithelium. Diphtheria cases in Indonesia increased from 2016 to 2017 by 339 cases and caused outbreaks in Indonesia. The most cases are in East Java Province with the number reaching 48%. This research is a review study. The purpose of this study was to identify the studies that had been conducted related to factors that influence the diphtheria in East Java. The results of the review show the factors that influence the diphtheria in East Java are the level of education, immunization status, physical condition of the home, population density, occupancy density, level of knowledge, and personal hygiene.

Keywords: Diphtheria, Factor Affecting, Scoping Review.

Introduction

Diphtheria is an acute infectious disease caused by the Corynebacterium diphteriae bacteria. This bacterium will produce a toxin that spreads systemically and attacks the upper respiratory system and can cause damage to the respiratory epithelium. This disease has symptoms of neck pain, fever, sore throat. Diphtheria is often characterized by the growth of a gray membrane that covers the tonsils and the respiratory tract causing difficulty breathing. Diphtheria generally attacks children aged 1-10 years.⁷,⁸,⁹

Diphtheria cases in 2016 in Indonesia were 415 cases, while diphtheria cases that died from 415 cases were 24 cases. So, the Case Fatality Rate (CFR) of diphtheria was 5.8%. The highest case in Indonesia, occurred on Java Island. Reported cases of diphtheria in Indonesia, out of 415 cases, 50.2% of them did not get vaccinations. November 2017 recorded 95 regencies/cities reporting diphtheria cases and 11 provinces reporting diphtheria outbreaks in their area.¹⁰

Diphtheria cases increased in 2017. During 2017, diphtheria outbreaks occurred in 170 regencies/cities and 30 provinces. The number of cases in 2017 reached 954 cases with 44 deaths. This case of diphtheria was found in East Java Province with a total of 48%¹¹,¹²,¹³.

With the most cases in East Java, preventive measures are needed. Prevention can be done by knowing what factors influence the diphtheria. Based on the description of the background, so the purpose of this study was to identify the studies that had been conducted related to factors that influence the incidence of diphtheria in East Java.

Method

This research is a review study. The review was carried out using an electronic database to look for research related to the case of diphtheria. Research search is limited in 2011-2017. The database used is like Google Scholar and ProQuest. The research that will be included in this review focuses on factors in the case of diphtheria in the East Java region.

Results and Discussion

Table 1 shows the research that has been done on factors that influence the case of diphtheria in East Java. Based on the search results on the database obtained as many as six studies that meet the requirements of this review.
Based on table 1, it can be seen that the factors that influence the case of diphtheria in East Java are education level, immunization status, physical condition of the home, population density, occupancy density, level of knowledge, and personal hygiene.

**Physical Environmental Conditions of Houses:** The results of a review of existing studies showed that respondents who have physical environmental conditions have a relationship with high cases of diphtheria in Bangkalan Health Center in 2016 with an OR of 4.18 which means that people with physical conditions that do not meet the requirements risk 4.18 times diphtheria compared to people with environmental conditions that meet the requirements. The physical environment of this house includes many factors, namely the condition of the walls of the house, the ceiling of the house, the floor of the house, humidity, lighting, ventilation and occupancy density.

Research outside East Java also showed the same results that the factors that influence the case of diphtheria are related to the home environment. The type of wall of the house has a significant relationship with the incidence of diphtheria with an OR value of 9.42. The type of floor of the house also has a significant relationship with an OR value of 20.7 which means that the type of floor is a risk factor for diphtheria.

**Immunization Completeness:** The results of the review of existing studies indicate that respondents who did not get complete DPT immunization had a risk of developing diphtheria by 4.667 times greater than respondents who did not get complete DPT immunization. The results of subsequent reviews also show that complete basic immunization can affect the prevalence of diphtheria in East Java by 0.33 times. The results of the last review, with spatial analysis showed that DPT3 immunization affected the occurrence of diphtheria. Regions that have low DPT3 immunization coverage have a high number of diphtheria.

**Population Density:** The results of the review indicate that population density can affect the prevalence of diphtheria in East Java by 0.01 times. Population density that is not balanced with its area, can result in the emergence of slums so that it can cause infectious diseases such as diphtheria, so the higher the population density in an area, the greater the chance of the spread of diphtheria. In general, diseases that can be transmitted through direct contact occur in communities in areas with high population densities. Blum states that environmental factors have a greater influence on public health compared to other factors of 45%.

**Education and Knowledge:** The results of a review of the research conducted by Arifin showed that respondents who had a low education had the risk of developing diphtheria by 1.67 times compared to respondents with high formal education. Subsequent reviews showed that the mother’s poor knowledge had a risk of diphtheria of 0.088 times for diphtheria compared to good maternal knowledge.

Widyastuti states that someone who has a higher level of education will be more oriented to preventive measures, know more about health problems and also have better health status. Economic levels also have an
influence on one’s health. A person with low income will influence the level of his family’s ability to meet family needs for nutrition, education and other needs(17). Notoatmodjo(18) states different things that income does not have a significant influence in influencing a person’s health, but if someone earns quite a lot, then he is able to provide better facilities.

**Personal Hygiene:** The results showed that poor personal hygiene had a risk of 4.27 times greater for diphtheria(4). Behavior factor is a very strong factor affecting people to be healthy or sick. Not infrequently behavior is formed due to lack of knowledge or possessing certain cultures or customs. There are people who know that exercise is important, overeating is not good but is not able to resist temptation, they are easily affected by hypertension or diabetes. There are also people or people because of their ignorance, they become sick (ignorancy)(20).

**Occupancy Density:** The results of the review indicate that occupancy density that does not meet the requirements has a risk of 0.225 times for diphtheria compared to the density of occupancy that does not meet the requirements(5). A study in West Java in 2015 also states that home density has an OR value of 22.7 which means that if most children live with a better home density, then the possibility of the child not getting diphtheria by 22.7 times(21). Another study in Central Java also stated the same thing that the average density of house occupants could affect the number of diphtheria cases(22).

**Conclusion**

Factors that affect the case of diphtheria in East Java are based on the results of a review of the level of education, immunization status, physical condition of the home, population density, occupancy density, level of knowledge, and personal hygiene.

ABSTRACT

Currently, scoliosis in humans is considered as one of the most common conditions that leads to various deviations from homeostasis and often to abnormalities in the functioning of internal organs. It becomes clear that scoliosis is manifested not only by the curvature of the spine, but also leads to a number of general changes in the body, not excluding the development of dysfunctions of the internal organs causing deterioration of the general condition, the occurrence of hypoxia and metabolic disorders in the tissues, which can cause a decrease in the overall resistance of the child’s body. The use of therapeutic physical culture, swimming and massage in scoliosis is reliable, long-term practice-proven methods for correcting the posture and treatment of scoliosis, which can restore slenderess and flexibility.

Keywords: rehabilitation, scoliosis, recovery, spine, exercise.

Introduction

Despite the serious progress of modern medicine, the pathological burden in society remains very high¹,². The cardiovascular system¹, the lungs⁴ and the musculoskeletal system⁵ remain very affected. Currently, scoliosis is one of the most common diseases of the movement system, the frequency of which, according to different authors, reaches 20%. Such a high prevalence of scoliosis is due to the fact that violations of posture in the frontal plane are often considered as scoliosis⁶.

Close attention to scoliosis is due to the fact that in severe forms of this disease, significant disturbances occur in the most important systems of the body, leading to a decrease in life expectancy, reduced working capacity, and often disability⁷. Changes in the respiratory, cardiovascular and autonomic nervous systems are well studied in patients with severe scoliosis⁸,⁹. There is evidence of impaired respiratory function, heart rhythm and metabolic processes in the myocardium, insufficient adaptation of the cardiovascular system to physical exertion, and a decrease in a number of physical development indicators in patients with I and II degree scoliosis¹⁰.

Due to the high risk of the effects of scoliosis on the lungs and the cardiovascular system, conditions are created in the body for insufficient supply of oxygen to tissues, especially the head mash¹¹,¹². In this regard, the question of finding approaches to minimizing and eliminating the manifestations of scoliosis at any age is becoming more acute. This dictates the need to develop rehabilitation programs for the treatment of this pathology.
Objective

To consider the physiologically sound approaches to the rehabilitation of scoliosis.

Rehabilitation for diseases of the spinal column should be based on the use of physical exercises, self-training, self-correction, often in combination with various additional physical effects.

There are different points of view between the specialists involved in organizing physical education with diseases of the spine, both on the forms of organization of classes, and on their maintenance and dosing of physical activity. It is believed that in case of dystogenetic states of the spinal column, it is necessary to attend classes of therapeutic physical culture.

The features of therapeutic physical culture in individuals with abnormal spinal development include, first of all, an increase in the functional capabilities of their organism as a whole. At the same time, great attention should be paid to improving pulmonary ventilation, increasing the mobility of the spine, strengthening the muscles of the trunk and limbs.

In the main part of the training, most of the means of therapeutic physical culture are used, aimed at fulfilling the main therapeutic tasks of this period of treatment. In this part of the exercises, exercises are used that ensure the production and training of general and strength endurance of the back muscles, abdominal muscles and chest to create a "muscular corset", corrective exercises in combination with general developing and breathing exercises.

The final part includes running, walking, coordination exercises and breathing. In some cases, it is advisable to include the game of attention in this part of the class while maintaining the correct posture.

In the introductory period of the treatment course, the individual features of the individual course of the disease in humans are clarified, the functional capabilities of the musculoskeletal system, cardiovascular and respiratory systems are determined, and the level of physical fitness is determined. In this period of treatment against the background of general developmental exercises in the appropriate dosage, the therapeutic task of creating physiological prerequisites for restoring the correct body position and stabilizing the pathological process is solved. Provides a normalizing effect on the internal organs and body systems, increases its resistance to adverse environmental factors.

In the main period of the treatment course, which continues until the stabilization of scoliosis is achieved and other therapeutic tasks are satisfactorily completed, the human motor sphere is improved with the help of general developmental exercises, the quality of basic movements is improved, the stimulating and normalizing effect of physical exercises is provided. The widespread use of physical methods of action aimed at the development and strengthening of the muscular system allows, in the main period of treatment, to begin optimizing the functions of the spine. To the extent possible, taking into account the stage of scoliosis, the existing defect is corrected with the help of special corrective exercises.

The final period of the treatment course is used to consolidate the achieved results of treatment and to develop the necessary motor regimen and recommendations performed at home or in the hospital, as well as to evaluate the effectiveness of therapeutic exercise.

Using modern methods of organizing the process of physical education, it is necessary to significantly increase the level of functional capabilities of their body and, thus, it is possible to achieve positive changes in relation to the correction of the existing pathology. At the same time, it is necessary to take into account the biomechanical features of the affected spine when dosing physical loads.

In correction of scoliosis, special corrective gymnastic exercises of two types - symmetric and asymmetrical, are used to provide a corrective action. Symmetric corrective exercises include only those that maintain the median position of the spinal column. An important advantage of symmetrical corrective exercises is the relative simplicity of the method of their conduct and selection, which does not require taking into account the complex biomechanical working conditions of the deformed musculoskeletal system in scoliosis.

Asymmetric corrective exercises allow concentrating their therapeutic action locally, in this part of the spinal column. For example, when the leg is retracted to the side of the bulge of the scoliosis arc, the position of the pelvis changes and the scoliosis arc decreases. When the
Four main mechanisms of the therapeutic action of physical exercises are distinguished: tonic effect, trophic action, the formation of compensation and the normalization of functions.

1. The mechanisms of tonic effect. The use of special and general developmental exercises helps to balance the processes of excitation and inhibition in the central nervous system. Against this background, improves the metabolism, enhances the function of external respiration and blood circulation, activates the protective reactions of the body. The psycho-emotional state of a person increases, his mood improves, which enhances the effect of physical exercises.

2. The mechanism of trophic action. Physical exercise in scoliosis activates metabolic processes, accelerates regeneration processes, retards the development of muscle atrophy and joint stiffness, and improves blood circulation.

3. The mechanism of the formation of compensation. This mechanism is manifested in the development of temporary or permanent substitutions of impaired functions. For example, when violations of posture, scoliosis decreases chest excursion. Under the action of physical exercises, the respiratory muscles are strengthened, the mobility of the spine, diaphragm, ribs increases, and, as a result, the skill of correct posture is fixed.

4. The mechanism of normalization of functions. Properly selected and accurately dosed physical exercises can normalize the activity of the main body systems: nervous, cardiovascular, respiratory and musculoskeletal.

In the complex treatment of scoliosis, massage is often used, which strengthens the muscles and also has a tonic effect. There are principles of massage for scoliosis. They consist in: determining the hyperalgetic zones, local muscle hypertonus, compaction in the form of cords, nodules in the tissues and acting on these formations using the techniques of segmental-reflex and acupressure; Differentially affect the back muscles: shortened, tense muscles on the side of the concavity of the arcs of the curvature of the spine stretch and relax, and on the side of the bulge perform tonic, stimulating techniques on the stretched muscles; differentially affect the shortened and stretched pectoral and gluteal muscles, as well as the muscles of the abdomen and limbs.

On the side of the spastic-contraction muscles in the area of the concavity of scoliosis, relaxation techniques (vibration, stroking) are used. On the side of the protuberance of scoliosis, where muscle tone is weakened, all the massage techniques in high dosage are used.

Medical swimming is an important stage in physical rehabilitation for scoliotic disease. It helps to improve health, instill skills that are important for life, foster moral and volitional qualities. It also has educational, health and hygienic, therapeutic, emotional and applied value. As a swimming treatment is used in the complex treatment of scoliosis. It is an important link in complex treatment. In the process of swimming, there is a natural unloading of the spine, asymmetry disappears in the intervertebral muscles, all the conditions arise so that the vertebral bodies develop normally. During sliding, spinal self-stretching occurs, which additionally relieves growth zones. At the same time, the muscles of the spine and the entire skeleton are strengthened, the coordination of movements becomes perfect, the correct posture is formed. Regardless of the severity of scoliosis, the prognosis of its course and type of treatment, all people with scoliosis can go swimming. Taking into account the degree of scoliosis, only swimming exercises are selected. When I degree of scoliosis perform symmetrical swimming exercises: breaststroke on the chest, crawl on the chest for the legs.

When swimming, the spine is unloaded, the asymmetric work of the paravertebral muscles is reduced due to their relaxation in warm water, which creates favorable conditions for performing movements, reduces pressure on the epiphyseal growth zones of the vertebral bodies, improves blood supply to the bone structures and soft tissues. The need to overcome the resistance of water during movement while performing swimming exercises is a means of strengthening and developing the paravertebral muscles and the whole musculoskeletal system of the child, improving coordination of movements, and developing a sense of correct body posture.
Conclusion

Currently, scoliosis in humans is considered as one of the most common conditions that leads to various deviations from homeostasis and often to abnormalities in the functioning of internal organs. It becomes clear that scoliosis is manifested not only by the curvature of the spine, but also leads to a number of general changes in the body, not excluding the development of dysfunctions of the internal organs causing deterioration of the general condition, the occurrence of hypoxia and metabolic disorders in the tissues, which can cause a decrease in the overall resistance of the child’s body. The use of exercise therapy, swimming and massage for scoliosis is reliable, long-term practice-proven methods for correcting the posture and treatment of scoliosis, which can restore slenderness and flexibility. However, their impact on the function of internal organs, which significantly heals the patient’s body.

ABSTRACT

Neurocirculatory dystonia is a syndrome of disorders of the cardiovascular system and its functions, in the etiology of which there are disorders of neuroendocrine regulation. The disease has several options for development, the symptoms are also varied. The most common symptoms of cardiovascular disorders due to stress. In the initial state, with neurocirculatory dystonia, signs of general asthenia, hypotension and bradycardia are characteristic, which sharply weakens the adaptive capacity of the organism. As a result of the course of traditional physical rehabilitation in girls with neurocirculatory dystonia, it was possible to achieve a slight increase in the reserve capacity of their cardiac and respiratory systems, with some weakening of the manifestations of hypotension and bradycardia. This did not allow, however, to reach the indicators at the level of the control group. The effectiveness of the author’s version of the physical rehabilitation of the tested girls with neurocirculatory dystonia showed the possibility of developing more pronounced positive changes in the body due to the powerful activation on their background of the backup capabilities of the main life support systems. The leveling in this group of manifestations of hypotension and bradycardia when the considered indicators reach the level of the control group during the application of the author’s rehabilitation option proved its advantages and high health potential.

Keywords: rehabilitation, hypotension, neurocirculatory dystonia, yoga, physical activity.

Introduction

Neurocirculatory dystonia is a syndrome of disorders of the cardiovascular system and its functions, in the etiology of which there are disorders of neuroendocrine regulation¹. The disease has several variants of development, the symptoms are also diverse²,³. The most common symptoms of cardiovascular disorders due to stress⁴. The course, as a rule, has a benign character and a positive prognosis⁵.

According to statistics, this pathology in the population is found in 12-35%. Basically, the disease develops in adolescents, since in older age it often develops into various forms of cardiovascular pathology⁶. In this regard, with neurocirculatory dystonia, early detection and early adequate treatment is advisable⁷,⁸.

According to the classification of ICD-10, the disease is classified as Class V disease with the code “F45.3”. This cipher includes a group of diseases, referred to as “somatoform dysfunction of the autonomic nervous system.” This group includes cardiovascular neuroses, syndrome of respiratory disorders (Da
Costa syndrome), gastroneurosis, cardiac rhythm disturbances of psychogenic origin, sweating, redness and tremor of the hands associated with vegetative dysfunction, hiccups, deep frequent breathing, that is, hyperventilation, frequent urination, a state of increased fatigue and fatigue, variable and fast-moving pain in all parts of the body, as well as feeling not bosnovannogo fear and concern for their health.

It is noticed that the age of development of neurocirculatory dystonia is getting younger. The reason for this is a progressive violation of the ecological situation, in cities, increasing mental and emotional stress on the population, the spread of a sedentary lifestyle. In this regard, the question of the early physical rehabilitation of this cohort of patients, especially adolescence, is particularly acute.

**Objective**

To develop an effective method of physical rehabilitation for adolescents with neurocirculatory dystonia of hypotonic type.

**Materials and Research Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11).

The study included 60 adolescent girls (13-14 years old), who were divided into 3 groups of 20 people each. The girls of the first group were clinically healthy and formed a control group. Girls 2 and 3 of the group suffered from neurocirculatory dystonia of hypotonic type for at least 2 years. In the 2nd group (main group), traditional rehabilitation was carried out, which included: 1) aerobic exercises 3 times a week, with a duration of 30-40 minutes; 2) daily recreational walking of at least 2 km at a speed of 1 km in 10-15 minutes; 3) morning, evening hygienic gymnastics - daily for a total of 15-20 minutes. In the 3rd group of girls taken in the study, they assigned the method of author’s physical rehabilitation 1) daily recreational walking - at least 3 km at a speed of 1 km in 10-15 minutes; 2) performing yoga asanas (dog face down, extended triangle posture, extended angle posture, warrior posture, inverted triangle posture, bend forward with legs wide apart, plow posture 1 minute each) at least 4 times a week; 3) morning and evening exercises with the use of the above asanas and breathing exercises for 25-30 minutes daily. Classes were held in both groups for 3 months.

In order to identify the dynamics of the functional state of the body in girls of groups 2 and 3, the following tests were carried out: the Shanga test, the Genchi test, the orthostatic test, blood pressure measurement of systolic and diastolic, heart rate. Girls of the first group were examined once by the same methods. The research results were processed statistically using Student’s t-test.

**Research Results**

The achieved results of the use of two options for physical rehabilitation in adolescent patients are presented in Table 1.

In the outcome, in the main and experimental groups, changes characteristic of neurocirculatory dystonia in the hypotonic type were found with significant differences in the recorded parameters compared to the control. So, in both observation groups, the systolic blood pressure level was reduced by at least 41.7%, and the diastolic blood pressure level was below the control by about 30.0%. At the same time, the heart rate level in both observation groups was lower than the control by about 32.0%. The results of the Shtange test in both groups of adolescents with neurocirculatory dystonia were reduced by almost 40.0%. The value of the results of the Genchi test in them was lower than the control level by almost 48.0%. Due to the presence in adolescents with neurocirculatory dystonia of pronounced disorders of the indicators taken into account, he carried out physical rehabilitation.

In the main group, rehabilitation effects were carried out according to the traditional method. As a result, it was possible to achieve some positive changes in the indicators taken into account, which, however, did not allow them to approach the values of the control group. After the rehabilitation measures in the main group, it was possible to increase the level of systolic blood pressure by 12.3%, diastolic by 14.8%. At the same time, in these adolescents, the heart rate increased by 9.0%. The indicator of the Stange sample increased by only 15.1%, while the Genchi sample increased only by 15.6%. The preferred values of the indicators taken into account were achieved in the experimental group after the physical rehabilitation was carried out according to the author’s scheme.

Legend: p - the reliability of differences in indicators of the main and experimental groups with the values of the control.

For all indicators in adolescents of the third group, it was possible to bring the values of the indicators taken into account to a level that does not differ from the values in the control. This was due to an increase in

1. their systolic blood pressure by 35.1%,
2. diastolic blood pressure by 25.8%,
3. the level of heart rate increased by 25.3%.
4. Their indicator of the Stange sample increased by 42.8%,
5. and the Genchi sample increased by 34.2%.
6. The results obtained exceeded those achieved in the main group and reached the level of control.

Discussion

Neurocirculatory dystonia is a functional symptom complex, the development of which can be based on unfavorable heredity, as well as strong and persistent psycho-emotional experiences. As a rule, with neurocirculatory dystonia, there is a paucity of morphological changes in the body and intense symptoms. According to statistics, a patient with this pathology has at least 26 symptoms, and they can be very versatile. The disease is not always and not all

flows stably - often there can be exacerbations of the disease, manifested in the form of crises. The disease progresses if it occurs at a young age\textsuperscript{12}. In the absence of the necessary treatment, the disease can develop into an organic pathology of the cardiovascular system\textsuperscript{13,14}.

In case of neurocirculatory dystonia of hypotonic type, active physical activity is recommended: dancing, swimming, walking, tourism. Also effective in the

physical rehabilitation of neurocirculatory dystonia is a massage of the head, abdomen, lower limbs, neck and collar area\textsuperscript{15}.

In the work performed, an effective approach to the physical rehabilitation of patients with neurocirculatory dystonia of hypotonic type was developed and tested. This method of physical rehabilitation of such patients was based on the use of a number of elements of yoga, breathing exercises, physical therapy and walking\textsuperscript{16}. The developed complex was very effective. With its application, it was possible to achieve a pronounced optimization of the cardiovascular parameters taken into account and increase its reserve capacity, which exceeded the effect of the traditional recovery option for this pathology\textsuperscript{17}. The achieved effect from the use of the author’s version of physical rehabilitation in neurocirculatory dystonia of the hypotonic type was more effective, since it provides a more pronounced health effect on systems and organs. Exercises and asanas, when regularly performed, develop strength, endurance, speed and coordination of movements, as well as stabilize the mental background. This is primarily aimed at performing asanas of yoga, which have a powerful psycho-physical health effect on the entire body\textsuperscript{18,19}.

As a result of the application of the tested complex of asanas of yoga as part of the author’s method, it was possible to comprehensively affect the body of a sick person to activate its reserves and, first of all, the
cardiovascular system. The achieved favorable effect on the body of the author’s scheme of physical rehabilitation was largely realized through the strengthening of metabolic processes\textsuperscript{20}. In the process of its use, a “mild” increase in the level of fitness of the body as a whole occurred, strengthening the cardiovascular system, revealing the reserves of the respiratory system, balancing the work of the hormonal system, the central and vegetative parts of the nervous system\textsuperscript{21}.

Obviously, from the early stages of asanas as part of the designated recovery complex, psychological phenomena develop and increase, reducing sensitivity to stress, improving the psycho-emotional background while increasing elasticity and endurance of muscles and flexibility of the spine\textsuperscript{22,23}. Asanas are known to normalize the production of certain neurotransmitters, especially acetylcholine, and catecholamines and histamine. It is also noted that daily yoga classes can increase intelligence and strengthen memory, providing a balance between the sympathetic and parasympathetic nervous systems\textsuperscript{24,25}.

When comparing the results in both groups of observation and control data, it became clear that the author’s technique has advantages over the traditional one and allows inferred indices for neurocirculatory dystonia of the hypotonic type to be derived to the level of healthy people\textsuperscript{26,27}. This suggests that it is highly effective and promising for widespread testing, including for all forms of neurocirculatory dystonia in patients of any age and if they have any associated diseases\textsuperscript{28,29}.

**Conclusion**

In the initial state, with neurocirculatory dystonia, signs of general asthenia, hypotension and bradycardia are characteristic, which sharply weakens the adaptive capacity of the organism. As a result of the course of traditional physical rehabilitation in girls with neurocirculatory dystonia, it was possible to achieve a slight increase in the reserve capacity of their cardiac and respiratory systems, with some weakening of the manifestations of hypotension and bradycardia. This did not allow, however, to reach the indicators at the level of the control group. The effectiveness of the author’s version of the physical rehabilitation of the tested girls with neurocirculatory dystonia showed the possibility of developing more pronounced positive changes in the body due to the powerful activation on their background of the backup capabilities of the main life support systems. The leveling in this group of manifestations of hypotension and bradycardia when the considered indicators reach the level of the control group during the application of the author’s rehabilitation option proved its advantages and high health potential.

ABSTRACT

The rehabilitation process involves assisting the patient by compensating for the deficiency of the lost functional capabilities of the body, which can be corrected. Rehabilitation of athletes after ankle injury is carried out in stages. At the first stage - peace and protection, then - restoration of the flexibility and mobility of the joint without the load on it. When using more intense exercise, it is possible to stand on an injured leg. With a gradual return to the previous level of activity should not stop exercise. Such patients should conduct an adaptive physical culture. Her theory and methodology is based on a general theory and method of physical culture and is well developed. It is extremely important to complete the program of adaptive physical exertion during the rehabilitation of each athlete with an ankle injury, as this significantly reduces the chance of a similar injury in the future. The use of physical culture in the form of morning hygienic gymnastics and breathing exercises, starting from the early stages of immobilization, largely contributes to the normalization of the functions of blood circulation, respiration and metabolic processes. According to animal studies, intensive exercise in some cases of regulatory characteristics of the brain, which speeds up recovery.

Keywords: rehabilitation, ankle, trauma, physiology, athletes.

Introduction

The concept of rehabilitation is commonly understood as the process of treating and restoring the body after the occurrence of an injury or illness to a normal state of health. The rehabilitation process involves assisting the patient by compensating for the deficiency of the lost functional capabilities of the body, which can be corrected¹.

Every year more than 70 million people are injured in the world, of which 24 million are athletes. The frequency of such injuries is so high that they are ahead of infectious diseases in the incidence of deaths and the resulting disability. Every year, almost a third of all athletes suffer from injuries, which temporarily excludes their participation in competitive activities²³. This is due to the fact that the risk of injury for professional athletes is significantly higher than for the public. In this case, the ankle is very often injured, which keeps this type of damage permanently in the field of vision of traumatologists⁴.

The largest percentage of injuries to the ankle comes from improper landings when jumping from a height and when landing on uneven surfaces. In these cases, the most characteristic sprains and fractures. However, damage to the soft tissues of this area can also be observed: the calf muscles, the Achilles tendon, stretching and inflammation of the ligamentous apparatus⁵.

In the process of rehabilitation for ankle injuries, athletes often face serious complications when they...
return to their professional activities. This makes this problem one of the most important in rehabilitology. It is recognized that the central place in the rehabilitation of this pathology is occupied by exercises that should not cause pain and their implementation provides for a gentle load on the injured joint. It is recommended to begin the process of developing the ankle joint after a long immobilization during exercises in water. At the same time, there are a lot of unresolved issues in the rehabilitation of the ankle injury, and this dictates the need to consider the available information.

Objective: to consider aspects of the physical rehabilitation of athletes who have suffered ankle injuries.

**Damage to the soft tissues of the ankle:** Damage to the ankle ligaments account for about 75% of all injuries to this part of the body. Depending on the mechanism of injury, various ligament components of the ankle can be damaged. For example, the external lateral ligaments are damaged during supination and inversion of the foot, and the deltoid and interfibular ligaments may suffer during pronation and eversion. By severity of damage, tears (sprains) and their tears are distinguished. If the tears of the ligaments are not severe trauma and usually end in complete recovery of the injured, the ruptures of the ligamentous apparatus, especially improperly treated, can often cause permanent damage to the function of the injured limb and permanently disable it.

In practice, distinguished uncomplicated and complicated injuries of the soft tissues of the ankle. Uncomplicated damage to the ligaments are treated without the use of surgical interventions and are not accompanied by complications that prevent the early development of joint mobility. In the presence of complications, treatment requires only surgical intervention.

**Damage to the bones of the ankle:** Other, more severe consequences of an ankle injury are fractures of his bones, which are the most often injured in the entire skeleton. They can occur when a direct impact of external force (falling on the shin of gravity, pressing it to a hard object, a direct blow) and indirect effects (falling with a sharp twisting of the tibia at a fixed foot). The bi-momentum of the traumatic power can cause a double fracture. Fractures can be tibial and fibula bones separately and immediately both of these bones. In practice, damage to both bones of the tibia is observed more frequently.

Fractures of the ankle bones are treated by three methods: conservatively - by stretching (if the fracture is displaced) for the calcaneus, after 2-3 weeks a blind plaster cast is applied from the base of the fingers to the upper third of the thigh; the imposition of the apparatus G.A. Ilizarov and operative reposition using clamps of bone fragments. Metal wires and tapes, as well as metal and bone pins are used as a fixator in modern traumatology. The limb in the postoperative period is fixed with a plaster Longuet - from the base of the fingers to the middle third of the thigh.

For non-displaced fractures, a plaster “boot” with a heel or with a stirrup is placed from the base of the fingers to the knee joint. After it dries, you can walk with crutches, stepping on a stirrup or heel, as well as engage in physical therapy.

One of the indispensable conditions for achieving good results in the treatment of injuries of the ankle joint is the exact anatomical restoration of damage to its elements, their retention until complete fusion and the subsequent restoration of joint function.

**Complications of ankle injuries:** The problem faced by many patients after injuries of the musculoskeletal system is post-traumatic disease. It is characterized by the following symptoms: impaired or decreased physical activity and problems with psycho-emotional state. It is necessary to take into account the fact that before the injury, almost all patients were relatively healthy people, so the main task in the post-traumatic period is to increase the physical activity of the patient, restore psycho-emotional status, return to the former social situation.

In the development of this shock, two phases are distinguished: the first is the erectile phase (the excitement phase occurs at the time of injury as a result of pain impulses coming from the damage zone, characterized by emotional excitement, anxiety, lethargy, heart rate and blood pressure increases, after 5-10 minutes excitement is replaced by depression), from this moment begins the second - the torpid phase (pallor, cold sweat, weak pulse, drop in blood pressure, shallow breathing, the victim is indifferent to ok uzhayschemu while maintaining consciousness suppressed the activity of all systems of the body, blood flow decreases sharply to organs, increasing oxygen deficiency, all of which can lead to death of the victim). The manifestation of shock largely depends on the extent of damage, its nature and location.
Basics of rehabilitation of athletes after ankle injury: Rehabilitation of athletes after ankle injury is carried out in stages. At the first stage - peace and protection, then - restoration of the flexibility and mobility of the joint without the load on it. With a gradual return to the previous level of activity should not stop exercise\textsuperscript{18}.

For ankle fractures, the situation is aggravated by the need for long-term fixation of the joint in a certain position, which always leads to muscle weakening and atrophy. Sometimes such injuries become chronic and patients may become disabled. And here the need for regular physical exertion becomes especially acute\textsuperscript{19}.

Common manifestations are expressed in a gradual, during immobilization, reduction of the main indicators of hemodynamics, external respiration and metabolic processes\textsuperscript{20}. Often also observed symptoms of increased patient irritability, deterioration of sleep, intestinal atony. Thus, the adynamy of the patient in the period of immobilization leads to disruption of the functional activity of many organs and systems\textsuperscript{21}.

Such patients should conduct an adaptive physical culture. The use of physical culture in the form of morning hygienic gymnastics and breathing exercises, starting from the early stages of immobilization, largely contributes to the normalization of the functions of blood circulation, respiration and metabolic processes. Exercising the muscles of an immobilized limb (isometric stresses, imaginary movements), as well as in joints that are free from immobilization, contributes significantly to the normalization of the main nervous processes and thereby prevents the formation of muscle atrophy and contracture of the joints\textsuperscript{22}.

Practice shows that for bone fractures, fixed fragments grow together more quickly if the surgeon creates the conditions for maximum tight contact (with metal tape, screws, bolts), that is, stable osteosynthesis or compression of fragments. In this regard, with conservative methods of treating fractures of the lower extremity, physical exercises in the form of therapeutic walking should be considered as a natural-biological method that ensures tight contact and compression of bone fragments\textsuperscript{23}.

Mechanisms of health effects of rehabilitation effects in injuries of the ankle: A proper and adequate rehabilitation program can help patients cope with the resulting deficiency in the functioning of certain organs and body systems affected by trauma. The main types of rehabilitation therapy include physical therapy, occupational therapy and speech therapy\textsuperscript{24}.

The restoration of lost motor skills involves a learning process that integrates information from psychology, neurology, physical education and rehabilitation. Indicators of the effectiveness of the rehabilitation program are the restored skills of professional motor actions that the patient had before the injury\textsuperscript{25}.

It is shown that not only physical activity, but also mental activity affects the effectiveness of rehabilitation rehabilitation processes. It is important that the patient sets himself simple tasks. In an effort to fulfill them, realizing the program of action, and understanding what each movement is being performed for, the patient more effectively restores lost professional skills and abilities and generally recovers faster\textsuperscript{26}.

The benefits of regular exercise are the faster and more efficient regenerative processes in damaged organs and tissues. In addition, physical exercise contributes to the emergence of positive emotional states, which helps to relieve stress and general mental relaxation\textsuperscript{27}.

Specially designed and developed in the complex of gymnastics physical exercises, as a result, increase the efficiency of muscle strength, improve coordination and increase endurance, promote the development of joint flexibility, control body weight, affect metabolism\textsuperscript{28}.

The stimulating effect of physical exercises on the ability of the brain to form new synaptic connections has been proven, which contributes to its self-healing. These data suggest that intensive exercise programs can improve brain performance, and thus speed up recovery processes especially after injuries\textsuperscript{29}. Some studies have shown that exercise can restore motor function through various mechanisms of molecular changes in the basal ganglia of the chain\textsuperscript{30,31}.

Conclusion

At the first stage - peace and protection, then - restoration of the flexibility and mobility of the joint without the load on it. When using more intense exercise, it is possible to stand on an injured leg. Such patients should conduct an adaptive physical culture. It is extremely important to complete the program of adaptive physical exertion during the rehabilitation of
each athlete with an ankle injury, as this significantly reduces the chance of a similar injury in the future. The use of physical culture, started from the early stages of immobilization, largely normalizes blood circulation, respiration and metabolic processes.

Primary Appraisal Antiretroviral Adherence and Nonadherence among People Living with HIV (PLWH)

Widia Shofa Ilmiah¹, Stefanus Supriyanto², Purwati³, Mochammad Bagus Qomaruddin²

¹Student of Doctoral Programme of Health Science, Faculty of Public Health, Universitas Airlangga, Mulyosari Street, Surabaya, Indonesia; ²Lecturer of Faculty of Public Health, Universitas Airlangga, Mulyorejo Street, Surabaya, Indonesia; ³Lecturer of Faculty of Medicine, Universitas Airlangga, Moestopo Street, Surabaya, Indonesia

ABSTRACT

HIV is an iceberg phenomenon that still needs a problem solving. The data from the voluntary counselling and testing in Waluyojati General Hospital show that every month about 8-15 new people got HIV infection and Antiretroviral Therapy. Some of them adhered to undergo ARV, but some did not. One of influential factors for adherence to ARV is individual factor which consists of primary appraisal includes perceived susceptibility, severity, benefit, barrier and motivational relevance and secondary appraisal includes self-efficacy, perceived control outcome and emotion, and external factors. The aim of this study is to describe primary appraisal of antiretroviral adherence and nonadherence among People Living With HIV (PLWH). This study is a qualitative study using a content analysis. This study carried out in-depth interviews with 10 PLWH who received ART for about two weeks – three months. The results show that non adherence to ART is caused by several factors, such as income, perceived susceptibility, perceived severity, perceived barriers. Some of non adherence patients are bored to taking ARV every day and get several side effects, such as nausea and vomiting, erythema, HIV disclosure, fear of stigma. Both patients who adhere and do not to ARV perceived that taking ARV makes them healthy, resistant to be tired, less anxious or hospital care costs, and motivated like people with no HIV infection. Patients who do not adhere to ARV have more perceived barrier than perceived benefit and motivational relevance.

Keywords: Primary Appraisal, Antiretroviral, Patient, Adherence, HIV

Introduction

HIV not only attacks the key population, but also has spread to general communities.¹ A treatment to address HIV cases can be given by giving Antiretroviral therapy (ARV).¹

According to World Health Organization in 2016, there were 36.7 million PLWH;² whereas in Bali, Indonesia from 1987 to December 2016, about 80% of its population got HIV AIDS and had spread to 80.2% of districts and cities. According to provinces, East Java province has the third highest number of HIV infections (0.08%). The cumulative HIV cases in Probolinggo district from 2012 to 2017 happened to 1,072 people (1%).³

A preliminary study conducted in the VCT Clinic of Waluyojati General Hospital. The researchers interviewed medical record staffs. It was found that in 2018, the cumulative number of HIV AIDS cases occurred to 1,140 people, and every month about 8-15 new people suffered from HIV infection. Seventy-five percent of them were qualified for ARV treatment, and a quarter of them had not received ARV treatment. From 75% of 10% lost to follow-up ARV, and 59.6% are active on ARV treatment.³ It indicates that some patients do not adhere to the ARV treatment based on doctor’s instructions.
Multi-factors that caused non adherence to ARV include beliefs and self-efficacy. Meanwhile, according to other researchers that adherence barriers are caused by lack of knowledge and motivation, alcohol addiction, unavailability of food, stigma, disclosure of HIV status, the number of pills taken by patients. Other factors of nonadherence are caused by social support, family or parent support, knowledge about a disease, self-motivation, beliefs about positive results. Other results of the preliminary study show nonadherence is also caused by stigma, disclosure, lack of support from her partner, transportation expense, side effects, service waiting time.

The aim of this study is to describe the primary appraisal of antiretroviral adherence and non adherence among people living with HIV.

Materials and Method

This qualitative study was conducted to patients in the VCT Clinic of Waluyojati General Hospital, Probolinggo Distric. The number of patients undergoing an ART about 2 weeks-3 months in Februari 2018. Ten participants were selected as samples. Five patients and the others do not adhere to the ART. Based on the inclusion criteria, the respondents involve females living with HIV aged more than 15 years old in Probolinggo District. Patients who are still on TB treatment are excluded to be respondents.

Respondents who agreed to participate in this study signed a written informed consent. The researchers uses a close ended questionnaire to identify the characteristics of patients and an interview guide using fourteen open questionaires to identify knowledge about ARV, perceived susceptibility, perceived severity, benefit, barrier, and motivational relevance, uses audio recorder after getting respondents’ consent. Respondents speak Indonesian or local language (Javanese/Madurese). Each interview lasted about 20-30 minutes. All respondents’ profiles were anonymous during the data transcription. The analysis was done manually by using a content analysis. The transcriptions were read for 3-4 times to identify all key ideas and current themes.

Findings

Sociodemographic Characteristics: Ten females living with HIV are 23 years old up to 50 years old. Based on education level, seven respondents went to elementary school, two respondents graduated from senior high school and 1 respondent from a college. In terms of salary, one respondent has no fixed income, four people earn < Rp.500,000,-, four people gain Rp. 500,000,- and one person earn Rp. > 500,000,- each month. Nine of the respondents are house wife, and one respondent is entrepreneur. Two of them are Javanese, and eight respondents are Madurese.

Patient’s Knowledge: The majority of respondents (five respondents who adhere and two who do not) have good knowledge about the side effects of ARV, problem solving, condition in taking ARV, time schedule to take ARV, impacts of unregular ARV therapy. However, almost of all respondents (four respondents who adhere and five respondents who do not) have bad knowledge about what ARV medicine is and objectives of taking ARV.

ARV medicine can prevent HIV in order to have healthy body and long life For the side effects, I’ll go to a doctor…drinking every day in the same time, if not.. we will be sick… (SR, 42, patient who adhere to ARV)

ARV medicine can fight the HIV to recover my body quickly… (HN, 35, patient who do not adhere to ARV).

Perceived Susceptibility Factors Affecting Adherence: In terms of perceived susceptibility of patients about ARV, three respondents (one respondent who adhere and two respondents who do not adhere) are bored for taking ARV every day. On the other hand, seven respondents (2 respondents who adhere nd five respondents who do not adhere) sometimes forget to take it on time.

Nothing..i did not forget…no difficulties.. (SC, 27, respondent who adhere to ARV).

I am bored for taking medicine continuously forever. Furthermore, taking ARV should be on time (PA, 27, respondent who do not adhere to ARV)

Perceived Severity Factors Affecting Adherence: In terms of perceived severity, eight respondents (three respondents who adhere and 5 respondents who do not adhere to ARV) stated that severity is caused by patient’s susceptibility.

Not too disturbing anyway…I can afford to solve it (HU, 44, respondent who adhere to ARV)
Quite annoying…I often forget…quickly got sick…like headaches…nausea…tired…often sleepy (IK, 32, respondent who do not adhere to ARV)

**Perceived Benefit Factors Affecting Adherence:** All respondents have benefit for taking ARV. This statement was captured in the below:

The benefit is to make my body healthy, so my activity goes well…(LS, 36, respondent who adhere to ARV)

Yes… sometimes my body felt fresher after taking ARV…I am more diligent to work…Like healthy people in general, they will not believe if I am HIV (JT, 23, respondent who do not adhere to ARV)

**Perceived Barrier Factors Affecting Adherence:** Six respondents (two people who adhere and four people who do not) mentioned that the side effect of ARV is the barrier. Two respondents said that another barrier is inadequate income (one respondent who adhere and one respondent who does not adhere). Two respondents who adhere to ARV do not have any barrier to take ARV. All respondents took ARV unless someone will disclosure their HIV status.

After taking ARV especially in the first week, I feel nausea, vomiting… Furthermore, I sometimes got headaches…(SR, 42, respondent who adhere to ARV)

Because of high transport fares and financial constraints. I do not have health insurance, so I do not take ARV…I have been drinking coconut oil herbal …drinking zaitun oil and eating more (IK, 32, respondent who do not adhere to ARV)

I am too busy to regularly take ARV, If I remember, I will take it soon (HU, 44, respondent who adhere to ARV)

**Motivational Relevance Factors Affecting Adherence:**

Seen from the motivational relevance of taking ARV, ten patients said that they want to be normal people who do not get HIV infection, can work normally, have healthy body, do not get stigma from society, and have a long life.

My motivation on taking ARV therapy is because I want to be like others who do not get HIV infection and work normally…being healthy…no stigma from neighbours (SR, 42, respondent who adhere to ARV)

Being healthy…can work…if I were healthy, they would not believe that I am HIV sufferer. They believe that PLWH are thin…I still look healthy (JT, 23, respondent who do not adhere to ARV)

**Discussion**

**Sociodemographic Characteristics:** In this study, all respondents have lower income than minimum regional salary. They have financial constraints, so they are unable to spend enough money for transport, take their medication as prescribed.

Adherence is a form of behavior arisen from the interaction between a doctor and a patient, so they understand, approve, and execute their plans and consequences. Multi-factors that affect to adherence include communication, social-economy, employment, level of knowledge about treatment, medical insurance, basic health services, and ethnics.

A patient with low income has more difficulties of adherence. Even though ARV medication is freely provided in Indonesia, but unemployment, transportation cost, and ownership of health insurance still affect patients to take ARV. Additionally, education level does not always get associated with adherence. In this study, five respondents who do not adhere to ARV went to elementary school, high school and college. According to the study done by Hanif, socio-demographic like education level does not get consistently associated with adherence.

**Patient’s Knowledge:** The majority of respondents have good knowledge about side effects, problem solving, condition in taking ARV, schedule for taking ARV, impact due to unregular ARV therapy. However, almost all respondents do not know what ARV medicine is and the objectives of this medication.

Knowledge is the results of knowing after someone conducts or senses something or a particular object. This is consistent with Van Dyk who mentions that maintenance group is patients who understand about ARV. In the contrary, nonadherence group is patients who lack knowledge about ARV and have missing meaning about ARV. The ARV therapy does not function to fight HIV, but it only suppresses the progression of HIV.

**Perceived Susceptibility Factors Affecting Adherence:**

The majority of patients in this study have perceived
Perceived susceptibility is one of the powerful beliefs to prompt people to adopt healthier behavior.\textsuperscript{15} It can be seen that a belief of increased susceptibility or risk is associated with healthier behavior and decrease susceptibility to unhealthy behavior.\textsuperscript{14} Perceived susceptibility about ARV and HIV disease is related. Denial of HIV status as identified needs to be addressed through intervention in order to accept HIV status, and the implication of the diagnosis will give patients clues to take ART.\textsuperscript{7}

**Perceived Severity Factors Affecting Adherence:** In this study, most of respondents argued that severity is caused by susceptibility that patients experience. Perceived severity is an individual belief in disease severity or the needs of ARV medication according to doctor instructions.\textsuperscript{16} Perceived severity will make patients stressed if they do not have a good self-efficacy. It is evidenced that patients who have perceived severity can cope the mecanism and adherence to ARV therapy. Respondents who do not have severity will adhere to take ARV.\textsuperscript{15}

**Perceived Benefit Factors Affecting Adherence:** All respondents in this study have benefits after taking ARV. Some of them do not have a good perceived benefits for taking ARV, but a half of them have a high level of adherence.

Perceived benefit is an individual belief about the efficacy and feasibility of particular actions to treat and prevent a disease or to take ARV medication according to doctor’s instructions.\textsuperscript{17} Some studies show that good perceived benefits are related to patients’ adherence. Patient’s belief in ARV benefits have been correlated with ARV adherence. Moreover, perceived effectiveness of ART is related to ARV adherence.\textsuperscript{17}

**Perceived Barrier Factors Affecting Adherence:** This study shows that the majority of respondents considered side effects as barriers of ARV adherence. Moreover, since they work, it is hard to hidetheir HIV status. Only few had no barriers.

Perceived barrier is individual belief in things that inhibit ARV adherence.\textsuperscript{1} Barriers give negative impacts on social and worklife, secrecy and stigma.\textsuperscript{13} Furthermore, many patients hide their HIV status because they are afraid of stigma which becomes a major barrier to change. It may be an important reason for why many patients take ARV on time or late.\textsuperscript{6}

**Motivational Relevance Factors Affecting Adherence:** All respondents in this study want to become normal people who can work normally, live healthily get no stigma from society, have a good immune system and long life.

Motivation is a part of primary appraisals in Transactional Model of Stress and Coping Theory. Motivational relevance is an individual belief to do something.\textsuperscript{17} People who have motivational relevance can cope their problems in taking ARV and decide whether or not to adhere. Autonomous motivation is strongly associated with perceived competence and correlated with adherence.\textsuperscript{18}

**Conclusions**

In conclusion, education level, employment, and ethnics do not always affect adherence, but income is significantly. Knowledge about ARV therapy, perceived susceptibility, perceived severity, perceived benefit, perceived barrier, and motivational relevance affect adherence to ARV as well. Moreover, self-efficacy, controlled outcome, controlled emotion, cues to action and others influence patients’ adherence to ARV therapy.

**Conflict of Interest:** This study didn’t have conflict of interest with General Hospital that become location of this study.

**Source of Funding:** This study have self findings by the authors.

**Ethical Clearance:** Prior to the research, an ethical approval was conducted by a reviewer of Health Science of Hafshawaty Pesantren (Islamic Boarding School) Zainul Hasan Probolinggo, East Java, Indonesia.

Living with Stigma: The Experience of Tuberculosis Patients and Family Caregivers in Indonesia

Windy Rakhmawati¹, Kittikorn Nilmanat², Urai Hatthakit²

¹Faculty of Nursing, University of Padjadjaran, Indonesia; ²Faculty of Nursing, Prince of Songkla University, Thailand

ABSTRACT

Background: People with tuberculosis (TB) lead to emotional distress because of stigma. Their stigma could extend to other family members particularly caregiver. Therefore, stigma could be a hindering factor on the successful of TB control.

Objective: This study aimed to explore the experience of stigma among TB patients and family caregivers in Indonesia.

Material and Method: A qualitative study was conducted among five TB patients and four family caregivers who had experienced with TB stigma, had a previous TB diagnosis (patients) or caring TB patients (caregivers), and can speak Indonesian or Sundanese language. Data were collected by in-depth interview, and content analysis was used for the data analysis.

Findings: Three main themes emerged from participants’ experiences for being stigmatized. The first theme was TB meaning, including TB as a dreadful disease, as a severe disease, and as a dangerous disease. Second theme was psychosocial aspect of TB stigma, consisting of feeling shame and social exclusion, which were influenced by their fear of causal transmission and blame from others. Finally, strategies to cope with stigma, including isolating themselves, keeping secrecy of TB, ignoring, and convincing others.

Conclusion: These findings suggest that persons affected by TB stigma need support from health care providers. These findings will be benefits to health professionals to develop stigma reduction intervention for patients and family caregivers to cope with TB and its stigma.

Keywords: Family caregiver, Indonesia, Patient, Stigma, Tuberculosis.

Introduction

TB stigma has emerged as an important barrier to the control and treatment of TB. TB stigma contributes to the quality of TB management such as delays in seeking health care, TB diagnostic delay, poor treatment compliance, non-adherence to TB screening in household contacts, and consequently poor quality of life. Stigma is defined as an “attribute that is deeply discrediting”. Several studies reported the experiences of stigma among TB patients including isolation, discrimination, rejection, and social exclusion. Stigma does not only affect a TB patient as an individual, but also the family caregivers who take care of and who have a close relationship with TB patients. Stigma that extends to others family members is known as “courtesy stigma”. Another study also reported the positive correlation between TB courtesy stigma and health-seeking behavior.

TB stigma also occurs in Indonesia. Even though World Health Organization (WHO) reported that the success rate of TB treatment in Indonesia was 85% in 2015, treatment default in several areas in Indonesia is still low. The misperception of TB showed a significant relationship with TB treatment default. One of the barriers in the TB control program is the non-compliance to treatment, morbidity, mortality, and risk to become
resistant to drugs are emerging among defaulters. Thus, the aim of this study is to identify the factors, especially knowledge and perceptions of TB and association with treatment default among patients treated in primary care settings, East Nusa Tenggara. METHODS: This study was part of a bigger cohort community-based controlled trial study. The subjects were newly diagnosed pulmonary TB patients from four districts in East Nusa Tenggara. Knowledge, perception of TB, and other related factors were assessed prior to the treatment. Patients who interrupted the treatment in two consecutive months were classified as defaulters, as World Health Organization stated. Odds ratio (OR. Most studies in Indonesia have focused on quantitatively measuring TB stigma and the relation of stigma on TB diagnosis and treatment. However, there are limited studies that have explored stigma among people with TB and the family caregiver. In order to reduce stigma in Indonesia and increase TB control programs, understanding about stigma within TB patients and family caregivers in Indonesia is essential. The objective was to explore the experience of stigma among TB patients and family caregivers in Indonesian.

Method

This study is a part of PhD dissertation, which used a qualitative study. This study was conducted in Bandung, Indonesia. The participants in this study were purposively recruited until data saturation. Five TB patients and four family caregivers voluntary participated. The inclusion criteria were persons who have experience with stigma related to TB, have a previous active TB diagnosis (for TB patients) or were caring for TB patients (for family caregivers), and can speak Indonesian or Sundanese language. The participants were obtained from a lung clinic, Bandung, Indonesia. TB patients are represented by codes P1-P5, while caregivers are coded by FC.1-FC.4.

Data were collected from December 2016 to July 2017 through in-depth interview. Each participant was interviewed for 2–4 times, and around 40-90 minutes was spent for each interview. The sample questions included “how do you perceive TB?” and “what were other people’s reactions when they knew that you had TB disease?” The interviews were recorded using a tape recorder and then transcribed verbatim before being translated into English. The member checking technique was applied to enhance trustworthiness. Content analysis method was used to analyze the data.

Findings

Three main themes emerged from the interview transcriptions, consisting of the meaning of TB, TB stigma experiences, and strategies to cope with stigma.

Meaning of TB: When asked how they perceived TB, the participants shared their meanings of TB in three aspects.

Dreadful disease: The perception of TB as a dreadful disease was reported by both TB patients and family caregivers. Participants perceived that having TB means persons were in a condition that approached death and only had a short life. These participants had experiences of seeing someone die because of TB. As a TB patient, P3 stated the meaning of TB:

*Having TB means only having a short life … when I was in the education room, there was someone who died because of TB. I was afraid to be like that, and it made me cry (P3)*

Similarly, family caregivers also shared the same dreadful meaning of TB. FC.4 mentioned that:

*Last time, there was my neighbor who got TB in here, and she died … I still did not know anything about TB. His wife was the first person who got TB. Then, she died. Her husband also got TB, and he also died. (FC4)*

Severe disease: TB patients described TB as severe disease. Having TB leads to the separation of utensils. Those who got TB would have several physical problems such as weakness, a persistent cough, and isolation by others. P3 stated:

*“I thought that TB is a severe disease, the worst disease, and it makes me feel helpless … I felt tired even when I did not do anything, I was sweating. My condition of TB disease was severe, would I lay down, and not do anything?” (P3)*

Family caregivers also perceived TB as a severe disease. Their perception of TB as severe disease was related to the long-term treatment of TB. The FC.1 as the family caregiver who took care of mother in-law with TB disease expressed their meaning of TB:

*TB seems a severe disease, it should be treated fully for 6 months. If it (treatment) does not work effectively it will lead her to be re-treated. (FC.1)*
Dangerous Disease: Both TB patients and family caregivers reported their meaning of TB as a dangerous disease. Knowledge about how TB is transmitted to others and that TB patients should be isolated led them to think that TB is dangerous.

TB is known as a disease that … dangerous, if everybody knows it, they will avoid us, (we) will be isolated … People who know someone has got TB, they will avoid him/her. If they do not know, they will not avoid him/her. (P4)

Another family caregiver described when knowing about the TB diagnosis of her mother in-law’s sister, she received information about TB transmission. This information made the family caregiver think that TB was dangerous.

The doctor said “You should take care of them (family member). Your mother in-law’s sister should use a mask, because TB can transmit through respiratory or chat, and also do not spit carelessly … It (TB disease) is dangerous and can be transmitted … this illness is dangerous and can transmit.” (FC2)

TB stigma experiences: The participants’ experiences of TB stigma can be classified into two categories of feeling shame and social exclusion.

Feeling shame: The symptoms of TB among adults is commonly related to loss of body weight and a persistent cough. Therefore, all TB participants felt shame because of the changes in their physical appearance. TB participants stated that others could notice their TB disease from their physical symptoms. These participants explained that others perceived TB as a disgusting and scary disease because TB can be transmitted to others, which later on they will be blamed as the cause of transmission.

I felt shame because my cough often appears. I was worried my neighbors will know of my TB and they were afraid of being infected with TB because of me (P1)

Social Exclusion: Social exclusion was experienced by both TB patients and family caregivers. Other people began to avoid and exclude them from their social life since the others knew about the TB diagnosis within the participants. For instance, one TB participant described how their neighbors behaved to her.

[after the neighbors knew that I got TB] some of my neighbors avoided me … they said “she (participant) has TBC, it is a transmitted disease. Do not come close to her” … they did not want to talk with me (P2)

Moreover, one family caregiver also reported that the experiences of social exclusion also had impacted on their children. Exclusion from their relative was experienced by FC.4.

She (participant’s relative) did not allow her son to play with my daughter, and did not allow him to come to our home … Maybe she was worry that TB in my home can be transmitted to her son (FC.4)

Strategies to cope with stigma: Four strategies to cope with TB stigma among the participants were identified, consisting of isolating themselves, keeping a secrecy of TB, ignoring, and convincing others.

Isolating themselves: Due to the feeling of shame, most TB patients preferred to isolate themselves from their community. They mainly stayed at home, in order to prevent themselves from and avoid social life.

I felt shame and also afraid, they may feel afraid to be close to me because I will infect them. Thus, I never went out of my home … because I was afraid they will know my TB (P1)

Keeping secrecy of TB: To avoid the exclusion from others, the participants preferred to hide the TB disease and keep it a secret. When their neighbors saw TB patients wearing masks or the caregiver with TB patients often going back and forth to the health services, they would ask about their disease. Then, the participants dissimulated their disease such as a lung disease or a common cough and/or to avoid dust.

When I used mask, there was my neighbors who asked me, “what happened to you, why do you use a mask?” then I said, “it’s only to avoid the dust” … So, I rarely went out, I often stayed in here (inside home) (P4)

Another family caregiver also expressed the same thing, which concealed the TB disease.

We did not want everybody to know about its disease (TB), both in my residence and my husband’s office (FC.3)
**Ignoring:** Some participants used an ignoring as a strategy to manage TB stigma. They also did not want to hear or see the reactions of others to them. One TB patient shared her story about coping with TB stigma.

I did not listen to them (neighbors), didn’t care it because I want to be cured. Let them talk about whatever they would like to say (about my disease) (P2)

Similarly, the family caregiver also ignored what other people thought about her family with TB. When the family caregiver went to hospital to pick up her husband’s medicines, her neighbor mocked her family.

When we went to the hospital. My neighbor who saw us, asked us “where are you going?” I said, “we are going to the hospital”, and they said “commonly, people are going together for a walk or for picnic, while you are going to hospital.” … I don’t care… they were not the persons who paid our treatment, they were not the persons who helped us. (FC.4)

**Convincing others:** This strategy was only reported by the family caregivers. Most of them described how to handle others’ negative views about TB within their families. They attempted to explain to others that their TB family member was undergoing treatment. Through their explanation, they hoped their neighbors would not worry with TB transmission.

They (neighbors) asked about my husband, my children and TB disease among us. I explained to them, how TB is transmitted to others, TB cannot be transmitted if only touching … some people understand … In here (their community), they think that TB can be transmitted only like this (touching hand) (FC.2)

**Discussion**

Participants perceived TB as a dreadful, severe, and dangerous disease. These meanings of TB were related to the understanding about the curability of TB, TB treatment, and the risk of TB transmission to others. This finding was similar with the previous studies that reported several perceptions of TB disease including as a dangerous, infectious, incurable disease, and scary disease related to approach death.

The participants’ perceptions of TB contributed to their experience of stigma, which was feeling shame to be noticed as a cause of transmission. Its feeling shame was caused by poor awareness and misperceptions about TB. Other previous studies also described people with TB had a fear of shame due to the TB disease and its transmission, and they also suffered because of TB disease particularly in resource limited settings, where rates of tuberculosis are high. The objective of this study is to assess health-seeking behaviour and health care experiences among persons with pulmonary tuberculosis, and identify the reasons patients might not complete their treatment. We performed qualitative one-on-one in-depth interviews with pulmonary tuberculosis patients in nine health facilities in rural western Kenya. Thirty-one patients, 18 women and 13 men, participated in the study. All reside in an area of western Kenya with a Health and Demographic Surveillance System (HDSS). Social exclusion was not only experienced by most TB patients, but also by some family caregivers. One family caregiver also mentioned the relative and neighbors who excluded their children. Stigma among TB patients could extend to other family members. Avoiding other people was contributed by other people perceptions about TB, which was as a disgusting and scary disease because it can infect them. This finding was congruent with the previous studies that reported the consequences of stigma among people with TB which included isolation and social exclusion from others.

The participants applied several strategies to cope with their stigma experienced. These strategies reflect the Indonesian value of family closeness, which is concerned with the loyalty of other family members’ lives to protect and help each other. Concealing TB disease by isolating themselves and keeping the secrecy of TB, helped them to avoid the feeling of shame and of being stigmatized. The previous studies also described hiding a TB diagnosis, keeping TB as a secret, and separating themselves were strategies to deal with discrimination from others. However, TB patients have to receive treatment in secret this may lead to a disruption in routine treatment. Ignoring was reported as a strategy to cope with stigma. The ignoring and keeping their live moved were useful to mitigate stigma among patients who have completed TB treatment. The family caregiver tried to educate and explain to their neighbors and relatives about the likelihood of their family member who had TB transmitting it to them. This strategy was similar with the previous study that reported educating others help to reduce any misunderstandings.
Conclusion: This study identified three TB meanings, including as a dreadful, a severe, and a dangerous disease, which contributed to the experience of stigma. Shame and social exclusion were common experienced by TB patients and family caregivers. TB patients and family caregivers described the coping strategies to cope with stigma, including isolating themselves, keeping secrecy of TB, ignoring, and convincing others. The findings are of benefit to nurses and other health care providers to develop stigma reduction interventions for patients and family caregivers.

Infections Risks of Medical Buildings: Perspectives Investigation in a Case-study

Yasaman Parsia¹, Shahryar Sorooshian², Mohammad Panjehpour³

¹Researcher, INTI International University, Nilai, Malaysia; ²Lecturer, University of Gothenburg, Gothenburg, Sweden; ³Associate Professor, Center for Advanced Concrete Technology (CACT), INTI International University, Nilai, Malaysia

ABSTRACT

Each medical building has a significant role in presenting high quality of health services for public, so, attention to medical risks, such as, Hospital Acquired Infections (HAIs) is essential. therefore, this article attempts to describe the HAIs situations of a medical building in the Middle East and mention some medical building’s factors which have role in increasing the rate of HAIs risks. The unstructured interviews with experts of the case were conducted. Based on the results, the medical building involves about HAIs like the other medical buildings and some factors, such as, poor personal hygiene can increase the rate of HAIs in the case. Any document like this article can be a useful evidence to nominate health risks, like HAI, in different medical buildings and remark issues which are relevant to decrease the rate of health risks in the other medical buildings. It can help to improve the quality of the health services and can give new ideas to the researchers and practitioners to find solutions in various fields to decline the risks of different medical errors, specially HAIs.

Keywords: Infection, Medical building, Case study.

Introduction

In each country, health and setting health care services are one of the significant issues at the primary level of each society strategies (¹). Medical building, likewise it is known as health-care facilities or similarly can be acknowledged as hospitals, are among infrastructures of public health. The goals of each medical buildings can be attained by some doings, such as, patient care, personnel-health education, health related study and health promotion (²). Despite the improvements and innovations in health and medical sciences and health management, health risks are still problems of the medical buildings. Hospital-Acquired-Infection (HAI) is one of those risks that require special attention. HAI or medical buildings cross-infection is a kind of infection wherein a patient becomes infected along his/her hospitalization or within a few days of his/her discharge (³-⁷). The history of HAIs, as one of the main problems and one of the 10 leading causes of death in medical buildings, is back to the many years ago (⁸). HAI is not limited to a special geographical area; it is a universal challenge (¹¹). HAIs extend duration of hospitality, lead to a long-term disability of the patients, increase the patients’ resistance to antimicrobials, can cause mortality, rise the financial load of medical buildings and extra costs for the patients and their families (⁹,¹⁰).

Methodology

For this research, a qualitative research method is used, through interview. In this study, viewpoints of the experts of a medical building (hospital) in the Middle East, as a case study, are presented in field of HAI. Additionally, some factors which can increase the rate of these infections risk have been discussed. Twenty therapeutic and diagnostic departments with 400 beds and 1,400 medical staff are belonging to this medical building. Though to some considerations, this article kept the name of the case medical building confidential.
The goal population for this research is the experts who are related to assessment of HAI risks in the medical building. The researcher, for this study, conducted interviews with experts of the medical building, in 2018. The face to face interviews were conducted. The researcher used unstructured interview format for this study. List of the medical building’s experts with their characteristics is tabulated in Table 1. The expertise of the selected list is validated in a session of discussion with the manager of the selected medical building.

Table 1: List of experts related to assessing HAI risks in the medical building case of Middle East

Finding and Discussion

About the situation of the HAIs in the medical building, based on the viewpoints of all experts, HAIs are one of the challenging issue of the medical building. Referring to expert N2, finding the origin of infections of patients is expensive and time-consuming. While in many developed countries the patient after being discharged is followed by a nursing force to complete infection treatment. Lack of this system leads to incomplete treatment and transmission of infection. In some cases, a patient attends the medical building with an intense infection, which causes high expenses to both the patient and the medical building and increases the death rate. This is the case with the medical building where the infection origin is not assessed, with the excuse of insufficient manpower in infection control department.

With respect to the question that how distant the medical building from ideal conditions to control infection is, the experts’ answer is that the main problem of the medical building is its construction; the departments are not in standard conditions and no precision is observed as to infection transmission possibility in their construction. According to expert N6, because of the type of medical building’s services, there exists the necessity to run several surgeries in the abdominal area, in specific, and many patients suffer breakages and brain hemorrhage; hence, HAI is inevitable.

If the infection test is positive, in case the patient is brought to the medical building recently, it is supposed the patient had the infection before. This holds true for urology patients with a urine infection and internal department patients with blood infection which do not get recorded. Some patients attend the medical building from other therapeutic centers where they get an infection during a surgery process and the infection does not get recorded. Only the medical building patients get recorded if their infection is proved after 24-48 h. But the origin and the reason for this infection is not assessed.

According to experts N1, N2, N3, N4 and N7, future strategies of the medical building to control and reduce
HAI constitute increasing supervision and observing personal hygiene by physicians and staff together with enhancing working conscience among personnel. By assessing the expert’s opinion, it is revealed the awareness of the medical groups for infection control within the medical building departments, where attempts are made to control and prevent the outbreak of HAIs through applying disinfectants, personnel hygiene, prescribing antibiotics, etc. Despite the made advances, HAIs are still one of the problems in the medical building.

About some factors of the medical building which can increase the risks of HAIs, referring to viewpoint of experts is the medical staff, physicians and medical students of every department who do not observe personal hygiene. According to experts N1, N3 and N4, infection is transmitted due to the training and research purposes of this medical building. The students are moving among the departments without changing their medical gown or observing hand hygiene and other items related to infection control. They enter departments like hematology/oncology, where sensitive patients with the very weak immune system are hospitalized and do not wear a medical gown, change gloves, wash their hands and observe other health items leading to an increase in infection transmission risk. In addition, the medical building physicians move among departments to visit patients and do not observe hand hygiene. For instance, they move from the infectious ICU department to other departments and increase the infection transmission possibility. This holds true for department technicians who move among departments like physiology and radiology. In addition to contact transmission, there exists the airborne infection transmission type of tuberculosis, in specific, based on viewpoint of experts N1 and N6.

Also, transferring of patients among departments can be the other reason of HAIs transmission in the medical building. Referring on experts N1, N2 and N3, due to long hospitalization, open surgeries and the necessity to undergo cerebrospinal fluid cultivation in order to obtain negative infection report, neurology patients have to move among various departments; hence, the possibility of infection transmission. According to experts N1, N2 and N6, at emergency department where hospitalization time is maximum 6 h and then the patients are discharged or transferred into a department corresponding to their diseases, there exists the possibility to transmit the infection to other departments. Inappropriate venipuncture at emergency department is considered as an infection resource which may transmit into other departments. Experts N1 and N2 state that a patient in the venipuncture discovers to have an infection after undergoing a surgery and being discharged. After running assessments, it is revealed that this patient got the infection during the surgery. In order to receive necessary services, patients may have to return to a previous department and based on the intensity of infection, they may need surgeries and therapeutic services of other departments, which in turn leads to an increase in infection transmission possibility.

Referring to all experts, there exists the possibility of infection transmission among departments. ICU department in the venipuncture is an example. According to experts N1, N2, N3 and N4, ICU department constitute the highest infection rate and is considered the infection resource. This is due to the long hospitalization of patients and the weakening of their immune system due to antibiotics consumption. These patients are prone to bed sore due to long hospitalization which is considered as an infection resource. Based on viewpoint of expert N1, in a case, a patient in ICU department in the venipuncture was suffering difficile diarrhea and another patient in internal department got diarrhea with the positive difficile test. This is an example that difficile infection is transmitted from ICU to the internal department, both patients had a same physician.

According to expert N6, in cases the hospitalization time of patients increases due to HAI, everything related to the patient is affected, expenses, in specific. This is due to the demand for medication, antibiotics in specific, infection consultation and infection visit and in some cases the necessity to undergo surgery, which depends on the infection type. The simpler the infection, the lower the expenses and manpower. In case of acute infections, a patient with osteomyelitis (an infection of the bone) in the medical building underwent 11 surgeries and did not recover. This is an instance of high expenses as to surgery, medication, equipment, and personnel for both the patient and the medical building because of HAIs. If necessary actions are taken to control infection, the suffering and expenses caused by infection may reduce to a considerable extent. According to the expert N6, the type of diseases and the physical structure of the medical building together with the arrangement of departments are contributive in generating and transmitting infection.
Conclusion

To conclude, it can be recognized that the prevention of HAIs is an essential factor for every medical building and government of countries. Based on the information which achieved through interview sessions with the experts of the medical building, it can be found that the strategies and standards which are relevant to control HAI are not implemented in a sufficient way in that medical building. This issue can be because of some factors, for instance, lack of knowledge of personnel in field of HAI control strategies and it’s standards; poor personal hygiene among physicians, nurses, medical students, medical staffs; lack of suitable constructor layout of medical buildings departments; transferring of patients, medical students, physicians, medical staff and technicians among departments and etc. Therefore, if the management and medical group of the medical building pay attention to these factors and try to decrease errors in them, it can help to decline the rate of HAIs in the medical building. These activities can improve the quality health services and reduce the rate of mortality, morbidity and financial load of HAIs in the medical building. Also, referring to the factors which mentioned in above sentences, researchers can work on fields of personal hygiene, medical building’s layout as an example of research fields to control and/or prevention risks of HAIs in the medical buildings around the world.

Effect Pregnant and Non-Pregnant on Haematological and Biochemical Parameters of Qatari Goats in Iraq

Yassen Taha Abdul-Rahaman¹, A. O. Humid², Hajir Shihab Hamad Al-Dulaimi³

¹College of Veterinary Medicine, ²College of Applied Science, University of Fallujah, Iraq; ³College of Sciences, University of Anbar, Iraq

ABSTRACT
This study was conducted in one of the animal farm, province of Baghdad, January 2019. This experiment included 10 (5 pregnant and 5 non-pregnant), Qatari goats. The blood samples for hematological, biochemical, plasma minerals and hormones assay. Excluding data for MCHC, lymphocyte and Eosinophil in pregnant goats showed higher significant differences (P≤0.05). All other hematological parameters showed higher significant differences (P≤0.05) in non-pregnant. Glucose, albumin ALT, AST, Alkalina Ph, Cholesterol, Triglycerides, HDL and VLDL exhibited higher significant different (P≤0.05) pregnant females goats. Urea was showed increased significant different (P≤0.05) non-pregnant female goats. Calcium and magnesium were increased significantly different (P≤0.05) higher in pregnant. Highest (P<0.05) level of progesterone and testosterone concentration was recorded in pregnant, and lowest in non-pregnant. Estradiol-17β concentration was significantly (P≤0.05) increased in the non-pregnant group as compared with pregnant group. The rest of the parameters were showed no significant different (P≤0.05) between pregnant and non-pregnant. In conclusion, effects of pregnant and non-pregnant were noticed on some hematological, biochemical, minerals parameters as well as levels hormones of Qatari goats in Iraq.

Keywords: Pregnant, non-pregnant, haematological, biochemical parameters, minerals, hormones, Qatari goats

Introduction
Goats are animals with basic demands. For a considerable production just a minimal investment is needed. Goats are very adaptable species. They use pastures and plant leaves of the many hilly and mountainous areas in our country(3).

Hematological and biochemical tests are important tools for evaluation of physiological and health status of farm animals and almost indispensable in organic farming, where permitted veterinary interventions are strictly regulated and limited in scope. Hematological and biochemical analyses in farm animals have been extensively discussed as an essential part of clinical examination often pointing to a specific differential diagnosis or suggesting a prognosis (2).

Materials and Method
This study was conducted in one of the animal farm, province of Baghdad, January 2019. This experiment included 10 (5 pregnant and 5 non-pregnant), Qatari goats of 2-3 years old and average body weight of 8-10 kg. Females were naturally mated with fertile male. Blood
samples were collected via heparinized vacatorner tubes (5 ml). The plasma were harvested following centrifugation of the samples (3000 RPM for 15 minutes) and stored under -20°C until assay. The blood samples were assessed for hematological parameters which includes. Packed cell volume (PCV) by microhematocrit, hemoglobin (Hb) by acid hematin (Sahl’s haemoglobinometer) method. White blood cells (WBC’s) and red blood cells (RBC’s) were counted according to⁹.ERYTHROCYTE sedimentation rate (ESR) was determined by Westergren Sedimentation tubes. Mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), and mean corpuscular hemoglobin concentration (MCHC) were calculated using the formula reported by⁶. Differential leukocytes count (DLC) (%) were estimated in thin May-Grünwald-Giemsa stained blood smears⁷. Biochemical parameters were also estimated includes; Glucose, total proteins, Albumin, Urea, Uric acid, creatinine, Alanine Aminotransferase Activity (ALT), Aspartate Aminotransferase Activity (AST), Alkaline phosphatase activity, Cholesterol, Triglycerides, High density lipoproteins (HDL), Low density lipoproteins (LDL) and Very low density lipoproteins (VLDL) were quantitatively determined using the kit provided by Agappe Diagnostice Company, Switzerland and Biomerieux Company, France. Globulin was calculated by taking the difference between total protein and albumin. The concentrations of some minerals (calcium, phosphorous, sodium and magnesium) were analyzed by spectrophotometrically. Radioimmunoassay (RIA) used to measure the plasma progesterone concentration (ng/ml), plasma estradiol-17β (pg/ml) and plasma Testosterone (ng/ml). Kits provided by Immunotech, France.

The pregnancy were detected by ultrasonography.

Statistical analysis were performed using General Linear Model (GLM) procedure in the SAS program⁸. Differences among means were compared using the Duncan multiple range test⁹.

Results and Discussion

The results of PCV in the groups showed significant difference (p≤0.05) (table 1). It is higher in Non-pregnant and decreased in pregnant. Blood volume expands in parallel with increases in body weight during pregnancy in goats¹⁰. The reduction in PCV levels at the end of gestation, represents “Pregnant Physiological anemia” a clinical condition described in various species, its importance as it lower the blood viscosity, thereby greatly expansion the blood flow in the small blood vessels¹¹. RBC’s showed increase in number (P≤0.05) in non- pregnant and significantly decrease in pregnant. Hemodilution is effect on increase in plasma volume at the last stage of gestation, improve the blood flow through placental blood vessels in late pregnancy to increase the transfer of nutrients and oxygen to the fetus¹². MCV, MCH and MCHC significant difference (P≤0.05) in the studied groups. It were lesser in non-pregnant, and significantly (P≤0.05) increased in pregnant. The increase observed in MCV MCH and MCHC could prevent a marked lower in total oxygen caring capacity of circulating blood¹³. The highest (P≤0.05) count of WBCs was recorded in non-pregnant, and the lowest in pregnant. The WBC count increase in lactating females may be attributed to increase Serum Lactic Dehydrogenase (LDH) in lactating females which may produce leukocytosis²⁴. A trend of increased neutrophil in non-pregnant, and significantly decrease in pregnant. Increased neutrophils of lactating females compared to other normal groups could be due to suspect that lactating females were more susceptible to systemic and local infection through the udder and also, or due to increased serum LDH levels¹⁵. Moreover, high percentage of lymphocyte (p≤0.05) was observed in pregnant, While low in non-pregnant. The percentage of Eosinophil was higher (p≤0.05) in pregnant, and decreased in non-pregnant. Basophils were significantly (p≤0.05) increased in non-pregnant and lower pregnant. Leukocyte count has been gradually increased with advancement of lactation. This may indicate lesser migration of leukocytes from blood into milk for phagocytosis and mammary gland defense against pathogens in mid and late stage of lactation as compared to early stage which can be correlated with gradual decline in milk yield with progress of lactation¹⁶. Effects of different groups on Hb, ESR and Monocyte were non-significant. Significant differences were noticed in glucose concentration over the study groups. Higher (P≤0.05) concentrations were observed in pregnant, and lesser in non-pregnant. Highest in glucose immobilized by the use of adrenergic alpha-2 anesthetics, which inhibit the release of insulin and increase glucose output from the liver¹⁷. Insulin responsiveness was reduced during late pregnancy. During the pregnancy the output of adrenocorticotrophic hormones, glucocorticoids and adrenaline for breakdown of liver glycogen is increased¹⁸. Plasma albumin was significantly increased (P≤0.05) in pregnant as compared with non-pregnant. Blood albumin was directed to foetal growth tissue, while globulin may be used mainly
for milk synthesis\(^{(19, 20)}\). Plasma urea was significantly greater (P≤0.05) in non-pregnant, and lesser in pregnant. Rodriguez et al.\(^{(21)}\) found that glomerular filtration and urea clearance were significantly reduced during late pregnancy. The effects of different groups on ALT, AST and Alkalina Ph. activity of the female goats were significant (P≤0.05). It was lesser in non-pregnant and increased significantly (P≤0.05) in pregnant. Increased intracellular levels of ALT and AST during pregnancy are disagreed with its value in the plasma\(^{(22)}\). Erythropoietic activity since young blood cells are characterized by increased activities of enzymes\(^{(23)}\), and the intracellular dehydration induced by increased extracellular fluid Na+ concentration\(^{(20)}\). The alkaline phosphatase normally produced by syncytiotrophoblast cells of placenta and may be involved in migration of primordial germ cell in developing fetus\(^{(24)}\). The Cholesterol, Triglycerides, HDL and VLDL activity were decreased in non-pregnant, and significantly increased (P≤0.05) in pregnant. Cholesterol are plays an important metabolic role as precursor of steroid hormones, bile acids, and some vitamins\(^{(25)}\). Triglycerides are the storage form of lipids and provide an energy source to the ovum during its maturation within the Graafian follicle. All through pregnancy and lactation periods the number of total insulin receptors (TIR) decreases and insulin stimulation of lipogenesis becomes in-efficient\(^{(26)}\). The increasing profile observed in triglycerides, HDL and vLDL levels in pregnant related to the excessive intake of glucose to maintain body reserves for the supply of fetal energy requirements\(^{(27)}\). Other biochemical parameters Total Protein, Globulin, Uric acid, Creatinine and LDL did not significantly different between pregnant and non-pregnant female goats (Table 1). Calcium and magnesium concentrations were significantly (P≤0.05) higher in pregnant and lower in non-pregnant. The requirements of Ca for pregnancy and lactation are higher than those for maintenance, foetus for skeletal formation and for milk formation which increases the quantity of Ca required at tissue level and thereby increase Ca absorption from the gastro-intestinal tract\(^{(28)}\). The variation in magnesium concentrations between pregnant and non-pregnant might be due to the property of magnesium to remain increased in the cells, the highest concentration is in the liver and skeletal muscles\(^{(29)}\). There are no significant effect of pregnancy and non-pregnancy on phosphorous and sodium (Table 1). Highest (P<0.05) level of progesterone concentration was recorded in pregnant, and lowest in non-pregnant (Table 1). Cholesterol plays a role in biosynthesized progesterone hormone by the corpus luteum and placenta. It intervenes also in metabolism of corticosteroids. Physiological effect of progesterone is amplified in the presence of estrogens, notably in the development of udder, and sodium metabolism by decreasing natriuresis\(^{(25)}\). Significant differences were noticed in plasma estradiol-17β concentrations over the study groups. Estradiol-17β concentration was significantly (P≤0.05) increased in the non-pregnant group as compared with pregnant group. Estradiol was regulating estrus cycle, development of female genital tissues and the udder. It is also involved in ovulation, preparation of implantation of oocytes in the uterus, pregnancy, and parturition in combination with progesterone\(^{(25)}\). In contrast, greater (P<0.05) testosterone concentration was observed in pregnant than in non-pregnant female goats. The analogous increase in follicle size and testosterone level suggested that hormone is secreted by the follicle as for other domestic species\(^{(25)}\).

The Role of Preoperative Subconjunctival Bevacizumab on Recurrence Rate of Primary Pterygium

Yousif Farhan Dawood

1Department of Ophthalmology, College of Medicine, University of Anbar, Anbar, Iraq; 1Department of Ophthalmology, Ibn Al Haitham Teaching Eye Hospital, Baghdad, Iraq

ABSTRACT

To assess the value of one week preoperative subconjunctival injection of bevacizumab on the surgical management of primary pterygia and also to evaluate the rate of recurrence after excision. This is experimental clinical trial included 110 eyes of 110 patients (59 males and 51 females) with a mean age of (49.62 ± 16.54 years), range (27-68) had primary pterygia. The dose of bevacizumab was a 1.25 mg (0.05 ml) one week before pterygium surgery. Surgery was done using excision with direct conjunctival suturing technique. All pterygia were followed up for 6 months.

Keywords: Bevacizumab, Pterygium, Recurrence

Introduction

Pterygium is an abnormal triangular fibrovascular growth that violates the cornea [1, 2]. It appears in the interpalpebral area, nasal side is the most common area of occurrence and frequently bilateral [1-3]. For long years, practitioners have known pterygia [2, 4-6], however the underlying pathology of pterygia is still not completely recognized [7, 8].

Several studies have involved circumferential influences [7-10], like ultraviolet light that the damaging effect of ultraviolet radiations can lead to decrease the number of corneal limbal stem cells, i.e. cause limbal stem cells insufficiency and stimulate tissue growth factors productions such as cell proliferation and angiogenesis. It is found that pterygia have many histopathological hallmarks of chronic inflammatory processes, which demonstrate lymphocytic infiltration consisting mainly of T lymphocytes, then mast cells and plasma cells. Mast cells have an essential role in chronic inflammatory processes that accompanied with angiogenesis and fibrosis. The increase of new blood vessels formation, number of fibroblasts, aggregations of degenerative collagen fibers, and the existence of abnormal elastic fibers also prove the presence of chronic inflammatory processes. New advanced studies have also found proof of genetic ingredients implication, such as growth factors, antiapoptotic mechanisms, immunological factors, some cytokines, viral infections, and extracellular matrix remodeling in the underlying pathology of the pterygia [10-12].

Several studies have founded that growth factors like vascular endothelial growth factor (VEGF) have been discovered in pterygia, more advanced immunohistochemistry studies also have founded that the amount of VEGF are more in pterygium than in healthy conjunctiva and as previously mentioned that underlying pathology of pterygia is still not completely recognized but their growth genesis and development are found to rely on mainly on abnormal new blood vessels formation [13-17]. It has been assumed that the occurrence of pterygia depend on alteration in angiogenic inhibitor to stimulator ratio as described in Jin et al [15]. Which founded that pterygium contains substantially reduced levels of angiogenic inhibitor factor, and increased vascular endothelial growth factor levels.

The presence of high level of vascular endothelial growth factor in pterygium may give the anti-VEGF agents...
an important role in the regression of new blood vessels and also in the reduction of the size of pterygium growth.

Bevacizumab is a recombinant humanized, monoclonal vascular endothelial growth factor directed antibody. It links to and counteracts the biological action of all kinds of humanized vascular endothelial growth factor, and this blocks the interactions with its receptors on endothelial cells surface [17]. Bevacizumab was the first U.S. Food and Drug Administration-approved antiangiogenic drug for first-line treatment of metastatic colorectal cancer. In clinical practice, off-label use of bevacizumab has been a promising therapeutic option for treatment of choroidal neovascularization of age-related macular degeneration (ARMD), and newly in the treatment of diabetic macular edema. Several clinical studies have shown that intravitreal injection of bevacizumab is well tolerated and associated with visual acuity improvement, reduction in central retinal thickness, and reduction in retinal angiographic leakage [18-20].

The recurrence rate of pterygium surgeries was evaluated to be about 40% to 75% in the simple surgical removal, about 3-5% in the free flap techniques [21], and about 30% recurred after pterygium excision with complete suture of conjunctiva [22], so the aim of this study is to estimate the recurrence rate of primary pterygium using trial of subconjunctival bevacizumab with surgical excision.

**Patients and Method**

This is experimental clinical trial included 110 eyes of 110 patients (59 males and 51 females) with a mean age of (49.62 ± 16.54 years), range (27-68) (Table 1). Had primary pterygium between October 2017 and January 2019 at Ibn AL Haitham teaching eye hospital.

Each pterygium was examined, measured and graded according to its extension over the cornea [1, 2, and 3]. According to slit lamp evaluation, the pterygia were categorized into three grades 1, 2 and 3:

- Grade 1 extends less than 2 mm onto the cornea.
- Grade 2 involves up to 4 mm of the cornea and may be primary or recurrent following surgery.
- Grade 3 encroaches onto more than 4 mm of the cornea and involves the visual axis.

Exclusion criteria included: 1) Previous ocular surgeries interfering with conjunctiva including pterygium excision. 2) Contraindication to bevacizumab such as allergy to bevacizumab, previous stroke or myocardial infarction, pregnant and lactating women. 3) Evidence of ocular surface diseases. 4) History of ocular trauma involving limbus, conjunctiva, sclera. 5) Patients unable to follow up during the period of the study. On basic assessment, grade 2 severity of pterygium and more were involved in this study.

The patient reviewed with prearranged follow-up program. In this study patient was reviewed after one week, one month, three months then six months from the surgery. In every followed up, full ocular assessment was achieved, included any adverse events or problems.

Recurrence was defined as the postoperative fibrovascular growth exceeds more than 1.5 mm over the clear cornea. Vascularization of the corneal stroma or conjunctival growth not extending over the cornea was not considered as recurrence [24-26].

**Results**

This study included 110 eyes of 110 patients. The patient’s pre-investigated data are shown in table 1. Including age, gender, grade of pterygium.

Subconjunctival hemorrhage has been occurred in 12 patients (10.9%) and cleared within 2 weeks, no other ocular adverse effects was noted such as ocular surface irritation, corneal abrasion, persistent epithelial defects, infections, or uveitis.

Discussion

Different surgical procedures have been considered for treatment of primary pterygium [5-7]. The recurrence of pterygium was approximated to be about 40% to 75% in simple surgical removal, about 3-5% in the free flap techniques[21], and about 30% recurred after pterygium excision with complete suture of conjunctivae[22]. Some materials like 5-FU and mitomycin C are used to reduce possibility of its recurrence, studies reveal recurrence rates about 0-13.3% after using intraoperative mitomycin C with surgical excision [27-29] but their uses is accompanied with serious complications like infections and scleral thinning and necrosis [6-8].

As pterygia are consisted of growing fibrous and vascular tissues and their genesis and development demand new blood vessels formation [17, 18], several substances that activate angiogenesis have been recognized, indicating that these factors may be implicated in the development of pterygia.

Many studies had been used bevacizumab in treatment of pterygium in different ways, mainly topical, subconjunctival after surgical removal. But this study use different method in using bevacizumab in treatment of pterygium, by subconjunctival injection of bevacizumab one week before surgical removal.

In this study, we decide to use subconjunctival than topical route because subconjunctival injection appeared to give better compliance, it was of low cost for patients, and it has been mentioned to be more efficient than the topical administration in treating diseases that cause corneal neovascularization [30].

El Shafie et al [31], use 0.05 ml (1.25 mg) of subconjunctival bevacizumab for primary pterygium in the same way of this study and in the same follow up schedule in El Minya University Hospital, Egypt. He found that recurrence was reported in 5 of 60 patients (8.3%) of primary pterygia. This study found that recurrence was noted in 12 of 110 patients (10.9%) of primary pterygia.

Although there was a difference in number of patients between this study and El Shafie etal, the major cause of difference in the recurrence rate between these two studies was attributed to the conjunctival flap technique that used in El Shafie et al.

Wu et al[32], Leippi S et al[33], Mansour AM et al[34], Dastjerdi et al[35], Sudhalkar A et al[36], found that the use of topical bevacizumab is a potentially useful, and safe treatment as an adjuvant to pterygium surgery, while Karalezli, et al [37] and Ozgurhan et al [38], found that topical bevacizumab seems to have no additional effect on pterygium recurrence.

Razeghinejad et al[22], Rashid Omar et al[39], H Khoshniat et al [40], Besharati et al [41], Alhammami et al[42], Teng et al[43], found that subconjunctival use of bevacizumab after surgical removal is beneficial in management of both primary and recurrent pterygium and no local or systemic unfavorable events were noted.

Anthony F et al [44], Bahar et al [45] found that the use of subconjunctival bevacizumab does not seem to be effective in reducing the rate of pterygium recurrence following excision and no local or systemic unfavorable events were noted.

Several studies reported that the commonest time of recurrence after pterygium removal is between 3-6 months [46-50]. In a trial performed by Asergadoo[51], he found that if pterygium has tendency to reappear, it commonly exhibits manifestations of recurrence and grows back through the first three months, so the first 6 months was very important in follow up for recurrence.

ABSTRACT

Introduction: Parental engagement in caring for children is very important and parents must have the ability to care for their children. Health promotion behavior efforts can be made by giving the child a good diet with balanced nutrition. The purpose of this study was to analyze indicators of parental engagement and health promotion behavior in caring for children with avoidant restrictive food intake disorder.

Method: This study was a cross-sectional design by simple random sampling with a sample size of 245 participants. The independent variables were parenteral engagement indicators and the dependent variable was health promotion behavior indicators. Data were collected using: a demographic questionnaire, parental engagement questionnaire, and health promotion questionnaire. The analysis used a simple linear regression test with a significance level of α≤0.05.

Results: Parental engagement can be influenced by parents’ age and health promotion behavior was influenced by the level of parental education, number of children and condition of the child. The results of simple linear regression test obtained significance results of 0.000 (p-Value <0.05), which means that there was a significant influence of parental engagement on promotive behavior.

Conclusion: Good parental engagement and health promotion behavior will reduce tension when providing care for children with Avoidant Restrictive Food Intake Disorder. When the stress of parents decreases, parents will be able to be more sensitive to read signals from their children.

Keywords: parental engagement, health promotion, avoidant restrictive food intake disorder.

Introduction

Engagement between parents in caring for children is very important. Father’s role in parenting involves physical, affective and cognitive processes in the interaction between father and child 1. The involvement of fathers is very important for child development in several aspects, such as assisting in child feeding2, accompanying children to play and learn and in helping children while learning about toileting3. Fathers also play a role in providing solutions to the difficulties experienced by their children4,5. A father, in carrying out his parenting role, needs to have fathering skills so that he can educate and nurture children to the maximum6,7. The obstacles in establishing engagement are accepting a different perspective from others. Parents tend to resist attempts to change their minds, especially when they are in conflict situations8.

Avoidant restrictive food intake disorder (ARFID) is a new term for describing infant and toddler age disorders with such characteristics as refusing to eat; poor mealtimes; low eating skills that are not in accordance with the child’s development stage 9; lack of interest in eating; avoidance based on sensory food, including appearance of food, smell and taste of food;
fear that occurs when eating, such as dysphagia; and fear of swallowing food. The distinctive difference from other eating disorders is that in ARFID there are psychological disorders, such as anxiety and lack of parenting.

Health promotion is an effort to empower individuals, groups and communities to maintain, improve and protect health. In addition, to achieve a perfect degree of health, both physical, mental and social, the community must be able to recognize, realize their aspirations and needs and be able to change or overcome their environment. The form of health promotion carried out by mothers to children is to improve health by adhering to strategies for monitoring healthy behavior in children. If the lifestyle that is lived by parents is a healthy one, the behavior that will be applied to children will also be a healthy lifestyle, one aspect of which is to get children to eat on time.

Method

Research Design and Setting: A cross-sectional design was used. This study was conducted at the 6 places in Malang Regency, Indonesia.

Respondents and Sampling: The respondents were recruited from five different health centers using simple random sampling method. The population included all families with ARFID children. A total of 245 families with ARFID children voluntary participated in the study and completed all questionnaires.

Instruments: The data collection tools were single questionnaires on demographic characteristic designed by the researcher. The demographic data included mother’s age, level of education, mother’s occupation, family income, number of children, children’s age, children’s sex, height, and weight. Tools for parental engagement consisted of eight items, namely: parenting; help feed children; accompany the child while playing, urinating and defecation; giving opinions to children; parents communicating with each other regarding children’s needs and communicating actively with children.

Data Collection: The data collection was assisted by eight research assistants. A questionnaire packet was completed with a description of the study, consent procedure, response confidentiality, and the researcher’s contact details.

Data Analysis: Original data were inputted into an excel spreadsheet and checked by the researcher. All data were analyzed using IBM SPSS 23.0 statistics. Descriptive analysis included frequency, percentages, means and the standard deviation was used to provide descriptive data. Data were analyzed using the chi-square technique and regression test. In this study, the statistical level of significance was set at P< 0.05.

Result

Most of the mothers were in the age range of 26-35 years (56.7%). Most mothers’ education was high school (36.3%) and not working (77.6%). Income was mostly between 1-2 million/month (51.4%) with the number of children 1 (42.4%) respondents. The maximum age of toddlers was ≤3 years (72.2%). The sex of most children was female (55.1%). The nutritional status of children was at normal height (60.8%).

Table 1 shows the results that parental engagement was related to the mother’s age (p=0.007). Engagement between parents had no relation to level of education (p=0.243), mothers’ occupation (p=0.062), family income (p=0.127), occupation of parents (p=0.924), income of parents (p=0.542), and number of children (p=0.924). The health promotion behavior was related to the level of the mother’s education (p=0.007), a number of children (p=0.008), and height of children (p=0.019). The strongest indicator of parental engagement was in parents communicate with each other regarding children’s needs, with the average of 4.37 (SD ± 0.952), while the weakest engagement in fulfilling the needs of children was to help children defecate, with the average 2.85 (SD ± 1.172).

Table 3 shows that the regression model of health promotion behavior was 31.653 and parental engagement was 0.392. The regression coefficient value of the Parental Engagement variable was 0.392. This value showed an increase that occurs in the Health Promotion Behavior variable if Parental Engagement increases. The $t_{\text{count}}$ was 4.647 with a significance value of 0.000. The value of $t_{\text{table}}$ at free degree 243 and the real level of 5% was 1.970. Because the value of $t_{\text{count}}$ was greater than $t_{\text{table}}$ or the significance value was smaller than the real level of 5%, it was concluded that there was a significant effect of parental engagement on promotive behavior with a positive direction of influence.

Table 3: The influence of parental engagement in improving health promotion behavior

The correlation coefficient ($r$) was 0.286, which means that there was a strong relationship between parental engagement and health promotion behavior. The coefficient of determination ($R^2$) obtained was 0.082, which means that health promotion behavior was influenced by parents’ engagement of 8.2%, while the remaining 91.8% was influenced by factors other than parental engagement.

Discussion
Parental engagement can be influenced by the mother’s age. Age was an indicator of maturity, the older they get, the more knowledge and experience they have about appropriate behavior to educate children. Ages that were too young or too old cannot perform this role optimally because physical and psychological strength was needed; besides affecting physical aspects,
the mother’s age also affects the psychological aspects of the mother because a mother who is too young is not ready to become a mother in terms of her child care skills. This young mother emphasizes her youthful nature rather than her motherly nature\textsuperscript{18}. Children with young parents will get more relaxed supervision because younger parents tend to have a high tolerance and tolerate children more\textsuperscript{19}.

Communication between parents and children can be seen as an effort to monitor, know and direct children’s development. Open communication will make children feel valued, loved and cared for by their parents. The existence of effective and efficient communication, carried out continuously, can create intimacy, openness and more attention between the couple and parents are more aware of developments in children, both physically and psychologically \textsuperscript{20}. Parents who become good listeners will have a better relationship with their children\textsuperscript{21}. New ways of communicating with children must be based on respect and skill\textsuperscript{22}. This contains two meanings, namely greetings should not hurt the self-esteem of children and parents must first show an understanding attitude to children, then give advice.

Health promotion behavior can be influenced by the level of education, a number of children and the condition of the child (height and age). Families with higher education levels will find it easier to receive health information specifically on how to educate toddlers on a daily basis. Children need strong support from their families; if family support for children is good, then the children’s growth and development will be stable\textsuperscript{23}. Education will have an impact on the mindset and views of parents in educating their children. Parents who have a high level of education and insight will pay attention to and care for their children according to their age of development and will show better personal and social adjustments that will make children have a positive outlook on others and society\textsuperscript{24}. This healthcare includes prevention and self-protection from diseases and other health problems, improving health and seeking healing if sick\textsuperscript{25}

Thing which can be an obstacle to parental involvement in children’s education are parental education levels, parental work conditions, past experience in education, parental inferiority feelings and other personal problems, such as distance from home to schools, culture and language\textsuperscript{26}. Characteristics of parents of toddlers, which include age, education, and work, can influence the process of behavior change. This shows that the average age of respondents is in the age of healthy reproduction when being self-motivated to obtain as much knowledge as possible. Health promotion is a form of an effort to improve maternal and child health that aims to reduce maternal and child mortality in a sustainable manner, by increasing community independence in the field of maternal and child health\textsuperscript{27}. The high rate of maternal and child mortality is one of the problems that occur in Indonesia in the health sector, as a result of the low level of the economy and public education in the health sector.

**Conclusion**

Good engagement between parents will reduce tension when providing care for children who experience ARFID. The higher the level of stress in parents will increase behavior problems in children. The good parental engagement was influenced by the age factor of parents. Maturity possessed by the mother causes the ability to provide care and pay attention to the good nutritional status of children. The most dominant indicator of parental engagement was communication between husband and wife related to the needs of the child. Health promotion behavior was influenced by maternal education level, number of children and the nutritional status of children. There was a significant influence between parental engagement and increasing health promotion behavior.

Recovery Self Efficacy, Coping Strategy, Adversity Quotient and Resilience among Intensive Care Unit Nurses in Indonesia

Yulis Setiya Dewi¹, Nursalam, Nursalam², Rachmat Hargono³, Rr Dian Tristiana⁴
¹Doctoral Student of Public Health Science, Faculty of Public Health, Lecturer of Faculty of Nursing, ²Faculty of Nursing, ³Faculty of Public Health, ⁴Faculty of Nursing, Universitas Airlangga

ABSTRACT

Introduction: Stress experienced by most critical care nurses can be caused not optimal nursing care. This study aimed to identify the correlation between recovery self-efficacy, coping strategy, adversity quotient and resilience among critical care nurses in three public hospitals in Surabaya, Indonesia.

Method: This study was cross-sectional study carried out on 91 critical care nurses. Data were collected using questionnaires. Descriptive statistic and Spearman’s Correlation were used to analyze the data.

Result: Totals of 91 nurses were involved in the study. Spearman’s correlation analysis showed that recovery self-efficacy (r=0.644, P<0.000) and adversity quotients (r=-0.217, P<0.039) were associated with resilience of critical care nurses whereas coping strategy (r=0.036, P=0.734) was not correlated to resilience of critical care nurse.

Conclusion: Resilience among critical care nurses was correlated with recovery self-efficacy and adversity quotients. Thus, enhancing their capacity in terms of recovery self-efficacy and adversity quotients may improve the resilience of critical care Nurses

Keywords: Intensive Care Nurses, resilience, recovery self-efficacy, coping strategy; adversity quotient

Introduction

The ICU nurses are confronted with unpleasant facts every day and it is very difficult to avoid the source of stress¹-³. The stressors include stressful work life, problems that occur during caregiving and the problems that exist in the healthcare system⁴. All these situations or experiences increase the possibility of prolonged stress and may become worse to nurse performance⁵. However, notwithstanding this adversity, many nurses choose to remain as a nurse⁶. Nurses can encounter all difficult situation and bounce back from adversity when they are resilience. Resilience is an illustration of the process and results of successfully adapting to adversity situation or very challenging life experiences, especially situations with high-stress levels or traumatic events⁶. In the Indonesian context, there is a relatively limited study which reveals nurse resilience. Therefore, gaining an understanding of resilience and factors that contributed can be very beneficial for nurses in helping them develop greater personal resilience and in learning to deal with patients.

The previous study⁷ indicated that there was a relationship between work stress and caring behavior where nurses did not display caring behavior because they experienced stress at moderate and severe levels. While other studies at the High Care Unit showed that nurses showed stressful behavior, experienced physical stress, and experienced emotional stress. The results of a preliminary study of researchers at a teaching hospital in Surabaya in July 2017 found that nurses showed symptoms of stress characterized by frequent sleep disturbance, loss of concentration and thinking small things were too detailed, irritable and tension when interacting with other health workers. Contact consistently with the events of death, interactions with patients and their families, conflicts with supervisors and uncertainty about therapy causing much higher stress in
ICU nurses. This situation will cause psychological problems and this can have an impact on interactions with other health workers, work, and an institution’s reputation. Other study indicate that there is a relationship between psychological stress and nurse caring behavior. But nurses who have good resilience show a decrease in stress symptoms. Other studies have found that resilience is related to nurse caring behavior.

The International Council of Nursing in 2016 states that many efforts have been made to deal with stress that occurs in nurses, but not in efforts to build how nurses are resilient to the source of stress in their work environment so that they can overcome any problems that arise. Therefore, a preventive strategy is needed to help ICU nurses adapt to sources of stress so that they can carry out the sublime functions of nursing care. One such strategy is to understand factors related to ICU nurse resilience. In this study, three-factor were examined namely adversity quotient, coping strategy, and recovery self-efficacy. Adversity Quotients is a score that measures the ability of a person to deal with adversities in his or her life. Hence, it is commonly known as the science of resilience. Coping is categorized into the problem and emotion-focused coping and avoidance coping. A study found that resilient characteristics may associate in athletes to the use of more potentially adaptive coping strategies. Moreover, based on the Health Action Process Approach (HAPA) model recovery self-efficacy describes the experience of failure and recovery from adversity. Recovery self-efficacy is related to one’s belief in the ability to continue positive actions after making behavioral changes in a negative direction. Recovery self-efficacy helps to gradually return to acting based on one’s wishes. Beliefs become strong if individuals can regain control of their behavior after falling on negative behavior.

It is important to help nurse identify factor may correlate with resilience in order to face and protect themselves from the impact of difficulties in the workplace. High resilience positively affects nurses’ attitudes towards the profession, the future, life, and their work and life outputs. Furthermore, the nurse needs to understand resilience as a vital characteristic for nurses in today’s complex healthcare system.

Only a few studies have examined the relationship between recovery self-efficacy, coping strategy, adversity quotient and resilience among ICU nurses. Therefore, this present study examined the correlation of recovery self-efficacy, coping strategy, adversity quotient and resilience among ICU nurses.

Materials and Method

Research Design and Setting: This investigation used the cross-sectional study to reveal the correlation of recovery self-efficacy, coping strategy, adversity quotient and resilience among ICU nurses. The population included all nurses except ICU head nurse at X General Hospital, Universitas X Teaching Hospital, and X General Hospital X from August – September 2018.

Respondents: A total of 95 nurses from three hospitals were recruited using total population sampling method. Only 91 nurses completed all questionnaires and the rest was dropped out from the study.

Measurement Tools: The data collection tools were questionnaires on the socio-demographic characteristic, on 91 ICU nurses. The questionnaires were adopted from the existing questionnaire. The researcher made some adjustment or modification on the questionnaire and tested the validity and reliability of the questionnaires on 26 ICU nurses in Darmo private hospital. The translation was accomplished by the researcher and proofread by Journal Development Team from Universitas X.

The Recovery self-efficacy questionnaire consisted of 25 questions. The Cronbach’s α was 0.735. The question featured a Likert scale with the following option: always, very often, sometimes, and never. The total score for this section was in the range 25-100 with a higher score indicating a higher level of recovery self-efficacy. The coping strategy questionnaire consisted of 25 questions. The Cronbach’s α was 0.774. The question featured a Likert scale with the following option: always, very often, sometimes, and never. The total score for this section was in the range 25-100 with a higher score indicating a higher level of coping strategy.

The Adversity Quotient questionnaire consisted of 40 questions. The Cronbach’s α was 0.936. The question featured a Likert scale with the following option: strongly agree, agree, disagree, strongly disagree. The total score for this section was in the range 40-140 with a higher score indicating a higher level of the adversity quotient which divided into climber, camper, quitter
The Resilience questionnaire consisted of 35 questions. The Cronbach’s α was 0.938. The question featured a Likert scale with the following option: always, very often, sometimes, never. The total score for this section was in the range 70-140 with a higher score indicating a higher level of nurse resilience.

**Data Collection:** The data was collected directly by the researcher. A questionnaire packet was completed with a description of the study, consent procedure, response confidentiality, and the researcher’s contact details. The questioner was completed independently by the respondents and collected by a researcher on the same day. It took about two months to reached all respondents from three different hospitals and due to shifting schedules of nurses. A total of 95 questionnaires were distributed but 91 were completed and the rest was considered incomplete and invalid therefore indicating 94.8% returned rate.

**Data Analysis:** All data were analyzed using the SPSS 20.00 software. Descriptive statistic included frequency, percentages, means and the standard deviation was used to describe quantitative variables. Data were analyzed using Spearman’s Correlation to identify the correlation between recovery self-efficacy, coping strategy, adversity quotient, and resilience among ICU nurses. In this study, the statistical level of significance was set at P < 0.05 for two sides.

**Result**

The majority of the respondent age at the range of 23 – 54 years old. Level of education was dominated at diploma level (64.8%) with work experience at 1-5 yrs (40.7%). A total of 64.8 % was female nurses (Table 1).

</tbody>
</table>

In this study, the recovery self-efficacy total score ranged from 40 to 87 with the mean score was 68.36 ± 7.30. The mean score of Recovery self-efficacy dimension namely self-believe and intention were 40.44 ± 4.33, 27.93 ± 2.97 respectively (table 2).
The coping strategy total score ranged from 38 to 97 with the mean score was 57.80 ± 11.19. The mean score of coping strategy dimension namely PFC, EFC, and AFC were 21.77 ± 3.26, 17.25 ± 3.63, 18.78 ± 4.30 correspondingly. The adversity quotients total score ranged from 60 to 138 with the mean score was 101.69 ± 13.45. The mean score of adversity quotients dimension namely: Control, Origin Reach Endurance were 19.32 ± 3.08, 23.76 ± 2.66, 23.59 ± 3.59 and 35.02 ± 3.40 correspondingly. Spearman’s correlation analysis showed that recovery self-efficacy (r = 0.644, P < 0.000) and adversity quotients (r = -0.217, P < 0.039) were associated with resilience of ICU nurses whereas coping and adversity quotients may improve the resilience of ICU nurses. However, another study conducted to sports performer indicated that resilience scores correlated positively to task-oriented coping and negatively to disengagement- and distraction-oriented coping during both periods. Analysis of variance indicated that athletes with high individual resilient qualities reached higher scores in task-oriented coping, using to a lower extent disengagement- and distraction-oriented coping16. A study conducted to Latvian nurses indicated that more nurses use the “escape/avoidance”

Since the level of stress was not constantly remain the same so nurses used difference strategy to cope with the situation. In addition, a study reveals that Intensive Care Unit nurses mainly adopted the strategy of denial7. It was found in this study that ICU nurses also used three types of coping strategy namely problem-focused coping, emotion focus coping and avoidance coping. However, emotion focus coping and avoidance coping used more compare to problem-focused coping. This may affect the correlation where emotion and avoidance focused coping may not effective coping strategies. Therefore, it may not be correlated with resilience.

In general, this study revealed that adversity quotients had a correlation with the resilience of ICU nurses. This result support similar study conducted to a patient with cancer that there was a correlation between adversity quotient and resilience 21. In addition, this study showed that ICU nurses had an endurance score (mean ± SD = 35.02 ± 3.40) higher than other adversity dimensions, namely control, origin and ownership, and reach (mean ± SD = 19.32 ± 3.08, 23.76 ± 2.66, 23.59 ± 3.59 respectively). This score shows that nurses who have good endurance will have better resilience because endurance involves someone’s resistance to dealing with various adversity.

**Conclusion**

Resilience among ICU nurses was correlated with recovery self-efficacy and adversity quotients. Thus, enhancing their capacity in terms of recovery self-efficacy and adversity quotients may improve the resilience of ICU nurses. Management of the hospitals may provide training to improve Adversity Quotation training and recovery self-efficacy for ICU nurses regularly to enhance resilient capacity. In addition, there were limited experimental studies were found
about improving the nurses’ resilience. Therefore, it was important and necessary to conduct studies to analyze and improve nurses’ resilience that possibly prevented such extreme consequences of stress exposure such as burnout, compassion fatigue, and vicarious traumatization.

**Ethical Clearance:** Ethical approval was obtained from the ethics committee of the three hospitals. Voluntary, confidentially, fair and harmless ethical principles were occupied in this study.

ABSTRACT

People who have lived more than 22 years in settlements around the fertilizer industry X are at risk of being exposed to $\text{SO}_2$ from the increase in exhaust emissions produced by the boilers and power generation equipment in the fertilizer industry. The purpose of this study was to determine the Risk Quotient (RQ) due to exposure to $\text{SO}_2$ and to measure the duration of exposure to $\text{SO}_2$ that is safe in the residential area around the fertilizer industry X.

This research is a quantitative study with an environmental health risk analysis method, with a sample size of 297 adult population respondents in residential areas around the center of $\text{SO}_2$ emissions in the fertilizer industry X area. Data analysis was done using manual data calculations to determine the intake of $\text{SO}_2$ (non-carcinogenic), risk level or risk quotient (RQ), and safe duration (Dt safe) exposure to $\text{SO}_2$ in the population around the fertilizer industry X.

The results showed that the average non-carcinogenic intake of $\text{SO}_2$ in settlements around the fertilizer industry X was at 0.057427415mg/kg/day. While the average risk quotient is 1.788347507 (RQ>1), from a total of 297 respondents as many as 197 respondents with RQ>1 and 100 respondents with RQ<1, it shows that>50% of the population in settlements around the fertilizer industry X have health risks resulting from exposure to $\text{SO}_2$. The average safe duration of exposure to $\text{SO}_2$ in the population in settlements around the fertilizer industry X is 23.47 years, depending on the food intake and body condition of the respondents. The recommendation that can be given is to increase the weight of respondents and the right diet pattern by consuming nutritional intake that can detoxify the main toxin to reduce sulfur dioxide levels in the body, one example is the provision of vitamins E and C which can reduce oxidative effects such as lipid peroxidation and membrane damage in erythrocytes due to exposure to sulfur dioxide. Besides that, a related stakeholder policy is needed to periodically measure $\text{SO}_2$ concentrations in community residential areas around the fertilizer industry X, so that the air quality of people exposed to $\text{SO}_2$ can be monitored and is still within safe limits. The company holds a CSR program involving the surrounding community by conducting routine health checks, greening programs around the fertilizer industrial area.

Introduction

Everyone can be exposed to exhaust emissions of sulfur dioxide every day. The main uses of $\text{SO}_2$ are industrial sulfuric acid production, refrigerators, disinfectants for fruits and vegetables, the textile industry and fertilizer industry. The population in residential areas around the fertilizer industry has a high risk of...
exposure to SO$_2$. People who lived in residential areas around the fertilizer industry for years were constantly receiving SO$_2$ exposure due to boiler exhaust emissions and power generation equipment from production activities. Sulfur dioxide (SO$_2$) is a gas that is colorless and non-explosive, very soluble to water droplets and rain, has a characteristic odor and stinging acid taste and can irritate. Significant health effects include breathing difficulty, asthma attacks, pulmonary edema, eye irritation, cardiopulmonary disease, and increased mortality. SO$_2$ is the main air pollutant that has a significant impact on human health. Effects of specific short-term exposure to SO$_2$ can cause cardiovascular disease (CVD). In addition, SO$_2$ also has a significant relationship with the occurrence of hand, foot, and mouth disease (HFMD).

Based on previous research (Solichin, 2016) about SO$_2$ in the environment have not conducted research or measurements of safe duration (Dt Safe) for residential communities around the fertilizer industry that are exposed to SO$_2$ emission gases. This measurement is intended to make prevention and control efforts earlier before the respondent is estimated when symptoms of the disease arise in his body, so as to prevent health problems (non-carcinogenic) due to exposure to SO$_2$. Then further research is needed regarding the measurement of the safe duration of SO$_2$ in residential communities around the fertilizer industry X, as well as to determine intake and risk quotient (RQ) exposure to SO$_2$ (non-carcinogens).

**Material and Method**

The type of this research is quantitative research with environmental health risk analysis methods. In this study focused on exposure to SO$_2$ as an increase in exhaust emissions produced by boilers and power generation equipment in the fertilizer industry X.

The subjects of this study were human samples, namely adults aged 17 years and over who lived more than 2 years in the study area which were divided into 3 clusters, within a radius of 800, 1,050, and 1,300 meters from the center of the fertilizer industry X, so that a sample of 297 respondents was calculated. Whereas environmental samples are ambient air in residential areas around the fertilizer industry X, collected by the pararosanilin method using a spectrophotometer with impinger equipment by officers of the Center for Environmental Health. The procedure for analyzing SO$_2$ samples in the laboratory refers to the reference SNI 19-7119.7.

The data were obtained by secondary data. Secondary data were obtained by collect of data measurements which included the concentration of SO$_2$ in the air, anthropometric conditions (respiration rate and weight), activity patterns (time, frequency, duration of exposure, daily average time period) of the respondent by research of Solichin R, 2016. While secondary data also was obtained from related literature.

The variables studied were the intake, Risk Quotient (RQ) and safe duration (Dt Safe) from SO$_2$ (non-carcinogenic) exposure to respondents in residential areas around the fertilizer industry X. Data analysis was carried out by quantitative data analysis to determine the concentration and safe duration of SO$_2$ exposure to respondents.

**Findings**

**A. Intake:** Determination of the amount of intake on SO$_2$ toxins that enter the body, the following formula is used:

$$\text{Intake SO}_2 = \frac{C \times R \times tE \times fE \times Dt}{W_b \times T_{avg}}$$

Notes:

- $C =$ Sulfur Dioxide Concentration (mg/m$^3$)
- $R =$ Respiration Rate (m$^3$/hour)
- $t_E =$ Time of exposure (hour/day)
- $f_E =$ Frequency or Average exposure in year (day/year)
- $Dt =$ Duration of Exposure (year)
- $W_b =$ Weight (Kg)
- $T_{avg} =$ Average Exposure of Sulfur Dioxide (non-carcinogen) $\rightarrow$ 30 years x 365 day/year

Based on the results of measurements on the data, it is known that the average exposure concentration of SO$_2$ (C) is 0.248456 mg/m$^3$. The average respiration rate (R) is 0.60 m$^3$/hour. The average exposure time (tE) is 21 hours/day. The average frequency of exposure (fE) is 356 days/year. The average duration of exposure (Dt) is 31.3 years. The average respondent’s weight (Wb) is 57.6 Kg. While the average exposure of SO$_2$
B. Risk Quotient (RQ): Determination of risk level for respondents to exposure to SO$_2$ or Risk Quotient (RQ) is formulated with$^{17}$($^{18}$):

\[
\text{Risk Quotient (RQ)} = \frac{\text{Intake}}{\text{RfC}}
\]

Determination of risk categories is intended to determine whether exposure to SO$_2$ toxins is at risk or does not pose a risk to the health of the human body. Risk Quotient (RQ) is the result of a comparison between intakes with Reference of Concentration (RfC) or Safe Human Dose (SHD). The RfC value is obtained from the calculation formula namely$^{13}$:

\[
\text{SHD} = \text{NOAEL} \times \frac{\text{Animal Km}}{\text{Human Km}}
\]

According to The Office of Environmental Health Hazard Assessment (OEHHA)$^9$, the value of No Observed Adverse Effect Level (NOAEL) SO$_2$ is 660 µg/m$^3$ or equivalent to 0.25 mg/kg. While Animal Km and Human Km are Km factors in animals and humans, with the following calculations:

\[
(\text{Animal or Human)Km} = \frac{\text{W (Weight)}}{\text{BSA (Body Surface Area)}}
\]

Based on Table 1. The results of the average value of Animal Km are 5.816471979 while the Human Km is 35.96304. Based on the SHD formula described above, an SHD value of 0.04 mg/kg is obtained.

**Table 1: Measurement of Animal Km by White Mice and Human Km**

<table>
<thead>
<tr>
<th></th>
<th>Animal Km</th>
<th>Human Km</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average</td>
<td>5.816471979</td>
<td>35.96304</td>
</tr>
</tbody>
</table>

After obtaining the intake value and SHD, then the average value of Risk Quotient (RQ) is obtained for the respondents of 1,420286877 mg/kg/day (RQ$>1$).

C. Safe Duration (Dt Safe): Safe Duration (Dt Safe) is associated with a safe duration at work for one day and a safe duration (in years). The formula used in determining safe duration (Dt safe) is$^{17}$($^{18}$):

\[
\text{Dt Safe} = \frac{\text{RfC} \times \text{Wb} \times \text{Tavg}}{\text{C} \times \text{R} \times \text{tE} \times \text{fE}}
\]

Based on the results of the calculations in Table 2. It is known that the safe duration of the average respondent is 23.47 years, depending on the nutritional value of the food intake and the condition or body anthropometry of each respondent. While the smallest safe Dt value of the whole respondents is 12.87 years.

Discussion

Based on the results of measurements by the Institute for Environmental Health Engineering, the median value of SO$_2$ concentrations contained in ambient air in the population around the fertilizer industry X was 0.246 mg/m$^3$ (0.0946 ppm). This value is in the category above the ATSDR Minimum Risk Level (MRL) value, which is from WHO (1979) explains that for 24-hour exposure limit the recommended exposure can be tolerated at 100-150 mg/m$^3$ (0.04-0.06 ppm) but under the ACGIH (1998) value TLV-TWA: 5.2 mg/m$^3$ (2 ppm) and NIOSH (1997) REL TWA: 5 mg/m3 (2 ppm)$^2$. When compared with the Minister of Manpower Regulation No. 5 of 2018$^8$, the SO$_2$ concentration value in this study is the same as the permissible threshold value, which is equal to 0.25 mg/m$^3$ (0.095 ppm). While the value of SO$_2$ concentration in this study is still below the threshold when compared with the Government of the Republic of Indonesia Regulation No.41 of 1999$^9$ at 24-hour exposure limit
with SO₂ quality standards of 365 μg/Nm³ (0.13 ppm). To prevent or minimize health risks to the human body, it is necessary to reduce the concentration of SO₂ exposure to the safe concentration limit.

It is known that the intake value is directly proportional to the chemical concentration value, frequency of exposure, duration of exposure and inversely proportional to the value of body weight. Then it can be interpreted for prevention and control efforts, the greater the weight, the smaller the occurrence of health risks. Likewise, if the lower chemical concentration value, frequency of exposure, duration of exposure, the intake of toxins that enter the body is also lower.

Based on the results of the calculation of NOAEL SO₂ in this study was 0.25 ppm. The results of this calculation are smaller than NOAEL (US EPA 1994, 1996a, Streeton 1997, ATSDR 1998, OEHHA 1999b, EC 2005, WHO 2006, US EPA 2008) of 1-2 ppm. This NOAEL calculation is also smaller than ATSDR which is equal to 5 ppm².

Based on the calculation of RfC SO₂ in this study was 0.04 mg/kg. The results of this calculation are smaller than RfC for exposure to SO₂ through inhalation based on the health risk assessment of SO₂ by Health Canada (2016) which is equal to 0.06 mg/kg². So, the results of this research are safer for humans.

It is known that the average value of Risk Quotient (RQ) on respondents is 1.420286877 mg/kg/day (RQ> 1) or as many as 197 respondents have RQ> 1 and 100 respondents have RQ <1. This shows that of the total respondents, > 50% have a risk to health due to exposure to SO₂.

Based on the results of this study the Dt value is safe in the residential environment around the fertilizer industry X is 23.47 years. This number is smaller than the normal safe Dt, which is 30 years. Thus, the safe Dt rate is not healthy for both workers and the community and risks to health. To normalize Dt, the concentration of toxin must be minimized so that it is in accordance with the safe limits of toxin concentration. So prevention and control efforts are needed earlier before the respondent is estimated when the symptoms of the disease arise in the body, prior control measures are taken, namely periodic measurement and management of exposure to SO₂ toxins in the environment by the company and related stakeholders and healthy lifestyle in the community.

### Conclusion

It was concluded that the population in settlements around the fertilizer industry X posed a health risk to exposure to SO₂ (non-carcinogenic). The safe duration of the average respondent is 23.47 years. The recommendations that can be given include the concentration of sulfur dioxide toxins to be reduced to reach the safe concentration limit. In this case, it is necessary to periodically measure gas emissions of sulfur dioxide by companies and related stakeholders (for example local related agencies). If there is information from the relevant office that the level of sulfur dioxide is high, it is necessary to encourage the public to limit outdoor activities². EPA recommends that the concentration of sulfur dioxide should not exceed 0.03 ppm. For short periods of 24-hour exposure, the limit may not exceed 0.14 ppm more than once a year. Other controls can also be supported by increasing respondents weight and proper dietary patterns by consuming nutritional intake which can detoxify the main toxins to reduce sulfur dioxide levels in the body, for example is giving vitamin E and C can reduce oxidative effects such as lipid peroxidation and membrane damage in erythrocytes due to exposure to sulfur dioxide². The company holds a CSR program involving the surrounding community by conducting routine health checks, urban greening programs around the fertilizer industry area (mainly using plants that are resistant to SO₂) ⁶.

### Conflict of Interest:
All authors have no conflicts of interest to declare.

### Source of Funding:
This is an article “Determination of Sulfur Dioxide (SO₂) Safe Duration in Residential Population Around the Fertilizer Industry X in Indonesia” of Occupational Safety and Health Department that was supported by Activity Budget Plans 2019, Faculty of Public Health, Airlangga University.

Does Gluten Free Diet and Delay in Celiac Disease Diagnosis Affect Dental Caries and Salivary Oxidative Stress in Children?

Zainab Qasim M. Al-Obaidi1, Nada Jafer MH. Radhi1

1Department of Pedodontics and Preventive Dentistry, College of Dentistry University of Baghdad, Baghdad, Iraq

ABSTRACT

Background: Celiac disease, also named celiac sprue, is chronic malabsorption syndrome characterized by intestinal inflammatory reaction to dietary gluten in genetic susceptible individuals. The available treatment is by strict lifelong gluten free diet. The disease manifestations are not restricted intestinally but interestingly are often presented orally.

Objective: To assess the effects of gluten free diet and delay in celiac disease diagnosis in children on selected oral variables.

Subjects and Method: A case-control study was carries out in Baghdad including 20 newly diagnosed celiac disease children aged 7-11 years before initiation of gluten free diet (group A) and another 20 children committed to the diet (group B) compared to 40 children free from the disease (control group). Dental caries and salivary malondialdehyde were studied.

Results: Dental caries was lower in study groups than in control, there was no significant difference between delay in diagnosis and dental caries (P>0.05). Significant difference was found among study and control groups mean values concerning salivary malondialdehyde (Fisher exact = 114.200, P= 0.000). Significant difference was found between delay in diagnosis and salivary malondialdehyde level in the group committed to gluten free diet (T=2.124, P=0.048).

Conclusion: There was a relationship among celiac disease, gluten free diet, delay in diagnosis and salivary malondialdehyde. Dental caries was experienced at lower extent in celiac disease children.

Keywords: Celiac disease (CD), Gluten free diet (GFD), malondialdehyde (MDA), dental caries.

Introduction

Celiac disease (CD) is defined as a chronic inflammatory disorder affecting the small intestine causing malabsorption induced by the ingestion of gluten in genetically predisposed individuals (1). Genes encoding for CD are Human Leukocyte Antigens DQ2 and DQ8 (2). Histological features of the duodenal disease are villous atrophy, crypt hyperplasia, increase number of intraepithelial lymphocytes and decrease in height of enterocytes (3). CD is often presented clinically with abdominal pain, diarrhea and weight loss (4) and/or with extra intestinal manifestation as a result of malabsorption such as short stature, delay puberty, dental enamel hypoplasia, recurrent aphthous stomatitis, osteopenia, osteoporosis, Iron deficiency anemia, liver and biliary diseases, dermatitis herpetiformis, arthralgia and arthritis, ataxia, psychiatric disorders and alopecia (5).

In 2005 an Iraqi study by Abdul-Wahid revealed a higher prevalence of dental enamel defects in both primary and permanent teeth in CD individuals as compared to control and that was associated with increased dental caries experience in primary dentition in contrast to the permanent (6). Lifelong Strict gluten free diet (GFD) is the only available treatment for CD, clinical improvement can be achieved few weeks after the treatment and 1-2

Email: zainabobaidi1989@gmail.com
years to establish histological repair (7). Increase duration of malabsorption clinical symptoms predisposes the patients to severe complications making early detection extremely important (8).

Dental caries is slowly progressive chronic infectious disease (9). Different findings concerning dental caries and its correlation with CD have been reported ranging from no correlation with DMFT, decrease in dental caries experience in CD children before treatment and due to GFD (10-12). Shteyer, et al. reported that dental caries in celiac children was lower in the newly diagnosed and raised slightly during GFD while higher dental caries experience was found in normal children with no statistical significant results (13). An Iraqi study considered CD as a member of oxidative stress syndrome by increased level of malondialdehyde MDA in sera of newly diagnosed adults CD patients (14). When intracellular concentrations of reactive Oxygen radicals exceed the normal values, cytotoxic effects of free radicals lead to cell damage by double chain fatty acids peroxidation producing MDA as an end product (15). A study of CD patients on GFD aged 16-28 compared to healthy control found a significant Redox imbalance by serum MDA measurement (16) another study included CD patients aged 17-18 years showed impairment of Redox balance by significant increase of serum MDA in both unresponsively treated and untreated CD patients as compared to responsively treated CD patients (17). Saliva is a biological fluid which can be used non-invasively as a mirror for the blood (18). As far as it is known for the researchers neither salivary MDA was studies in CD patients before nor the effect of delay in CD diagnosis on oral health.

Material and Method

Study groups consisted of 20 newly diagnosed celiac disease patients before the initiation of gluten free diet GFD (CD at diagnosis) and 20 CD patients after 6-12 months of strict GFD (CD on GFD), both groups subjects were at age (7-11) years and devoid of any systemic disease rather than CD and were receiving neither medication nor nutritional supplements collected from three different teaching hospitals in Baghdad. 40 school students were strictly matched in age and gender who were free from any chronic or transient disease and receiving neither medications nor nutritional supplements selected randomly as control group after parents approvals.

The study was carried out during the period from November 2018 to March 2019. Clinical examination was carried out by using sterile dental mirrors, probes and tweezers. The criteria of Muhlemann, (1976) were used for the assessment of D_{1,4}MFS/d_{1,4}mfs (19). Unstimulated salivary samples were collected according to Tenovuo and Lagerlof, (1996) (20). Salivary MDA was determined by the principle of Spectrophotometry.

Delay in diagnosis was expressed as duration of CD malabsorption symptoms before diagnosis that was taken from patients’ medical files expressed by half year intervals since the first appearance of complains.

Descriptive statistics was applied, level of significance was set at 0.05, Games-Howell and Tukey HSD were used as ANOVA post hoc tests.

Results

Distribution of the sample was statistically not significant concerning gender in the study and control groups besides the sample was considered as one age group as shown in table (1).

Duration of symptoms with salivary MDA was only statistically significant in CD on GFD group (T-test = 2.124, P= 0.048) that in more than 5 years duration (salivary MDA mean ± SE) = 11.509 ± 0.607 and in duration equals or less than 5 years = 9.889 ± 0.480.

### Discussion

Celiac disease CD as an inflammatory enteropathy is interestingly associated with decrease in dental caries experience and the effect of gluten free diet GFD is controversial (21-24). Dental caries is one of the most prevalent infectious diseases affecting humans (9). This study is in a contrast with a Turkish study that found the better adherence to GFD, the lower caries experience explained by lower Mutans Streptococci and Lactobacilli salivary counts, lower cariogenic diet consumption and better oral hygiene practice due to periodic health care follow ups (12). Median of time elapsed between first CD complains and diagnosis in the current Iraqi study was less than that of a Swedish study of CD adults that was 9.7 years (25). CD is accused of increasing oxidative stress damage in affected children (26,27) two hypotheses explain increased lipid peroxidation in sera of CD patients one by the overproduction of free radicals caused directly by gluten ingestion and the second is involved with decrease dietary antioxidants as a consequence of malabsorption (26,28). In the present study salivary MDA was elevated in CD children before treatment and lower in children after strict GFD while normal children had the least salivary concentrations. Salivary MDA was observed as significantly positively correlated with serum MDA in apparently healthy individuals (29) and in disease conditions (30,31) thus the current study findings are homogenous with the previous serum studies concerning...
serum MDA in CD patients\(^{14,16,17}\). The correlation of salivary MDA level and the delay in CD diagnosis in patients on GFD illustrates the extreme importance of early CD diagnosis in symptomatic and asymptomatic children by national screening campaigns and health workers advanced education\(^{(25)}\).

**Conclusion**

Dental caries was less experienced in celiac disease children besides dietary gluten exclusion and delay in diagnosis had no effect upon caries experience. Celiac disease was associated with an increase in salivary lipid peroxidation of affected children, gluten free diet could decrease the level of malondialdehyde in 6-12 months but fails to normalize its concentration besides delay in diagnosis may act as an obstacle against the recovery effect of gluten free diet.

Study the Incidence of *Acinetobacter Baumannii* as a Nosocomial Pathogen

Wathiq Abbas Hatite Al-Daraghi¹, Saif Adel Al-Taliby¹

¹Institute of Genetic Engineering and Biotechnology for Postgraduate Studies/University of Baghdad, Iraq

ABSTRACT

**Background:** *Acinetobacter baumannii* is considered one of the most important causing agents of nosocomial infections especially in immune compromised and intensive care units patients. So that it remains one of the main causes of mortality and morbidity in hospitalized patients. The aim of current study was to identify the incidence of *Acinetobacter baumannii* as a cause of nosocomial infection in AL-Najaf hospitals.

**Method:** Two hundred seventy six clinical and environmental specimens were collected from burns, wounds and environmental infections from different hospitals in Al-Najaf Al-Ashraf Governorate from November 2017 to April 2018). All of these samples were cultured by specific and differential media.

**Results:** Data showed that 52 *Acinetobacter baumannii* isolates were identified by using microscopic examination and biochemical tests. The identification of 52 *A. baumannii* isolates was confirmed using the VITEK-2 system.

**Conclusion:** *Acinetobacter baumannii* is the most common cause of nosocomial infection in burn patients in Iraq.

**Keywords:** *Acinetobacter baumannii*, burn, PCR, nosocomial infection, antibiotics resistance.

Introduction

*Acinetobacter baumannii* designated as a “red alert” human pathogen, generating alarm among the medical fraternity, arising largely from its extensive spectrum of antibiotic resistance (¹). It is a Gram-negative, aerobic, non-motile, pleomorphic and opportunistic bacilli. It has a high incidence among immunocompromised individuals, particularly those who have experienced prolonged hospitalization (²). *Acinetobacter baumannii* can cause a variety of infections including pneumonia, bacteremia, meningitis, urinary tract infections, peritonitis and infections of skin and soft tissue. Multidrug resistant *A. baumannii* have become an important nosocomial pathogen that particularly affects critically-ill patients. The multi resistance is common in this species which complicates its therapy and elimination in severe infections, with extremely limited therapeutic alternatives available (³). *A. baumannii* is resistant to dehydration, detergents, UV radiation and common chemical sanitizers, making it extremely difficult to eradicate. Also, there is an increasing resistance of *A. baumannii* to antimicrobial drugs including aminoglycosides, quinolones and carbapenems (⁴). Therefore, the aim of current study was to identify the incidence of *Acinetobacter baumannii* as a cause of nosocomial infection in AL-Najaf hospitals.

Materials and Method

**Collection of specimens:** During the period extended from November 2017 to April 2018,276 clinical and environmental samples were collected from hospitalized patients and from the hospital environment (medical equipments and patients’ beds, tables, sinks and floors).

**Bacterial Identification:** Colonial morphology on MacConkey and Blood agars was depended initially
to identify bacterial isolates. Also, colony shape, texture, color and edges were examined. In addition to macroscopic characteristics; slides stained with Gram stain were examined under light microscope with a special regard towards cell shape and arrangement. Biochemical tests and VITEK 2 system were depended to complete the identification of *Acinetobacter baumannii* isolates.

**PCR amplification:** DNA template of all isolates was prepared by boiling method (30min in 100°C). The DNA of isolates was targeted only for the abaI and pgaD genes using the primers (SinaClon, Iran) listed in Table (1). A 25-μl reaction mixture [contained 3μl of DNA, 1μl of each primer, 13μl of Master Mix 2X (SinaClon, Iran) and 7μl of deionized distilled water]. The experiment was continued according to the following program: initial denaturation at 94°C for 5 minutes, followed by 35 cycles at 94°C for 1 minute, 60°C for 1 minute, 72°C for 1 minute and final extension at 72°C for 5 minutes. The PCR products were analyzed using gel electrophoresis (1% agarose), stained with safe dye and visualized by Gel Doc apparatus (BioRad, USA) Table (1).

**Results and Discussion**

**Isolation and Identification of *Acinetobacter baumannii***:
Out of 276 clinical and environmental samples analyzed for the presence of *Acinetobacter baumannii*, the results of bacterial isolation and identification revealed the detection of 52 isolates of *A. baumannii*. By using some biochemical tests, results showed negative results for oxidase test, motility test, indole production and urease production tests, while (52) isolates were positive for catalase and citrate utilization tests, the other (*Acinetobacter pittii, Pseudomonas aeruginosa, Klebsiella pneumonia*) isolates were identified as other strains. All isolates appeared as Gram-negative coccobacilli and occasionally arranged in diplococci.

**Biochemical tests:** All isolates showed negative results for oxidase, motility, indole production and urease production tests, while the isolates gave positive results for catalase and citrate utilization tests. Kligler iron agar developed an alkaline slant, no change bottom, H₂S negative without gas production. Also when *A. baumannii* isolates were cultured on MacConkey agar they appeared as small, pale and lactose non fermenter colonies, while on blood agar they appeared as opaque creamy and non-hemolytic colonies (Table 3).

**Table 3:** The Diagnostic results of biochemical test for *A. baumannii*

(+ Positive result; (-) Negative result.)
At the species level, growth at 44°C was positive for all *A. baumannii* isolates which showed the ability to grow at this temperature. This test was used to distinguish *A. baumannii* from other *Acinetobacter* species which were unable to grow at this temperature (7).

The identification was performed with the automated VITEK -2 system using the GN-ID cards which contain 64 biochemical tests. Out of the (52) isolates of *A. baumannii*, 50 were positive for the *A. baumannii* demonstrated.

**Distribution of *Acinetobacter Baumannii* according to type of specimens:** Out of (276) collected specimens, 52(18.8) were positive for *A. baumanii*. The percentages of positive results from burns, environment and wounds specimens were 21.7%, 17.1% and 8.3%, respectively, Table (4).

</tbody>
</table>

Low percentage was found in wound specimens that accomplished 8.3%. Results obtained by (8) reported that the highest percentage of *A. baumanii* isolates were from wounds (23.48%) which was higher than the figure reported in current study. In addition, (9) found that the highest percentage of isolates was obtained from burns (20.6 %). This finding was in agreement with our present findings.

*A. baumannii* is an important cause of burn infections although it is difficult to differentiate between infection colonization of burn sites. On the other hand, because of the high rates of multidrug resistance and the poor penetration of some antibiotics into burn sites, these infections can be extremely challenging for clinicians. Moreover, multidrug resistant *A. baumannii* is the most common cause of nosocomial infection in burn patients in Iran (10). Because of destroyed skin barrier and suppressed immune system, burn patients are at high risk of developing nosocomial infection especially by multidrug resistant gram negative bacteria (11).

**Molecular Detection of *Acinetobacter baumonnii* by bla*\_\_\_\_51*like gene:** The results of PCR analysis, concerning the oxa 51, showed that *A. baumannii* possesses the gene *bla\_\_\_\_51* like gene. Out of 50 positive isolates, 34(20%) were from burn, 12(17.1%) from environment and 6(16.3%) were from wounds (Figures 1 and 2).

**Figure 1:** Agarose gel electrophoresis of PCR amplification products (*bla\_\_\_\_51* like gene) for *A. baumannii*. Lanes 1-13 showed positive results
Figure 2: Agarose gel electrophoresis of PCR amplification products ($bla$\text{oxa51like}$ gene) for Lanes 14-20 showed the 100bp DNA marker

Conclusion

Acinetobacter baumannii is the most common cause of nosocomial infection in burn patients in Iraq.

Isolation of Some Pathogenic Bacteria and Fungi From Student’s Mobile Phones (Part I)

Taghreed Khudhur Mohammed¹, Mohammed Abed Jwad², Ola Kamal³, Ali Hafedh Abbas¹, Ali Shallal Alabbas⁴

¹Institute of Medical Technology, Al–Mansour, Baghdad, Iraq; ²Al-Nosor University, Baghdad, Iraq; ³Tropical-Biological Research Unit, Science College, University of Baghdad, Baghdad, Iraq; ⁴CBRN Division, Iraqi National Security Service

ABSTRACT

Background: Mobile phones are approximately widely used everywhere like in hospital wards, clinics and universities as well as biomedical laboratories. They have become very important tool in students’ life. In contrast, these tools carry many harmful bacteria which are responsible for infectious diseases in human because they serve as a reservoir for different pathogens. Current study was aimed to isolate bacteria from students’ mobile phones at the Institute of Medical Technology/Al-Mansour/The Middle Technical University, Baghdad, Iraq. Also, the study investigated microbial resistance to many antimicrobial agents as well as the appropriate remedial measures.

Method: Four hundred and fifty swabs from mobile phones were collected from 450 students (271 males and 179 females). Their age range was (17-30) years. Swabs were collected from students during March 2018.

Results: Out of the 450 swabs, 150(33.33%) swabs were positive. The percentages of the isolated bacteria according to gender were 53.33%(80 isolates) from males’ mobile phones and 46.66%(70 isolates) from females’ mobile phones. The most frequent Gram-positive bacteria isolated were Staphylococcus aureus (50%) followed by S. epidermidis (20%), whereas Gram-negative bacteria isolated were Escherichia coli (6.0%), Proteus mirabilis (2.66%), Proteus vulgaris (2.66%) and Pseudomonas aeruginosa (2.66%). The isolated bacteria showed variable antimicrobial sensitivity patterns for different antibiotics. Most S. aureus isolates were resistant to Cefotaxime, Gentamycin, Amoxicillin, Ciprofloxacin and Augmentin, whereas other isolated species showed the highest resistance to many antibiotics of interest. The isolates of Micrococcus spp. were sensitive to all the studied antibiotics except Tetracycline and Fucidic acid.

Conclusion: The present findings indicated that contaminated students’ mobile phones could serve as reservoirs of bacterial agents. Also, most of the latter were resistant to many commonly prescribed antimicrobial agents.

Keywords: Mobile phones, contamination, pathogenic bacteria, Gram-positive bacteria, Gram-negative bacteria.

Introduction

The hands and mobile phones (MPs) of students and faculty members in most universities around the world played an important role in infections transmission. Previous studies in Iraq and other countries showed that MPs have a role in the transmission of bacteria. Mobile phone has become an essential item in hospital wards, clinics, medical laboratories, universities and even in operation rooms and toilet. So, it became a reservoir for pathogenic microorganisms causing different diseases especially those associated with skin [¹].

Many microorganisms are presented on human skin, respiratory and gastrointestinal tracts as normal flora...
like *Staphylococcus epidermidis* and *Staphylococcus aureus*. Skin and noses of healthy people have 20-25% *S. aureus*. Also, hands serve as a major transmission vehicle of various pathogenic bacteria, parasites, fungi and viruses including the enteric species. *Proteus mirabilis, proteus vulgaris, Escherichia coli* and *Pseudomonas aeruginosa* are the most common Gram-negative bacteria caused nosocomial infection, urinary tract and wound infections, in addition to meningoencephalitis and osteomyelitis. All these microorganisms can be isolated from MPs. In Turkey, many researchers studied bacterial contamination of MPs in teaching hospitals. They isolated *Escherichia coli, Enterococcus faecalis, Pseudomonas aeruginosa, Pseudomonas fluorescens, Klebsiella pneumoniae* and Methicillin-Resistant *Staphylococcus aureus* (MRSA). Also, another study in Morocco revealed that all samples from MPs had 66.6% *Klebsiella pneumoniae* and 33.3% *Escherichia coli* that were resistant to many antibiotics. Although, MPs have become essential items in human life, it increased the spread of pathogenic microorganism from person to another through contact and held close to the face especially in students’ communities. Therefore, this study was conducted to detect bacterial and fungal contamination of student’s MPs at the Institute of Medical Technology/Al-Mansour/The Middle Technical University (IMT/M/MTU) in Baghdad, Iraq. Also, the study investigated microbial resistance many antimicrobial agents as well as to take the necessary remedial measures.

### Materials and Method

#### Sample collection:
A collection of 450 swabs were collected from 450 students’ MPs (271 swabs from males’ phones, and 179 swabs from females’ phones). The swabs were collected from the covers of MPs of students studying at Pathologic Analysis, Medical Instrument, Pharmacology, Ophthalmology and Health Management departments at IMT/M/MTU/Baghdad, Iraq (Table 1). The samples were immediately transferred to the laboratory for culturing on enriched selective culture media.

#### A. Isolation and Identification of pathogenic microorganisms:
The swabs were inoculated in Brain Heart infusion (BHI) broth, as an enriched culture medium to increase the number of bacteria before isolation on a selective culture media, and then incubated at 37°C for 18-24hr, then they were cultured on Blood agar, MacConkey agar, Nutrient agar and Eosin Methylene Blue agar. Gram stain and biochemical tests were conducted by using API 20E, API staph. In addition to detecting the growth of *S. aureus* on Mannitol salt agar. Oxacillin testing was done for identification of MRSA and the result was interpreted according to Clinical Laboratory Standards Institute guidelines.

#### B. Antibiotics susceptibility test of the pathogenic bacteria:
The sensitivity test of bacteria was done by using antibiotic discs (Cefotaxime 30μg, Gentamycin 10μg, Streptomycin 10μg, Ciprofloxacin 5μg, Amoxicillin 10μg, Augmentin (Amoxicillin/Clavulanic acid) 20/10μg, Tetracycline 30μg and Fucidic acid 90μg) (Table 2).

C. Statistical analysis: The statistical analyses were done by using the WinPipe computer program (version 11.65). Pearson’s chi-squared test and Fischer’s exact probability were used to express the significant differences among bacterial and fungal isolates.

Results and Discussion

Out of the 450 collected swabs, 271(60.22%) were from male students and 179(39.77%) were from females, 150(33.33%) swabs were positive for culturing of pathogenic bacteria (Table 3). The distribution of bacterial isolates percentages according to gender showed that 53.33%(80 isolates) were from male’s phones and 46.66%(70 isolates) were from females. The most frequent bacterial isolates were S. aureus (50%) followed by S. epidermidis (20%). The Gram-positive bacteria were S. aureus isolate, while the gram-negative bacteria were E. coli (6%), Proteus mirabilis (2.66%), Proteus vulgaris (2.66%) and Pseudomonas aeruginosa (2.66%).

</table>

Also, the results showed that the percentage of S. aureus bacteria was 64.28%(45 isolates) from females’ MPs and 37.5%(30 isolates) from males. In addition, most females in the study have been infected with acne, so the potential contamination of these MPs might have come from the face and this is very dangerous in bacterial transfer to healthy persons. In contrast, S. epidermidis percentage in males’ phones was 26.25%(21 isolates) and this percentage was higher than in females 12.85%(9 isolates; Table 4).

In the current study, we detected that most of students involved in the study used to call their friends when they were in the toilet or when they worked in the Institute’s laboratories during training on bacterial isolation and diagnosis from clinical samples. The highest percentage of bacterial isolates was from students enrolled in pathological analysis department followed by pharmacology department students (Table 5).

The present findings agreed with the results of \cite{12} who demonstrated that the MPs bacterial contamination percentage was high and the results of bacterial contamination distribution according to the gender were compatible with the present results. On the other hand, the decreased contamination percentage in females’ MPs than in males’ may be referred to the fact that most females keep their MPs in their handbags, while males hold their MPs in their palms, laboratory coat pocket or put them on contaminated tables or other surfaces.

The results for the variable antimicrobial sensitivity patterns of the isolated bacteria for different antibiotics. Most \textit{S. aureus} isolates were resistant to Cefotaxime, Gentamycin, Amoxicillin, Ciprofloxacin, and Augmentin, the susceptibility percentages were 55%, 72%, 66.66%, 69.33% and 72%, respectively. Also, the results demonstrated that \textit{S. epidermidis} isolates were resistant to Cefotaxime, Gentamycin, Ciprofloxacin, Amoxicillin, and Augmentin, their susceptibility percentages were 66.66%, 66.66%, 96.66%, 83.33% and 80%, respectively. However, \textit{S. pyogenes}, \textit{E. coli}, \textit{Proteus mirabilis}, \textit{Proteus vulgaris}, \textit{Pseud. aeruginosa} and \textit{Bacillus subtilis} showed the highest resistance to many of the antibiotics in question. Moreover, \textit{Micrococcus spp.} isolates were sensitive to all antibiotics under study except Tetracycline and Fucidic acid.

Although MPs are important tools for communication, they have become dangerous tools in transmitting pathogenic microorganisms from one person to another. The high numbers of isolated bacteria from students’ MPs were due to their contact with contaminated surfaces and environment. In the present study, the prevalence of bacteria might be explained that students deal directly with items in the laboratories then contact their MPs with the laboratory benches or even culture media containing bacteria through culturing or examining bacteria. Other studies \cite{13-15} agreed with results of current results and revealed that 21 isolates (17.5%) gave positive bacterial growth and the most frequent bacteria were \textit{S. aureus} (47.6%) followed by \textit{S. Epidermidis} (19%), \textit{E. coli} (14.2%), \textit{Strep. Pyogenes} (9.5%) and \textit{Bacillus subtilis} (4.7%). Also, they referred that MPs could become good tools for nosocomial infections in hospital units. Therefore, the proper decontamination of MPs devices is by using 70% isopropyl alcohol which helps reduce the risk of pathogenic bacteria transmission. Another study \cite{21} reported a high percentage of isolated bacteria from MPs’ handset which appeared resistant to all antibiotics used in that. This finding was incompatible with the results reported by \cite{17,18} who found that \textit{Staphylococcal} species were sensitive to Ciprofloxacin, Clindamycin and Vancomycin.

Gram-positive bacteria isolated from MPs in current study included \textit{S. aureus} and \textit{S. epidermides} that are considered opportunistic pathogens and can cause infections to humans, yet they are considered normal flora of the skin and nose. Many studies approved that \textit{S. aureus} was the most pathogen that causes acne, abscesses, wound, burn infections, impetigo, toxic shock syndrome, pneumonia and meningitis. Also, \textit{S. epidermidis} can cause wound and burn infections. These species of bacteria presented in asymptomatic carrier and can be transmitted from hand to hand via animate or inanimate objects like MPs. Moreover, other species of Gram-positive bacteria isolated from students’ MPs such as \textit{Strept. pyogenes} could colonize the human nasopharynx and often secreted from respiratory tract into the air during coughing and sneezing and may settle on the skin of the hand, so eventually transferred to the surface of MPs causing diseases when entering the human body \cite{19,20}.

\textit{Micrococcus} spp. is a Gram-positive bacterium considered normal flora of human skin and can be transmitted through direct hand to hand contact indirect contact via dust, so it may be found on a MP \cite{21}. Furthermore, \textit{Bacillus spp.} spores can spread in nature, they are found in soil or adhered to dust particles and could contaminate the laboratories and hands of students.

\textbf{Conclusion}

Students’ MPs were colonized with Gram-positive and Gram-negative bacteria which might serve as a potential source of infection for students and other peoples. Therefore, it is important to wash the hands carefully after using a MP and the phone must be cleaned with alcohol to reduce the transmission of pathogenic microorganisms.

Association of Genetic Polymorphism of GNB3 Gene in a Sample of Iraqi Arabs Patients with Type 2 Diabetes Mellitus

Sarah N. Majeed¹, Nagham E. Al-Essa¹, Najwa Sh. Ahmed²

¹Biology Department, College of Sciences for Women, University of Baghdad, Iraq; ²Biotechnology Research Center, Al-Nahrain University, Iraq

ABSTRACT

Diabetes mellitus is one of the most common chronic diseases in nearly all countries, and continues to increase in numbers and significance. Various environmental and genetic factors interact and increase the risk of Type 2 diabetes mellitus and its complications.

The study consist of 105 patients having Type 2 diabetes mellitus and 50 healthy controls, measured some biochemical parameters, genomic DNA extracted from whole blood, and C825T polymorphism was detected by polymerase chain reaction- Restriction fragment length polymorphism (PCR-RFLP) and DNA sequencing of amplified product of GNB3 gene for studies group.

The results of molecular analysis for GNB3 genetic polymorphism shows that the frequency of (CC) genotype in T2DM patients and controls group (5.7%; 4%) respectively and the (CT) genotype (65.7%; 86%) respectively, while the (TT) genotype frequency was (28.6%; 10%) respectively. So, There were significant differences in CT and TT genotype when compared T2DM patients to control group, but no significant in CC genotype. Furthermore the TT genotype nearly (3.6) fold increases the risk factor for T2DM. We also observed that the levels of fasting blood glucose and Triglyceride increased in individuals who have the CT and TT genotypes.

Keywords: T2DM, G protein, GNB3, C825T polymorphism.

Introduction

Diabetes mellitus (DM) mentions to a number of disorders that part the common feature of elevated blood glucose levels. There are two main sub types of diabetes are type 1 diabetes and type 2 diabetes (1). Type 2 diabetes mellitus (T2DM) is the most common type of the disease affecting 90% to 95% of persons with diabetes results from an imbalance between insulin sensitivity and insulin secretion (2). T2DM is one of the most prevalent metabolic disorders worldwide, the prevalence of diabetes worldwide has increased dramatically and in Iraq approximately 668,000 adults affected in year 2000 and this is expected to rise to 2 million by 2030 (2,3).

T2DM is not a single disease but a heterogeneous disease. Some 90% of cases of T2DM have multifactorial pathogenesis resulting from complex interaction between unhealthy life style habits (over nutrition, lack of physical activate, obesity, etc), and 10 % of cases genetically determined (4). The hereditary component makes susceptibility to the disease is very strong. Several genetic loci are probably involved in this susceptibility. Therefore, T2DM is due to from interaction of both genetic and environmental factors (5).

(G proteins) Guanine Nucleotide Binding Proteins are a group of proteins implicated with second messenger, that transmit signals from numerous hormones, neurotransmitters, chemokines, and autocrine and paracrine factors. Heterotrimeric G proteins consist of 3 subunits – alpha (α), beta (β) and gamma (γ). The
beta (β3) subunit encoded by the GNB3 gene in human. GNB3 gene that is existent on chromosome 12 and is composed of 11 exons and 10 introns. The polymorphism (C825T) occurs due to the replacement of cytosine to thymine in 825 position(6). This polymorphism induces the happening of a splice variant in which in exon 9 the nucleotides 498–620 are deleted. This deletion causes a lack of 41 amino acids of exon (9). The C825T polymorphism is known to be related with enhanced signal transduction through the G protein system (8).

Several studies have evaluated the association between GNB3 C825T polymorphism and obesity (9), (10), hypertension (11), (12) and cardio vascular disease CVD(13), (14).

The aims of this study was compared the genetic distribution of genotypes of GNB3gene between type 2 diabetic patients and non-diabetic subjects, and evaluates the association between genetic polymorphism in GNB3 gene and some risk factor in the etiology of type 2 diabetic

Our study is the first in Iraq that evaluated the association between genetic polymorphism of GNB3 gene and T2DM patients.

**Materials and Method**

The study consisted of 105 patients having T2DM (50 males and 55 females; mean age 55.2 ± 8.0) and (50) healthy controls (25males and 25females; mean age 56.4 ± 9.2). This study was carried out at The Specialized Center for Endocrinology and Diabetes (AL-Kindy Hospital) in Baghdad-Iraq.

**Collection of blood samples:** Blood samples were collected by taking blood from each patient and healthy human by vein puncture, between (8.30-11.0) A.M after fasting. The total collected blood (5ml), it was divided into two tubes: (3ml) for biochemical tests and (2ml) for DNA extraction.

**Genomic DNA extraction and genotyping:** The DNA of the samples was extracted according to instructions (DNA purification kit, ITRON), the DNA isolation from 200µl from the whole blood cells; all samples showed bands when the electrophoresis of gel. The polymorphism of the GNB3 gene was detecting by using PCR-RFLP according the method by Chandrasekaran in 2012 (15). The total volume of reaction mixture of PCR was contained in 25µl, consisted of 1.5 µl genomic DNA, 5 µl master mix, 16.5 µl D.W. and 1 µl of each primer. GNB3 forward were 5’ TGA CCC ACT TGC CAC CCG TGC 3’ and GNB3 reverse were 5’ GCA GCA GCC AGG GCT GGC 3’. The condition were: initial denaturation at 94°C for 3 min, followed by at 35 cycle program with denaturation at 94°C for 30 S, annealing at 68°C for 30 S, elongation at 72°C for 30S and final elongation at 72°C for 7 min. The PCR product was then electrophoresed on 2% agarose gel in 1X TBE buffer; DNA band was imagined by electrophoresis to observed at level 268bp. After PCR, five microliter of PCR product was digested with one microliter (ten unite) of the restriction enzyme, BsaJI (Bacillus stearothermophilus J695) (Biolabs) incubation at 60°C for 60min. The digested fragments were electrophoresed on 3% agarose gel mixed with red stain to visualized. Then, sequencing of amplified product of GNB3 gene for studies group.

**Statistical Analysis:** In this study The data were expressed as mean ± SD, the significant differences were showed by using ANOVA table through using the statistical analysis program IBM SPSS version 24, Pearson’s chi-square, Fischer exact probability, odd ratio were used to expressed the significance between the studied groups for polymorphisms and related parameters by using the portable statistical program WinPepi version 11.65, while for genotyping and allele frequency calculation, the online Hardy-Weinberg equilibrium calculator was used.

**Results**

The amplified DNA products were digested with BsaJI either in retention of the 268 bp product or complete digestion to (114, 154 bp) fragment. The PCR product with C allele, presence of cytosine at position 825 the enzyme has restriction site the fragment was digested into two fragments(114, 154 bp), while the PCR product with T allele remained undigested (268 bp) because the fragment lost restriction site, whereas PCR product with CT genotype was gave three fragments (114, 154, 268 bp). Figure (1). To further confirm the PCR-RFLP result, the DNA sequence analysis using forward and revers primers was also preformed Figure(2).
Figure 1: Photograph of the PCR products of the GNB1 gene after BsaJI enzyme digestion and electrophoresis at 3% agarose gel. Show lane M: (Ladder) DNA molecular weight marker, (4,8,12) homozygous (CC-114 bp and 154 bp), lane (6, 7, 9, 10, 11, 13) heterozygous (CT- 114 bp, 154 bp, 268 bp). and lane (1, 2, 3, 5) homozygous (TT-268 bp).

Figure 2: Photograph of sequencing GNB3 gene. A: CC homozygote, B: CT heterozygote and C: TT heterozygote.

Table (1) shows the distribution of GNB3 polymorphism in total patients compared to control groups. Finally, Table (2) shown the mean of fasting blood glucose and lipid profile of patients according to genetic polymorphisms of GNB3 gene.

Discussion

In this study, we want to find if there is a coexistence between the C825T polymorphism and T2DM in Iraqi Arab patients. It may be the first study of association between T2DM and GNB3 polymorphism in Iraqi population. According to Table (1), the C allele and CT genotype showed decreased frequency in patients comparing in control while the T allele and TT genotype showed an increased frequency in patients, which means that CT genotype was considered to be a protective factor because of the rate of OR in patients have only T2DM when compared with control less than one (0.09), but the TT genotype was considered risk factor and had 3.6 times increased a risk for T2DM, while the CC genotype revealed that it has no role in the susceptibility of the disease in our studied group. The pathogenesis of the C825T polymorphism depends on the fact that the 825T allele of GNB3 is related to enhanced stimulated G protein activation, and it is established that G proteins play roles in many path physiological mechanisms which contribute of T2DM (16).

According to these results GNB3 C825T polymorphism may be associated with T2DM. Other studies were in agreement with this finding. Kiani et al., (2005) (17), noticed that the 825T variant showed a positive association with the risk of T2DM in Emirati population. Another study on Canadian population showed significant association of GNB3 polymorphism with type 2 diabetes (18), also it has been found a significant association of the genotypes TT and CT with T2DM in Japanese population (19). On the contrary, this association with T2DM has not been replicated in North Indian subjects (20), and Greek (21).

One of the most valuable results of our study was the observation of a significant relationship among the C825T polymorphism and Triglyceride (TG) in patients. The mechanism that explains correlation of GNB3 gene with serum lipid level is not fully understood; a study suggests that C825T polymorphism of GNB3 might be associated with abnormality in serum lipid metabolism (22). This finding corresponds to previous studies for example Moiseenko and Prystupa, (23), who showed there was an association between C825T polymorphism of GNB3 gene and levels of blood lipids in patients with hypertension. And Lee et al. (24), revealed that the boys and girls with the T allele have higher TG than C allele carriers in obesity Korean children. Also, Ko et al. (25), noticed that in obese Korean women with T allele have a higher serum lipids. While we observed the means of (TC, HDL, LDL and VLDL) no significant polymorphism of GNB3 gene. This agrees with many studies that showed no significant increase in some or all lipid profiles (26, 27, 28). The difference that appeared might be revealed to the small numbers of the selected studied groups, the variety of genetic polymorphisms is due to ethnic differences and to additional factors that are associated with the disease susceptibility.

Conclusions

Our result revealed The CT genotype has more frequency in this study groups and the GNB3 gene polymorphisms may play an important role in type 2 diabetes mellitus pathogenesis and the TT genotype increases the risk factor for T2DM without complication(G1) more than T2DM with complication (G2).

Association of Interleukin-6 Level with Some Clinical Parameters in Iraqi Juvenile Idiopathic Arthritis Patients

Sawsam Jassim Al-Harbi1, Kareem Hameed Rashid2, Maysaa Adil Hadi2

1Department of Anatomy, College of Medicine, 2Department of Biology, College of Science, University of Babylon, Iraq

ABSTRACT

Interleukin-6 (IL-6) is the major pro-inflammatory cytokine, which exerts multiple effects within the disease activity in juvenile idiopathic arthritis (JIA) and rheumatoid arthritis (RA) patients. The aim of this study was to evaluate the association of IL-6 with some clinical parameters in JIA and RA disease Iraqi patients. A case-control study involved (86) patients with JIA and RA disease, who visited Merjan Teaching Hospital in Babylon. All patients and control had the same ethnic group (Arabic). The serum IL-6 level was measured by ELISA kit.

Results: The female gender was more frequent in rheumatoid arthritis. The percentage of uveitis was decreased (11.4%) in JIA compared with RA (25.5%). IL-6 serum level was significantly elevated (P≤0.05). There was significant decreasing in the mean of ESR in JIA patients (35.74 ± 15.28) in comparison with RA patients (68.78 ± 25.09).

IL-6 assessment in both JIA and RA patients can be helpful in determining the activity of disease, and plays a significant role in its relationship with both rheumatoid disease (JIA and RA).

Keywords: Juvenile Idiopathic Arthritis, Rheumatoid Arthritis, Interleukin-6, Uveitis.

Introduction

Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood and is of unknown origin and etiology [1]. The disease spectrum consists of various clinical conditions. Endogenous and exogenous antigens with increased inflammatory response have been shown to play a central role in the pathogenesis of the disease [2, 3]. Interleukin-6 is a multifunction cytokine that has a wide range of biological activities in various target cells and regulates immune responses [3]. Human IL-6 is a soluble mediator with a pleiotropic effect on inflammation, immune response, and hematopoiesis [4, 5]. The cytokine IL-6 is a four-helical glycopeptide that was initially identified as a T cell derived cytokine capable of inducing B lymphocyte differentiation into Ig-producing cells and was named B cell stimulatory factor-2 [6, 7]. Elevated serum IL-6 has been observed in patients with these diseases and the IL-6 levels correlate with disease activity although there are differences in IL-6 levels among the diseases [3]. It is found at high levels of IL-6 in the synovial fluid, and is associated with indicators of inflammatory activity such as ESR and C-reactive protein (CRP). In addition to classical activation of IL-6 response through binding a membrane-bound IL-6 receptor (IL-6R) [8].

Materials and Method

This case-control study involved (35) JIA patients selected from Merjan teaching hospital (14 male and 21 female) with age ranged from (1-18 years). The JIA patients diagnosed by physician according to the International Study Group ILAR classifications of childhood arthritis [9]. In addition, (47) adult RA patients (4 male and 43 female) with age ranged from (25-76). The control group included apparently healthy and age-matched (57) subject included (30) children with age
range (1–18 years) and (27) adult with age range (25-60). All patients and control were from the same ethnic group (Arabic). The level of (IL-6) was measured in serum by using ELISA kit (Elabscience.com).

Statistical Analysis

Statistical analysis was carried out using SPSS version 20.

Discussion

In the current study, measuring of IL-6 level in serum with JIA and RA disease and comparing with control group shows significant increasing of IL-6 between all rheumatoid arthritis group (P<0.001) compared with control group and between JIA and RA patients compared with their control groups. Firstly, IL-6 has previously been shown to be correlated with the efficacy of the disease in JIA, and most notably in systemic JIA, where it has been proposed as a key mediator of the disease process [9, 10]. This interpretate the high levels of IL-6 in the serum of both JIA and RA than control group. This is an observation supported by previous study [11]. Furthermore, plasma levels of IL-6 are significantly higher in RA patients than controls [12]. Chronic high levels of IL-6 are found in the synovial fluid and serum of patients with RA [13]. Secondly, the IL-6 level is correlated with disease activity may be improve by IL-6 inhibition, as appear by JIA and R, however IL-6 is involved in liver regeneration and intestinal epithelium protection so it is possible that elevated levels of IL-6 product organs from damage or promote recovery from dysfunction [14]. After all, this study had found a statistically differences between all of the patients group corresponding type with gender (p≤0.00). This study has also showed that there were non-significant alteration between the means of IL-6 according to the duration of disease and subtype of arthritis. Consequently, it is found that the excess transmission from IL-6 only to systemic JIA patients with age at onset (5) years and no significant association found with the other subtypes. However, these findings in consistent with the other studies by [15]. As a matter of fact, higher mean of IL-6 (82.04 ± 17 pg/ml) in JIA than RA patients (76.88 ± 8.54 pg/ml) although it was non-significant and when the patients were grouped by subtypes of arthritis, the higher mean of IL-6 was in polyarthritis (80.87 ± 12.90 pg/ml) in all rheumatoid patients and (83.08 ± 16.54 pg/ml) in JIA patients than other subtype. These finding is accepted with other study [16]. IL-6 has previously been shown to be associated with the activity of disease in JIA [17]. Most notably in systemic JIA, where it has been proposed as a key mediator of the disease process and anti-IL-6 therapy, it has recently shown to be effective in treating this subtype [18]. IL-6 is associated with the activity of the disease in JIA found at higher level and is associated with the indicators of inflammatory activity such as ESR. Thirdly, significant increasing (P<0.001) in the level of ESR in all patients compared to control group although non-significant correlation between IL-6 and ESR among the
patients. Also, significant decreasing in the mean of ESR in JIA patients (35.74 ± 15.28 mm/hour) in comparison with RA patients (68.78 ± 25.09 mm/hour). These results agreed with [19], who recorded that overexpression of IL-6 controls development of chronic inflammatory diseases, such as rheumatoid arthritis, ESR and CRP levels have also been used as markers of inflammation, while it is a useful marker for evaluating disease activity; it is a non-specific measure of inflammation [20]. Uveitis, typically chronic anterior uveitis, is the most common extra-articular manifestation in JIA patients and JIA is the most common systemic association of uveitis in children [21]. In the current study, (11.4%) of JIA and (25.5%) of RA patients were diagnosed with uveitis, children are less likely to be infected with uveitis twice as much as RA. This maybe belongs to the hygienic awareness and parent’s fear on their children and looking after them in order to prevent the infection in Uveitis [22]. This result may be correlated with the increasing level of ESR in rheumatoid patients as indicated by previous report, which revealed that elevated ESR appears to be a predictor for the occurrence of uveitis in patients with JIA [23].

Conclusion

These results had provided important and novel data on the levels of IL-6 during active JIA in Iraqi patients.

Assessment of Alpha Ketoglutarate Dependent Dioxygenase Levels in Different Genotypes of ALKBH9 Gene in Patients with T2DM in Babylon Province

Mena Y. Abd¹, Hamzah H. Kzar², Manal M. Murad²
¹Biomedical Engineering Department, University of Warith Al anbiya’a, Iraq; ²Department of Chemistry and Physiology, Veterinary Medicine, Al-Qasim Green University, Iraq

ABSTRACT

Diabetes mellitus (DM) can be describing as a metabolic changes that characterizing by chronic hyperglycaemia and imbalance of carbohydrates, fats and proteins metabolism resulting from disorders in pancreatic secretion of insulin, action of insulin, or both. Development of T2DM can be attributing to the both effects, the genetic an environmental factors. The enzyme encoded by the ALKBH9 gene in human genome that located on chromosome sixteen is Alpha ketoglutarate dependent dioxygenase.

A case-control study of 45 patients with T2DM and 45 healthy controls was conducted at the Al-Qasim hospital in Babylon province. We analyzing the allelic frequency of ALKBH9 genetic polymorphism in study cases. AKDD levels was measuring by ELISA method while SNP of ALKBH9 was investigated by PCR-RFLP method.

The results of this study shown highly significant increase in the levels of serum AKDD in patients group comparing to control group (17.9 ± 1.7 vs. 11.2 ± 1.2). The allelic frequency of A allele was 68% compare to 32% for T allele in patient group. The results of this study showing highly significant differences in levels of AKDD in comparing to risk factors such as ages, genders, smoking, and obesity status (p-value < 0.001). In conclusion, there many risk factors increase the frequency of AA allele comparing to AT, and TT alleles in patients with T2DM in Babylon population, Iraq.

Keywords: Diabetic mellitus type2, ALKBH9 gene, SNP rs9939609.

Introduction

Diabetes mellitus (DM) can be describing as a metabolic disorder that characterizing by chronic hyperglycaemia and changing of sugars, lipids, and proteins catabolism and anabolism that resul from disorders in pancreatic secretion of insulin and insulin resistant (¹). Advancement of T2DM can be crediting to the two impacts, the hereditary and an ecological elements (²). A non autoimmune, heterogeneous and polygenic metabolic disorder has been accurse in T2DM (³). The enzyme encoded by the ALKBH9 gene in human genome that located on chromosome sixteen is Alpha ketoglutarate dependent dioxygenase (⁴). The first mRNA demethylase that has been identified is AKDD because it is one homolog in the Alk-beta family proteins, and specific different forms of ALKBH9 gene appear to be connected with over weight in mammalians (⁵). Alk-beta which oxidative demethylates sequence of an amino acids is similar to the amino acids sequences of alpha ketoglutarate dependent dioxygenase protein (⁶,⁷). The ALKBH9 gene is excessively expressed in both of adult and fetal tissues (⁸). ALKBH9 expression with Small interfering RNA leading to increased amounts of methylation of polyA tails (⁹). The genotyping of the ALKBH9 gene are also suggested by other studies to correlation with overweight and obese subjects having...
high body mass index \cite{10,11}. Speakman JR et al. (2008) was suggesting that human with allelic genotypes AT and AA of ALKBH9 gene at rs9939609 sequence those that consuming the range of (500 -1250) kilojoules in calories more each day than those having the TT genotype \cite{12}. The similar studies showing that there were no effects of the single nucleotide polymorphism of ALKBH9 gene on cost of energy. The finding of an effect of the AA, AT, and TT genotyping on food intake were described by many studies \cite{13-17}. The effects of variation in two different SNPs in the ALKBH3 gene (rs17817449 and rs1421085) was exploited by Do R et al. (2008) and there were suggesting the effect on levels of leptin in circulation and energy requiring \cite{18}. The aim of this study to investigating of rs9939609 SNP of ALKBH9 gene and comparing the genotypes AA, AT, and TT with different risk factors in patients with T2DM in Babylon province.

Materials and Method

The current study was done in the laboratories of Chemistry Department, Veterinary medicine, Al-Qasim Green University. The patients group including in this study were 60 patients, the range of age was (40-65 Y), the mean ± standard deviation (SD) was (49.3 ± 3.5 Y). This group included of males (58%), with their age ranging from (40-62 Y), the mean ± SD was (49 ± 6.4 years), and females (42%) with age ranging from 44-65 years, and mean ± SD was (47.1 ± 7 Y). The control group was 60 subjects (37-59 Y).The age and gender of control group were matching to age and sex of patient group. The statistical analysis showing no significant differences in the age and gender between two groups (p> 0.05). Each patient and control subject who participate in the current study submit full history asking: age, gender, smoking, education, family history of diseases and drug used.

Mesurment of AKDD: Alpha ketoglutarate dependent dioxygenase (AKDD) concentration was measured by using ELISA kit and the method performed depending on the manufacturer’s protocol.

Analysis of ALKBH9 gene: The AccuPrep Genomic DNA Mini Kit (Bioneer, Korea) provides an optimal protocol for extraction and purification of the genomic DNA from whole blood. Proteinase K and the specific buffers were used to lyses cells and destruction of proteins. Amplification conditions of amplicon (182bp)(40 cycle) of ALKBH9 gene was performed by polymerase chain reaction (PCR) depending on the method that described by Lo’pez et al(2008)(19), The following pairs of primes (forward and reverse) were using in PCR analysis:

\[
5'\text{-}AACTGGCTCTTGAATGAAATAGGATTCAG A\text{ -3'}F\text{-}primer
\]

\[
5'\text{-}AGAGTAACAGAGACTATCCAAGTGCAGTAC\text{ -3'}R\text{-}primer
\]

The investigation of the SNP in the ALKBH9 gene is done by PCR-RFLP in patients with T2DM and control groups involved in this study by using ScaI as restriction enzyme (RE). gel electrophoresis was running the final products on a 2.5%, the T allele generated a 182bp band and the A allele generated 154 and 28bp bands, as shown in figure(1). The restriction site of ScaI was:

![Fig. 1: Electrophoretic picture represents the PCR-RFLP by RE(ScaI) of ALKBH9 gene(182, 154, and 28bp)](image)

Results

Clinical pathological information of the patients with T2DM(n = 60) whom including in the current study were classified into two groups according to (age, gender, Family history, Smoking behavior, Obesity status) (Table 1).

### Discussion

The long-term of metabolic disorder has been characterizing by hyperglycemia, resistance of insulin, and relative decreasing in insulin levels is diabetes mellitus type 2 (T2DM) (20). The common symptoms in T2DM are increasing thirst, frequent of urination, and unexplained weight losing (21). ALKBH9 is a gene that coding AKDD protein and the diseases associated with its AA, AT, and TT genotypes were including growth retardation, developmental delay, and facial dysmorphism (22). There is a considerable lack of information from the Arab region including Iraqi and Babylon population regarding the role of SNP gene polymorphisms of ALKBH9 gene and many risk factors related in patients with T2DM. Polygenic obesity is recorded by SNP of ALKBH9 gene causing and the strongest associations between ALKBH9 SNPs and body mass index are belong to intronic SNPs, which may be have the main role in the regulation of ALKBH9 gene. The risk alleles of ALKBH9 gene are located within a 47 kb at first two introns and exon 2 and these locations are associated with obesity and high body mass index (24). The effect of ALKBH9 gene polymorphism (AA, AT, and TT) on phenotypic parameters such as obesity status, age, and gender shown an important differences between the three alleles of (AA, AT, and TT). The results of present study is agreement with the previous study that showing significant differences on phenotypes that discuss by Hussein G. Osman et al., 2014 (25). By using the allele frequency analysis that described by Moead E Al-Gazally et al.(2016), the rs9939609 SNP of three genotypes were found(AA, AT, and TT) and they were significantly association in the development of T2DM by increasing the levels AKDD (26). ALKBH9 mRNA was found to be abundantly expressed in the brain tissue of wild-type mice, particularly in hypothalamic nuclei governing energy balance (27). Another studies discussing the effects of genetic polymorphism on the different types of diseases to explaining different cases (28-30). In this manner, it is possible that the ALKBH9 quality may control the pathogenesis and advancement of corpulence basically through its effect on the energy controlling center of the hypothalamus. Few studies have investigated the rs7195539 locus in FTO. Loci rs8050136 and rs9939609 were reported to associated with T2DM in multiple studies, yet there is some inconsistency (31). This association has been reported to be both mediated by BMI (32).
**Conclusion**

There are many risk factors increase the frequency of AA allele comparing to AT, and TT alleles in patients with T2DM in Babylon population, Iraq.

Musculoskeletal Trends Over Physical Therapy for Curing Knee Injuries

Abdul-Samad Uleiwi Hassan¹, Rawiyah Abdulla Salman², Zahraa Falah Abd-Alaali³
¹Clinical Pathology Department, ²Sport Unit, Health & Medical Techniques College, Al-Forat Al-Awsat University, Iraq

ABSTRACT

Our study was applied a special mechanical curing idea as a tool treatment that’s fixed as a biomechanical theory to recover about 35 cases of football players who had got knee injury of several degrees. By using leg extension instruments we will apply gradual forces to the lever system to rebuild the knee joint.

Conclusions of our tests prove that biomechanical engineering of knee responds positively for physical application during injuries.

Keywords: knee, physical therapy, musculoskeletal system, sport

Introduction

Knee’s injuries in footballer are a conditions those occurs due to sport activities. The most predominant injury is anterior cruciate ligament which often occurred during sports activities; like soccer, football, and basketball. Rapid direction change or docking from a jump inaccurately can crack the ACL. About 60% of all abuse to the anterior cruciate ligament appear along with damage to other parts in the knee, such as articular meniscus, cartilage, or other ligaments (¹).

Leg extensions are workouts mostly performed with a lever machine. You sit on a stuffed seat and hike a stuffed bar with the legs. The workout activates mainly the quadriceps muscles of the front of the thigh—the rectus femoris and the vastus muscles (²).

Technically, this is an “open chain kinetic” training, which is dissimilar from a “closed chain kinetic activity,” i.e., squat (³).

Aim of our project is to explain the physical theory of lever, fulcrum and load in treatment ACL cases.

Materials and Method

1. Site of tests done in Arnold institution for body building sport in Najaf city, particularly in Al-Tadhamon FC club, Central educational hospital while investigations in Baghdad city include Ibnul-Haitham center for magnetic resonance imaging.

2. Model designation: 16 players aged 20 to 25 years old have knees injury compared with the same number of controls at the same time from 1/9/2018 to 1/2/2019.

3. Physical tests administered through using leg extension machine with a limited extended scale under control rod.

4. Radiology tests were applied by using magnetic resonance imaging (Buff, etal. 2018).

Results

MRI imaging of ACL tears should be explained secondary signs. Look figures 1 below. Secondary shows bone contusion, anterior drawer sign, arcuate sign, reduced PCL and lateral collateral ligament injury.

Anterior cruciate ligament rupture here may be without (a,d) and with (b,c) fat saturation shows waviness and a cloud-like appearance with an abnormal course of the fibers of the AC.
The force is applied between the fulcrum and the load. Therefore the load lever arm is always greater than the force lever arm. A classic example is a pair of tweezers or a diving board. Mechanical Advantage = Less than 1.

Our experiments was not used a sensor system for fitted naturally with the mechanics of machine and the biomechanics of legs and knees. An athlete performs a leg extension on a machine using a less kg mass at A located 350mm away from the knee joint center. The leg is moving at a constant angular velocity of 30 degrees per second when $\theta = 60^\circ$ (Figure 2).

### Figure 1: The MRI of ACL for 4 players with different cases of secondary type signs

### Figure 2: The biomechanics of knee’s injury players explaining the levels of curing mechanism
Discussion

Secondary signs include proved by MRI bone contusion in lateral femoral condyle and posterolateral tibial plateau, >7 mm of anterior tibial translation, also known as the anterior tibial translocation sign or anterior drawer sign, uncovered posterior horn of the lateral meniscus, Segond fracture, and to a lesser degree arcuate sign, reduced PCL angle due to buckling of PCL, positive PCL line sign and medial or lateral collateral ligament injury (6,7).

When an leg extension exercise using a cushion disposed under the injured knee is did, the quadriceps and hamstring muscles give force to press the leg into this cushion, creating a cushion reaction force and, an ankle reaction force, if the ankle is restrained. With a given cushion force Fr, the hamstring force and the quadriceps force can be obtained by solving the governing equations for a given CY and an assumed value for 6. Giving numerical values for several cases make discuss the implications of our theoretical results possible (8,9).

We apply a cushion force of 12-24 kg and suppose that it is equally distributed between the femur and the tibia (ie. q = OS): The hamstring force F, the quadriceps force f, the shear force FSf, and the compression force FF at the femoral-tibia contact point are calculated for both the case of the loose ankle (u = 0) and the restrained ankle (a = 0.35) at flexion angle (Y = 5°, 15°, and 30°). The results shows that without the ankle restraint the hamstring force is much greater at each flexion angle than with the ankle restraint, whereas others shows that without the ankle restraint the quadriceps force is always less at each flexion angle than with the ankle restraint. The variation of both the quadriceps force and the hamstring force over the flexion angle range is not significant for either the case of the loose or the restrained ankle. Clearly, the ankle should not be constrained if the main purpose of the exercise is to strengthen the hamstring muscle, but the ankle should be restrained if the main purpose of the exercise is to strengthen the quadriceps muscle (10,11).

Conclusion

Biomechanical engineering of knee responds positively for physical application during injuries.

ABSTRACT

The study aimed to prepare a proposed negotiating approach to develop the skills of negotiation and crisis management for the leaders of the Middle Euphrates Clubs. The program consists of 4 weeks with two units per week. The unit time is 120 minutes, divided into two parts (60 minutes - 10 minutes rest - 60 minutes) the researcher then applied the criteria (negotiation skills and crisis management) in two stages (tribal and remote) to the sample. The researcher then categorized the results, analyzed them and interpreted them scientifically, and reinforced them with sources that contributed to explain the results more clearly. The proposed effect is evident in the some negotiation and crisis management skills of leaders of clubs. The method of presentation based on an expert system has a clear impact in providing and facilitating information to sample members. It is easy for an individual to learn the skills of negotiation as he has the elements of good education from trainers and a training program scientifically and sequentially.

Keywords: negotiating, managing crises and expert system

Introduction

Most researchers are still urging the pace of finding the most successful modern means and methods of development that enable the workers in the field of sports in particular to develop their intellectual abilities and provide information to the learner or trainee in the simplest and most recent ways.

So we have to think and look for modern and fast ways to learn and gain experience. The use of expert systems is one of the main features of the science of artificial intelligence and its applications. Although there are several definitions of artificial intelligence, the essence is to make the computer think like a human. The expert system has been a prominent place for decades in various scientific and educational fields in different parts of the world. The use of expert systems and knowledge bases built by specialists enables inexperienced sports leaders to benefit from these systems in the development of ideas, address many of the problems they face and make decisions that are difficult for non-experts to take.1

In view of the areas of expert systems and their uses, we find that they have been employed in many sectors, including legal, industrial, agricultural, medical and educational, as well as in the administrative and financial fields also to plan and solve problems and make different decisions. On the mathematical level, we find none. This study is of great importance for the lack of studies. The subject of expert systems in the field of sports. Hence, it was necessary to use these systems to develop and provide negotiating advice and solve the problems facing leaders in the sports field because of the advantages and benefits it offers to those who deal with them and those who use them and their ability to provide high effort and money. This is what prompted the researcher to do this research.2

The importance of this research is evident in the development and activation of the negotiation methods and skills of the Iraqi sports leaders, the management of crises in the field of sports and how to find solutions
using expert systems which is one of the branches of artificial intelligence. This also serves a large sector which is the sports leadership which in turn serves the Iraqi society directly and great.

**Materials and Method**

**Community and Sample Search:** The researcher identified the research community and they are the leaders in the 408 Middle Euphrates clubs, taking into consideration the number of years of service distributed among (5) clubs from Qadisiyah clubs that have been identified for the research community if they constitute (24%) of the total number of society The search is (170) leading.

**Preparation of a proposed negotiating approach:** The researchers prepared a negotiating approach to develop negotiation skills and crisis management on the target sample, taking into account the scientific conditions and proper procedures in preparing it. The contents were then presented to a group of experts and specialists in the field of administration, management and human development. (4) Weeks per week and 2 teaching units at a rate of 120 minutes per unit divided between beginning, introduction, explanation, group work and exercises.

**System Building Procedures Expert:** Expert systems are one of the first applications of artificial intelligence and the most important since the development of the first successful system based on knowledge or experience and used for the analysis of chemicals in 1970 took the idea of producing systems on human experience to spread quickly to other scientific fields because of the amazing results achieved.

The term expert systems consists of two main parts. The first represents systems, which is a collection of the word system, which represents a group of interconnected parts that collect, process, store and distribute information to help control and make decisions within the enterprise. The second part (the expert) is a sign that these systems have experience is the deep knowledge accumulated over time and experience with the facts, rules and procedures in the scope of a particular work.

In other words, expert systems are originally information systems that receive and process inputs to produce outputs that help in decision-making. However, they use and apply prior experience or experience in data processing rather than applying mathematical equations or algorithms for solutions.

Through the previous definitions of expert systems, it is generally agreed that expert systems acquire their ability to act in decision-making, solve problems from the knowledge of human experts, and thus behave - so to speak - as the expert behaves when confronted with a circumstance requiring a specific decision. Expert systems are different from traditional systems. The person who uses them does not necessarily have to be proficient in computer usage. The process of using them starts with directing the user to a question of the expert system, and the system in turn directs user queries (dialogue between the system and the user).³

---

**Figure 1: The components of the expert system**
Team Building and System Development Expert:
By reviewing the components of the expert system, there are a number of people who deal with the system directly and indirectly in terms of construction and use. The following is an explanation of the concept and roles of each team member:

1. **The end user**: Is the person who uses the system after it is developed to help solve the problems or make the decisions that it faces and requires the experience to deal with them, often this person is an employee who does not have the experience to qualify to deal with the situation on his own. It is worth mentioning that the end-user deal with the expert system does not necessarily require a great skill in the use of the computer; it deals with the system through the devices such as (keyboard, screen, etc.) and through the communication with the system by asking certain questions and respond to queries of the system about the situation in question and receive solutions or recommendations ready.

2. **Field expert**: Is the person who has the greatest experience or knowledge in a particular field or field, and is able and skillful in solving problems, and represents the experience that has the basis that will build the knowledge base of the expert system through which should be able to communicate knowledge and also has the desire to participate in Develop the expert system in terms of effort and time required. The field expert is the most important person in the system development team because his experience is the cornerstone of the success of the system.

   It is noted through the concept of the expert of the scope that his dealing with the expert system is indirectly, he actually does not use the system itself, in terms of inputs or outputs, but gives the knowledge and knowledge about the field of expertise to the knowledge engineer, which in turn is introduced and stored on the knowledge base.

3. **Knowledge Engineer**: The knowledge engineer represents the person who is capable of designing, building and testing the expert system and is responsible for selecting the appropriate task for the system. Many personal meetings are held with the domain expert to find out how to solve a particular problem. Through the communication and interaction with the expert, the knowledge engineer determines the methods of thinking used by the expert in dealing with facts and rules, determines how they will be represented in the system and then selects some systems of development programs or establishment of the system of expertise, and selects the programming languages to write the knowledge code. Finally, the knowledge engineer is responsible for selecting, reviewing and integrating the system in the workplace.

   The knowledge engineer works to extract the expertise of the domain expert into a language that can be stored in the knowledge base and plays a major role in the inference engine. It identifies the way in which the inference engine handles data and the type of inference techniques that should be used to answer the system of knowledge is also modified and updated by the knowledge engineer if necessary. It should be noted that the modification and modernization of the system is not usually related to data processing and problem solving but rather by expanding and increasing the information stored within the knowledge base to include new knowledge or expertise not previously addressed.

4. **Programmer**: The individual responsible for the actual programming describes the knowledge of the field expert in a language that can be understood by the computer and therefore must have skills in symbolic programming in artificial intelligence languages such as lisp, prolog and opss. He should also be familiar with traditional programming languages such as C, Pascal, FORTRAN, Pisk.

5. **Project Manager (Researchers)**: Is the leader of the team building and developing the expert system and responsible for the continuity of the project from start to finish of running the system successfully. It communicates with the field expert, knowledge engineer, programmer and end-user.

**Main Experience**: After the completion of the procedures for the preparation of the scale and design of the system and the extraction of sound scientific foundations, the main application was carried out on the sample of the researchers who represent the clubs of Qadisiyah Governorate (40) for the period from
15/7/2018 to 10/8/2018, And configuring the tools to ensure accuracy of the answer on the scale, with the formation of the auxiliary staff. Then, the content and application of the negotiation and crisis management skills development program was presented to a sample of 15 people who had low level of negotiation skills. After the application was completed in two stages (tribal and remote), the researchers categorized the results and analyzed them for the purpose of discussing and interpreting them.

(*) At the level of significance (0.05) and the degree of freedom 14

The results of table (1) show that there are differences between the tribal and remote indices for all the axes of the negotiation skill and crisis management. The value of the calculated (t) for the negotiation method axis was (5.77) and it is at (0.000), And a function at the level of significance (0.000), while the axis of the characteristics of the leader, the value of (t) calculated (5.59), a function at the level (0.005), while the value of (t) axis of crisis management requirements (8.67) The center of the steps of crisis management as the value of (t) calculated (3.32) which is a function at the level of significance (0.013). As for the measure as a whole, the value of (t) calculated (11.61) is a function at the level of significance (0.000). As shown in Figure (2).

![Figure 2: The differences between the tribal and remote indices of the skill of negotiation and crisis management](image)
Discussion

By noting the results of the above table, there is an improvement in the level of negotiation skills and crisis management in the sample of the study, if the researchers attribute this to the effectiveness of the proposed negotiation method by the researchers, which was prepared in a scientific manner and took into account the capabilities of the sample including the best vocabulary and development examples related to negotiation techniques and skills. The crisis as participants recognize during this training program on the knowledge of negotiation crisis management and logic behind the investment of time and effort in planning crises and the most important methods of negotiation and skills, which contributed significantly to change ideas towards the nature of management and this Its consistent with the study, 5 as illustrated, which showed results of the effectiveness of the proposal for the development of the negotiation and self-efficiency skills of social studies teachers in basic education training program, the program also contributed to know the sample on their abilities and aspirations and are more positive. Whose results showed that the development of negotiation skills through open education using the internet in New Zealand has proved effective in teacher development. 6

And the study of which showed that the preparation of programs is important in developing the negotiation skills of the student - the teacher in preparing for success in post-graduation education. 7 the results indicated that negotiation exercises were possible and contributed to the development of students’ critical thinking skills. 8 this is indicated by the results of the post-measurement, (0.05) in most results.

The researchers believe that such a level is good, despite the lack of interest in the early development or development of such skills in various areas of the Iraqi educational and practical environment, and these results confirm that it is possible to learn the skills of negotiation and crisis management well if the circumstances The appropriate program and instructors are of a high level of craftsmanship. 9One of the steps to the success of the negotiation process that the individual learns first negotiating skills, the teacher has scientific expertise in negotiating skills is able to manage the negotiation process in light of the specific objectives and available information and methods and methods that help to achieve the objective of negotiation. 10 and sees that by learning the skills of negotiation, the individual is able to divide the general objective of negotiation into sections of progress according to the importance of each and to achieve the general goal. 11

Conclusions

1. The proposed approach has a clear impact in the development of some of the skills of negotiation and crisis management among the leaders of clubs.

2. The method of submission relying on the expert system has a clear impact in providing and facilitating information to the sample members.

3. It is easy for the individual to learn the skills of negotiation as he has the elements of good education from the trainers and the training program scientific and sequentially.

Effect of High Intensity Training Exercises in the Development of Some Explosive Capacity and Biochemical Indicators of Technical Gamma Players

Sarraa Hasan Kawish¹, Sadeq Yousif Mohammed¹
¹Faculty of Physical Education & Sport Sciencesl, University of Thi-Qar, Iraq

ABSTRACT

The importance of this research lies in the preparation of high intensity training exercises for players and the knowledge of their role. The Problem of Research: The weakness of Physical preparation, The Objective of Research:

1. To prepare ad hoc high intensity training exercises for the development of leg muscles and physiological indicators.
2. To recognize the effect of high intensity training exercises on development of some physical capabilities of leg muscles and the physiological indicators.

The researchers used experimental approach and apply it to 10 players sample as representatives of Al-Muthana Specialist Center. The research lasted for (8) weeks among the important findings with which the researcher has come out is that high Intensity interval Training Exercises have a positive effect on the development of some physical capabilities and physiological indicators of technical gymnastic young players.

Keywords: Training exercises, explosive capacity and biochemical indicators.

Introduction

The modern training methods have varied according to the requirements of physical performance of each athletic activity, especially the muscle strength, because it has a large role in the performance in many sports activities and events, including gymnastic. The method of high-intensity interval training is one of the important ways that can be used to develop physical qualities and bringing about physiological and biochemical changes. However, this method needs high tolerance, so that a trainee should have an internal respite to recover healing. Physical abilities have a clear and significant importance in the sport field for they result in significant achievement and raising the level of technical performance of the athlete, as can be seen in many sport events, including gymnastic, which requires a lot of physical abilities due to the difficulty of performing skills such as the ground carpet movements. Based on this, a gymnastic athlete must be equipped physically and functionally as much as possible because any mistake, however minor, will clearly affect the physical and skilful level of the same player. That’s why the preparation of high intensity training exercises for young gymnastic players is considered the most important starting point for this research, to learn how these exercises will develop physical capabilities and physiological indicators.¹

Based on observations, opinions of coaches, and the interview conducted by the researcher with the coach of the specialized technical gymnastic training center in Muthana, the researcher found that the most important reasons for weakness in the technical performance of the skills are attributable to the weakness of the physical preparation of the physical abilities of legs (explosive ability and distinctive power) Which negatively affects the achievement of a strong push and a high height of the center of the weight of the body and this in turn has adversely affected the application of skills as required.

DOI Number: 10.5958/0976-5506.2019.03168.1
Materials and Method

Research Objectives:

1. To prepare special high-intensity interval training exercises to develop the explosive capacity.

2. To identify the effect of these exercises on the development of explosive capacity of both legs’ muscles and biochemical indicators.

3. To identify the differences between the control and experimental group in the explosive capacity of the legs’ muscles and the biochemical indicators.

Research hypotheses:

1. There were statistically significant differences between the pre and posttests in some physical abilities and physiological indicators of the control and experimental groups.

2. There were statistically significant differences between the pre and posttests of the control and experimental groups in some physical abilities and physiological indicators in favor of the experimental group.

Research Methodology: The researchers used the experimental approach in designing the equivalent control and experimental groups for being appropriate to the research problem.

Research Community and Sample: The sample of the research was represented by the players of the Muthanna Specialist Training Center of the Junior Technical Gymnasium. It consisted of (10) players who were purposefully chosen and were divided by lottery method into two groups: an experimental group and a control group as shown in Table (1).

Tools and Devices used in the Research:

1. Syringe of Blood sucking number: (40).

2. Gel containers for blood-preserving for the sample (Polish-make).

3. Cards to determine the percentages of physiological variables (imported from Italy’s Sentinel).

4. Blood pressure gauge and manual pulse rate (2).

5. FUJIFILM (1).

8. Medical Scale and Ruler for height measurement.

Field Research Procedures: Determination of the explosive capacity under study/after having reviewed a lot of references and sources, the researcher and the supervisor resorted to select the explosive capability.
Determination of the biochemical indicators under study: The researcher and the supervisor selected some biochemical indicators that contribute to the research.

Characterization of the explosive capacity test and the biochemical indicators and measurements used.

Characterization (vertical jump test as per Sargent curve): Anthropometric measurements: the researcher took the measurements of the research sample players.

Biochemical measurements: Blood is drawn out after tension during the relaxing period. The blood sample taken 5CC by a medical paramedic, the blood is placed in tubes to be chemically analyzed by specialists. The blood sample is to be divided into two groups: The first group is placed in anticoagulant tubes, then the blood is treated by Mindray device to detect the percentage.

Exploration Experiment: To identify the difficulties that may be encountered during the main experiment, the researcher carried out two experiments; the first on Wednesday, 11/7/2018, to perform the physical tests, while the second was executed on Thursday, 12/7/2018 by the help of cadre. It was intended to measure the biochemical indicators.

Main experiment: The Pre Tests; the researcher carried out the pre tests before the special preparation period, where the tests were conducted according to the following schedule: on the first day: 20/7/2018 the Anthropometric and physical measurements were taken. On the second day: 7/2018, the biochemical measurements were taken before and after the tension.

Biochemical measurements before tension: Blood sample was taken from the research sample on Saturday 13/7/2018 before tension that is the players are in a state of complete rest without exerting any physical effort.

Biochemical measurements after tension: Blood sample was taken from the player after tension at the same time when the indicators were measured before tension.

Exercises Used: Based on the scientific references, the researchers prepared exercises to train the research sample and to determine the effect of the items of this exercise in the research sample.

1. The first training module was conducted on 22/7/2018 after the pre tests
2. The exercises application took (8) week s at the rate of (3) training modules per week (Sunday, Tuesday, Thursday) and the researcher used exercises in the beginning of the main section.
3. The total number of modules is (24) and the total training time of module is (120) minutes, and the devoted for research or experiment ranged between (24.54-27.3) minutes.
4. The intensity (80%) was defined as a starting point for the application of exercises items, adopting a high-intensity interval training method in the training of anaerobic exercises.

Posttests: They were carried after the two-month period of training had ended, performed on Wednesday and Thursday, 19-20/9/2018.

Discussion of the results of the pre and post testing of the control and experimental groups for the test of the explosive capacity: The researcher attributed these differences to the pre and posttests of the control group to the development of capabilities as a result of the impact of the curriculum prepared by the trainer and the exercises used for this purpose have led to the improvement of this ability. The development of the experimental group was attributed the effectiveness of training exercises designed by the researcher, which improved the explosive capacity.
These exercises were also based on scientific planning to achieve the objective and since “muscle strength” was the resultant force or which was generated by the muscle when contracted as per the number of common muscle fibers contracted and it also varies according to the type of Muscle contraction”.3

View and analyze the results of the biochemical indicators of the control and experimental groups:

Discussion of the results Pre and Posttests of the physiological indicators of the control and experimental groups: Lactic acid before and after tension: the results of the measurement of lactic acid after and before tension of both control group and experimental as shown in Table (5) indicated that there were differences between the pre and posttests of lactic acid but they were not statistically significant as it was for lactic acid After tension of the control group, where an increase was obtained which was attributed by the researcher to the effect of continuous intensive training. While the ad hoc high intensity interval training exercises which were prepared by the researcher, The physical highly intensive training leads to the athlete’s toleration of the highly concentrated of lactic acid, and to increase his ability to get rid of it.4

Blood acidity before and after tension: The results of the measurement of the blood acidity before and after the tension of training of both control and experimental groups as shown in (6) indicated that there were differences between the pre-test and post-test blood acidity, yet, they were not statistically significant. Significant differences were seen in the post training tests, which were attributed by the researcher to the training curriculum proposed by the trainer and the exercises prepared by the researcher, which contributed to improve the work of the vital organs, which maintain the acidity of blood, that the relative reliability of (PH) blood leads to the possibility of maintenance of blood for long period even after the outputs of acid metabolism entered.5

Calcium before and after training tension: The differences between the pre-tests and post-tests of blood acidity as seen in table (4) were not statistically significant. However, it’s attributed by the researchers to the training curriculum proposed by the trainer and the exercises prepared by the researcher that, “Training increases the amount of calcium ion Ca ++, which should be invested in the production of a series of enzymes in the muscle”.6

View and analyze the results of the post tests of physical abilities and physiological indicators of the control and experimental groups:

Discussion

Lactic acid before and after the tension: Before training, the lactic acid rate varied between the two groups but these variations were not statistically significant. But after the training, significant differences appeared in the results of the experimental group, which were attributed by the researcher to the performance of highly intensive exercises, which resulted in an increase in the concentration of lactic acid in the blood. Such increase in the lactic acid production is due to the type of muscle work and its intensity exerted by the player. When the muscle work is of moderate intensity and performed under the use of oxygen, the production of lactic acid does not increase in the blood, while if the work of muscle is of high intensity and performed in the absence of oxygen, Lactic acid pool increases in the blood “.7

Blood acidity before and after training: There were differences observed in the blood acidity rate before training between the two groups but these differences were not statistically significant, but after training, significant differences were observed in the results of the experimental group, which the researcher attributed to the continuation of the high intensity interval training exercises applied scientifically by the study sample, where the pH of blood was increased and this increase led to the disengagement of hemoglobin from oxygen.7

Conclusions

1. Special exercises of high-intensity training have a positive effect on the development of the explosive capacity of the leg muscles and the biochemical indicators of the technical gymnastic young players.

2. There were no significant differences between the pre and posttests of the experimental group in the biochemical indicators before training performed by the technical gymnastic players.

3. There were significant differences between the pre and posttests in the in favor of the experimental group in the biochemical indicators after training performed by the technical gymnastic players.

4. The traditional approach adopted by the control group had a positive effect on the development of the explosive capability and biochemical indicators of the technical gymnastic players. This was due to the organization and continuation of the training modules throughout the experiment. However, this development did not reach the level achieved by the experimental group.

The Effectiveness of Proposed Consensual Exercises to Correct the Error Associated with the Performance of the Layup Scoring Skill of Beginner’s Basketball

Omar Ahmed Mosleh¹, Ali Khalid Mukhlif¹, Qusay Rashid Sabti¹
¹Faculty of Physical Education and Sports Sciences, University of Anbar, Iraq

ABSTRACT

The use of harmonized exercises in learning locomotives has an effective effect in the educational process because of its benefits. It remains in great need for the teacher and the good coach as it is assigned to perform its task well. Despite the many studies that specialized in teaching scoring through a few exercises, Of studies have used these harmonics exercises in the teaching of basic basketball skills, which may help to accelerate the process of learning as a result of short time and the construction of a true motor perception. The researchers used the experimental method of tribal measurement and telemetry to suit the nature of research.

The sample was randomly selected from students of the first stage (48) students, constituting (38.4%) of the original research community. After conducting the tests, the data were collected and processed statistically to reach the most important conclusions, which include the use of the proposed exercises and the effort and time for the teacher and the learner to learn peaceful scoring skill well.

Keywords: Consensual exercises, performance and layup scoring.

Introduction

The basketball game occupies a distinct place in the world, like the rest of the various sports. It depends on the interplay of the team because it is linked to physical abilities, mobility, skill, psychological, educational and planning, and is characterized by many skills that are exciting and exciting.

This has been pointed out by some scientific sources that “(basketball is one of the collective activities and is prolific with individual and collective skills). And dynamic learning is one of the branches of the general educational process, which characterizes the shyness of the living organism from birth until death, where human activity is not free of all kinds of learning and motor learning, and as the process of learning with motor sports training in the process of transmission of information from the coach or teacher to the player or student As well as in the changes that occur in the motor behavior resulting from the educational process, which aims to provide the individual learner or player of physical qualities or motor skills and skill. And that the difference between learning and dynamic learning is that the response in the field of learning locomotives be in the form of motor behavior with large muscle groups to reach a certain goal, “2On the other hand, we find that learning locomotors or motor behavior is strongly linked to control the work of muscle groups and that control has to do with In the central and peripheral nervous system and how the peripheral nerves work effectively to move the parts of the body accurately and from this we find that learning is the link between psychological character and physiological “.2

Perhaps one of the most important foundations and requirements in the process of detecting the level of performance of some of the abilities of motor skills and skill requires the evaluation and by the development of exercises based on the correct learning assets, which is an important basis for knowledge of the level of sports, which can be applied to students of faculties of physical education and sports sciences, The building blocks of the distinctive sports building Based on the scientific curricula and studies, and that the use of harmonized exercises in learning locomotives has an effective effect in the educational process because of its benefits, it remains in severe need for the teacher and the good coach as it is assigned to perform its task well and despite the multiple studies that specialized in teaching scoring
through exercises suggested, a few Studies have used these harmonized exercises to teach basic basketball skills that may help accelerate learning as a result of shortening time and building a true motor perception.³

**Research aims:**

1. The development of the proposed consensual exercises to develop the level of performance of the pacific pacification basketball students on the first stage Faculty of Physical Education and Sports Sciences Anbar University.

2. To recognize the effect of the use of harmonized exercises in the development of the level of technical performance of Layup scoring shot basketball

**Hypotheses:** The exercises have a positive effect in improving the level of technical performance of Layup scoring shot basketball.

**Research Methodology:** The researchers used the experimental method in the method of pre measurement and telemetry in order to suit the nature of the research.

**Research community:** The research society consists of students of the first stage in the Faculty of Physical Education and Sports Sciences/Anbar University for the academic sciences (2016 - 2017) and the number of (80) students, which constitute the community of research.

**The research sample:** The sample was randomly selected from the students of the first stage (48) students (38.4%) of the research community.

**Data collection tools and means:** The researchers used the following tests and tools in collecting search data and implementing the experiment.

**Tests used in research:**⁴

1. The Layup scoring test (performance evaluation).
2. Objective of the test: The test aims to measure the skill of Layup scoring shot.
4. Performance Specifications:
   5. Draw a starting line away from the final limit by (10) meters and parallel to the player stands behind this line and then the ball is tilted until he approaches the basket to lead the steps of a Layup score and then aim the ball on the goal.
6. Registration:
   7. The player is given (5) degrees if successful footsteps and injury target.
   8. The player is given (3) grades if the success of the steps of the feet.
   9. The player is given (zero) in case of injury goal and the success of footsteps.

**The test of the Dribble ended Layuply:**⁵

**Objective of the test:** Measuring the skill of the plotters and the Layup pursuit.

**Devices and tools used:** The number is 3, basketball and stopwatch. The distance between the starting line, which is 19.5 meters away from the point of the center of the loop and the first person is 6 meters, and the distance between the figures is 4.5 meters.

**Test Conditions:** The laboratory stands at the starting line and when it hears the starting signal starting with the right hand side of the first person (for the player using his right arm) and upon reaching a suitable distance from the goal he is a Layup target and quickly returns the ball if the score succeeds. Succeeds in injury and then returns quickly and the time is counted which is a test guide.

**The tools used:**

1. Basketball basket balls
2. Basketball court
3. High cones (30) cm
4. Metric measuring tape
5. Whistle

**Basic Study:** The basic study was conducted in the period from 15/1/2016 to 23/4/2017 by 8 weeks. The number of training units reached (8) units by (1) units per week and unit time (90).

**The pretest:** Were made on 15/1/2016 on the same research (experimental).

**The proposed program:** Was implemented from 22/1/2016 to 17/4/2017 on the following two research groups:

**Posttest:** Were carried out on 23/4/2017.

* Not significant below the level of error > (0.05) in front of the degree of freedom (24 + 24-2 = 46)

Table 5 shows that the control group achieved a mean of 16.028 and a standard deviation of (4.1364) in the post-test. The experimental group achieved a mean of 15.932 and a standard deviation of (3.661). The results of the study of the technical performance of the skill of layup scoring, the researchers adopted the test (t) for asymmetric samples to verify the significance of differences, the value of (t) calculated (0.085) at the degree of freedom (48) and the level of significance (0.05) Significant difference between the two groups and for the benefit of the experimental group.

Discussion of Results

Discussion of the results of the control and experimental research groups in the tests of the technical performance of layup correction through the results presented in tables (3.5.4). It is clear that the amount of learning was clear and the development rates of the control and experimental groups in learning the technical performance of the layup scoring skill When the tables were highlighted (3.4), there was an improvement in the level of performance in the post-test compared to the pre-test and the achievement of development and learning ratios in the technical performance of the skill in question, but at a different level between the control group and experimental and experimental The effect of the use of (the proposed exercises).7

The researchers attributes this to learning and remarkable development as the educational means (based on the involvement of all senses in the learning processes, which leads to the consolidation and deepening of this learning and thus helps to establish strong and firm relationships between what the student learned and the consequent survival of the impact of learning). Numerous research and studies have pointed out that the various exercises raise the tendency of individuals and work to consolidate learning as well as shortening the effort and time required for the learning process.

The development rate achieved by the control group is the result of the application of the applied curriculum, which provides many repetitions of skill learning, presentation of the model and feedback used by the teacher. When reviewing the experimental group’s schedule, which was subject to the proposed curriculum, there is an improvement in the performance of the post- In learning the skill in question compared to the pretest and achieving a good rate of development in learning the technical performance of layup scoring skills, skill is a function of performance effectiveness as the learner develops some of the motor responses in the organization of a new dynamic. And that each motor skill requires the organization and arrangement of the work of certain muscle groups, and in a certain direction).

The researchers attributed the progress achieved by the experimental research group to the use of the proposed exercises in the educational curriculum, which defines the learner with the correct motor path, which serves the mechanical foundations of the skill in question. Some studies have shown that “when the learner knows the mechanical bases of the skill, the
performance. Since skill is a function of performance effectiveness as the learner develops some of the kinetic responses in the organization of a new motor, and that each skill requires the movement of the organization and arrangement of the work of certain muscle groups, and in a certain direction.12

**Conclusion**

The proposed exercises as an aid and an effective role in learning the required skill. The use of exercises suggested and provide effort and time for the teacher and the learner to learn layup scoring skills well. The use of exercises suggested to have a positive impact in the interaction of learners during the lesson and their presence. Get good ratios in the amount of learning the technical performance of the skill of layup scoring.

A 4-Day Plaque-Regrowth Anti-Plaque Effect of a Combination of Green Tea and Salvadora Persica L.: A Randomized Controlled Crossover Clinical Trial

Rasha Salah¹, AN Mohammed¹, Hayder Raad Abdulbaqi¹

¹Department of Periodontics, College of Dentistry/University of Baghdad, P.O. Box 1417, Baghdad, Iraq

ABSTRACT

Background: In earlier studies, a combination of 0.25mg/ml green tea and 7.82mg/ml *Salvadora persica* L. aqueous extracts (Co) had been found to exhibit anti-bacterial and anti-adherence effects against primary plaque colonizers biofilm *in vitro* and antiplaque effect as a mouthwash for a period of 24h *in vivo*. The aim of current study was to evaluate anti-plaque efficacy of Co mouthwash for a longer period of 4 days *in vivo*.

Method: A 4-day plaque re-growth double-blinded randomized crossover trial was carried out. A week after receiving polishing and scaling, all participants (n=14) received polishing at base line and rinsed with 15ml of randomly allocated mouthwashes (either Co, 0.12% chlorhexidine or placebo) twice daily without oral hygiene measures for 4 days. After 24h and 4 days’ time points, plaque index was recorded, and then the participants entered a 6-day washout period with regular oral hygiene measures. The same protocol was repeated for the next 2 mouthwashes.

Results: The Co mouthwash significantly reduced plaque accumulation as compared to Placebo and chlorhexidine).

Conclusion: The Co mouthwash has antiplaque activity for a 4-day period and might be a potential alternative to synthetic mouthwashes.

Keywords: *Salvadora*, green tea, dental plaque, mouthwash, chlorhexidine.

Introduction

Dental plaque is a soft mass accumulated onto tooth surfaces. Its formation starts by adhesion of oral commensal bacteria, known as primary colonizer, to acquired pellicle-covered tooth surfaces. When these bacteria establish firm attachment on tooth surfaces, they offer receptors for the attachment of the other secondary colonizing bacteria. This process of bacterial attachment continues and contributes to the buildup of mature dental plaque within few days (1). Dental plaque requires around 24h to be clinically detectable (2). Accumulated dental plaques onto tooth surfaces elicit inflammation in adjacent gingival tissue (3). Thus, the removal of dental plaque from tooth surfaces on daily basis is essential as a preventive measure. The best control of tooth plaque is tooth brushing and using interdental aids. However, the efficiency of these procedures depends on individual’s dexterity (4) and poor individual performance has been reported (5). Consequently, the use of chemicals such as mouthwashes has been suggested to adjunct tooth brushing and flossing. Till these days, chlorhexidine (CHX) mouthwash has been considered the first choice as adjunctive chemical; its anti-plaque activity has been ensured (6). Unfortunately, CHX has been reported to have several side effects such as tooth staining and bitter taste (6, 7). For that reason, an alternative mouthwash having anti-plaque activity comparable to CHX with less undesirable effects is a topic for many studies. Extracts of medicinal plants have received much attention over the past few years, due to its biological activities that enhance oral health such as *Salvadora persica* L., family: *Salvadoraceae*, (Sp) and green tea (Gt), leafs of...
Camellia sinensis var. assamica (family: Theaceae)\(^8-10\). Recently, the combination of 0.25mg/ml green tea and 7.82mg/ml Salvadora persica L. aqueous extracts (Co) (patented, IP 2015704777) was reported to exhibit antibacterial and anti-adherence activities against primary colonizers of dental plaque in vitro\(^11\) and anti-plaque activity better than CHX for short period of 24h \textit{in vivo}\(^2\). For that reason, this study was carried out to confirm the anti-plaque activity of Co for 24h and to evaluate its anti-plaque activity for a longer period of 4 days \textit{in vivo}.

**Materials and Method**

**Study design and population:** This study was a randomized, double blinded, 4-day plaque re-growth crossover clinical trial. It was carried out at the Faculty of Dentistry/University of Baghdad between November 2018 and January 2019. Subjects included in the study should be 19-23 years old, in good general health and had more than 20 teeth. However, subjected excluded from the study were those having active cavitated caries and/or periodontal disease, undergoing orthodontic treatment, having history of antibiotics treatment within the past 4 months, those need prophylactic antibiotic coverage and/or non-steroidal anti-inflammatory drugs (systemic/topical) for the past 4 months, those known to have heart valve replacement and/or any systemic disease. This study was approved by the Ethical Committee, Faculty of Dentistry University of Baghdad following the guidelines of the Declaration of Helsinki and Tokyo for humans (reference no:011618 in 8 January 2019). Written informed consent form was obtained from all participants.

**Sample size:** The sample size was determined after collecting data from literature\(^12\). The sample size of 9 participants was found enough to reject the null hypothesis between Co and placebo (Plc) mouthwashes at probability power of 0.95 and 0.05 type I error probability. Due to crossover design of the study, involving follow up period of 6 weeks, a sample size of 16 participants was decided to be enrolled in this study to compensate for unanticipated drop out.

**Clinical Measurements**

**Plaque index:** The plaque quantity was recorded using modified Quigley Hein plaque index (PI)\(^13\). The labial/buccal and lingual/palatal surfaces of each disclosed tooth except wisdom teeth and filled tooth surfaces were recorded. The mean of PI was calculated by collecting the scores over the total number of surfaces examined. All plaque scores were recorded by single examiner. Alignment and assessment of the examiner was carried out as described by\(^14\). Absolute intra-examiner agreement, kappa value of 0.915, was achieved according to Landis and Koch\(^15\).

**Interventions:** The Co, 0.12% chlorhexidine (CHX; positive control) and Placebo (Plc; negative control) were used in this study. A full description of the mouthwashes was shown in Table (1). The mouthwashes were contained in identical opaque bottles, which were given random sequential number codes (1, 2 and 3) by a third party not involved in this study. A number-coded interventions’ sequence list, generated by using a random number generator (Microsoft Excel 2010), was given to the examiner to assign the blinded intervention. Thus, all participants had an equal probability of assignment to the interventions sequence. This trial was double-blinded as the examiner and participants were unable to identify the corresponding intervention. Decoding was done at the end of the study.

**Clinical trial:** After participants’ selection, the aim and flow of the clinical trial were illustrated for the participants 7 days before the launch of clinical trial and all participants received oral hygiene education, scaling and polishing. In the clinical trial period, participants attended dental clinic three times, at baseline (0h), after 24h and after 4 days. PI scores were recorded at 24h and after 4 days.

At the beginning of each period, participants’ teeth were disclosed with a disclosing agent (erythrosine tablets). Then, participants’ teeth were polished to have plaque-free teeth surfaces at baseline. After that, participants were asked to rinse with undiluted 15ml of the allocated mouthwash solution for 1 minute under supervision and instructed to refrain from eating and drinking for 30 minutes after rinsing. Participants were asked to repeat the rinsing at home twice daily for the next 4 days and to refrain from mechanical oral hygiene measures or using chewing gum for 4 days. At the following day, participants’ plaques were disclosed and PI was recorded. The same procedure was repeated at day 4. After that, participants entered a 6-day wash out period and they were asked to resume oral hygiene measures. After the washout period, the same protocol was repeated for the next two mouthwashes. On the last day of the study, participants received polishing\(^12\). Adverse events were recorded except those unrelated to the intervention such as traumatic ulcers, food burns and lip bites.

**Statistics:** Data were analyzed using Statistical Package for Social Sciences (SPSS; version 22.0) for windows. For mouthwashes comparison, PI scores and percentages of plaques coverage were described in term of mean and standard deviation. Kruskal-Wallis H test (P<0.05) was used to detect any differences among interventions. Then, Mann-Whitney U test (P<0.0167) was used to test the difference between each pair of interventions. The intra- and inter-examiner agreements were assessed by using kappa test. G*Power software (version 3.1.9.2) was used to determine sample size, intervention effect size and power of the study.

**Results**

The participants were 14 male dental students with mean ± SD age of (22.35 ± 0.497). The mean ± SD values of PI at 24h and at day 4 were summarized in Tables (2 and 3). The mean PI of Co was significantly lower than that of both Plc and CHX (P<0.05).

Discussion

The main finding in this study is the potent anti-plaque efficacy of Co mouthwash. 24 h After rinsing with Co, PI scores were found significantly less compared to CHX and Plc; a finding supported by a previous study (12). The Co solution was found to exhibit antibacterial and anti-adherence effects against primary colonizers of dental plaque. The initial adherence of the primary plaque colonizers to the tooth surface is essential for the development of dental plaque by providing new binding sites for secondary plaque colonizers (16). Constituents of green tea and Salvadora persica L. aqueous extracts such as tannins (17) and polyphenols (18) were reported to adsorb onto, and modify, teeth covering acquired pellicle and may subsequently disturb bacterial attachment to tooth surface. Thus, the potent anti-plaque efficacy of Co mouthwash could be attributed to the reduction in the availability of primary colonizers in saliva and impairment of the attachment of these bacteria onto tooth surface which therefore retard plaque development.

At day 4 following rinsing with Co, PI scores were still significantly less as compared to CHX and Plc. This finding could be due to continuous antibacterial effect of Co mouthwash with consequent reduction of bacterial load in saliva after establishment of dental plaque on tooth surfaces.

Interestingly, despite absence of oral hygiene measures, the amount of dental plaque formed on the already established plaque on tooth surfaces was found significantly less after rinsing with Co mouthwash as revealed by the differences between PI scores at 24h and after 4 days; a finding that was not evident for CHX. This represented a potential advantage of Co mouthwash over CHX, which needs a clean tooth surface to work perfectly by binding pellicle-covered tooth surfaces (19), particularly for those who do not brush their teeth regularly.

A 4-day non-brushing plaque regrowth model was used, a duration that has been used in previous studies (20-22), in a crossover setup to counteract patient-specific parameters and possible bias in the determination of plaque growth and accumulation. Also, the blinding of investigator and participants ensured unbiased evaluation of the results.

The re-formation of supra-gingival plaque is similar for healthy and periodontitis subjects (23). This suggested that the test mouthwash could have similar antiplaque effect in subjects with periodontitis and it can be used in healthy and periodontitis subjects.

Conclusion

Rinsing with 15ml of a combination of 0.25mg/ml green tea and 7.82mg/ml Salvadora persica L. aqueous extracts twice daily can significantly reduce dental plaque accumulation after 4 days with no observed adverse effects. This combination might be a potential alternative to synthetic mouthwashes.

Some of Surrounding Environment Perceptions and its Correlation to the Psychological Flexibility of the Players of Babylon University Futsal

Amer Said Al-Khikani¹, Ayman Hani Abd Al-Jubouri², Alsajjad Abbas Mkhat³

¹The College of Physical Education and Sport Sciences, University of Babylon, Iraq; ²The College of Physical Education and Sport Sciences, University of Kufa, Iraq

ABSTRACT

The research aims to:

1. Recognition of some of the perceptions of the Environment and psychological flexibility in the players of the University of Babylon futsal.
2. to identify the relationship between some of the perceptions of the Environment and psychological flexibility in the players of the University of Babylon futsal.

The researchers used the descriptive approach in the methods of survey and interrelationships. The research society included the players of the University of Babylon with a total of 12 footballers. The tests of some of the Environment’s perceptions and psychological flexibility were determined. The tests were then applied to the research community for the purpose of conducting relations. Using SPSS version 17 to address its research data, and in the light of the findings of the current research and the subsequent interpretations, we can draw a number of conclusions, the most important of which are the following:

1. The players of the University of Babylon futsal club with a high level of some of the perceptions of the Environment and psychological flexibility.
2. The existence of a strong correlation between each of the positive perceptions of the Environment and the psychological flexibility of the players of the University of Babylon futsal.

Keywords: surrounding environment and psychological flexibility.

Introduction

In view of the scientific progress and increasing the importance of sports psychology in achieving achievement for athletes, there is an urgent need to activate the psychological aspects and employ them in a scientific way to help players achieve maximum athletic achievement and ensure the mental health of players and protect them from the pressure of training they are subjected to. The player reaches the best level before and during sports competitions.

Futsal is one of the most popular games in the world, regionally and locally. It is a sport that requires high fitness, skillful performance, planning, mental abilities and a special psychological preparation. Perception of the Environment is one of the most important variables that affect the power of attention, as well as its obvious effect in concentration, control and interpretation of the stimuli surrounding the performance skill and psychological flexibility is an important factor and essential for the players, and must be available and attention to enable them to work to achieve achievement, as psychological flexibility plays an important role and effective As well as physical, skill and planetary factors and they directly affect the behavior of the human and emotional. In the light of the foregoing, the importance of research is to know the relationship between some of the perceptions of the Environment and psychological flexibility.

The psychological variables in futsal halls are the most important means of success for the team as it is the seeds of the basis for excellence and the implementation of the performance of the team and then achieve the optimal performance to achieve the achievement of sports, and psychological variables play an important role in achieving achievement, whether on the personal...
level of the player as an individual or at the level The team as a whole and through the follow-up researchers and their interest in being specialists in this game noted that there is a disparity in the activation and employment of psychological aspects and mental abilities of the players and have a significant impact on the situations of play and skill performance and the results of the entire team so will work Researchers to identify some of the Environment perceptions of psychological resilience and the extent of the relevance of those variables while among these players.\textsuperscript{2)}

Research Methodology

The researchers used the descriptive approach in survey methodology and correlative relationships to suit the nature of problem solving.

Research Community: The research community consists of the players of the University of Babylon team for the academic year 2017-2018, the number of (12) players were all selected by (100%).

Means, instruments and devices used in research:

- Observation.
- Questionnaire.
- Arab and foreign sources and references.
- Benchmarks and tests.
- Electronic type calculator (CLTON).
- Personal Type Calculator (DELL) Number (1).
- Stationery (papers, pens).
- Manual stopwatch type (KENKO) number (3).

Field research procedures: Procedures for the selection of tests of some of the Environment’s perceptions and psychological flexibility: The tests were conducted in the psychological laboratory at the Faculty of Basic Education at the University of Babylon and the researchers adopted a measure of the selection of the scale of psychological flexibility that he built.

Kilometric Characteristics of the Scale (Psychological Flexibility)\textsuperscript{3)}

First: The truth of the measure:

1. The truth of content: This kind of honesty was achieved when the three scale was presented to a group of experts and specialists in the field of psychology and sports psychology and testing and measurement to validate the terms of the scale and the ability of those words to measure the components of the behavior measured by the number (15) An expert is considered Annex 2 and the experts have agreed on the validity of all the terms of the scale.

2. Second, the stability of the scale: To verify the stability of the scale, the researchers used the half-split method. This method is based on dividing the paragraphs of the scale into two parts: the individual and marital paragraphs. The differences between the individual and matrices were calculated according to the coefficient F. When comparing the calculated value of the psychological elasticity index (0.05), we find that the difference is not statistically significant. This means the homogeneity of the individual and marital variance of the scale. The correlation coefficient Pearson was then calculated and its values were (0.804). Correlation coefficient extracted In order to achieve complete stability of the scale.

Application of tests (some Environment and psychological flexibility) on the application sample: After the completion of the selection of the psychological flexibility test and the preparation of the other tests, the tests were applied to the application sample of (12) players on 5-6/11/2018 Perceptions of the Environment and Psychometric Resilience) in the Psychological Laboratory at the Faculty of Basic Education at the University of Babylon by the researchers and with the assistance of the assistant staff, Appendix 3 is considered and the results were collected to achieve the research objectives.

</table>
Table (1) shows the measurements of the Environment perception tests, where the test of the force of attention reached an average of (66,764) and a standard deviation (2.987). The torsion coefficient for the scores of the sample on this test is 0.17, the average score of the test is higher than the recommended average of the test. This means that the sample has a distinct level of attention intensity. In order to determine the average of the test scores, the statistical significance of the differences between the two averages, and the test was used (T) of (11.76), which is greater than the value of sig (0.000), is smaller than the significance level (0.05).

Table (1) shows the arithmetic mean of the field of vision (62,098), with a standard deviation (1,765). The torsion coefficient for the scores of the sample of the research sample on this test is (0.29), the average of the test scores is higher than the mean of the test. This means that the sample has a distinct level of field of view. In order to determine the statistical significance of the differences between the two averages, And the T-test was used for one sample. The value of (t) Calculated (8.438), which is greater than the value of sig (0.000), is smaller than the significance level (0.05).

Table (1) shows the arithmetic mean of the concentration test (control) with (67.831), with a standard deviation (1,693), and the torsion coefficient for the scores of the members of the research sample on this test is (0.44), the average test score is higher than the mean of the test. This means that the sample has a distinct level of concentration (control), and in order to determine the statistical significance of the differences between the tests was used for a single sample the value of (t) calculated (11.763), which is greater than the sig value of (0.000), is smaller than the significance level (0.05).

Table (1) shows the arithmetic mean of the Environment perception tests (66,897) with a standard deviation (2.148). The torsion coefficient for the scores of the sample of the research sample on this test is 0.39, indicating that the scores of the sample members are distributed moderately. On the test, when comparing the mean of the test sample to the test with the mean average of (50) degrees, it was found that the average of the test scores is higher than the average of the tests. This means that the sample has a distinct level of the Environment’s perceptions. In order to determine the statistical significance of the differences between the two averages, the use of the test for one sample the value of (t) calculated (12.855), which is greater than the value of (sig) of 0.000, is smaller than the significance level (0.05).

Table (2) shows the statistical description of the results of the Psychological flexibility

<table>

<td>0.000</td>
<td>Moral</td>
</tr>
</tbody>
</table>

Table (2) shows the arithmetic mean of the psychological elasticity index (144,432) with a standard deviation (3.987). The torsion coefficient for the scores of the sample on this test is 0.665, On the test, when comparing the mean of the test sample to the test with the mean average of (120) degrees, it was found that the average of the scale of the sample is higher than the average mean of the scale. This means that the sample has a distinct level of psychological flexibility. In order to determine the statistical significance of the differences between the two averages, using the test for one sample, (T), which is greater than the value of (sig) of (0.000), at the level of significance (0.05), and the degree of freedom (11).

The researchers attributed this to the fact that the members of the research sample act rationally disciplined with different play situations and without recklessness, resulting in the implementation of the requirements of the game. The members of the sample also make the right decision in the compatibility of the implementation of the decision according to the psychological situation and the situation experienced by the player, especially in the variable flexibility.

They are not worried about the games they are playing, whether they are friendly or official. Psychological flexibility is an important factor in achieving good results and reaching higher levels in most sports games and events, especially those that require continuous physical effort. For long periods as in the performance skill which requires a great physical effort and continuous during the matches,
and therefore, psychological flexibility has a prominent role in the nature of the performance of the player with volleyball, and this is consistent with what has been indicated that “must focus in the period before the feelings of willingness to support the sense of self-confidence and prevent the intervention of defeatist ideas can be strengthened because it can cause an increase in the level of arousal or directing thinking to what happens inside the body at an early time is not in favor of the player and finally that the player wants to enter into a positive state of mind and physical activity appropriate (Psychological and physical shipping) leads him to the game and is in full readiness”.

Table 3: Shows the nature of the inter-relations between the variables under consideration

Conclusions

1. The players of the University of Babel enjoy a high degree of futsal in some of the Environment and psychological flexibility.

2. The existence of a strong relationship between the positive, between the perceptions of the Environment and the psychological flexibility of the players of the University of Babylon futsal.

Detection of Cytolysis Peptide Toxin Gene (Candidalysin) in *Candida albicans* Isolates

Sara K. Al-zubaidi

Department of Medical Lab. Technology, Al-Zahrawi University College, Karbala, Iraq

Abstract

This study was launched to identify the presence of the gene; *ece1* (extent of cell elongation 1), encodes for a precursor protein related to the candidalysin, a cytolytic peptide toxin important for the induction of mucosal-related infections, in isolates of *Candida albicans*. Initially, 30 isolates of *C. albicans* were provided by Merjan Teaching Hospital, Hilla City, Iraq. These isolates had been originally recovered from 10 children suffered mouth thrush (MT) infection, 10 women with infection of vaginal candidiasis (VC), and 10 patients with immunocompromised-based candida (ICC) infection. The samples were Lab-based processed using a polymerase chain reaction (PCR) method to amplify an *ece1*-specific-362bp region. The results revealed the presence of the current gene in 4 (40%) of the ICC samples, 1 (10%) of the VC samples, and 3 (30%) of the MT samples. The current findings of the current investigation indicate the presence of the *C. albicans* candidalysin virulence gene in the tested isolates from Hilla City, Iraq. The work also suggests performing future studies or adopting novel control standards to overcome the virulence processes initiated by this gene.

Keywords: *Candida albicans*, candidalysin, immunocompromised candidiasis, mouth thrush, vaginal candidiasis.

Materials and Method

**Sample Collection:** Thirty isolates of *C. albicans* were provided by Merjan Teaching Hospital, Hilla City,
Iraq. These isolates had been originally recovered from 10 children suffering mouth thrush (MT) infection, 10 women with infection of vaginal candidiasis (VC), and 10 patients with immunocompromised-based candida (ICC) infection.

**Molecular Identification**

**Extraction of genomic DNA:** The EZ-10 Spin Column Fungal Genomic DNA Mini-Preps Kit (BioBasic, Canada) was employed to extract the *C. albicans* genomic DNA (gDNA) from the current collected samples. The protocol used to perform the extraction procedure was the kit instruction. The obtained gDNA was exposed to quality and quantity-based estimating processes using a NanoDrop.

**Polymerase chain reaction:** The gDNA (10-50ng/µl) was used as a template at 5µl in the mastermix reaction that also contained the primers; F: CCATCATCCACCATGCTCCA and R: TCTGACGACGGCATTAGCAA, 10pmole 1.5µl/each primer direction, utilized to amplify an *ece1*-specific-362bp region. Moreover, pre-prepared solution of Taq DNA polymerase, dNTPs, 10X PCR buffer, and some stabilizer with a tracking dye was also added to the previous mixture. PCR-based water, 7µl, was also added to complete the total volume, 20µl, of the reaction. The thermocycler conditions used to perform the amplification reactional processes were 5min at 95°C for one-cycle initial denaturation, (30s at 95°C of denaturation, 30s at 58°C of annealing, and 30s at 72°C of extension) for 30 cycles, and 5min at 72°C of final extension. The PCR products were ethidium-bromide-pretreated-1%-agarose electrophoresed followed by screening the process under a UV-light-based imager.

**Results**

The results revealed the presence of the current gene in 4 (40%) of ICC samples, 1 (10%) of the VC samples, and 3 (30%) the MT samples. Amplification of the current region related to the *ece1* gene was successfully induced and observed in the positive samples, figure 1. The figure shows the amplification at the 362bp region of the gene.

![Figure 1: Image of the candidalysin-gene-based agarose gel electrophoresis in the isolates of the *C. albicans*. M is the used ladder (2000-100bp). Positive, 362bp, lanes: S1 to S4 for the immunocompromised patients, S7 to S9 for the mouth thrush from children, and S11 for the vaginal candidiasis](image)

**Discussion**

*Candida albicans* is an opportunistic fungal pathogen that causes important human and animal diseases. Although the fungus is a normal member of the bodily tract microflora, it can produce different infections in individuals with depressed immune system encouraging colonization by these opportunistic normally present microorganisms.

The current results recognized the presence of the candidalysin-encoding gene in the tested samples. The candidalysin is an important factor indicating if the *C. albicans* is virulent or not as this agent acts on destroying the epithelial cells of mucous membranes. This agrees with Moyes et al. (2016) identified that candidalysin existence in *C. albicans* refers to the virulence status of this microorganism as candidalysin damages these epithelial cells. The current study findings also are
matched up with those observed by (14,15) who revealed that candidalysin is important in *C. albicans* related oral infections leading to the secretion of some cytokines related to the inflammatory processes such as IL-1β, IL-6, CCL20, and G-CSF. In the case of the VC, Richardson et. al (2019) found that candidalysin is critical in inducing *C. albicans* related vaginal epithelia cell damages with the release of some proinflammatory cytokines related to the inflammatory based destruction of the epithelial cells (16). Some of those cytokines are IL-1β, IL-6, CCL20, and G-CSF. Moreover, some chemokines are released during the invasion of the vaginal epithelial cells with the fungal hyphae of *C. albicans* (16).

For the ICC, reduction in the immune system sufficiency have been recognized to enhance the induction of candidalysin-*C. albicans* based infections leading to systemic spreading of these fungi with high possibilities of death occurrence in those ICC patients (17,18). The current findings of the current investigation indicate the presence of the *C. albicans* candidalysin virulence gene in the tested isolates from Hilla City, Iraq. The work also suggests performing future studies or adopting novel control standards to overcome the virulence processes initiated by this gene.

Effect of Active Learning on a Role-Playing Strategy in Improving Some Types of Handball Scoring

Abdulabbas Abduljaleel Kareem¹, Asraa Yaseen Abdulkareem¹
¹Department of Physical Education and Sport Sciences, Faculty of Basic Education, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

Active learning is a way of teaching and learning at the same time, in which learners participate in a variety of activities and effectively through a rich and diverse learning environment that allows them to listen positively, to discuss richly, to think consciously, and to analyze soundly in keeping with the modern view of keeping students away from memorization and memorization. This strategy assumes that the student has a role to play, expressing himself or someone else in a specific position. The research problem and through the reading and follow-up of the researcher found that most professors do not use the new strategies and applied in the field of physical education where the process of learning to conduct a diagnosis and analysis from time to time as the researcher used the experimental approach to design the equal groups, in order to suitability and nature of the problem to be resolved. Part of the original research community the research community was identified as students of the second stage of the Faculty of Physical Education and Sports Sciences/University of Dhi Qar. From the results, the most important conclusions reached by the researcher exceed the experimental group that implemented the program according to the strategy of role play in improving some types of handball scoring.

Keywords: Active learning, role-playing strategy, handball.

Introduction

The term active learning emerged in the last years of the 20th century. Educators and those interested in the learning process learned many definitions as they knew it. Active learning is a way of teaching and learning in one, in which learners participate in a variety of activities and effectively through a rich and diverse learning environment that allows them to listen positively, rich discussion, conscious thinking, sound analysis, and deep reflection on everything that is taught between And that the achievement of this depends on the use of instructional strategies should be compatible with the modern view of these strategies strategy (role play).

The importance of research as a new attempt and the addition of quality in the field of teaching and education, which provides the learner a simulation system, in which the students in different roles of individuals and groups in the my attitude is real, and it represents the way that students can not feel embarrassed in expressing their opinions, thoughts and feelings.¹

The great progress in the field of education, especially in sports activities, showed that the results of the usual method prevailing in our universities are few and still need new methods and teaching methods that make the learner the center of the educational process in an effective way to eliminate the individual and unilateral trends that permeate the educational situation found in the usual learning methods Which focused on memorization and indoctrination and that the results of the skillful performance of students in handball do not produce suitable results that correspond to the level desired by both the student and the teacher where the educational process requires the diagnosis and analysis from time to time. The role-playing strategy is provided

as a new strategy for university students that transfers these experiences to a better physical education lesson and is in itself a strong educational activity to imitate skills and master their performance and to deliver, absorb and retain material and to dispel boredom in students. And make the educational process more interesting and increase their desire.²

**Research aims:** The preparation of modules using active learning according to the role-playing strategy to improve some types of handball scoring. To identify the effect of the units in the improvement of some types of handball scoring

**Hypothesis:**

1. There are statistically significant differences between the results of the pretests and the results of the post tests of the experimental and control groups in improving some types of handball scoring and for the tests of the dimension.

2. There are statistically significant differences between the results of the post tests of the experimental and control groups in the improvement of some types of handball scoring and for the benefit of the experimental group.

**Materials and Method**

**Community and sample research:** The researchers used the experimental approach in the design of equal groups, where the research community was identified as students of the second stage of the Faculty of Physical Education and Sports Science - University of Dhi Qar (60) students divided into Division (C) and Division (D) were chosen. (20) students and hall (C) taught in the manner followed by the teacher (20) students and excluded the researcher a number of sample members, including the sample of the pilot experiment, the number of (16) students, as well as students retreating (4) students.

**Search procedures:**

**Tests used in research:**³

**The first test: the scoring test of stability:**

**Purpose of test:** Accuracy of scoring of stability.

**Tools:** (8) Hand balls, Star to close the goal (4) boxes of 40 * 40 cm.

**Performance:** The player stands behind a 7-meter throw line holding the ball. When the signal is given, the player hits the goal (1), (2), (3), and (4). Repeats performance again.

**Rules:** Take into account the stability of one of the player’s feet and not move during the performance of the throw. Play the ball within three seconds of starting to hear the signal.

**Registration:** A point is calculated for each correction within the custom box.

A zero score will be scored if the player commits a legal offense such as moving his second foot or not scoring during (3second) of hearing the signal.

**The second test: the whistling scoring:**⁴

**Test Name:** Whip Test

**Purpose of the test:** Accuracy of whip scoring.

**Tools:** (10) hand balls, high jump apparatus, curtain mounted on the jump device

**Rules:** A helper stands midway between the jumpers of the jump device at 1/2 m and holds the handball.

**Performance:** The player stands on the 9-meter line and in front of the jumper, the player moves towards the forearm to pick up the ball. (1 - 3) Steps in the direction of the player’s path If the player is right or in the right direction of the player, if the player is easier and then points to one of the boxes (1) or (2) the player performs the previous work itself to aim in the other box.

**Rules:** Do not take more than three steps.

**Registration:** A point for each score is counted within the box.

Zero is counted if the player committed a foul (3 steps or 3 seconds).

**Three test: Test the scoring of the jump:**

**Test Name:** Test the scoring accuracy of the jump.

**Purpose of the test:** measuring the accuracy of scoring near the jump.

**Hand tools:** (10) Handballs, handball, drawn on the wall within five circles (60 cm). Four of them are drawn
in each corner and the fifth is drawn in the middle of the bottom of the bar.

**Method of performance:** The player stands with a ball behind the line length of one meter, beginning with the circle in the upper right corner and left then center to the lower right corner and then the lower left corner.

**Pilot study:** The pilot study was conducted on Tuesday 8/10/2018 on a sample of 16 students. The pilot experiment was conducted at 10 am with the working team on a random sample of students from the Faculty of Physical Education and Sports Sciences/Dhi Qar University/Non-research sample and community of origin.

**The scientific foundations of the tests:** Stability coefficients were calculated and re-applied by taking 16 students and not the main research sample during the trial period. After (7) days, the same tests were repeated on Monday 15/10/2018. As shown in table (1).

**Main experience:** The researcher identified all the main experiment requirements by determining some types of handball scoring.

**Pre Tests:** The pre-test was carried out on the control and experimental groups before starting the program to determine the level of skills in the sample. The tests were conducted on 16-17/10/2018 at 10:30 am. And under the direct supervision of the teacher of material and researchers and the team work assistant in the stadium College of Physical Education and Sports Sciences - University of D-Qar for students of the second phase.

**Parity:** To avoid the factors affecting the results of the main experiment, and to achieve equivalence of the sample of the researcher, the researcher divided the research sample into a control group and the experimental one.

Note in table (3) that all computed values are smaller than the values of (tabular) which were (2.02) at the error rate (0.05) and the degree of freedom (38) there were no statistically significant differences between the two groups in all search variables indicating that the two groups are equal.

**Program:** The researcher began the implementation of the program on Thursday, 22/10/2018 for the first educational unit, which examines the vocabulary of the program in the role-playing style of the first group and in the manner followed by the teacher of the second group. The duration of the educational program is three months (10) weeks. The number of weekly educational units (2 units) is (20) units distributed over three months (90 d).

**Steps of implementation according to strategy Role-playing:**

1. **First: administrative and boot.**
   1. Taking attendance and absence.
   2. Introductory introduction to the skill of preparation in handball.
   3. The teacher explains to the students what roles they should represent.
4. The teacher begins by explaining or presenting the skill by presenting a video or educational medium such as pictures or others.

5. One of the outstanding students in the group apply the skill to be the exchange of roles between the group and observation of performance by the student noted.

**Second: Create Location**: Equip the college playground for the handball game.

**Third:**

1. The educational part The teacher explains the skill and presents it quickly or through an explanatory video or one of the other means, and then the students perform the roles they chose before the applied activity to determine what is required to do any consultation with the students in the group to choose the appropriate role for each of them) the rest of the students play the role of observers or viewers using the observation paper to analyze performance and exchange roles between them.

2. **The applied part**

**Working groups**: The researcher divided the experimental group into four groups. Each group consisted of (5) students and the roles were distributed among the group members.

**The role of the student prepared**: The student is represented by the player in the handball and moves to apply skill in all the centers within the stadium and is the basic in the group is a playmaker and is also the backbone and then the rest of the group exchange roles among them.

**The Role of Observers or Viewers**: Their work shall monitor the performance of the students in each group, taking into consideration the exchange of roles so that they are once observed and again be performed or prepared in the group.

**Fourthly**: Extraction: The student’s personal actions are represented by his/her role and then the cognitive aspect is evaluated. The focus is on the levels of memory, understanding, application, analysis, and composition.

**Fifth**: Evaluating the performance of role play:

1. Individual calendar (self)
2. Collective calendar (Observers)
3. Evaluation of the cognitive side by the teacher and focus on the levels of memory, understanding, application, analysis and installation
4. Evaluation of the skill and emotional side and through the working paper that was written by the observers.

**Posttests**: The researchers used the same steps in the pretest, and distributed the results with separate lists for each group. Processed statistically in order to achieve the research objectives.

### Results and Discussion

Discussion

The results show that there are significant differences between the tests of pre and post and for the benefit of posttests the skill of scoring handball and attributed the researcher the reason for these differences of the experimental group to the impact of the program Prepared by the researcher, which had a positive effect in improving some types of handball scoring through the use of role-playing strategy.6

So that he can reach the level of good performance skill to be taught as he pointed out that the program is the strategy used to achieve the objectives of the educational institution and this is through the design of activities in the learning environment in a way that the learner to achieve the success of performance and helps to increase the motivation of learners and help them in the formation Positive attitudes towards interactive learning with the atmosphere of the lesson in a spirit of seriousness and suspense without boredom or fatigue in the performance.7

On the other hand, the division of learners into small groups working separately made it a state of competition between As well as that some types of scoring as a loss of stability and whipping and aspiration of the jump requires the work of the spirit of the community when performing in the stadium, which includes three elements (teacher, learner, program) and the purpose of these elements to provide students with knowledge, Skills, values, attitudes, and dispositions to achieve specific goals while traditional teaching represents a one-way conceptual communication process from teacher to student. Traditional teaching is often limited in its components (teacher, the Platform), and therefore the rest of the elements (educated) be neglected and the mandatory process orders begin to be the teacher and students to end the implementation of these commands. (The achievement of the maximum in educational situations is due to the program, because it is the method of organizing the subject matter on the basis of step steps, so that the learner can easily acquire them).8

Conclusions

1. There is a preference in the impact of role-playing strategy on the method used in the development of some types of handball scoring among college students, especially in the development of skills and cooperation and commitment and this is what emerged from the results of the research.

2. Show the results of the search the group that used the role-playing strategy achieved the highest ratios on the research sample that implemented the method used by the teacher in improving some types of handball scoring.

Aknowledgment

The authors would like to thank Mustansiriya University (www.uomustansiriyah.edu.iq)Baghdad-Iraq for its support in the present work.

The Impact of the Differentiated Learning Strategy on the Way of Learning Stations in Learning the Skills of Putting Down and Handling Football

Emad Toma Radi¹, Raad Abdallah Kadem¹

¹Department of Physical Education and Sport Sciences, Faculty of Basic Education, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

Through the work of researchers in the teaching profession and as a teacher of mathematical education in the Directorate of Education Baghdad Karkh/3 and to see many of the recent studies in the field of teaching football shows that many students have difficulties in improving skills and that their education requires the application of some modern teaching methods that lead to increase. The researchers found the lack of studies in the education strategy, which is different in the way learning stations, despite its importance in the field of learning skills football according to the researcher’s knowledge, which led him to address this problem and develop appropriate solutions. The researchers used the experimental method to suit the nature of the research procedures. The society defined the research in a deliberate manner, represented by the middle of the mark Hussein Ali Mahfouz for boys in the directorate of Education Baghdad, Third Karkh to provide the appropriate numbers for the sample of the research (A, B, C, D).

Following the implementation of the tests and data collection, the statistical analysis was carried out through which the most important conclusions were reached. The use of the different learning strategy according to the method of learning stations has an effect on learning some of the basic skills of football (handling and put down).

Keywords: learning strategy, learning stations, football.

Introduction

The processes of learning and improvement continue in the teaching methods and methods of learning and exercises and schedule and organization in accordance with the specificity of the game and the skill required to learn and in line with the capabilities and abilities of learners and their stages of study and age and the available capabilities and available for education within the time specified for learning. Each sport has its own specificity through the diversity of skills. This diversity requires trainers and teachers to learn the methods of learning and methods that help to learn and retain the basic skills, including the game of football.

There are many skills in the game of football so they need the supplies and requirements of diversity in the processes of learning because the goal of the teacher is not to provide the mind of the learner information only, but to help him to develop scientific and creative thinking according to different types of learners and this is achieved using strategies and methods that depend on the contribution and participation of the learner in a positive and effective In the process of learning through the use of the education strategy differentiated by the way learning stations in the same unit, and so we can make a diversification in the educational process during the lesson ¹.

In this way we can achieve the objectives of the overlapping teaching methods and their advantages of control, system and good performance in the differentiated
learning strategy according to the method of learning stations, increasing the repetitive attempts of the exercise and giving the learner the opportunity to practice and behave through his behavioral decisions. And reach a goal to take responsibility for decision-making in the correction and give the learner an opportunity to give feedback and exchange between them and increase social interaction among students through the strategy of education distinct. As a result, we have achieved many goals and advantages by linking the differentiated learning strategy in the way of learning stations in the single educational unit. Hence the importance of research in a serious scientific endeavor that the researchers wish to try and find an educational medium in which we may achieve broader goals, whether physical or knowledge or other through the use of learning strategy distinct in the way learning stations to learn the skill of football in the same unit, an idea that is in itself a scientific addition to research and studies specialized in learning the skills of football.²

Research aims: The design of educational units and the differentiated learning strategy according to the method of learning stations in learning some of the skills of football (roller skill and skill handling). To recognize the impact of the differentiated learning strategy according to the method of learning stations in learning some of the skills of football (skill put down ball and handling skills).

Hypotheses:
1. There is a difference of statistical significance for the pre-tests and the results of the tests of the two groups of the skills under study and for the benefit of posttests.
2. There are statistically significant differences between the results of the post tests of the two groups in learning some skills of football and for the benefit of the experimental group.

Materials and Method
The experimental approach was used to suit the nature of the research procedures.

Community and sample search: The number of students in the second stage is average (135) students divided into four divisions (A, B, C, D). (32) Students and (B) (33) students and then selecting (23) students from each department, noting that the rest of the students in Division (A) And (B) entered the experiment, but excluded a number of them to be a sample of the search (46) students distributed in two equal groups. A choice was chosen to be a trial group and Division (B) to be a control group and formed the sample (34.07%) of the research community. The researchers determined the homogeneity of the research sample based on some measurements (length, weight and age) as shown in table (1).

Table 1: Anthropometric measurements

Table (2) shows that the values of the torsion coefficient of the above variables are less than (±3) and indicate the homogeneity of the sample and distributed naturally.

Means of collection of information, instruments and tools used:
- Data collection form and discharge of research information, tests and measurements.
- Football Legal Number (10).
- Football field, flags and flags with different heights.
- Burke planning and identification of test areas.
- Bar length measurement, stopwatch number (2) type (Casio) Japanese.
- Whistle number (2).
- Laptop Type Calculator (DELL).
- Electronic balance type (Sanyo) Japanese-made units of measurement (kg) number (1).
- Swedish Terrace.

Technical tests of football:
Test Name: Test the wall handling for 20 seconds;
Objective of the test: Know the measurement of handling accuracy.
**Test Name:** Put the ball inside the box with measurements (2 mx 2 m):⁴

**Purpose of the test:** Measure the accuracy of stopping the ball in all parts of the body except the arms.

---

**Pilot study:** The researchers conducted a pilot study on a sample of (14) students who were not in the basic research sample was tested on Sunday, 20/10/2018 the aim was:

- Verify the suitability of the tests, the suitability of the equipment, the understanding of the auxiliary team, the time spent on the tests and the knowledge of the obstacles that may arise. And that the tests are based on scientific grounds that the tests applied to the Iraqi environment.

**Pre Tests:** The pre tests were conducted on Tuesday at 10 am on 29/10/2018

**Sample equivalence:** The two researchers performed equivalence on the skill side (handling - put down) of the pulley and as shown in table (2).

**Table 2: The sample parity of the skill side of the football**

Table (2) shows that the degree of error percentage (Sig) is greater than the level of significance (0.05), indicating the random differences between the two groups in the skills under study football for pretests and this indicates the equality of the two groups.
Implementing learning units with a learning strategy that is different in learning methods: A week-long workshop was held for the working team to learn about the differentiated learning strategy according to the learning stations. Two introductory units were given to the students before starting the implementation of the learning strategy.

The curriculum was implemented on Sunday, 3/11/2018. The curriculum included 11 weeks with 22 educational units and two educational units per week, with a 45 minute time, according to the time of the physical education lesson. Thus, the time of the two educational units per week 90) minutes per week. The two researchers set up an educational unit in accordance with the differentiated learning strategy and the method of learning stations. The lesson went according to scientific steps as follows:

1. Divide the students into distinct groups among them after making the parity.
2. The students were divided according to their skill level for each skill.
3. Stations were defined for each learning skill transmitted by the student in the station to the other.
4. Different totals are divided from skill to skill.
5. The unit was used as a whole and not only in the main section.
6. Educational exercises have been diversified in each educational unit.

In the development of the educational curriculum, some of the educational principles and principles were taken into account:

1. Setting goals for the educational unit and has an educational goal or two goals at the most.
2. To achieve each exercise goals and determine its time, taking into account the age of the sample.
3. The use of the ball most of the duration of the unit (the preparatory section, the main section, the final section).

Completion of the application of all educational units on 14/1/2019.

Posttests: Post-tests of the two research groups were conducted on Thursday, 16/1/2019.

Results and Discussion

The researchers attribute this progress to the fact that the use of teaching in the learning strategy of different learning stations, which works on self-reliance as it makes the learners more positive and makes a more dependent self-reliance in the learning process and works to give the learner the freedom to choose which leads to achieve the goals planned and the teacher works on guidance and guidance And provide feedback (A distinct education strategy is dependent on each individual is characterized by the background and speed of learning as well as teaching methods and the way to activate a cycle in the process so that the learner is the focus of the educational process at a time when the teacher role Advisor and Assistant to the learner).5

The researchers also believe that the experimental group offers a unique learning strategy based on the method of learning stations, which considers the learner as active and active, builds his knowledge and knowledge through his correspondence with information and with mutual experiences with others, and focuses on the implementation of innovative ideas in the teaching
line. These results are in particular consistent with what Ahmed Salah has asserted. He pointed out that it is necessary for another person to intervene at appropriate times to help the learner accomplish a task. This is linked to the idea of the region of near growth, which represents tasks that the learner can accomplish alone, and the tasks that can be accomplished with the help of others and this is called differential education which is In other words the support provided to learners when necessary to help them accomplish the tasks required and leave them to learn on their own and based on their own abilities. The exercises that were given during the units came in line with the ability of the students and trying to get balance and control the ball and make the exercise skill is balanced and balanced and this is what is on my understanding “That the student tries to obtain a balance and compatibility is appropriate in order to maintain the strength and smooth movement during the delivery of the ball with the speed and accuracy appropriate “.6

The two groups attribute this progress to learning. The experimental group, which used the differentiated learning strategy according to the method of learning stations, takes into account the individual differences of the students and thus helps to improve the motivation of the student towards what he learns. The differentiated education strategy is based on the principle of education for all students without taking into account their abilities and performance. Their experiences are owned by the assumption that the class contains students varied according to their different environments and different levels of cultural experience, and this is consistent with the scientific sources confirmed that “begins the distinct education calendar that determines the potential of each student mainly to learn and evaluate education starting from its objectives, methods and sources to judge whether the learner has received from the education fit in, calendar to determine the collection of the learner, which indicates for learning”.7

The exercises that were used in the educational units have clearly affected the work of the researchers in the high coordination in the selection of exercises that fit the ability of learners and work with the principle of gradual difficulty of exercise in the skills and the explanation of the good exercises (Explain and explain and understanding the movement and linking with the presentation leads to the advancement of motor skill after comparing the presentation And explanation) 8. Exercise is the quality of the exercise and means how the exercise is performed and depends on motivation, repetition, avoidance of mistakes, and understanding the conditions of the exercise environment 9

The reason for this progress was the continuity and organization in the educational units, which had a positive effect on the progress of the level of skill performance as the students were subjected to the students studied a distinct education to deal with their tendencies and desires. “The differential education provided the opportunity to invest students activities and various exercises that he created This type of education is known as the level of real and according to the activity they perform, and the availability of a number of alternatives represented by activities and exercises varied number led to the student to study and learn the skills of football by choosing the appropriate exercises, and colleagues “.10 The educational units within a curriculum inevitably lead to an improvement in the level that established a scientific basis in the order of the education process, and the choice Exercise is difficult to take into consideration the individual teams as beginners and the use of technological means under the supervision of a specialist according to the atmosphere of education appropriate through the time and space used tools.

### Conclusions

1. The use of the differentiated learning strategy according to the method of learning stations has an impact on learning some of the basic skills of football (handling and put down) and is more effective than the traditional method.
2. The involvement of all students in the application of the performance of different exercises each according to its level and taking into account individual differences contributed to improving their learning process.

3. Taking into account the individual differences in the use of differentiated learning strategy according to the method of learning stations has helped to accelerate the learning of students and according to their abilities and potential in the performance skill.

Biofilm Formation and Antibiotic Resistance of Coagulase-Negative Staphylococci Isolated from Lactating Women with Mastitis in Baghdad, Iraq

Batool Abd Al Ameer Baqer¹, Likaa Hamied Mahdi¹

¹Department of Biology, College of Science, Mustansiriyah University, Iraq

ABSTRACT

Background: Mastitis is a significant problem for many lactating women. It is most common during the first 3 months postpartum. Antibiotics resistance is a trouble of deep scientific anxiety both in hospital and the public settings. Spreading of utilization of a wide spectrum antibiotics increased the rate of antimicrobial resistance among mastitis-causing agents. In addition, biofilm building is great virulence agent of the strains involved in mammary gland infections, taking into account the capacity of drug to cross through bacterial biofilm is related to each antibiotic. Therefore, this study was aimed to isolate Coagulase-Negative Staphylococci and to determine their biofilm production capacity and antibiotics susceptibility.

Method: A total of 247 specimens (breast milk) were collected from lactating women, 147 lactating women with mastitis and 100 from healthy women. The primary identification was based on macroscopic appearance, Grams staining and biochemical tests.

Results: A total of (74) coagulase–negative Staphylococcus isolates were detected (56 from mastitis cases and 18 from controls). Isolates demonstrated the diverse species of the CoNS isolates. Significantly higher rates of isolation of CoNS from lactating mastitis cases was during the later months of lactation than in early months for the same cases. The results of the present study showed a high incidence of mastitis (28/56; 50%) in the period of 12-24 months post-partum than other times.

Conclusions: Coagulase-negative staphylococcus species are an important cause of lactating mastitis and significantly more than in lactating control cases. As there is a significantly higher rate of isolation of CoNS from lactating mastitis cases during the later months of lactation than in early months, particularly in those who fed their babies normally (breast feeding) than in case of those who practiced a mixed type of feeding (breast + bottle). The resistance to diverse antibiotics and a higher ability to form biofilms, found among the strains isolated from milk of women suffering mastitis, might explain the chronic and/or recurrent nature of this infectious condition.

Keywords: Staphylococcus epidermidis, coagulase–negative Staphylococcus, Mastitis, lactating women, antibiotics resistance, biofilm.

Introduction

Mastitis is a significant problem for many lactating women. It is most common during the first 3 months postpartum [1]. Despite available prevention and treatment regimens for mastitis, its incidence remains high [2]. In relation to a survey by the (WHO), the occurrence of mastitis varied from 2.5% to 33% among breastfeeding women [3]. The formation of slime layer, the major part of biofilm production, has a noticeable action in growth of bacteria on external surfaces [4], this slime not only supports bacteria in adhesion to host cells, but also provides protection from phagocytosis and from the activity of antibiotics [5]. Biofilm is an extracellular polymeric substance, which is also denoted to as slime (although not everything described slime is a biofilm).
Biofilms may initiate on living or dead surfaces and can be widespread in natural, industrial and hospital settings\(^6\).

Antibiotics resistance is a trouble of deep scientific anxiety both in hospital and the public settings \(^7\). Spreading of utilization of a wide spectrum antibiotics increased the rate of antimicrobial resistance among mastitis-causing agents \(^8\). In addition, biofilm building is great virulence agent of the strains involved in mammary gland infections, taking into account the capacity of drug to cross through bacterial biofilm is related to each antibiotic \(^9\). Therefore, this study was aimed to isolate Coagulase-Negative Staphylococci and to determine their biofilm production capacity and antibiotics susceptibility.

**Materials and Method**

**Isolation and detection of Coagulase-Negative Staphylococci (CoNS):** A total of 247 samples (breast milk) were collected from lactating women (147 lactating women with mastitis and 100 from healthy lactating women) from Baghdad and Al-Kadhimiya Teaching Hospitals. Women who had antibiotics before 7-14 days were excluded from the study. Each specimen contained 2-3 ml of milk, one ml in each sterile container. The specimens were collected according to \(^8\).

**Identification of CoNS:** A single colony was cultured on Baired barker agar medium and cultivated on mannitol salt agar and on Staph No.110 agar medium and it was identified depending on biochemical test and complete final identification was done according to \(^9\). Growing colonies were identified according to their morphological and biochemical characteristics as described previously by \(^10\) and confirmed by the Vitek2E compact system.

**Antibiotic Susceptibility Test:** Antibiotics susceptibility testing was performed by Kirby-Bauer method according to the Clinical and Laboratory Standards Institute \(^11\) guidelines for the following antimicrobials: Ampicillin (10μg/disc), Erythromycin (15μg/disc), Ampicillin-Sulbactam (10/10μg/disc), Carbenicillin (100μg/disc), Methicillin, Cefepime (30μg/disc), Cefotaxime (30μg/disc), Cefoxitin (30μg/disc), Cefazidim (30μg/disc), Ciprofloxacin (5μg/disc), Gentamicin (10μg/disc), Nalidixic acid (30μg/disc), Temocillin (30μg/disc), Trimethoprime-Sulphamethoxazole (1.25/23.75μg/disc), Tobramycin (10μg/disc).

**Biofilm formation assay for S. epidermidis isolates:** Method of Deka \(^12\) was used to determine the potential of biofilm formation depending on the measurement of Optical Density (OD) of the culture. The OD of each well was measured at 630nm using a microplate reader.

**Results and Discussion**

**Isolation and identification of S. epidermidis:** Microbiological findings, summarized in Table (1), revealed that out of the 147 specimens of breast milk from lactating women with mastitis, only 56 bacterial isolates were obtained and eighteen isolates from the 100 samples collected from the healthy subjects. These isolates were grown on Baired parker medium which differentiates CoNS as dark gray to black, shiny, medium-sized colonies without obvious halos around them \(^13\). In case of Coagulase-Positive (CoP) staphylococci, they appeared the same, but surrounded by a clear hallo. However, on mannitol salt agar, colonies appeared as white, round, smooth, raised, mucoid and glistening, while others which did not have these criteria were discarded. These results were similar to those reported by \(^14\).

**Distribution of Staphylococcal spp. isolates:** Table (2) pointed that most predominant bacterial isolates in lactating women (patient and healthy) were *S.epidermidis* 25(44.64%), 9(50%), respectively. In addition, *S. hemolyticus* formed 25% in mastitis, while no isolation found in case of healthy subjects. Also, *S.hominis* formed 10(17.85%) in cases of mastitis and 6(33.33%) in healthy members. Regarding the non-typable species of CoNS, they were 3(16.66%) in healthy subjects 7(12.5%) among mastitis cases. *S. epidermidis* was the commonest staphylococcus spp. in human milk of mothers suffering breast infection and controls \(^14\).

</table>

When CoNS isolated from both mastitis patients and controls were reviewed, it was seen that S. epidermidis ranked the highest number followed by S. haemolyticus then S. hominis. This finding was in agreement with what was found by [14] who isolated 200 S.epidermidis from 207 milk samples. In addition, [15] found that CoNS followed by S. viridans bacteria were often isolated from milk samples.

The predominance of S. epidermidis can be explained by the fact that this microorganism is normal flora on the breast skin and have the ability to become pathogenic for any cause as it was confirmed by [16].

Time of occurrence: Table (3) showed that there was significantly higher rate of isolation of CoNS from lactating mastitis cases during later months of lactation than during early months for the same subjects and also when compared to control group.

*: Significant P value.

The results of current study showed a high incidence of mastitis (28/56; 50%) occurred within a period of 12-24 months post-partum than other times. This result agreed with [5] who mentioned that mastitis may occur at any stage of lactation, including in the second year. It was also different from the results of [17] who stated that the first three to six months of postpartum period is more vulnerable for breast infection in lactating mothers.

It could also be attributed to the fact that the child in this age can eat food which may have an impact on the oral bacterial flora and may lead to contamination of the breast and then may leads to breast infection, while other age groups approximately are completely breast-fed. Also, children in this age have teeth by which they can bite the nipple and cause infection.

Type of feeding: Table (4) showed that the rate of isolation of CoNS was significantly higher in women who fed their babies normally (breast feeding) than in those who practiced a mixed type of feeding (breast+bottle feeding). The explanation for these data was that frequent sessions of breast feeding end with more breast trauma and/or more exposure to babies’ oral flora and nipple fissure, so more chance of breast infection [18].

Antibiotic susceptibility test: Current study revealed that in vitro susceptibility of S. epidermidis isolates to antibiotics (Figure 1) exhibited a marked variation in the susceptibility pattern to different antibiotics. The highest resistance percentages were found towards Ampicillin and Erythromycin (100%), Trimethoprim-Sulphamethoxazole (98.52%), Methicillin (97.05%), Carbencillin (95.58%), Gentamicin (72.05%), Cefotaxime (61.76%), Temocillin (60.29%), Cefazidim (58.82%), Cefepime (55.88%), Ciprofloxacin(54.41%), Ampicillin–Sulbactam (52.94%), 52.94%, 48.52% and 45.58% of all S.epidermidis isolates were resistant to Cefoxitin, Nalidixic acid and Tobramycin, respectively.

On the other hand, Tobramycin was the most effective antibiotics since it recorded the lowest resistance percentage (45.58%). Also, all the 33 isolates of S.epidermidis industrialized multidrug resistance.
Biofilm detection by using microtiter plate: All the 34 (100%) S. epidermidis isolates were found to be biofilm producer. However, 25 isolates (73.52%) formed strong biofilm, whereas one isolate (2.94%) was weak biofilm former. Alongside with 8 isolates (23.52%) were moderate biofilm producer (Figure 2).

As shown in Table (5) there were differences in OD values which were corresponding to the differences in thickness of biofilm compared to control OD$_{540}$ (0.092). The S. epidermidis isolates S. 6 and S. 25 gave the thickest (strong) biofilm (1.809 and 1.582, respectively). S. epidermidis 32 isolate recorded the lowest OD$_{540}$ (0.137) which was designated as weak-producer isolate. It could be concluded from this table that there was good association between antibiotic resistance and biofilm formation. Methicillin-resistant S. aureus and CoNS were referred to as MRSA and MR-CoNS, in respect, even though methicillin was not used yet in clinical, but altered by other penicillinase-stable penicillins such as oxacillin and flucloxacillin [19]. Currently, however, many infections of CoNS Staphylococci resistant to vancomycin are now appearing, as a majority has developed the biofilms [20].

These results were similar to those reported by [21] who suggested that the findings of their study showed that staphylococcal isolates containing biofilm character showed more resistance to antimicrobial agents, so they were difficult to treat [22].

Conclusions

Coagulase-negative staphylococcus species are an important cause of lactating mastitis and significantly more than in lactating control cases. As there is a significantly higher rate of isolation of CoNS from lactating mastitis cases during the later months of lactation than in early months, particularly in those who fed their babies normally (breast feeding) than in case of those who practiced a mixed type of feeding (breast + bottle). The resistance to diverse antibiotics and a higher ability to form biofilms, found among the strains isolated from milk of women suffering mastitis, might explain the chronic and/or recurrent nature of this infectious condition.

Late Electrographic Seizures in Iraqi Patients with Stroke; The Role of Antiepileptic Therapy

Fizel Abbas Al-Himyari
Hammurrabi Medical College, University of Babylon, Babylon, Iraq

ABSTRACT

Background: Studies on post-stroke seizures whether clinical or subclinical have given conflicting results. Therefore, the aim of our study was to elucidate the incidence of late electrographic (EEG) seizures (after one month from the stroke) and to observe the role of antiepileptic therapy in reducing proceeding clinical seizures or epilepsy in Iraqi patients.

Method: The study was done in Iraq in both Baghdad and Babylon Teaching Hospitals. Follow up was done after that and the patients were given antiepileptic therapy for 2 years. The number of patients was 198. One hundred and thirty of them had ischemic stroke and 68 had hemorrhagic stroke. The number of male patients was 110 and that of females was 88. The control group patients were (100). The drug levitiracetam was given to 50% of the patients with ischemic stroke and to 50% of those with hemorrhagic stroke with late electrographic seizures and follow up was done for both groups on levitiracetam and those without for 2 years.

Results: The results showed that late electrographic seizures were seen in 30% of ischemic stroke patients and 50% of hemorrhagic stroke patients. Clinical epilepsy was observed in only 5% of those with hemorrhagic stroke patients on levitiracetam and in 20% of those hemorrhagic stroke patients without medication. Clinical epilepsy was also observed in only 2% of ischemic stroke patients on levitiracetam and in 10% of those with ischemic stroke, but without medication.

Conclusion: Late electrographic (EEG) seizures commonly occur in stroke patients. Prescribing antiepileptic therapy to those patients reduced the incidence of clinical seizures or epilepsy. We recommend giving antiepileptic drugs, especially levitiracetam to stroke patients with late electrographic seizures for at least 2 years.

Keywords: Epilepsy, EEG, Levitiracetam, Hemorrhagic stroke, Ischemic stroke.

Introduction

Stroke commonly causes seizure in old age population (1-3). Also, the incidence of stroke increases in old age. Cerebrovascular disease seems to be the initial cause of epilepsy in elderly population (1-4). Post-stroke Epilepsy in young patients is a problem that effects the outcome in a negative way, even after 10 years after ischemic stroke (5). Seizures occurred in one third of patients with intracerebral hemorrhage and more than half were purely electrographic. Electrographic seizures were associated with increasing hemorrhages and poor outcomes (6). Our study stresses on late electrographic seizures (after one month) in both ischemic and hemorrhagic stroke in Iraqi patients.

The EEG in patients with stroke was studied especially in the acute phase. Its features showed weak correlation with the clinical state and to the recovery (7-12). It has been sought that the EEG could be used to show involvement of the cortex undetected by computed tomography (C.T. scan) (13) and to evaluate the outcome of endarterectomy (14).

The objectives of current study were to elucidate the incidence of late electrographic seizures (after one month) in Iraqi patients with stroke and to observe the role of antiepileptic therapy in reducing proceeding clinical seizures.

Materials and Method

Study population: One hundred and ninety eight patients were studied. The study was done in Iraq in both Baghdad and Babylon Teaching Hospitals. One hundred and thirty patients were with ischemic strokes and sixty eight were with hemorrhagic strokes. Those with brainstem, cerebellar strokes, subarachnoid hemorrhage, arteriovenous malformation, transient ischemic attacks pseudostroke and subdural hematoma were excluded from the study. Male patients were (110) and females were (88). In addition, (100) age-comparable subjects were recruited as control group. Antiepileptic therapy (Levitiracetam 500mg daily) was given to 50% of ischemic stroke patients and to 50% of hemorrhagic stroke patients with late electrographic seizures and follow up was done for both groups with and without antiepileptic therapy for 2 years.

A 16-channel EEG device was used for this study. The EEG electrodes were connected to the scalp using a head cap according to the international (10) system. The electrical signal was amplified and filtered.

EEG evaluation included the followings: Normal EEG 2-Focal slowing 3-focal sharp and slow wave,s 4-focal sharp waves 5- focal spikes and slow waves, 6-generalized slow waves7-focal spikes and PLEDS.

Clinical testing: Neurological examination, routine blood evaluation and head C.T scan were performed for every patient. The NIHSS were used to evaluate the stroke severity as 0 (no stroke symptoms) 1-4 (minor stroke) 5-15 (moderate stroke) 16-20 (moderate to severe) and 21-42 (severe stroke).^{(15)}

Statistics: It was done by means of chi-squared (measurement of P- value). Collection and analysis of the EEG data were done at the baseline level and then every 3 months for 2 years for the stroke and control groups

Results

Our study showed that late electrographic seizures (after one month) were seen in 30% of ischemic stroke and in 50% of hemorrhagic stroke. We defined post-stroke (clinical) epilepsy as a condition in which patients have a single seizure happening with a situation that could cause epilepsy (such as stroke) met the criteria of epilepsy.^{(16,17)} Post-stroke seizures were divided into early onset seizures (within 7 days after stroke) and late seizures (occurring later).^{(18)}

Patients with late electrographic (EEG) and late clinical seizures were added to the study. Clinical seizures or Epilepsy were only observed in 5% of those with hemorrhagic stroke patients on antiepileptic therapy and in 20% of those with hemorrhagic stroke patients without antiepileptic therapy. Only 2% of those patients with ischemic stroke on antiepileptic therapy had clinical epilepsy, while it was seen in 10% of those without antiepileptic therapy. The tables below showed demographic profiles and parameters for both the studied stroke patients and their controls (with significant p-values).

**Discussion**

This study suggested that late electrographic seizures commonly occur in stroke patients. Prescribing antiepileptole therapy reduces the incidence of proceeding clinical seizures or epilepsy. This study also recommended giving antiepileptole therapy, especially levitiracetam for at least 2 years (19-22).

Antiepileptole drugs (as a prophylaxis) may not be prescribed in most types of strokes except in Aneurysmal Subarachnoid Hemorrhage (Ruptured type). When early seizures occur, treatment was given, but may not be for a prolonged time. If late seizures occur, chronic anticonvulsant treatment is advised (23).

The European guidelines advice the use of antiepileptole drugs to prevent after-stroke seizures, but prophylactic therapy for patients who have not sustained a seizure is not recommended (24,25).

Levitiracetam was well-tolerated in our study. Other studies also showed no significant interactions between Levitiracetam and antiplatelet therapy or warfarin (26). Further studies are needed to evaluate the correlation between late electrographic seizures and the mortality in stroke.

**Conclusion**

Our study showed that giving Levitiracetam to stroke patients with late electrographic seizures reduced the incidence of epilepsy by 10%. We recommend giving antiepileptole therapy especially Levitiracetam for stroke patients with late electrographic seizures for at least 2 years.

The Spectrum of Resistant Respiratory Infection in a Group of Iraqi Patients with Chronic Lymphocytic Leukemia

Waseem F. Al-Tameemi¹, Hawraa D. Tuma¹, Jabbar S. Hassan³

¹Department of Medicine (Hematology Unit), College of Medicine, Al-Nahrain University, Iraq; ²Baghdad Teaching Hospital, Medical Complex, Hematology Unit, Iraq; ³Department of Microbiology, College of Medicine, Al-Nahrain University, Iraq

ABSTRACT

Background: Chronic lymphocytic leukemia (CLL) is the most common form of leukemia in the Western world but it significantly less frequent in Asia. Infectious complications continue to be the major cause of morbidity and mortality in CLL patients. Indeed, they account for the leading cause of death in most series that ranged between 30 and 50%. They were rendered susceptible to infections due to disease-related immunosuppression in addition to prolonged immunosuppression induced by treatment agents. The aim of current study was to define the microbiological spectrum of resistant respiratory tract infection in a group of Iraqi chronic lymphocytic leukemia (CLL) patients.

Method: Thirty-eight patients were enrolled in this cross-sectional study which was conducted from March 2017 till June 2018 in different hematology centers in Baghdad, Iraq. It included any CLL patient presented with chest infection that didn’t respond to empiric treatment. One to two early morning sputum samples were taken from each patient that subsequently examined by direct Gram stain, culture media and direct fungal stain with culture, as well as special stain for diagnosis of Pneumocystis jirovecii infection.

Result: The median age was 60.58 ± 7.76 years with a mean of disease duration 3.42 ± 2.61 year. Advanced age was associated with increasing risk of chest infection (P= 0.003). Bacterial infection represented (42%) of cases followed by fungal infection as (26%). Gram-negative bacteria were the commonest pathogens as (34.2%). P. aeruginosa being the most common species, while (26.3%) had Gram-positive bacteria such as S. pneumonia. Five patients (13.16%) were labeled as positive for Mycobacterium tuberculosis. Pneumocystis jirovecii was detected in (3%) of patients.

Conclusion: Bacterial infection continued to be the most common pathogens comprising Gram-negative and followed by Gram-positive microorganisms in addition to Mycobacterium Tuberculosis with an increasing incidence of fungal infection.

Keywords: Chronic lymphocytic leukemia, immunosuppression patients, Bacterial infection, Fungal infection, Chest infection.

Introduction

Chronic lymphocytic leukemia (CLL) is the most common form of leukemia in the Western world, but it significantly less frequent in Asia (¹). In Iraq, the incidence of all subtypes of leukemia is 4.43 cases per 100,000 of which 5.34% of cases are CLL according to annual report of cancer disease in Iraq 2013. Infectious complications continue to be the major cause of morbidity and mortality in CLL patients. Indeed, they account for the leading cause of death in most series that ranged between 30 and 50% (²). They are rendered susceptible to infections due to disease-related immunosuppression in addition to prolonged immunosuppression induced by treatment agents (³).

There are both quantitative and qualitative defects in immune effector cells that results in abnormal cellular-and humoral-mediated immune responses with a
reduction in normal immunoglobulin (IgG, IgA and IgM) levels during the course of the disease. Seventy percent of CLL patients develop hypogammaglobulinemia within 7 years of diagnosis (4). Its severity tends to increase with the prolonged duration and advanced stage of the CLL. Even in successfully-treated patients, there is rare recovery of immunoglobulin levels, however, a recent study suggested that use of high doses of rituximab in CLL can improve immune dysfunction and restore, in part, the production of immunoglobulins (5).

Therapies can contribute to increasing respiratory infections by inducing T-cell defects and neutropenia resulting in pyogenic infections due to S. aureus, S. pneumoniae, H. influenza, Klebsiella and E. coli (6). Other infections like Candidiasis, Aspergillosis, Nocardia, Listeria, Mycobacteria and Pneumocystis jirovecii pneumonia can occur, but are uncommon in CLL patients treated with alkylating agents alone (7).

Patients and Method

Study Design and Setting: A hospital-based cross sectional study was conducted in the haematology department at Al-Imamian Al-Kadhmain Medical City, Baghdad Medical City and the National Center of Haematology at Al-Mustansiriyah university over 15 months duration from March 2017 till July 2018.

Study Subjects: Thirty eight patients, who were diagnosed to have chronic lymphocytic leukemia (CLL) on basis of manifestations and laboratory tests, were enrolled in this study. They presented with non-responsive chest infection (chest infections did not show clinical improvement within 72 hours of empirical therapy initiation). They were usually under chemo–immune therapy according to their disease characteristics. Patients having any of other lymphoproliferative diseases, in addition to those with active pulmonary TB, were excluded from the study.

Data Collection: Demographic data were collected from patients and included stage and the duration of disease, the previous lines of treatment, radiological evidence of chest infection and result of complete blood count (CBC).

Specimen Collection and Handling: Sputum sample (5-10ml) was directly collected from each patient by sterile screw cup bottles and labeled by case number and name, and immediately placed on ice then transferred into the laboratory (microbiology department at College of Medicine/Al-Nahrain University) for processing and investigations on the same day.

Statistical Analysis: Data were statistically analyzed using the Statistical Package for the Social Sciences (SPSS; 2015). Continuous variables were expressed as mean ± standard deviation (SD). The Pearson’s Chi-squared test or Fisher exact test was used for comparing categorical variables. A two-sided significant level of 0.05 was considered to indicate a statistically significant difference.

Results

Demographic characteristics of study populations were shown in Table (1).

Results of current study (Figure 1) revealed that 18(74.37%) received two previous lines of chemotherapy, while 13(34.21%) of received only single line of chemotherapy. The most frequent regimen was fludarabine, cyclophosphamide, rituximab (FCR) in twenty-two patients (57.89%).

Microbiological characteristics: Conventional microbiological investigations revealed that 16(42%) patients had bacterial infection, while 10(26%) of them had fungal infection. Mixed bacterial and fungal infections were reported in 9 (24%) patients. However, two patients showed no microbial growth (Figure 2).

Direct Gram stain revealed that 13(34.2%) patients had Gram-negative bacteria, while the rest (26.3%) had Gram-positive bacteria. It was found that *P. aeruginose* and *Klebsiella spp.* constituted the highest percentages (15.79%, 7.89%), respectively, followed by the *Acinetobacter baumanni* (5.26%) and then *Proteus species* and *Ewingella Americana* at a percentage of (2.63%) for each. Acid-fast bacilli (AFB) staining was positive in five patients (13.16%). Fungal infection was discovered in (26%). The most common isolated fungi being *Candida albican* (15.79%) followed by *Aspergillus* (7.8%), *Cryptococcus neoformans* (5.26%), *Rhizopus spp.*, *Candidia glabrata*, *Chrysosporium zonatum*, *Candida tropicalis*, *Candida parasilosis* each one (2.63%). Modified Giemsa stain (Diff-Quik stain) detected one case with positive *pneumocystis jirovecii pneumonia* (PJP). Spectrum of microbial pathogen was shown in Figure (3).
Hematological Parameters: Laboratory data revealed that the maximal level of WBC in this study was $209 \times 10^3$ ml, while the minimal level was $0.8 \times 10^3$/ml, with a mean level of $34.6 \times 10^3 \pm 52 \times 10^3$/ml (median was $12 \times 10^3$/ml). There was no statistically significant association between WBC count and development of chest infection ($P = 0.515$; Table 3). The absolute neutrophils count (ANC) ranged from $(0.4–10) \times 10^3$/ml, with a mean of $6 \times 10^3 \pm 12 \times 10^3$/ml (median was $4.1 \times 10^3$/ml) without statistically significant association, too ($P= 0.44$). Platelets count ranged from $7 \times 10^3$ to $355 \times 10^3$/ml) and the mean $\pm$ SD was $133 \times 10^3 \pm 88 \times 10^3$/ml, with statistically significant association ($P= 0.025$; Table 3).

Discussion

In spite of the improvement in supportive care, infection is still a significant cause of mortality and morbidity in CLL patients. Approximately, 80% of patients developed an infectious complication during the course of their disease with the lung being the most common site (8).

In the current study, bacterial infections were recognized in (42%) of patients, mostly identified as Gram-negative bacilli (34%) which is compatible with (9) who reported that (37%) of CLL patients were affected by Gram negative bacteria. Similarly, (10) reported that 35% of CLL patients were exposed to Gram-negative bacterial infection. This can be explained as the most prevalent microorganism in any immuno-compromised patients or those acquiring infection during their hospital stay. In most medical centers, *P. aeruginosa, Klebsiella* and *E. coli* were responsible for 60 -70 % of Gram-negative infections (9,10) being the most prevalent infectious pathogen which is in agreement with this study.
Regarding Gram-positive bacteria, *S. pneumoniae* was found to be the most frequent pathogen in this group which represented (15.79%), followed by *S. aureus* (10.53%). This finding was higher than that reported by (11) who identified only 4% of CLL patients with respiratory tract infection in a study done over a period of 18 years. This difference can notify the importance of general hygiene principles in avoiding community acquired infections.

Current study had emphasized on the rate of occurrence of *Mycobacterium Tuberculosis* in CLL which was in this investigation (13%). It was higher than what that recorded in a large retrospective study done over 10 years from 1990-2000 on 917 patients with hematological malignancies where the prevalence of TB was 6.9% (12) in contrast to other older repots (13). This variation report can be explained that TB is considered endemic in our region.

It seemed that results of fungal infection in current study were higher than what was observed by (14) which was a large monocentric retrospective study. All patients had chronic lymphoproliferative disorders admitted between 2006 and 2014, from those 305 CLL patients, four patients (1.3%) only found to have fungal infection, (1%) with candida infection and (0.3%) with aspergillus infection. The risk of fungal infection was reported in many studies such as (15) who found that the incidence of fungal infection in CLL was 7.8%, while (16) reported that the risk of fungal infection was (4%). It was believed that these findings were so worrisome for raising possibility of fungal infection in resistant respiratory tract infection in CLL patients that can be assumed to be secondary to liberal prophylactic antibiotics used by most patients.

It is already known that fludarabine-based treatment had resulted in increasing risk of pneumocystis jirovecii infection which current study reported to be prevalent in (3%) of patients only. This figure was lower than the 33% reported by (17). Those patients were commonly advised to use prophylactic trimethoprim–sulfamethoxazole that may lessen this infection rate.

In current study, no growth of bacteria was detected in (5.26%) of patients which may be due to prophylactic antibiotics use or presence of viral infection or the presence of unculturable bacteria. Generally speaking, it is documented that a good quality sputum could be obtained only in 14.4% of cases (18).

There were no statistical association among any of hematological parameters with risk of infection apart from prolonged thrombocytopenia (P= 0.025) which simply could be attributed to the effect of infection on recovery of some blood parameters.

**Conclusion**

An increasing risk of recurrent and resistant respiratory tract infection in CLL patients is a common heath burden. Bacterial infection is still continued to be the most common pathogen comprising Gram-negative micro-organisms and followed by Gram-positive micro-organisms in addition to *Mycobacterium* infection. A progressive scale of increasing fungal infection is already reported as a second frequent etiology in respiratory infections.

Genotyping of Ataxia-Telangiectasia Mutated (ATM) Polymorphisms in Patients with Breast Cancer

Maryam Sabah Naser1, Rabab Omran1, Shakir H. Mohammed Al-alwany1

1College of Science, University of Babylon, Iraq

ABSTRACT

Background: The Ataxia-telangiectasia mutated (ATM) gene encodes a protein kinase with PI-3 kinase–related domain that plays a significant role in the activation of cellular responses to DNA double-strand breaks through subsequent phosphorylation of central players in the DNA damage-response pathway. Many studies explained that specific variants in the ATM gene are related with malignant breast tumors risk. The aim of current study was to assess the rates of Ataxia-telangiectasia mutated (ATM) genetic polymorphism in a group of breast cancer and apparently normal breast tissues.

Method: One-hundred and fifty 150 frozen fresh breast tissues were enrolled in this study as 100 biopsies were from breast carcinoma and 50 were from apparently normal breast tissues as control group. Detection of ATM (c.IVS10–6T > G) variants was performed by using polymerase chain reaction (PCR)-restriction fragment length polymorphism (RFLP) analysis.

Results: Detection of ATM (IVS10–6T > G) mutation in tissues with breast carcinoma was observed in six out of 100, while in apparently normal breast tissues (control group) was one biopsy out of 50. The statistical differences between the rates of ATM (IVS10–6T > G) mutation were non-significant (P≤ 0.05).

Conclusion: Our results indicated that the ATM gene c.1066–6T > G (IVS10–6T > G) mutation did not contribute to the development of a subset of breast malignant tumors in Iraqi population.

Keyword: ATM genotyping, Breast cancer, PCR-RFLP, polymorphism, protein kinase.

Introduction

Cancer is a group of diseases that cause cells in the body to change and spread out of control. Most types of cancer cells eventually form a lump or mass called a tumor. Breast carcinoma is the most frequent malignancy in women in most populations, constituting about 20% of all female carcinomas (1). Breast carcinomas are potentially highly malignant tumors. The latter are pathologically and clinically heterogeneous diseases with variable prognosis (2). It was estimated that heritability explains about 30% of the variation in breast cancer risk, the remaining 70% being attributable to several environmental risk factors. Thus, approximately one-third of the variation in breast cancer risk in a population can be accounted for by inter-individual genetic differences (3). As the authors highlighted, this estimate includes both cancer-specific genetics and genetic contributions to some cancer risk factors, such as obesity, that have a genetic component (4). Although genetic factors overall are presumed to play a rather small role in the etiology of breast cancer, mutations in BRCA1 or BRCA2 genes remarkably increase the risk of breast cancer, especially in early-onset disease. One affected first-degree relative doubles the risk and the risk increases further with more affected relatives (5).

ATM is a serine/threonine protein kinase that is recruited and activated by DNA double-strand breaks located on the long (q) arm of chromosome 1, between positions 22 and 23 (11q22-q23) (6). It phosphorylates several key proteins that initiate activation of the DNA damage checkpoint, leading to cell cycle arrest, DNA repair or apoptosis. The protein was named for the disorder ataxia-telangiectasia caused by mutations of ATM (7).
There are two main checkpoints, the G1/S and the G2/M, during the cell cycle, which preserve correct progression. ATM plays a role in cell cycle delay after DNA damage, especially after double-strand breaks (DSBs) (8).

The aim of current study was to study ATM mutation in relation to a set of breast cancers in Iraq population.

**Method**

**Study Population:** A case-control study was conducted between January 2018 and December 2018 in the Biotechnology and Genetic Engineering Laboratory, Department of Biology, College of Science/University of Babylon, Iraq. In addition, biopsy samples were collected from private laboratory. This study was performed using 100 samples. The biopsy samples were collected from patients suffering from malignant breast cancer (100 samples) and 50 samples apparently healthy as a control group.

**DNA isolation and PCR-RFLP amplification:** Genomic DNA was extracted from fresh tissues using DNA extraction kit (zymoresearch). Genomic DNA was dissolved in TE (10mM Tris-HCl and 0.1mM EDTA, pH 8.0), confirmed by agarose gel electrophoresis. Spectrophotometry was used to quantify DNA using the Nanodrope Plus spectrophotometer. Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis was performed to determine the IVS10–6T > G variants of ATM gene.

**ATM IVS10–6T > G polymorphism analysis:** A PCR–RFLP assay was used to detect the ATM IVS10–6T > G variant using Thermal Cycler (Applied Biosystems). A 193bp PCR product was amplified using the following primers: Forward; 5-ACAGCGAAACTCTGGCTCAAA-3, Reverse; 5-TGATCTTTTATTTACTTCCCCAGCTTAGT-3 in a final volume of 20μL as described in Table (1). Cycling conditions were 94°C for 4min, followed by 36 cycles of 20s of denaturing at 94°C, 20s at 53°C, and 20s of annealing at 72°C, with a final extension at 72°C for 7min. The PCR products were digested with the RsaI restriction enzyme. Digestion was performed in a total volume of 20ml containing 10ml PCR product, 1X digestion buffer, 0.1mg/mL BSA and 3U of RsaI by overnight incubation at 37°C. The digested products were separated by electrophoresis on a 3% agarose gel staining with ethidium bromide.

**Statistical Analysis:** Statistical analysis was carried out using SPSS version 16, where data were expressed as Means ± Standard Error. One-sample t-test, One–way ANOVA, Chi–Squared test, Pearson’s chi-square (X2) test, Odds ratio were used to identify the danger factors of renal failure with their 95% confidence interval (CI), were used to find the association between the categorical variables, P≤ 0.05) was considered statistically significant.

**Results**

**Genotyping of ATM Polymorphisms:** The results revealed that the presence of a single band (196bp) of the target sequence of ATM gene in the agarose gel electrophoresis (Figure 1).

**Figure 1:** Amplified product of the target sequence of ATM gene in breast cancer patients and healthy controls. M: DNA size marker; the amplified products were a single band of 196bp in size. Electrophoresis conditions were 1% agarose concentration, 75V, 20mA for 120min and stained with ethidium bromide.

After that, the amplified products of the ATM target sequences were digested with Rsal (5’ GT+AC 3’) restriction enzyme (Figure 2) to detect the IVS10–6T > G SNP in ATM gene shown in Figure (1).
Figure 2: Allele typing patterns of ATM gene; where A: a homozygous allele (GT) had two bands (58 and 135bp) molecular size in breast cancer and B: homozygous allele had single band with 196bp molecular size. M: DNA ladder 100-1100bp. The digested products using Rsal enzyme by PCR-RFLP were migrated into 3% agarose, 75V, 20mA for 120min, 15µl in each well, and stained with ethidium bromide.

ATM-PCR-RFLP: The results of PCR-RFLP showed ATM polymorphism which appeared as two bands (58 and 135pb), while the uncut band (193bp) indicated the wild type allele due to lack of Rsal restriction site. All restricted fragments were observed for homozygous genotype. Statistical analysis showed non-significant differences (Table 2).

Discussion

Breast cancers have been ranked as the top on the commonest ten cancers in Iraqi provinces and districts, accounting for about one third of the registered female cancers. The majority of molecular events in the genesis of breast cancer are unknown. Hereditary, hormonal (estrogenic hormones and derivatives), environmental and life style factors have been attributed to play a role in breast carcinogenesis (1).

The ATM gene, encoding a large protein kinase, is mutated in ataxia-telangiectasia (AT), an autosomal recessive disease characterized by neurological and immunological symptoms as well as cancer predisposition. Previous studies suggested that heterozygous carriers of ATM mutations have an increased risk of breast cancer compared with non carriers, but the contribution of specific variants was difficult to estimate (9).

In the present population-based case-control study, we evaluated for the first time the involvement of ATM mutations IVS10–6T>G. The results of the PCR-RFLP showed non-significance of the (IVS10–6T > G) in Iraqi patients suggesting that the frequency of those variants is extremely low (or not present) in Iraqi population. The ATM gene has long been hypothesized to be a breast cancer susceptibility gene, but the evidence was contradictory. Most mutation analyses of ATM in patients with breast cancer and in control subjects did not find increased frequency of mutations in case of patients that would be expected if these mutations did predispose to breast cancer (10,11). Also, (12) found no evidence for a difference in the risk of breast cancer or other cancers according to the type of ATM mutation, while the risk estimate (13) was based mainly on truncating mutations. Haplotype analysis could also reveal a role for common variants in the ATM gene in causing breast cancer. Five biallelic haplotype tagging
single nucleotide polymorphisms (SNPs) have been estimated to capture 99% of the haplotype diversity in Caucasian populations. On the other hand, IVS10–6T?G ATM mutation has been detected in the homozygous state in one German patient with full blown A-T (14). This leaky splicing mutation appeared to be the most common pathogenic ATM gene mutation at the population level although it was infrequently compared with other ATM mutations in ataxia-telangiectasia patients (15). Our results thus refute those of who proposed that the ATM IVS10–6T > G mutations are high-risk breast cancer-susceptibility alleles (16).

Conclusion

Our results might point for none existent role for the ATM mutation in the early stage of development of a subset of breast cancers in our Iraqi patients.

STR Mutation at D13s317 Locus in 18D-V2.0 Powerplex Kit and 24 Loci Global Filter Kit in Paternity Match cases

1Medico-Legal Directorate, Ministry of Health, Iraq; 2Genetic Engineering and Biotechnology Institute, University of Baghdad, Iraq; 3Public Central Health Lab, Ministry of Health, Iraq

ABSTRACT

Background: Mutations that occur in short tandem repeats technique, might lead to alleles mismatched between the child and their parents, which complicate the forensic decisions in Paternity cases. Most of reported microsatellite was confined to single-step mutations. In the present study we reported case of a paternity case processed by 18 loci PowerPlex kit from (Promega) with a mismatch in locus D13S317.

Method: The genotypes of the alleged father, the mother and the child in D13S317 locus were 11/12, 8/12 and 8/13, respectively. These samples were reprocessed with another forensic kit of a different primer which is 24 loci Global Filer from (Applied Bio System) to ensure the mutant alleles. After interpretation of data was made and statistical analysis was calculated in dependable software (Gene Marker HID).

Results: The results stated that the alleged father is the biological father of the child.

Keywords: Paternity match cases, STR mutation, single-step mutation, multiple-step mutation, forensic decision.

Introduction

Short tandem repeat (STR) technique is an efficient tool used worldwide to ensure the paternity match between children and their parents which follows the traditional Mendelian Inheritance. One problem with it is the STR mutations which cause the allelic mismatches in the child compared to parent, making the forensic interference more complex in paternity testing. Most of the reported microsatellite mutations were confined to single-step mutations [1-5]. Several factors can affect the rate of slippage events, among which the repeat unit which is the most important factor. A negative correlation was suggested between the length of the repeat unit and the rate of slippage [6]. In addition, [7] showed that the rate of slippage was the highest in dinucleotide STRs and the lowest in tetranucleotide STRs. This is consistent with the observation that the longer the repeat unit, the less the total amount of STRs. Probably because longer repeat units would require the strand to slip further before the bases could pair correctly again, and then they become less common in the genomes. Besides the repeat unit, other factors such as the number, location and sequence of repeats are also likely to affect the rate and direction of slippage [8]. For instance, in humans, the rate of slippage events exponentially increases with the increasing repeat number [9]. Multistep-mutations were rarely discovered in STR loci compared to single-step mutation and they only account for a very limited number of STR mutation events. Previous studies reported a single-step mutation at locus D13S317 in paternity testing [10,11].

Materials and Method

Samples: Blood samples were collected from the alleged father, mother and child. Informed permission was obtained from the parents to use their FTA blood samples in DNA profiling and subsequent research.

STR Profiling: Genomic DNA was processed by direct PCR by Punching the FTA with Puncher (Harris). The kit used was the powerplex 18 V2:0 (Promega
corporations as per manufacturer’s instructions). The PCR amplifications were performed using Gene Amp PCR system 9700 (Applied Biosystems) as follows:

- 5µl was added primer per mix
- 5µl Master Mix 5X
- 15µl Distalled Water, Amplification grade
- 2µl Control DNA samples for father, mother & Child.
- As a total volume of 12µl for processed samples.

Vortex for the amplicon then loaded into PCR System 9700 for 28 Cycles. (Instruction of use was found in powerPlex 18D system technical manual+Tmd031). WwW.promega.com/Protocols

**Post PCR**

PCR products were loaded into ABI 3130 XL Genetic analyser using:

| WEN internal lane stander 500 | 0.5µl |
| Formamide | 9.5µl |
| DNA Samples | 2.0µl |

Denaturation for samples was done in PCR 9700 for 5min, soaked in ice for 5min.

Then loaded in the plate in Genetic Analyser using polymer 4, buffer and deionized distal water. The analyser was set for the standardization of PowerPlex Criteria (standard Labs).

STR profiling was generated by gene mapper ID V3.2 software (applied Biosystems).

The samples were processed for a second time in different primers to ensure the mutation at locus D13S317 in global filer STR Kit 24 loci from applied bio system. The same procedure was done for the direct PCR loading in 3500 Genetic Analyser (Applied bio System).

**Statistical Analysis:** The paternity index was calculated in standard using the frequency of alleles from the population genetic data for 20 autosomal STR loci in an Iraqi Arab population: Application to the identification of human remains [12].

Figure 3: The family pedigree for the alleged father, mother and the child showing all genetic markers involving the mutant alleles.
The PI was calculated for the same individual, coded C, was the child male sex XY and he had a PI E+21^7. The PI for the alleged father, who coded A, was calculated with the child and the value was E+04^4. In addition, the PI for the mother, who was coded B, with the child was E+07^2.

All results led to conclude that the alleged father was the biological father.

**Discussion**

This study presented a standard paternity test to examine autosomal STR loci using both PowerPlex 18 D STR Kit and 24 loci of global filer STR kits (Applied Bio System) and they got the same results for that all loci were matched accurately by Mendelian Inheritance law, except locus D13S317 was mutant. Most of the abnormal STR inheritances were confined to single-step mutations which were considered a match paternity case.

These results were greed with\textsuperscript{[13]} who explained the paternity index was calculated for each 10 loci and then individual PI value were multiplied together to obtained the combined paternity index (CPI) for the entire set of genetic loci examined.

They generally accepted minimum standard for an inclusion in paternity is a PI of 100 or greater\textsuperscript{[13]}. PI of 100 correlates to the probability that the alleged father has 99 to 1 better chance of being the father than a random man. Also, the results were agreed with\textsuperscript{[14]} who stated that most of the abnormal STR inheritance was confined to a single-step mutation, whereas multiple-step mutations were rarely reported. The higher of mutation steps, the less likely the mutation would happen\textsuperscript{[14]}.

This went with\textsuperscript{[15]} who stated that the more genetic systems examined, the greater the chance of random mutation to be observed with STR analysis of the examined battery of a dozen or more loci uncommon to see two inconstancies between a child and the true biological father\textsuperscript{[15]}.

ABSTRACT

Background: Azo dyes are receiving high attention in scientific research and they have great importance in chemical analysis. Cancer is a major public health problem in the world. Chemotherapy is one of the commonly-used strategies in breast cancer treatment. This therapy is usually associated with adverse side effects. The aim of current study was to produce a combination between Paracetamol and L-thyroxin drugs by synthesis of new pharmaceutical azo dye in order to reduce the growth of human breast MDA-MB231 cancer cells in vitro.

Method: The (S)-2-((4-acetamido-2-hydroxyphenyl)diazenyl)-3-(4-(4-hydroxy-3,5-diiodophenoxy)-3,5-diiodophenyl)propanoic acid (1) was synthesised. The synthetic azo dye was derived from two different drugs (paracetamol and L-thyroxine). This azo dye was then characterized using m.p., UV-visible and IR spectrum.

Results: The synthetic azo dye provided non-toxic effects using different concentrations and it didn’t show any haemolytic effect in the cells. Furthermore, the cell viability (cytotoxicity) assay presented the ability of azo dye in destroying and reducing the growth of human breast MDA-MB231 cancer cells.

Conclusion: The synthetic azo dye may be useful as a novel anticancer drug.

Keywords: Azo dye, Cytotoxicity assay, Human breast cancer cells, Cell viability, conformational analysis.

Introduction

Azo dyes are receiving high attention in scientific research [1,2,3,4] and they have great importance in chemical analysis. A strongly coloured compound can be yellow, red, orange, blue or even green depending on the exact structure of the molecule due to make azo dyes extremely important as dyes and also as pigments for a long time [5]. The structural features in organic compounds, that usually produce colour, are C=C, N=O, N=N, aromatic rings, C=O and NO₂. However, the groups that invariably confer colour are the azo (–N=N–) and nitroso (–N=O), while other groups actually do so under certain circumstances [6]. Azo dyes contain one or more azo groups (–N=N–) which are linked to SP₂ hybridized carbon atoms, based on the number of such groups [6]. These compounds contain more than one active group, which is able to formulate chelatic coordinational complexes with metal ions distinguished by their colour and ability to dissolve in different solvents [6]. Further, the azo is reactive compound [5] that was reported for its pharmaceutical importance as antidiabetic [6], antineoplastic [6], antibacterial [5,6] and anticancer agent [6].

Cancer is a major public health problem in the world [6]. Chemotherapy is one of the commonly-used strategies in breast cancer treatment. This therapy is usually associated with adverse side effects [10] ranging from nausea to bone marrow failure [6] and development of multidrug resistance (MDR) [6]. Cytotoxicity has been defined as the cell-killing property of a chemical...
compound independent from the mechanism of death [6]. Cytotoxicity assay is an appropriate method for screening new substances within a short time in order to determine their cytotoxicity on cancer cells [6]. Usually in oncology research and clinical practices, in vitro testing is preferred prior to in vivo testing. The in vitro cultures can be refined under controlled environmental conditions (pH, temperature, humidity, oxygen/CO$_2$ balance etc.) resulting in homogenous batches of cells and thus minimizing experimental errors [16]. The aim of current study was to make a combination between the paracetamol and L-thyroxin drugs by synthesis of new pharmaceutical azo dye in order to reduce the growth of human breast MDA-MB231 cancer cells in vitro.

**Method**

The melting point of the azo dye was attended using Buchi B190K. The IR spectrum was carried out on a FT-IR-8400S. Fourier Transform Infrared Spectrophotometer Shimadzu (Japan) by using a KBr disc in the range 500–4000cm$^{-1}$. Absorption spectrum in ethanol with the concentration of (1x10$^{-4}$M) was determined on a spectrophotometer. The IR, UV-Visible spectrophotometer and the melting point were performed in the Chemistry Department/College of Education for pure science/University of Basra, Iraq.

**Synthesis of (S)-2-((4-acetamido-2-hydroxyphenyl) diazenyl)-3-(4-(4-hydroxy-3,5-diiodophenoxy)-3,5-diiodophenyl)propanoic acid:** This azo dye was synthesised by a method similar to that nominated by Fox [17]. It was prepared by dissolving paracetamol (0.006mol; 0.907g) in concentrated HCl (2.1mL) followed by adding 10mL of distilled water with continuous stirring in ice bath to keep the temperature below (-5°C). Also, the NaNO$_2$ was prepared by dissolving 0.468g in 5mL of distilled water and then was added to the first solution drop by drop with keeping the temperature below (-5°C). The resulting solution was then added to the L-thyroxine (0.006mol; 4.661g) in 25% NaOH. The resulting crude were recrystallized in ethanol and hexane to yield the titled azo dye (3.5g; 63%)mp showed decomposition of azo dye; $\nu_{max}$: 3327.21, 3302.13, 3207.62, 3041.74, 1662.64 and 1375.25cm$^{-1}$.

**Solution of azo dye in ethanol:** The solution of the azo dye was prepared by dissolving ethanol to give (1x10$^{-4}$M) concentration.

**Cellular toxicity:** The Xian-guo and Ursola method [6] was applied to measure the toxicity of azo using hemolytic red blood cells as follows: A stock solution of 200mg/mL was prepared and followed by preparing a series of diluted (0.2, 0.3 and 0.4mg/mL) solutions. Then 0.8mL of each diluted solution was added to Eppendorf tubes and 0.2mL of red blood cells was also added to each tube. In addition, two Eppendorf tubes were equipped; in the first tube, 0.8mL of Ringer solution was added as a negative control, but the tap water as a positive control was added to second tube. Then 0.2mL of red blood cells was added to each tube. The results were recorded after the incubation of these tubes for 37 minutes in a special incubator and the changes in the solutions were checked.

**Cell culture:** Human breast cancer MDA-MB231 cells were maintained in 10cm plate contained DMEM supplemented with 10% FBS, 100units/ml penicillin and 100μg/ml streptomycin at 37°C and humidified atmosphere with 5% CO$_2$.

**Cytotoxicity:** The MDA-MB231 cells were grown in 96-well plate for 24h and then treated with 100μM of the prepared azo dye for 24h. Cells viability was measure at 570nm in a micro-plate reader (Thermo Scientific) and the experiment was repeated 3 times. The results were measured in Salman Abad University in Pakistan.

**Result and Discussions**

The azo dye, named (S)-2-((4-acetamido-2-hydroxyphenyl) diazenyl)-3-(4-(4-hydroxy-3,5-diiodophenoxy)-3,5-diiodophenyl)propanoic acid, was synthesised [17] (Figure 1).

![Synthesis of the synthetic azo dye](image-url)
This azo dye was derived from two different drugs (paracetamol and L-thyroxine) using a method similar to that designated by Fox \cite{17} with optimizing the stoichiometry and the conditions of the reaction. Thyroxine \cite{6} was the first hormone replacement therapy, first initiated more than a century ago. Its absorption after ingestion is largely in jejunum and ileum. The absorption is affected by many pharmacological agents and herbal remedies. Levothyroxine is a commonly prescribed thyroid medication that is used to treat hypothyroidism and goiter \cite{6}. A previous study mentioned that oxidative stress could be increased using levothyroxine medication, because it leads to the overproduction of reactive oxygen species (ROS) in the body. Due to the hypermetabolic status, increased oxidative stress induces chronic inflammation. However, some studies also confirmed that chronic inflammation is usually connected to some chronic conditions such as cancer, diabetes, and heart disease \cite{19}. As human cell structure and function could be altered owing to overproduction of ROS; hence, imbalance of body function may induce somatic mutations and neoplastic transformation. In addition, oxidative stress has been linked to cancer initiation and progression, because it promotes DNA damage and cell proliferation by increasing DNA mutation. A recent study has shown that activation of phosphoinositol 3-kinase (PI3K) and the mitogen-activated protein kinase (MAPK) due to the effect of thyroid hormone are responsible for breast cancer cell proliferation. Indeed, thyroxine can activate these pathways and promote breast cell proliferation \cite{19}. Though paracetamol/acetaminophen is one of the most popular and most commonly used analgesic and antipyretic drugs around the world, it is available without prescription, both in mono- and multi-component preparations \cite{6}. It is the drug of choice in patients who cannot be treated with non-steroidal anti-inflammatory drugs (NSAID) such as people with bronchial asthma, peptic ulcer disease, haemophilia, salicylate-sensitized people and children under 12 years of age, pregnant or breast-feeding women. It is recommended as a first-line treatment of pain associated with osteoarthritis. The mechanism of action is complex and includes the effects of both peripheral (COX inhibition), and central (COX, serotonergic descending neuronal pathway, L-arginine/NO pathway, cannabinoid system) antinociception processes and redox mechanisms. The current study was focused on combination between the paracetamol and L-thyroxin drugs by synthesis of new pharmaceutical azo dye in order to reduce the growth of human breast MDA-MB231 cancer cells \textit{in vitro}.

The synthetic azo dye was then characterized using m.p. (which showed that the azo dye was decomposed), UV-visible and IR spectrum. The UV-visible spectrum was documented at the range 250-450nm. The results showed that the maximum wave length of the azo dye was equal to 260nm and 380 and 430nm related to (π-π*) and (n-π*), respectively, as shown in Figure (2).

Figure 2: The UV-Vis spectrum of the synthetic azo dye
The IR spectrum of the synthetic azo dye (Figure 3) was also studied. The results showed that the stretching vibration of the $\nu$ (OH) group appeared in the region 3327.21 cm$^{-1}$.

![Figure 3: IR spectrum of the synthetic azo dye](image)

But, the $\nu$ (N=N) stretching vibration band seemed in the region 1456.26 cm$^{-1}$\textsuperscript{2,3}. Other bands with this region can be considered as skeletal vibrations. The (C=C) stretching vibration of the aromatic ring showed a strong band in the region 1510.26 cm$^{-1}$\textsuperscript{2,3} and the aromatic CH band appeared in the region 3041.74 cm$^{-1}$\textsuperscript{3}.

The method of\textsuperscript{11} was then applied to measure the toxicity of the synthesised dye using haemolysis of red blood cells \textit{in vitro}. The results showed that the azo dye provided non-toxic effect and didn’t induce any haemolytic effect despite using different concentrations. The cell viability (cytotoxicity assay) was used for to observe its (azo dye) ability in destroying live cancer cells and reducing living cells growth for human breast MDA-MB231 cancer cells. After 24h treatment with 100µM, the results were presented in Table (1) below.

**Table 1: Values of the cell viability test after 24h of treatment with 100µM of the synthetic azo dye**

<table>

The results of the cytotoxicity assay revealed high cytotoxic action of the azo dye on the viability of cancer cells in contrast to the control. In addition, the average of this effect was 52.04391, which indicated that the action of the azo dye was around 50% in contrast to the 100% action in the controls.

Theoretical studies were performed on the synthetic azo dye to understand the effect of its structure in its anticancer activity. Conformational analysis of the azo dye in question was also studied theoretically. The results showed that the conformational energy around single bond in each side of azo group was generating eclipsed and staggered conformers. The energy of C(26)-C(27)-N(25)-N(23) and N(25)-N(23)-C(20)-C(19) conformers were presented in Figure (4a and b) below.

![Figure 4](image)

**Figure 4:** The conformational energy of each C(26)-C(27)-N(25)-N(23) (a) and N(25)-N(23)-C(20)-C(19) (b) conformers in the synthetic azo dye

The results showed that each rotation around each side can generate eclipsed and staggered conformers as seen in Figure (4) above. Figure (4a) showed that the eclipsed E for E(-180°), E(0°) and E(135°) were equal to 137.89, 151.19 and 143.54kcal/mole, respectively. However, the staggered conformers for E(-130°), E(6°) and E(180°) were equal to 128.07, 129.26 and 137.89kcal/mole, respectively. On the other hand, Figure (4b) showed that the eclipsed E for E(-150°), E(-20°), E(55°) and E(180°) were equal to 141.48, 147.92, 205.08 and 137.89kcal/mole, respectively. In addition, the staggered conformers for E(-180°), E(-85°), E(30°) and E(135°) were equal to 137.89, 136.17, 136.47 and 134.35kcal/mole, respectively.

Furthermore, the MM2 properties were envisioned for the azo dye of interest, the results revealed that the stretch, cubic stretch, quartic stretch, bend, stretch-bend, torsion, non-1,4 VDW, 1,4 VDW, dipole/dipole and the total energy were equal to 37.0880, -2.0000, 2.3330, 20.2607, -0.3695, 29.3927, -5.2310, 1.3248, 1.6257 and 84.0915kcal/mol, respectively. When comparing these results with those received by anticancer activity, we found that the azo dye gave better ability in destroying living cancer cells. Therefore, the non-toxic azo dye can be used as a novel anti-cancer drug. Further, the MM2 minimization for the azo dye was studied and data from current study showed that the stretch, bend, stretch-bend, torsion, non-1,4 VDW, 1,4 VDW, dipole/dipole and the total energy were equal to 1.9484, 11.0444, 0.1601, -20.4440, -11.5854, 24.0501, -3.4969 and 1.6767kcal/mol, respectively. The MMFF94 total energy, MMFF94 minimization iteration energy and MMFF94 minimization/sampling energy were equal to 131.660, 80.0929 and 79.8793kcal/mol, respectively. All these results showed that the minimization was attended successfully.
Conclusion

The azo dye was cheap to prepare, because the starting materials are available and most of the chemistry is completed at or below room temperature. Also, the synthetic azo dye gained good colour, delivered non-toxic effect and didn’t show any haemolytic effect in the red blood cells. Furthermore, the azo dye had good ability to bind breast cancer MDA-MB231 cells and affect their viability. The molecular mechanics calculated the energy of a molecule and then adjusted the energy through changes in bond lengths and angles to obtain the minimum energy structure. The rotation of atoms about the single bonds is the subject of conformational analysis. This can affect the internal coordination because it affects the binding of molecules and can make this azo dye novel anti-cancer drug.

Role of Some Enzymes in Early Diagnosis of Ovarian Cancer

Tamara A. Subhi¹, Firas A. Hassan¹, Alaa Hussein j Al-qaisi¹

¹Department of Chemistry, College of Science, Al-Nahrain University, Baghdad, Iraq

ABSTRACT

Background: Ovarian cancer is the most deadly gynecologic malignancy. It’s well-known as the silent killer since in most cases there are no warning symptoms and signs until the spread of cancer to other organs. Therefore, the aim of current study was to measure the levels of enzymes such as α-Amylase, Lactate Dehydrogenase A, 5-Nucleotidase and 17-Beta-Hydroxysteroid Dehydrogenase type 14 were measured in the blood stream of ovarian cancer patients and healthy groups with different age ranges in try to find new biomarker that could be used a potentially assistance in early diagnosis of ovarian cancer.

Method: Blood samples were collected from 80 women at local hospitals in Baghdad. The subjects were divided into 2 groups depending on their age. Group 1 (25 females) aged between (20-40) years with ovarian cancer and 15 healthy women as controls. On the other hand, group 2 aged between (40-60) years and included 25 patients with ovarian cancer and 15 healthy women as controls. Enzymes levels (α-Amylase, Lactate Dehydrogenase A, 5-Nucleotidase and Human17-Beta-Hydroxysteroid Dehydrogenase type 14) were measured for both groups.

Results: Data from current study showed that there was an increase in all measured enzymes concentrations in the serum of patients with ovarian cancer in comparison with their controls for both age groups with (P-Value = 0.0001).

Conclusion: Elevated serum levels of the enzymes α-Amylase, Lactate Dehydrogenase A, 5-Nucleotidase and 17-Beta-Hydroxysteroid Dehydrogenase type 14 level would be employed as potentially new biomarkers that can assist in early diagnosis of ovarian cancer.

Keywords: Ovarian cancer, Oxidative stress, Antioxidant, Enzymes, Biomarkers.

Introduction

Ovarian cancer is an extremely heterogeneous tumor which has been generally described by its diverse histological subtypes and degrees of variation. Type I, are low-grade tumors that exemplify 25% of ovarian cancers and generally show slow development with a variable reluctance to conventional chemotherapy, while type II are high-grade exemplify more than 70% of all ovarian cancers and show aggressive actions since are diagnosed in progressive stage and are described by their high sensitivity to chemotherapy [1-2].

“Oxidative stress” is imbalance between production of reactive oxygen species and absence of antioxidants. Oxidative stress and free radicals play critical roles in carcinogenesis [3]. Antioxidants perform as protection system to avoid damaging effect of reactive oxygen species [4]. Ovarian cancer has no symptoms and warning signs so always detected in advanced stage. New biomarkers will be potential guide for early diagnosis which could enhance patient survival. Therefore, the aim of current study was to measure the levels of enzymes such as α-Amylase, Lactate Dehydrogenase A, 5-Nucleotidase and 17-Beta-Hydroxysteroid Dehydrogenase type 14 were measured in the blood stream of ovarian cancer patients and healthy groups with different age ranges in try to find new biomarker that could be used a potentially assistance in early diagnosis of ovarian cancer.

DOI Number: 10.5958/0976-5506.2019.03181.4
Materials and Method

Study group: Fifty Iraqi women with ovarian cancer were selected according to their ages, collected from local Hospital in Baghdad, Iraq. All patients completed the primarily planned treatment and had no history of cancer. The patients were divided into 2 subgroups; group 1 aged between (20-40) years and included (25) females and group 2 between (40-60) years and included (25) females.

Control group: Thirty healthy Iraqi women were chosen as controls; they were from Baghdad and had no history of cancer or other diseases. They were divided into 2 groups; group 1 aged between (20-40) years and included (15) females and group 2 aged between (40-60) years and included (15) females.

Blood samples collection: A 5-ml blood sample was drawn from each patient. The samples were directly transferred to gel tubes and allowed to clot at room temperature for 20min. The tubes were centrifuged at 3000rpm for 10min. Serum for each patient was transferred to clean Eppendorf tube using micropipette and all tubes stored at -20°C until time of analysis.

Analysis of serum enzymes levels: The enzymes (α-Amylase, Lactate Dehydrogenase A, 5-Nucleotidase and Human17-Beta-Hydroxysteroid Dehydrogenase type 14) levels in the serum of patients and controls were measured by ELISA kit on ELISA system (Biotech/USA). The enzymes α-Amylase and Lactate Dehydrogenase A were analyzed by Elabscience ELISA kit, USA (catalog numbers: E-EL-H2235, E-EL-H0556), respectively, while the enzyme 5-Nucleotidase was analyzed by MyBioSource ELISA kit, USA (catalog numbers: MBS760122). However, 17-Beta-Hydroxysteroid Dehydrogenase Type 14 was analyzed by CLOUD-CLONE CORP, ELISA kit, USA (catalog numbers: SEF175Hu). All analyses were done according to the manufacturers’ instructions.

Statistical Analyses: Statistical analyses were performed with Graph Pad Prism (version 6, Graph Pad Software Inc., La Jolla, CA). The results were expressed as mean ± standard deviation. Student t-test was performed to analyze the statistical significance of the both groups. P-value ≤0.05 was considered statistically significant.

Results and Discussion

The results showed that mean(SD) serum amylase levels of patients with ovarian cancer and their controls, aged 20-40 years, were 436.6(74.67)ng/mL and 65.57(12.38)ng/mL, respectively, (Figure 1), whereas the enzyme levels in ovarian cancer patients and their controls, aged 40-60 years, were 391.3(44.97)ng/mL and 63.82(10.44)ng/mL, respectively, (Figure 2). The study demonstrated that in both groups there was significant increase in amylase level in ovarian cancer patients in comparison with their controls (P-value =0.0001). Our results were agreed with another study that documented statistically significant increase in serum amylase level in ovarian cancer patients. This rise may be due to increased production or decreased clearance of the enzyme [5].
level in ovarian cancer patients in comparison with their controls (P-value = 0.0001). Our results were agreed with other study that reported significant rise in serum LDHA level in patients with malignant ovarian cancer \cite{9}. This increase may be due to high glycolytic activity.

![Figure 3: Serum Lactate dehydrogenase A concentration in ovarian cancer patients and their controls aged (20-40) years](image)

Moreover, the mean(SD) serum 5’Nucleotidase (5’NT) levels in ovarian cancer patients and their controls, aged (20-40) years, were 14.92(1.851)ng/mL and 12.86(1.585)ng/mL, respectively, whereas the enzyme levels in ovarian cancer patients and their controls, aged (40-60) years, were 15.1(1.235)ng/mL and 13.14(1.03)ng/mL, respectively (P= 0.001; Figure 5). A previous study showed that 5’NT level was significantly increased in ovarian cancer patients in comparison with healthy subjects \cite{7}. The results demonstrated that the rise in serum enzyme concentration was less than 5%; therefore it may be due to a successful response to treatment.

![Figure 4: Serum Lactate dehydrogenase A concentration in ovarian cancer patients and their controls aged (40-60) years](image)

Furthermore, the mean(SD) serum 17-β-hydroxysteroid dehydrogenase type 14 levels in ovarian cancer patients and their controls, aged (20-40) years, were 102.2(13.83)ng/mL and 56.53(10.28)ng/mL, respectively, whereas enzyme levels in ovarian cancer patients and their controls, aged (40-60) years, were 106(14.63)ng/mL and 63.13(6.15)ng/mL, respectively (P= 0.0001; Figure 6). These results didn’t agree with \cite{8} who suggested that normal breast cells prefer oxidative enzymatic direction, favoring the conversion of Estradiol to Estrone, while tumor progression is related to a shift towards a reductive environment.

![Figure 5: Serum 5-Nucleotidase concentration in ovarian cancer patients and their controls aged (40-60) years](image)

**Conclusion**

Serum levels of the enzymes α-Amylase, Lactate Dehydrogenase A, 5-Nucleotidase and 17-Beta-Hydroxysteroid Dehydrogenase type 14 level was elevated in ovarian cancer patients. Also, results showed...
a statistically significant increase with (P-value =0.0001) between patients and control groups.

Antibacterial Activity of Zinc Oxide Nanoparticles and Poly (B-hydroxybutyrate)/ZnO Bionanocomposites Against *Escherichia coli*

Zaman salman¹, Wejdan R.taj Al- een¹

¹Department of Biology, College of Science, University of Babylon, Iraq

ABSTRACT

**Background:** Zinc oxide (ZnO) is an inorganic compound widely used in everyday applications. It is currently listed as a generally recognized safe (GRAS) material by the Food and Drug Administration and is used as food additive. ZnO nanoparticles have been incorporated in polymeric matrices in order to provide antimicrobial activity to the packaging material and improve packaging properties. The aim of current study was to evaluate the antimicrobial activity of ZnO nanoparticles and PHB/ZnO nanobiocomposites against *E. coli*.

**Method:** Biosynthesis of ZnO nanoparticles by *Lactobacillus casei* and studying the characterization of these particles such as structure and morphological measurement including X-Ray diffraction measurements and scanning electron microscope and optical measurements including UV-Vis diffuse reflectance measurements and Fourier Transform Infrared (FTIR) measurements done in other studies.

**Results:** Data from current study revealed that ZnO nanoparticles exerted concentration-dependent inhibition of bacterial growth against *E. coli*. However, ZnO/PHB nanobiocomposites exerted stronger inhibition than ZnO nanoparticles.

**Conclusion:** ZnO nanoparticles enhanced antibacterial effects of the ZnO/PHB nanobiocomposites maybe via mechanical performance, barrier and/or antibacterial properties of polymers.

**Keywords:** antibacterial activity, ZnO, *E. coli*, UV-Vis, ZnO/PHB nanobiocomposites.

Introduction

Lactic acid bacteria (LAB) and the widely accepted probiotics (derived from Greek means pro= for and bio= life) bacteria with beneficial healthy effects are a major factor in dairy technologies. When administered in adequate amounts and good viability, probiotics maintain the balance and composition of the gut microflora increase the resistance to pathogens and protect the host intestine from several disorders (¹).

The synthesis of nanoparticles (NPs) with various methods; chemical physical and biological make changes in sizes and shapes of nanoparticles. Biological methods have advantageous more than other chemical methods as they are low cost and do not use temperatures, toxic chemicals, energy and high pressure (²). The oxidized form of synthesized NPs was more useful, because these NPs have good magnetic, electrical and optical properties (³).

Zinc oxide (ZnO) is an inorganic compound widely used in everyday applications. It is currently listed as a generally recognized safe (GRAS) material by the Food and Drug Administration and is used as food additive. The advent of nanotechnology has led the development of materials with new properties for use as antimicrobial agents. Thus, ZnO in nanoscale has shown antimicrobial properties and potential applications in food preservation (⁴). ZnO nanoparticles have been incorporated in polymeric matrices in order to provide antimicrobial activity to the packaging material and

improve packaging properties. Poly-β-hydroxybutyrate (PHB) is thermoplastic polyester. It is biocompatible and biodegradable, and therefore, of industrial interest in the cell. PHB is an intracellular storage material synthesized during unbalanced growth conditions. All bacteria which are capable of PHB synthesis accumulate PHB during the stationary phase of growth when the cells become limited for an essential nutrient but have an access for carbon sources. Species from more than 50 genera are known to be capable of synthesizing PHB. Despite the fact that PHB was also detected in actinomycetes and yeasts, it is most often accumulated by bacteria of various morphological and physiological groups. Only the monomer was detected in the mycelium of micromycetes. The amount of PHB production by the genera of Lactobacillus, Streptococcus and Pediococcus is not well studied and documented. Plastics are widely using in packaging, building materials and commodities is not well studied and documented. Plastics are widely and studying the characterization of various morphological and physiological groups.

The supernatant was discarded and pellet was treated sample of culture was centrifuged at 5000rpm for 15min. A 10-mL Extraction and quantification of PHA: measurements done in other studies. PHB spectrophotometer assay: A sample containing polymer in chloroform was transferred to a clean test tube. The chloroform was evaporated and 10ml of concentrated H₂SO₄ were added. The tube was capped with a glass marble and heated for 10min at 100°C in a water bath. The solution was cooled and after thorough mixing, a sample was transferred to a silica cuvette and the absorbance at 235nm in a UV spectrophotometer was measured against a sulfuric acid blank. A standard curve was established with PHB (Sigma Aldrich) concentrations according to (6-9).

**Material and Method**

**Biosynthesis of ZnO Nanoparticles:** Lactobacillus casei was selected as biological model for synthesis of ZnO nanoparticles from several strains including (L. plantarium, L. bifidium, L. Acidophilus and L. fermentium), by screening the ability of all strains to produce ZnO nanoparticles, this strain has ability to synthesis ZnO nanoparticles. This strain was taken from advanced microbiology Lab in Baghdad University. It was isolated naturally from the dairy products. Its nonpathogenic bacteria were diagnosed by microscopic examination using Gram stain to this colony, colony morphology on different media and basic biochemical test.

**Synthesis of ZnO nanoparticles by Lactobacillus casei:** Biosynthesis of ZnO nanoparticles (ZnONPs) by Lactobacillus casei and studying the characterization of ZnONPs such as structure and morphological measurement including X-Ray diffraction measurements and scanning electron microscope (SEM) and optical measurements including UV-Vis diffuse reflectance measurements and fourier transform infrared (FTIR) measurements done in other studies.

**Extraction and quantification of PHA:** A 10-mL sample of culture was centrifuged at 5000rpm for 15min. The supernatant was discarded and pellet was treated with 10mL sodium hypochloride and the mixture was incubated at 30°C for 2h. The mixture was centrifuged at 5000rpm for 15min and then washed with distilled water, acetone and methanol, respectively. The pellet was dissolved in 5ml boiling chloroform and evaporated by pouring the solution on sterile glass tray kept at 4°C and weighed. The relative PHB accumulation by the different isolates was compared to help in identification of the best producer.

**Screening of polyhydroxybutyrate producing bacteria by Nile Red:** The isolates were qualitatively tested for PHB production by culturing the colonies on MM plate supplemented with Nile Red at a concentration of 0.5μg/ml. The agar plates were examined by UV light (235nm) after a suitable period of incubation at 30°C.

**Infrared spectroscopy (IR):** IR analysis of PHB-like granules was performed using a commercial customer service, Aarti Industries, Tarapur, India. Briefly, extracted sample and standard PHB from Sigma® were separately made into solid pellet by making an intimate mixture of a powder sample with potassium bromide for IR analysis. The relative intensity of transmitted light was measured against the wavelength of absorption in the region 800 to 4000cm⁻¹ using IR double beam spectrophotometer (Shimandzu®). IR spectra of samples were measured at ambient conditions.

**Qualitative analysis of polyhydroxybutyrate granules**

**Fluorescent Microscope:** The bacterial cells were cultured in MRS broth, heat fixed on a glass slide and flooded by the Nile Blue A solution 1% and incubated at 55°C for 10 minutes, then the slide washed with 8% of acetic acid solution for 1 minute to remove unbound stain. The slide was rinsed with tap water and covered with a glass cover slip and observed under oil immersion using 100x magnification fluorescent microscope fitted with cellSens® Version 1.4 Software.
Antibacterial activity assay of ZnONPs: In order to examine the antibacterial activity of the ZnONPs on these microorganisms, they were suspended in deionized water and constantly in ultrasonic apparatus until a uniform colloidal suspension was formed to yield a powder concentration of 500mg/ml. To assess toxicity range of ZnONPs against seven strains of bacteria including Gram positive, an appropriate volume of test bacteria was inoculated in nutrient broth medium supplemented with serially diluted ZnONPs with two various particle sizes and bulk suspensions, including 5, 2.5, 1.25, 0.625 and 0.313mg/ml. Colony forming units (cfu) were quantified after an overnight incubation at 37°C.

Determination of zone of bacterial growth inhibition: A volume of 0.05ml of various concentrations of different ZnONPs in discs, respectively. After inoculation and cultivation of different target bacteria on top of nutrient agar, discs were placed in selected area on different plates. The zone of inhibition (ZOI) was measured after 24h incubation. The antibacterial activity of different concentrations of ZnO was compared. To gain different nanoparticle sizes, equal amounts of synthesized ZnONPs were dried at 70°C. High temperatures result in bigger particle size.

Preparation of PHB films and PHB-ZnO nanobiocomposite films: The conventional solvent-cast technique was used for PHB films and PHB-ZnO composite films preparation. PHB films were prepared by dissolving (0.025, 0.0125, 0.0625, 0.0313, 0.0156mg/ml of the extracted polymer in 10ml of chloroform in a Schott bottle with stirring magnetically for 30 minutes then poured into a glass Petri dish (5cm in diameter) as the casting surface. The Petri dishes were covered with punctured Aluminium sheets and left in a dark place for 24 hours at room temperature (30°C) for complete evaporation of chloroform. The ZnONPs were used for composite preparation which was prepared in a manner resembling the conventional solvent-casting method in concentrations (0.025, 0.0125, 0.0625, 0.0313, 0.0156mg/ml were dissolved in chloroform to create five concentrations (5, 2.5, 1.25, 0.625, and 0.313 mg/ml).

Results and Discussion

Extraction of polyhydroxybutyrate from lactobacillus casei

Primary screening of polyhydroxybutyrate production: The Nile Red staining of viable colonies was used as a direct and a rapid tool for direct detection of PHB accumulation within bacterial cells (12, 13). Three isolates had positive results, but only one of these isolates was visible and more fluorescent with Nile Red stain isolated from standard isolate. A pink fluorescent under UV illumination was obtained as a result of the binding between stain and polymeric granules (14). The production of pink fluorescent can discriminate the isolate that produced PHB when compared to both the PHB-positive control (lactobacillus casei) and PHB-negative control (Bacillus spp) (Figure 1).

PHB spectrophotometer: UV-Vis scanning of the extracted polymer showed a peak at 235nm reading extract from L. casei (Figure 2). This peak indicated the occurrence of PHB (19).
The anti-bacterial activity of ZnONPs and PHB/ZnO Bionanocomposites against *E. coli*: The antibacterial activities of ZnONPs and ZnO/PHB nanobiocomposites were tested by the disc diffusion agar methods (Table 1).

Moreover, Figure (3) showed significant increase (P≥0.05), for both inhibitors, in rate of inhibition diameters for *E. coli*. Data showed that the efficiency of incorporated ZnO/PHB nanobiocomposites as bacterial inhibitor was greater than ZnO nanoparticles, because ZnO nanoparticles have been shown to be very effective in enhancing the mechanical performance, barrier and/or antibacterial properties of polymers such as poly(ether ether ketone) (PEEK) (23).

Figure 3: Effect of bacterial inhibitor type on rate of inhibition diameters for *E. coli* L.S.D 0.05 = 0.341

Also, Figure (4) showed significant increase (P≥0.05) in all nanoparticles concentrations used against *Escherichia coli* revealed that the antibacterial activities increased as the concentration of ZnO nanoparticles increased which were in line with results of (20). On the other hand, Figure (5) showed a comparison of antibacterial activity of ZnO nanoparticles and ZnO/PHB nanobiocomposites but ZnO/PHB were more effective and the inhibition zone increased with increasing inhibitor’s concentration.
These results completely agreed with (24) who reported that ZnO NPs have antibacterial activity against *Escherichia coli* bacteria. Also, the results were in agreement with those obtained by (25). Improvement of ZnO biological activity was reflected as a consequence of the created free radicals by the way ZnO absorbs UV light (26).

**Figure 4:** Effect of bacterial inhibitor concentration on rate of inhibition diameters for *E. coli* L.S.D 0.05 = 0.540

**Figure 5:** Comparison of antibacterial activity of ZnO nanoparticles and ZnO/PHB nanobiocomposite on *E. coli*.

The Relationship between Postmenopausal Women and Some Hormonal Changes

Kadhem Mohammed Sabae

1College of Education of Pure Science, University of Al-Muthanna, Iraq

ABSTRACT

Background: Menopause is defined as loss of ability of ovarian follicles to develop. The period of menopause is affected by age and genetic factors. Also, toxic factors can affect ovarian activity such that women who smoke have earlier menopause. The irregular menstrual cycle is the most characteristic of menopause that the ovary never responds to the pituitary gland stimulation. Current study was aimed to estimate blood levels of estradiol, cholesterol, triglyceride, ALT and AST in postmenopausal women.

Method: The present study included 120 postmenopausal women their ages ranged from 46 to 65 years and divided into two groups; 46-55 years and 56-65 years. In addition, 30 before menopausal women were recruited as a control group.

Results: The result showed a significant increase (p<0.05) in estradiol level in all postmenopausal women compared with control group. Also, results showed a significant increase (p<0.05) in cholesterol and triglyceride levels in all postmenopausal women compared with control group. The results of ALT and AST revealed a significant increase (p<0.05) in all postmenopausal women compared with control group.

Conclusion: According to the results of current study, we can conclude that postmenopausal age is associated with a decrease of estradiol hormone, an increase in cholesterol and triglycerides levels, and significant differences in AST and ALT levels.

Keywords: postmenopause, cholesterol, GPT, triglyceride, estradiol.

Introduction

Menopause is defined as loss of ability of ovarian follicles to develop (1,2). The period of menopause is affected by age and genetic factors. Also, toxic factors can affect ovarian activity such that women who smoke have earlier menopause (3). The irregular menstrual cycle is the most characteristic of menopause that the ovary never responds to the pituitary gland stimulation (4).

The physiological characteristic of menopause is regarded as part of female reproductive processes based on decrease of estrogen and progesterone secreted from ovary and that lead to cardiovascular dysfunction (5). During postmenopausal period, levels of ovarian hormones are decreased and that lead s to elevation in circulating LH and FSH hormones (6).

The decrease of ovarian activity in postmenopause and the drop of female steroid hormones have greater metabolic and pathological effects accompanied with cardiovascular dysfunction and a rise in blood pressure as well as abnormalities in lipid profile and glucose metabolism (7). Current study was aimed to estimate blood levels of estradiol, cholesterol, triglyceride, ALT and AST in postmenopausal women.

Material and Method

The study was carried out at the Teaching Hospital in Al-Muthanna province, during the period from September 2018 to February 2019. The study included 125 postmenopausal women. Subjects were divided into two age groups; (46-55 years) and (56-65 years). The study also included 30 women aged 30-39 years old as a control group.
Assessment of hormonal parameters: Estradiol was determined by Enzyme-Linked Immune Sorbent Assay (ELISA) technique using a kit provided by Moonblind Inc, USA. The absorbance was read at wavelength (450nm) (8).

Assessment of biochemical parameters

1. Assessment of total cholesterol: According to the method described by (BURTIS and Ashwood, 1999), as shown in the following, cholesterol concentration was determined enzymatically:

   Cholesterol esters + H₂O ……………………..
   Cholesterol + Fatty acids

   Cholesterol + O₂…………………………….
   Cholesterol 4-one +H₂O₂

   H₂O₂ + phenol + ATP ……………………..
   Quinonimine (pink) + 4H₂O

2. Assessment of triglycerides: Triglycerides concentration was determined enzymatically according to the method described by (9) as showing in the following reaction:

   Triglycerides ………….. lipase …………..
   glycerol + free fatty acid

   glycerol + ATP …………… glycerol kinase
   ……………. glycerol-3-phosphate + ADP

   glycerol -3-p + PAP ……………. peroxidase
   …………….Quinonimine + 4H₂O

   The absorption of the colored complex (quinonimine) is proportional to the amount of triglycerides in the specimen.

3. Assessment of alanine aminotransferase (ALT): ALT was determined enzymatically according to the method describe by (10) as shown in the following reaction:

   a – Oxoglutarate + L- alanine …………. GPT
   …………… L-glutamate + pyruvate

4. Assessment of aspartate aminotransferase (AST): AST was determined enzymatically according to the method describe by (10) as shown in the following reaction:

   a – Oxoglutarate + L- aspartate …………... GOT
   …………… L-glutamate + Oxalacetate

Statistical Analysis: All values were expressed as a mean ± standard deviation (SD). Data were analyzed by using a computer-based statistical program (SPSS). Student’s t-test was used to explain differences between groups and ANOVA was used to perform multiple comparisons between subgroups. In addition, p<0.05 represented the lowest significant limit (19).

Results

The results (Table 1) showed a significant decrease at (p<0.05) in estradiol levels in all postmenopausal women compared with control group (13.22 ± 42.73, 8.28 ± 32.54 and 37.28 ± 130, respectively). In addition, data from current study revealed that there was significant increase at (p<0.05) in the level of cholesterol in postmenopausal women (5.85 ± 0.30, 6.3 ± 0.25) compared with control group (5.25 ± 0.23). Also the result showed a significant increase at (p<0.05) in triglycerides level in all postmenopausal groups (1.50 ± 0.20, 1.30 ± 0.05) compared with control group (1.06 ± 0.10). Moreover, current study reported significant increase at (p<0.05) in ALT level in postmenopausal women (8.21 ± 10.7, 6.05 ± 20) compared with control group (1.38 ± 4.50). Also, the results showed a significant increase at (p<0.05) in AST level in postmenopausal women (9.92 ± 20.30, 9.02 ± 25.70) compared with control group (8.30 ± 15.22).

#: Represents a significant difference between postmenopausal subgroups and control group at p<0.05. The result were shown as a Mean ± SD.
Discussion

**Estradiol Level:** The major symptoms of postmenopausal period are related primarily to estrogen deficiency and that is due to loss of ovarian follicles \(^{(11)}\). Our study showed a significant decrease at \((p<0.05)\) of estradiol hormones in all postmenopausal women compared with control group. The risk factors that are related to decrease of estradiol level in postmenopausal women include osteoporosis and changes in biochemical parameter of bone turnover \(^{(12)}\). Therefore, a sex-specific hormonal factor may lead to aneurysm formation and rupture. The collagen wasting commonly noticed in bone and skin in the postmenopausal period due to decreased estrogen levels could be responsible for the formation of aneurysms in the proximal parts of the cerebral arteries as it occurs in various connective tissue diseases \(^{(13,14)}\).

**Cholesterol and triglycerides levels:** The results of current study showed a significant increase in cholesterol and triglycerides at \((p<0.05)\). The changes in lipid profile levels may be due to altered hormonal levels at postmenopausal women. The biological effect of estrogen replacement therapy that alters lipid profile levels is the best mechanism to protect against cardiovascular disease \(^{(17,18)}\).

**Alanine aminotransferase:** The results obtained in this study indicated a significant increase at \((p<0.05)\) in ALT levels in postmenopausal women compared with control group. This finding was in agreement with \(^{(15)}\) who found that the increase of ALT was because of the destroyed hepatic cells. Naturally, women lose approximately 1% of their bone density every year at postmenopausal period. The increase in ALT level can detect women who lose the density of bone per year \(^{(16)}\).

**Aspartate aminotransferase (AST):** The result showed a significant increase at \((p<0.05)\) in AST level in all postmenopausal women and this finding was in agreement with \(^{(17,18)}\). The latter authors explained the increase of AST as due to the destroyed hepatic cells and this enzyme filtrates from the cytoplasm of hepatic cell to the circulation. AST is considered an important enzyme in the production of energy and can increase in the case of heart cells breakdown as in the case of myocardial infarction. However, these finding disagreed with \(^{(11)}\) who found no difference in AST levels in postmenopausal women.

Conclusions

According to the results of current study, we can conclude that postmenopausal age is associated with a decrease of estradiol hormone, an increase in lipid profile and significant differences in AST and ALT levels.

Osteoporosis Knowledge and Osteoprotective Behavior among Female Patients Attending DXA Clinic: A Cross-Sectional Study

Heba M. Attash¹, Harith Kh. Al-Qazaz¹, Layth A. Al-Hajjar²
¹Department of Clinical Pharmacy, College of Pharmacy, University of Mosul, Nineveh, Iraq; ²Nineveh Physical Rehabilitation Center, Mosul Directorate of Health, Nineveh, Iraq

ABSTRACT

Background: Osteoporosis is a serious public health concern. Both males and females are prone to osteoporosis; but it is more common in females, especially after menopause. The most frequent type of osteoporosis is primary osteoporosis. The objectives of current study were to validate an osteoporosis knowledge instrument and to determine female patient’s knowledge about osteoporosis and its prevention.

Method: A cross-sectional study design with convenience sampling method. It was conducted among (202) female patients attending DXA clinic in Mosul city, Iraq from February to November 2018. The assessment was performed using a structured questionnaire including Osteoporosis Knowledge Assessment Tool (OKAT), concern about osteoporosis and osteoporosis health belief scale (OHBS). Bone mineral density (BMD) measurements were carried out by Dual-Energy X-ray Absorptiometry (DXA). Univariant and Logistic regression were used in data analysis.

Results: The reliability value was 0.881 for the nineteen items in OKAT. The mean(SD) age of the participants was 56.18(11.4) years. Around half of the females (49.0%, n =99) had an intermediate score (9 to 13) of knowledge, while 43.6% (n =88) had a low score (<8). Significant correlation between age and osteoporosis knowledge was found. Only 41.6% had a normal BMD, whereas osteopenia and osteoporosis were found in 47.0% and 11.4% of participants, respectively.

Conclusions: The translated OKAT was reliable and valid instruments for assessment of knowledge and health beliefs toward osteoporosis in female patients. The tools were suitable to recognize patients requiring bone health-promoting intervention concerning changes of lifestyle behavior in a clinical setting.

Keywords: Osteoporosis, Knowledge, Osteoprotective behavior, OKAT, DXA.

Introduction

Osteoporosis is a serious public health concern. The World Health Organization’s definition of osteoporosis is a “bone mineral density value more than 2.5 standard deviations below the mean for the normal young white women” [2]. Both males and females are prone to osteoporosis; but it is more common in females, especially after menopause [3]. The most frequent type of osteoporosis is primary osteoporosis [4].

Osteoporosis knowledge is documented to be important in reducing the prevalence of the disease [5]. Previous studies revealed that many females of all ages require knowledge concerning osteoporosis [6].

Valid and reliable tools are required to assess females’ knowledge and beliefs about osteoporosis [7]. To the best of our knowledge, there were no previous studies on osteoporosis in Iraq that assessed the incidence and prevalence of osteoporosis related to women’s knowledge about osteoporosis. Therefore, the aims of this study were to validate and test the reliability of an instrument, which is used to measure osteoporosis knowledge among female patients attending DXA clinic, and to determine female patient’s knowledge and attitudes concerning osteoporosis and its prevention.
Methodology

Study design and setting: A cross-sectional study design was employed to measure osteoporosis knowledge among female patients attending DXA clinic. The DXA clinic is located inside Nineveh Physical Rehabilitation Center in Mosul city, Iraq. Data were collected between February and November 2018.

Participants and sample size: The study participants were female patients attending DXA clinic. Patients were collected using convenience sampling method. Inclusion criteria were adult females attending DXA clinic, while the exclusion criteria were pregnant women and female patients less than 18 years old.

The entire number of patients who attended DXA clinic annually is around 1000; this number was employed as the whole population from which the sample size was drawn. Raosoft sample size calculator (http://www.raosoft.com/samplesize.html) was employed for calculating the required sample size. Employing an accepted margin of error of 5% and a 95% confidence interval, the sample size must be 198 participants [8]. In this study; we had a response rate of 100%.

Current study was approved by the Medical Research and Ethics Committee of the College of Pharmacy, University of Mosul. In addition, an approval from the Ethical Committee of the Nineveh Directorate of Health was also obtained. A written informed consent was taken from all the participants. All participants were assured that their personal information are anonymous as well as confidential and their participation in the study is entirely voluntary.

Measurements: BMD measurements was carried out using DXA [Stratos DR dosimetry (February 2009), DMS–393 - France] at the DXA clinic.

The (OKAT), which was developed by [9], consists of 20 questions to measure knowledge. One question was omitted, so it consists of 19 questions. Every item was answered with “yes”, “no” or “don’t know”.

The (OHBS) was employed to evaluate beliefs which were developed based on the Health Belief Model (HBM) theory. OHBS was developed by [10]. This scale consists of questions on perceived susceptibility, perceptions towards barriers to calcium intake, towards benefits of calcium intake, perceived seriousness and health motivation towards osteoporosis [11]. Females were classified as osteoporotic, normal and osteopenic based on DXA T-scores.

Translation and validation: The five parts of the data collection sheet were translated in accordance with international guidelines [12,13], this was achieved as follows:

1. A forward translation of the original questionnaire was carried out via translation from English to the Arabic.
2. A backward translation from Arabic to English was undertaken by another translator.
3. The translated questionnaire was distributed to 25 females (staff from College of Dentistry at Mosul University) who completed the questionnaire. These females were not included in the final study.
4. The last version of the Arabic questionnaire was finished and made available to study validity and reliability. Around 10 minutes were needed to complete the questionnaire.

Statistical analysis: Data from current study were processed and analyzed using computer-based Statistical Package for Social Science (SPSS, version 18; SPSS Inc., Chicago, III). A p-value <0.05 was regarded as statistically significant. To test reliability, the internal consistency was evaluated using Cronbach’s alpha and the criterion for accepting Cronbach’s alpha is a score above 0.5 [14,15]. In addition, inferential statistical methods such as t-test, ANOVA and Binary logistic regression was ere also employed.

Results

Validity and Reliability: For the fifteen items in OHBS, Cronbach’s alpha test of internal consistency was 0.788 that is around 0.7 and within the suggested satisfactory result for reliability [16]. For the nineteen items in OKAT, Cronbach’s alpha test was 0.881.

Demographic characteristics: Current study recruited 202 females whose average (SD) age was 56.18 (11.40) years and ranged from 28 to 85 years. The average (BMI) was 31.64 kg/m² (SD = 5.50) and ranged from 15.52 to 47.67.

Osteoporosis knowledge: The mean ± SD score for the test was 9.96 ± 3.40. The OKAT total score ranged from
Three levels of participants’ knowledge (low, medium and high) were developed by classification of knowledge scores. The frequency(%) of low, medium and high knowledge were 88(43.6), 99(49.0) and 15(7.4), respectively.

Non-parametric statistical tests to find differences in OKAT scores between independent groups were employed. There were significant differences in the OKAT scores between the three educational levels.

**Shortened osteoporosis health belief scale:** Total belief ranged from 5 to 50 with mean(SD) of 34.84(5.96). No significant differences in the belief scores were found between groups of demographic characteristics.

**DXA finding:** The mean T-score of study participants was $-0.78 \pm 1.42$. According to DXA measurements, 84(41.6%) of participants had normal BMD, whereas osteopenia and osteoporosis were reported in 95(47%) and 23(11.4%) of them, respectively. No significant correlation was found between T-scores and total knowledge scores of the study participants ($p=0.5$).

**Concern about osteoporosis:** Table 1 showed that 48.5% of participants were “very concerned” about osteoporosis, 37.1% of them rated their risk of getting osteoporosis as being lower than similarly-aged females. In addition, 43.1% of participants rated their risk of having a fracture as lower than age-matched females. Only a small proportion of participants recorded a higher self-rating risk for fracture (26.7%) and to osteoporosis (29.2%). Table (1) presented the differences in OKAT scores among concern about osteoporosis variables of the study population. There were significant differences in the OKAT scores with concern of osteoporosis.

**Logistic regression analysis of osteoporosis:** The dependent variable (outcome) is T-score. It was dichotomized into either normal or pathological bone status. The independent variable (predictors) included age, BMI, education, employment, income, dichotomous smoking, chronic illness and medication, lastly total knowledge and belief scores. Wald test was used to determine the predictor/s that significantly contributes to developing osteoporosis with its odd ratio (Exp B). In summary, 22% of variation in chance of developing osteoporosis is explained by this logistic model. Table (2) showed the results of logistic regression between factors and T score.

Discussion

The aim of current study was to measure osteoporosis knowledge among female patients attending DXA clinic. The OKAT was used by many studies. A number of studies used OHBS [11]. Concern about osteoporosis was used by a study conducted in Australia [3].

The 15-item OHBS was internally reliable with a good overall Cronbach’s alpha (0.788). Additionally, the degree of consistency for OHBS was comparable [10].

The 19-item OKAT was internally reliable with a good overall Cronbach’s alpha (0.881). Moreover, the degree of consistency for OKAT was comparable to [9]. The reliability and validity results revealed effective cultural adaptation of the translated tool from the English version in an Arabic population.

The mean score of knowledge in current study was 9.96. A study among Syrian females revealed similar results as the mean score was 9.4 [7].

The majority of women in this study reported having a “lower or same” risk compared to other aged-matched females who were rating their own risk of getting osteoporosis and future fracture. The same result was found by a study conducted among Australian female participants [9]. The results of this study showed that osteoporosis knowledge was significantly associated with concern of osteoporosis. An unexpected result that appeared in the present study was the inverse relationship between osteoporosis knowledge and concern of osteoporosis. The majority of patients were concerned regarding osteoporosis. Concern was not significantly associated with behavior besides looking for medical advice [3].

Osteoporosis health beliefs were examined in this study. The present study did not find a significant association between the belief scores and demographic characteristics of participants. Significant differences in belief scores were found with history of secondary osteoporosis, however, no significant differences in belief scores were found with concerns about osteoporosis variables. The osteoporosis knowledge was significantly associated with perceived susceptibility. It was a sensible finding that females with low level of knowledge felt more susceptible to develop osteoporosis than others with intermediate or high levels of knowledge. As the latter had more information about the disease and its risk factors which they can avoid, they considered themselves less susceptible to osteoporosis.

The findings of this study revealed a significant association between T-score, Z-score (with history of secondary osteoporosis) and history of using drugs for osteoporosis, as T-score and Z-score decrease in patients with osteoporosis and osteopenia. Similarly, significant differences in T-score and Z-score were found with history of use of corticosteroids in last 3 months. The latter finding could be attributed to the adverse bone-related biochemical effects of oral and inhaled corticosteroids, which had been verified in animal studies to induce bone resorption and cause osteoporosis [18]. There was no significant association between T-score or Z-score and concerns about osteoporosis variables or with the five belief domains.

Conclusion

Current study found that the translated OKAT, OHBS and concern about osteoporosis were valid and reliable instruments to recognize persons who are in real need for educational intervention to provide protection against the disease. Actions to enhance concerns in addition to knowledge are required, particularly for individuals who have other risk factors of developing osteoporosis complications. Determining female’s beliefs, behaviors and knowledge concerning osteoporosis is useful in formulating effective interventions and conducting community health programs to avoid the disease.

Isolation and Identification of Dermatophytes Causing Dermatophytosis in Hilla City, Iraq

Nibras AA Hindy¹, Abed-Ali A Abiess²

¹Department of Dermatology and Venereology, Al-Imam Al-Sadiq Teaching Hospital, Hilla, Iraq; ²Department of Pathological Analysis Technique, Al-Mustagbal University Collage, Hilla, Iraq

ABSTRACT

Background: Dermatophytes are a group of closely related keratinophilic and keratinolytic filamentous fungi, which are most commonly of the Trichophyton genus and less commonly of the Microsporum or Epidermophyton genera. Cutaneous fungal infection is divided into superficial and deep mycosis. Superficial infection is limited to the stratum corneum affecting the skin (Tinea corporis, Tinea cruris, Tinea pedis), hair (Tinea capitis), beard (Tinea barbae), nails (onychomycosis or Tinea unguium). The purpose of this study was to determine the dermatophyte species causing superficial fungal infections among patients attending dermatology out-patient clinic in Al-Imam Al-Sadiq Teaching Hospital of Hilla city, Babylon Province, Iraq during the period from June 2017 to May 2018.

Method: One hundred and twenty nine samples were examined by 10% KOH and cultured on Sabouraud’s dextrose agar with cyclohexamide and chloramphenicol to identify the dermatophytes species. All skin, hair and nail samples from clinically suspected cases of dermatophytosis were included in the study.

Results: Data from current study showed that 74 females and 55 males were considered as the total number of patients selected. Dermatophytes were isolated from 95 out of the 129 patients included in this study. The isolated Dermatophytes included predominantly Trichophyton species [T. rubrum 19(20%), T. verrucosum 11(11.57%) and T. violaceum 11(11.57%)] followed by Microsporum species [M.gypseum 10(10.52%), M.canis 7(7.36%) and M.nanum 6(6.31%)], all rated from high to low incidence. Tinea unguium was the most common 31(32.63%) clinical type of dermatophytosis encountered in our study, as compared to other types like tinea pedis 23(24.21%), tinea capitis 20(21.05%), tinea mannum 13(13.68%), tinea barbae 5(5.26%)and tinea corporis 3(3.15%). The study also showed that the incidence of Dermatophytosis was higher in females with 61(64.21%) cases as compared to males with 34(35.79%) cases.

Conclusion: Dermatophytosis is a major public health problem in tropical and subtropical countries, like Iraq, yet remains unresolved. Most common fungal species isolated were Trichophyton species.

Keywords: Dermatophytes, Dermatophytosis, Tinea, Trichophyton, 10% KOH.

Introduction

Dermatophytes are a group of closely related keratinophilic and keratinolytic filamentous fungi which are most commonly of the Trichophyton genus and less commonly of the Microsporum or Epidermophyton genera. The anthropophilic dermatophytes (commonly isolated from human infection) are the most common source of human dermatomycosis. These tend to evoke a limited host response and are less likely to be accompanied by severe inflammation or to clear spontaneously.

Dermatophytosis is due to severe inflammatory reaction, particularly true in the case of tinea infections caused by zoophilic species (commonly isolated from animal infection). Tinea capitis, tinea pedis and onychomycosis are common dermatologic diseases that may result from such an infection. Skin infection
due to dermatophytes has become a significant health problem affecting children, adolescents and adults (5). Cutaneous fungal infection is divided into superficial and deep mycosis. Superficial infection is limited to the stratum corneum affecting the skin (Tinea corporis, Tinea cruris, Tinea pedis), hair (Tinea capitis), beard (Tinea barbae) and nails (onychomycosis or Tinea unguium). Most of deep mycosis are evidence of disseminated infection with a pulmonary focus, especially in the immune compromised patients (4,5).

Dermatophytic infections of the skin are variable in clinical presentation which varies according to location of infection and the specific dermatophyte species causing it (7). The inflammatory symptoms are often absent in skin infection, but in other cases they may be very pronounced, in particular when caused by zoophilic Dermatophytes (8). Clinical diagnosis should be supported by laboratory diagnosis. Culture is a necessary adjunct to direct microscopic examination for the identification of etiological agent and the choice of therapy depends upon the specific identification of the fungi causing the Dermatophytosis (4).

Tinea infections can be treated either topically or systemically; the method chosen will depend on type of tinea infection, severity of infection and patient’s preferences (7). Some cases (moderate to severe disease) require systemic anti-fungal therapy for adequate tissue penetration. The purpose of this study was to determine the dermatophyte species causing superficial fungal infections among patients attending dermatology outpatient clinic in Al-Imam Al-Sadiq Teaching Hospital of Hilla city, Babylon Province, Iraq during the period from June 2017 to May 2018.

Materials and Method

The study was conducted at the dermatology out-patient clinic in Al-Imam Al-Sadiq Teaching Hospital in Hilla city, Babylon Province, Iraq, during the period from June 2017 to May 2018. Total number of patients was 129 for skin scraping, hair stubs and nail clipping. Patients were referred to out-patient clinic, department of dermatology in Hilla city, Province of Babylon, Iraq. The study population consisted of 74 females and 55 males. Collected samples were preserved in laboratory test tubes and sent to the laboratory for microorganisms’ isolation and diagnosis. Samples were marked for cases data (name, age, sex, type, site of infection and date of collection). Skin samples were collected using a sterile scalpel blade and the skin scraping was collected onto prepared Sabouraud’s media in duplicate. One culture media was incubated at 37°C, while the other was incubated at room temperature (25°C). Incubated plates were inspected for fungal growth on a daily basis. Fungal isolates that existed as mixed growth were sub-cultured each on different plates so as to obtain pure growth. Having obtained pure growth (which took about 3 to 7 days) cultures showing no growth in a period of 4 weeks were discarded. The macroscopic features on the forward as well as the reverse side of the plate were observed under a Biosafety Cabinet Class-II. Thereafter, a drop of lacto phenol cotton blue was put on a clean slide and using a piece of cello tape, the fungi were gently touched and fixed on a slide containing lacto phenol blue. The slides were viewed under low power (10x objective) and then under medium or 40x objective lens. The microscopic appearance was recorded by drawing.

The samples were subjected to 10% KOH and 20% for identification of nail samples. After 30 minutes the specimens were examined for the presence of hyphae or erythro-spores. Clinical samples followed appropriate techniques for handling specimens as per established guidelines. Culture media used were Sabouraud’s Dextrose Agar (SDA), prepared by using 65.0 grams suspended in 1000ml distilled water, heating till boiling to dissolve the medium completely, then sterilized by autoclaving at 15 lbs pressure (121°C) for 15 minutes and cooled down to 45-50°C. Chloramphenicol and Cyclohexamide were added, then mixed well and poured into sterile Petri plates (9).

Results

Current study recruited 129 patients divided into 74 females and 55 males. Dermatophytes were isolated from 95 out of the 129 patients included in the study and identified 18 species related to 6 phenotypes (Table 1). The isolated Dermatophytes included predominantly Trichophyton species [T. rubrum (20%), T. Verrucosum (11.57%) and T. Violaceum (11.57%)] followed by Microsporum species [M. Gypseum (10.52%), M. Canis (7.36%) and M. Nanum (6.31%)], all rated from high to low incidence (Table 1 and Figure 1). Tinea unguium was the most common 31(32.63%) clinical type of dermatophytosis
encountered in our study, as compared to other types like tinea pedis 23 (24.21%), tinea capitis 20 (21.05%), tinea mannum 13 (13.68%), tinea barbae 5 (5.26%) and tinea corporis 3 (3.15%). Also, the Yeast species (Candida) was isolated notably candida parapsilosis 4 (4.2%) cases that infect the nail (Tinea unguium) (Table 2, Figure 2).

The study also showed that the incidence of Dermatophytosis was higher in females with 61(64.21%) case as compared to males with 34(35.79%) cases and Tinea unguium 20(21.05%) was the most common clinical type caused by 10 dermatophytes species (T. rubrum, T. violaceum, T. verrucosum, M. canis, T. kanei, Epidermophyton floccosum, Candida tropicalis, Candida parapsilosis, Candida albicans, T. mentagrophytes, var. mentagrophytes) followed by Tinea pedis 16(16.84%), Tinea capitis 15(15.78%) and Tinea mannum 10(10.52%) (Table 2).

Discussion

Dermatophytosis is a major public health problem in tropical and subtropical countries like Iraq, yet remains unresolved. The incidence is increasing due to wide spread use of corticosteroids and antifungal agents without appropriate microbiological investigations (4). Therefore, it is essential that good laboratory methods are available for the rapid and precise identification of the dermatophytes involved in order to apply appropriate treatment and preventive measures (10). In the present study, 129 clinically suspected cases of tinea infections were examined over a period of 12 months, among which the most common fungal species was Trichophyton species then Microsporum species, and this result was in agreement with (11,12) who found that infection with Trichophyton species was the highest. T. rubrum was the most common isolate, followed by T. verrucosum, T. violaceum then M. gypseum, M. canis and M. nanum, 6(6.31%), 19(20%), 11(11.57%), 10(10.52%), 7(7.36%) and 11(11.57%), respectively. These results were in agreement with (13-19) who found that Trubrum was the most common isolate (Table 3), and disagreed with other Iraqi studies (20-22) who found that tinea capitis and tinea corporis were the commonest clinical types. So the reason may return to enzymes lipase and phospholipase produced by this dermatophytes which play a major role in penetrating the tissues of the host. On the other hand, T. verrucosum and T. violaceum were less common isolates which cause different types of tinea, notably tinea unguium, tinea corporis, tinea capitis and tinea barbae that may be attributed to high ability to produce elastase enzyme.

T: Trichophytone.
Tinea unguium was the most clinical type of dermatophytosis with an incidence of 32.36%, caused by 10 dermatophyte species, and the most common was *T. rubrum*. Onychomycoses in females were more frequent than in males. This is mainly due to the contact with water and detergents in home work and potential fungal nutrient such as sugar as well as trauma produced by manicure and modern life style. Similar results were shown by other studies (23-28).

**Conclusion**

Dermatophytosis is a major public health problem in tropical and subtropical countries, like Iraq, yet remains unresolved. Most common fungal species isolated were *Trichophyton* species.

Dental Plaque as a Probable *Helicobacter Pylori* Reservoir

**Muayad Mahdi kadhum⁠¹, Hasanain Khaleel Shareef⁠²**

⁠¹Laboratory Units, General Shomali Hospital, Babylon Health Directorate, Iraq; ⁠²Biology Department, College of Science for Women, University of Babylon, Iraq

**ABSTRACT**

**Background:** The natural reservoir and the specific mode of transmission for *Helicobacter Pylori* are unknown. Although the importance of *H. Pylori* culturing resides in the knowledge gained about their growth characteristic. Polymerase chain reaction had demonstrated great sensitivity and specificity than considered as the optimal method for identifying *H. Pylori* DNA in the oral cavity. The goal of this study was to investigate the occurrence of *H. Pylori* in the oral cavity with the biochemical characteristics and molecular identification of its strains by culturing and targeting 16S ribosomal RNA.

**Method:** During the period of study, a total of 95 dental plaque samples from patients in the age group (6-65 years) were collected. Dental plaque sample was discrete separately in 3ml of urea broth with urea supplement to detect the urease activity through change in color after one night and in 3ml of trypticase soy broth with 5% serum for proliferation and activation of microorganisms present in the plaques.

**Results:** Urease-positive activity was detected in 53(55.9%) out of the 95 samples. Then, just urease-positive specimens were cultured in chocolate agar under standard conditions for these bacteria. Only 11(11.7%) out of 53 urease-positive samples showed positive results according to biochemical test and morphologic characters. The isolated bacteria were confirmed by one sets of 16S ribosomal RNA primer F (AGAGTTTGATCCTGGCTCAG), R (GGTTACCTTGTTACGACTT) were used for PCR after total DNA extracted from isolated colonies of bacteria by specific methods. Pure DNA for 28(52%) of 53 samples was amplified with universal primer that we chose and yielded 1500bp DNA product when monitored by 1.5% agarose gel and visualized by UV-light instrument. Twenty-five (47.16%) out of 53 samples displayed negative results.

**Conclusion:** We believe that it is necessary to pay close attention to dental plaques as a second reservoir of *H. Pylori* coloniztion and possible source of infection. In this study we found the presence of *H. Pylori* was more in healthy children dental plaques than in adult patients, perhaps related to their living conditions.

**Keywords:** Helicobacter pylori, polymerase chain reaction, dental plaque, Chocolate agar, urease-positive.

**Introduction**

*Helicobacter pylori* (H. pylori) are gram negative bacteria that cause most prevalent disease in the world. The organism is found in the stomach of half of adults in developed countries and it is almost universal in developing countries (¹). *H. pylori* first isolated by Warren and Marshall in 1983, it is the most common cause of gastritis, gastric ulcer, duodenal ulcer and gastric adenocarcinoma, one of the most common causes of cancer death in the world (²). It is also linked to gastric mucosa-associated lymphoid tissue (MALT) lymphoma (³). Mode of transmission for *Helicobacter Pylori* is unknown yet (⁴). Humans usually acquire bacteria in the first few years of life and persist lifelong unless treated (⁵). *H. pylori* has many virulence factors, some of these are present in all strains of bacteria such as urease and flagella, but not all strains are contracted with clinical symptoms (⁶). Motility and urease production are very important to establish infection and colonization. Urease enzyme neutralizes stomach acidity by hydrolysis of urea into carbon dioxide and ammonia ions, thus allowing *H.
to persist in acidic environment (7). Other most significant virulence factors associated with gastric pathogenesis include production of cytotoxin (cagA protein) and vacuolating cytotoxin (vacA). *Helicobacter pylori* infection elicits a strong immune response, resulting in high titers of anti-\textit{H. pylori} antibodies (Abs) and this response is not adequate for elimination of the pathogen unless treated with antibiotics (8). Although several previous studies investigated routes of transmission of \textit{H. Pylori} infection, the exact mode and type of transmission of \textit{H. Pylori} infection is not known yet, but it was assumed to be person-to-person by the fecal-oral contamination or by contact with gastric secretions in some other way (9,10). The presence of \textit{H. pylori} in stomach, saliva, dental plaque and feces shows that the oral and fecal cavities are most likely involved in \textit{H. pylori} transmission. Consideration of oral cavity as the secondary reservoir for \textit{H. pylori} remains controversial since the isolation rate of this bacterium in the mouth is very diverse (11). However, there are a number of reports concluded that there is a major relationship between gastric and oral \textit{H. pylori} infections (12). Recently, diverse studies in different geographical areas had evaluated the prevalence of \textit{H. pylori} genes in saliva and dental plaque, but it has not been extensively studied in Iraq.

The aim of current study was to evaluate the prevalence of \textit{H. pylori} in dental plaque by adapting two different approaches, culture method depending on biochemical characteristic with culturing morphologic form of these bacteria and polymerase chain reaction (PCR) method to confirm isolates and to assess the presence of 16S rRNA genotypes in dental plaque of Iraqi people with and without peptic ulcer.

**Material and Method**

**Sample Collection:** An informed consent was obtained from patients whereby patients who agreed to take part in a study gave a permission to collect information and patient’s history. In this study, 95 dental plaque samples from patients between (6-65 years) with mean(SD) age of 25.8 (14.8) were recruited from different areas in Babylon Health Directorate (Al-Shomaly hospital, The Specialist Dental Center, The health Center in Shomaly) during the period from August to November 2018. Dental plaque was removed from the at least two teeth surfaces (one anterior and one posterior) with a sterile periodontal curette. Both supra- and sub gingival plaques were collected by an upward scrape against the teeth surfaces. Subjects with diabetes, HIV-positive patients, smokers, pregnant women, and patients who had taken antimicrobials within the previous 2 months were excluded from the study.

**Isolation of Helicobacter pylori:** All dental plaque samples cultivated in trypticase soy broth which was prepared according to manufactured procedures supplemented with 5% human free \textit{H. pylori} antibody serum and incubated at 37°C overnight for bacterial activation and proliferation. All test tubes having bacterial growth were centrifuged and the supernatant removed. Remaining pellet was transferred to urea broth with phenyl red indicator and incubate at 37°C overnight to detect bacterial urease activity through change in color. Each urease-positive sample was spread onto chocolate agar supplemented with trimethoprim, vancomycin and fluconazole to prevent over growth of gram positive bacteria and fungi and plates were incubated for (4-7) days at 37°C under microaerophilic condition (5% O2, 10% CO2 and 95% humidity) (13). Bacterial isolates were reliable with \textit{H. pylori} in shape, morphology, enzymatic activity (oxidase, catalase, urease) and Gram-negative status.

**Molecular Identification of Helicobacter pylori:** Fifty-three isolates of \textit{H. Pylori} from ninety-five samples by morphological characters and biochemical tests were confirmed by molecular method using (PCR) technique. DNA extraction from isolated colonies with wizard genomic DNA purification kit (promega/USA) according to manufacturer’s procedures then amplified by PCR with specific sequence of 16S rRNA primer (forward [F27] 5’-AGAGTTTGATCCTGCTACGAG-3’ and reverse [R1492] 5’-GGTTACCTTTGAGACTT-3’) (14). These primers bind to universally conserved regions and allow the amplification to occur producing approximately 1500bp fragments. The PCR amplification was carried out by PCR system (cleaver/USA). The amplification conditions were as follows: initial denaturation at 94°C for 10min and 35 cycles of denaturation at 95°C for 30s; annealing at 56°C for 1min; extension at 72°C for 1min; and final extension at 72°C for 10min. The presence of 1500bp specific PCR products (16S rRNA) was visualized by running 1.5% agarose gels.
Results

During the period of study, 95 dental plaque samples were collected and analyzed to detect the prevalence of Helicobacter pylori in oral cavity. Samples from patient were distributed according to age into 6 groups (Figure 1), then we adopted two different methods in this study, and the results of these methods were widely different from each other.

![Distribution of samples according to the age of patients](image)

Figure 1: All 95 dental plaque samples distributed in to the six groups according to patients ages

**Culture part of the study:** After incubating samples with TSB and subculture in chocolate agar for early diagnosis, 53 (55.9%) samples from the total 95 gave urease-positive when incubated with urea broth, while only 11 (11.7%) samples demonstrated *Helicobacter pylori* characters, morphologic form and biochemical activity in chocolate agar (Table 1).

Discussion

*H. pylori* infection is considered one of the most common bacterial infections in human. The infection is widely accepted as an important cause of gastritis and is strongly associated with peptic ulcer disease and gastric cancer. The human stomach was considered to be the only reservoir for *H. pylori* until bacteria were discovered in the oral cavity of humans (dental plaque, saliva) (15). There were various reports from different studies about the isolation rate of *H. pylori* from dental plaques ranged from 0 to 90%. In addition, there was a disagreement among several studies about the relationships between the prevalence of *H. pylori* in dental plaque and it is pathogenicity for the stomach. Some studies shown that there was no association between *H. Pylori* of dental plaque and stomach (16) and some researchers suggested that *H. pylori* should be categorized as normal flora of the oral cavity (17). This controversy among different studies reflected differences in the design as well as target populations of those studies. Our study adopted culturing and PCR methods for detected *H. Pylori* in dental plaques. The results exhibited wide variation between these methods as shown in (Tables 1 and 2). In Table (1), we shown 53 samples gave urease positive test, while PCR analysis gave only 28 isolates from the entire population of current study (95 samples). On the other hand, Table (2) suggested that urease-positive bacteria recovered from dental plaques perhaps belong to *H. Pylori*-like organisms, but they were negative on *H. Pylori* specific PCR examination thus demonstrating the possibility of false identification (18). For this reason, in our study urease test was not used for detection thus we continued and cultivated urease-positive organisms in chocolate agar under specific *H. Pylori*-cultivating conditions. The results showed few *H. Pylori* organisms as shown in Table (1). Several previous studies attempted to cultivate oral cavity *H. Pylori*. Indeed, the reported culture-positive rates were very low from various oral samples including dental plaques (19). Finding of these past studies were approximately similar to our findings. The main difficulties of bacterial cultures from oral cavity specimens were due to the presence of coccoid forms of *H. Pylori* maybe caused by the increased oxygen environment, the presence of numerous other microorganisms in the oral cavity which competed with *H. Pylori* then made culturing more difficult and/or there might be a small number of colonies of *H. Pylori* for culture (20). On the other hand, our PCR results in this study (Table 2) revealed that children harbored more *H. Pylori* than adults. This finding was in agreement with a previous study that suggested that the infection is most often acquired in childhood (21). Poor oral hygiene and socioeconomic conditions such as living in crowded areas probably responsible for almost incidence of present *H. Pylori* in children between the age of 6 and 15 years (22). By depending on culture and molecular methods for isolation of *H. pylon* from patients in different ages, we have shown that the prevalence of these bacteria in the oral cavity of children was higher than that in adult patients (Figure 2).

Conclusion

We believe that it is necessary to pay close attention to dental plaques as a second reservoir of *H. Pylori* colonization and possible source of infection. In this study we found the presence of *H. Pylori* was more in healthy children dental plaques than in adult patients, perhaps related to their living conditions. Our final results were discussed above confirmed by PCR technique. Although the culture is considered an important methodology for isolating bacteria, PCR method is considered more reliable especially with dental plaque samples.

![Figure 2: Adopted three methods (urease test, growth on solid media and molecular test) to isolate H. pylori from dental plaques of different six groups of patients.](image-url)

Exploration of Potential Link between Prevalence of Irritable Bowel Syndrome and Seropositivity for *Helicobacter Pylori*

Hasanain Abdulhameed Odhar¹, Ahmed Fadhil Hashim¹, Douha Hassan Obaid¹, Ruba Samer Majeed¹, Omaima Abbas Habeeb¹, Nooralhuda Mohammed Abdalhadi¹

ABSTRACT

**Background:** Irritable bowel syndrome (IBS) is a chronic gastrointestinal condition mainly manifested by abdominal pain, discomfort and alteration in gut habits. Therapeutic approaches are mainly focused on symptoms mitigation and modification of life style. It was believed that GIT infection, inflammation and changes in mucosal flora may be involved in IBS development. Abnormal modification of gut-nervous system interaction may be also implicated. *Helicobacter pylori* (*H. pylori*) is a well-known cause of peptic ulcer with greater prevalence in developing communities. Some studies have linked this gram negative bacterium with several extra-gastric diseases like pre-eclampsia. It was proposed that infection with *H. pylori* can initiate systemic inflammation leading to IBS development through alterations in gut permeability, normal flora and interaction with nervous system. However, the precise association between IBS prevalence and *H. pylori* infection is still controversial. The aim of current study was to evaluate any possible relationship between irritable bowel syndrome prevalence and *Helicobacter pylori* seropositivity.

**Method:** Lateral flow immunochromatographic assay was employed to screen 30 IBS patients and 30 control (without IBS) volunteers for *H. pylori* IgG antibodies.

**Results and Conclusions:** Our regression analysis didn’t show any significant association between irritable bowel syndrome prevalence and *H. pylori* seropositivity.

**Keywords:** Irritable bowel syndrome, *Helicobacter pylori*, nervous system, seropositive, flow immunochromatographic assay.

Introduction

Irritable bowel syndrome (IBS) is a functional gastrointestinal disorder with a global incidence ranging between 10% -15% (¹). This chronic condition is mainly characterized by changes in bowel habits associated with abdominal discomfort and pain (²). The incidence of IBS is more common among female patients and the onset of IBS symptoms can be observed in early adulthood (³). Therapeutic strategy is mainly focused on modification of life style and symptoms alleviation (²).

The underlying cause of irritable bowel syndrome is not clear, but several hypotheses had been proposed. An alteration in interaction between gastrointestinal tract (GIT) and nervous system seemed to be mainly involved (⁴). Additionally, GIT mucosal inflammation, changes in gut normal flora and infection are well recognized in IBS patients (⁵,⁶). The end result of these proposed mechanisms is a pathological alteration of mucosal permeability and sensitivity of GIT (⁷).

*Helicobacter pylori* (*H. pylori*) is a well-known microbial cause of peptic ulcer and gastritis, it has been linked to several extra-gastric diseases like asthma and pre-eclampsia (⁸). Some strains of this gram negative bacteria possess several virulence factors like cytotoxin associated gene A (CagA), this antigen can trigger an inflammatory reaction that may predispose the host to develop IBS (⁹).
It was believed that systemic inflammation triggered by *H. pylori* infection can enhance mucosal permeability of GIT and change gut flora \(^9,10\). Mucosal infiltration of lymphocytes and mast cells in GIT can elicit the release of inflammatory mediators like substance P leading to modification of gut-brain interaction \(^11\). Finally, the ongoing inflammation can stimulate hypothalamus-pituitary-adrenal axis (stress axis) \(^12\). 

However, the precise link between *H. pylori* infection and prevalence of IBS is still controversial and a matter of debate in scientific community \(^7\). The aim of current study was to obtain a better insight into such possible relationship by screening IBS patients and normal volunteers for *H. pylori* IgG antibodies.

**Materials and Method**

**Study Sample:** Our screening study was performed between December 2018 and February 2019. For this case-control research, sixty volunteers were selected randomly from several gastroenterology clinics in Karbala, Babylon and Baghdad provinces. The implemented protocol for this project was in accordance with the guideline of Iraqi board of medical specialities.

Of these volunteers, thirty patients with a confirmed IBS diagnosis were selected as a case group, the diagnosis was in compliance with Rome IV criteria \(^2\). The other thirty individuals with no IBS diagnosis were included as a control group. A verbal consent was acquired from each volunteer.

Both demographic and clinical characteristics were reported for each participant. A previous history of having *H. pylori* eradication therapy was considered as an exclusion criterion.

**Immunochromatography assay:** The Accutest *H. pylori* cassette test kit from Jant Pharmacal Corporation was used for serological screening of IgG antibodies. Five milliliters of blood were collected from each volunteer in a vacutainer tube. After clotting of blood specimen, the serum was separated and collected by centrifugation.

As specified by the manufacturer, one drop of serum was applied to the cassette well followed by the addition of washing buffer; the final result was then reported after 2-3 minutes. The appearance of the control line only was regarded as a negative reading, while the recognition of both control and test lines was an indication for presence of *H. pylori* IgG antibodies. Failure to develop any line or the appearance of only test line in the cassette was considered invalid reading.

**Statistical analysis:** Our continuous data were described as median and range, both case and control groups were compared by using Mann-Whitney test. On the other hand, categorical data were reported as frequency and percentage. The difference between control and case groups was assessed by using Chi-squared test; Fisher’s exact test was employed in some instances when small sample size is encountered. The above statistical analyses were accomplished by using Graph Pad prism version 5.01.

Logistic regression was utilized to investigate the relationship between IBS prevalence and *H. pylori* seropositivity. The difference in gender was implemented as a covariant to calculate degree of association. IBM SPSS Statistics version 20 was used to evaluate regression. Statistical significance was reported when a two-tailed P value lower than 0.05 was encountered.

**Results**

The demographic and clinical characteristics of both IBS patients and control volunteers were concisely described in Table (1). No significant difference can be noticed between control and IBS groups regarding age, body mass index, smoking habit, concomitant diseases and family history of IBS. However, the only significant difference was reported for gender distribution with P value = 0.007. Our IBS sample did include more female patients (80%) as compared to male counterpart (20%).

| Table 1: Demographic and clinical characteristics of study subjects |
|------------------------|------------------------|------------------------|------------------------|
| Variable               | Control                | Case (IBS)             | *P* value              |
|                        | Median (range) or No. (%) | Median (range) or No. (%) |                      |
| Age (years)            | 23 (19-55)             | 23 (19-50)             | 0.086 (NS)             |
| Gender:                |                        |                        |                        |
| Male                   | 16 (53.33%)            | 6 (20%)                | 0.007                  |
| Female                 | 14 (46.67%)            | 24 (80%)               |                        |
| BMI (Kg/m²)            | 23.89 (19.53-50.15)    | 24.31 (19.11-35.94)    | 0.739 (NS)             |
Based on Table (2), our regression analysis didn’t detect any significant association between prevalence of irritable bowel syndrome IBS and seropositivity of *H. pylori* (P value adjusted to gender = 0.103). The distribution of *H. pylori* IgG antibodies among study individuals was well illustrated in Figure (1).

**Figure 1: Distribution of Helicobacter pylori** seropositivity among study volunteers

**Discussion**

According to gastroenterologists’ opinions, IBS is a frequently observed GIT disorder that can affect quality of life for many patients (2,13). In the absence of any GIT organic or structural abnormality, the underlying cause of IBS seems to be multifactorial and poorly defined. As a consequence, the currently available therapeutic options are mainly symptoms directed with variable effectiveness (2,4).

Some studies suggested that *Helicobacter pylori* may play a critical role in irritable bowel syndrome development (9). Systemic inflammation triggered by virulent antigens of *H. pylori* can increase GIT permeability, modify gut normal flora and also change the interaction between nervous system and GIT (7,10,11).

According to observational studies, the exact relationship between *H. pylori* infection and IBS development is still questionable (7). As an objective, we
tried to explore this controversial association and satisfy our uncertainty.

To minimize the possibility of having false positive results in immunochromatographic screening, we excluded any individual with a previous history of *H. pylori* eradication therapy, because having this treatment course can eliminate the bacterium but not the corresponding immunoglobulins which can stay in host circulation for long periods (14).

It is worth mentioning that we included gender distribution difference as a covariant during our association analysis. Based on our demographic data, more females were recruited into IBS group (80% females versus 20% males). It is well-known that IBS is more common in females than males with a ratio of 2:1 (3).

Our regression study failed to report a significant association between *H. pylori* seropositivity and prevalence of IBS with adjusted P value = 0.103. This result was in agreement with a previous study carried out in China (7). However, additional screenings with larger samples from different communities are highly recommended to shed more light on this controversial relationship.

The Anti Inflammatory Effect of Pumpkin Seeds Oil in Treatment of Gingivitis; Clinical Study

Ahmed Adel Othman¹, Muntaha Fawzi Saleh², Taif Mahdi Saleh³
¹College of Dentistry, Oral Diagnosis Department, Uruk University, Iraq; ²College of Dentistry, Oral Diagnosos Department, AL-Mustansiriyah University, Iraq; ³College of Dentistry, Periodontic Department, Uruk University, Iraq

ABSTRACT

Background: Many studies had focused on investigating the anti inflammatory roles of herbal medicines such as oils rich in fatty acids. Pumpkin seeds oil contains omega-3, omega-6 fatty acids and other fatty acids (oleic, linoleic and palmitic acids). Six phenolic acids (protocatechuic, caffeic, syringic, vanillic, p-coumaric and ferulic) were detected. Pumpkin seeds oil is a good source of vitamins, minerals and anti-oxidants. Many people have difficulty in controlling plaque build-up and preventing gingivitis using only conventional teeth cleaning. The objective of this study was to determine the anti inflammatory properties of pumpkin seeds oil for treatment of gingivitis.

Method: In this study 58 healthy male patients were involved their age ranged was (20-30) years. They were diagnosed having gingivitis according to the criteria of Loe and Sillness gingival index. These 85 patients were equally divided into two 29-subject groups as study and control groups. The patients in the study group were instructed to brush their teeth twice daily morning and before the bed time and then apply few drops from the pumpkin seeds oil on the brush and make a gentle massage for one minute to the gingiva. Patients in control group were instructed to do the same protocol but using normal saline (placebo without any active ingredient) instead of the pumpkin seeds oil. All the patients were examined again after one week to evaluate the cases prognosis.

Results: Data from current study showed the index of gingivitis for selected teeth before treatment. The highest score was for the maxillary right first molar (2.7), while the lowest score was for the mandibular right first bicuspid (1.8).

Conclusion: This study proved that pumpkin seeds oil is a potent anti inflammatory agent that can be used topically for treatment of gingivitis without any side effects.

Keywords: Pumpkin seeds oil, gingivitis, anti-inflammatory properties, Omega-3.

Introduction

Pumpkin is a commonly used vegetable all around the world. Its seeds are rich in proteins and fatty acids (1). Increasing natural drug demand for pharmaceutical uses has encouraged scientists all around the world to investigate medicinal plants recognized as efficient remedies (2). Nutritional values and health protective characteristics of pumpkin attracted considerable attention of food scientists in recent years (3). Many studies had focused on investigating the anti inflammatory roles of herbal medicines such as oils rich in fatty acids (4). Pumpkin seeds oil contains omega-3, omega-6 fatty acids and other fatty acids (oleic, linoleic and palmitic acids). Six phenolic acids (protocatechuic, caffeic, syringic, vanillic, p-coumaric and ferulic) were detected (5). Pumpkin seeds oil is a good source of vitamins, minerals and anti-oxidants (6).

Gingivitis is inflammation of the gums and it is a reversible condition as the gingiva become red, swollen
and can bleed easily (7). Many people have difficulty in controlling plaque build-up and preventing gingivitis using only conventional teeth cleaning (8). In susceptible people, gingivitis may lead to periodontitis which is not reversible. Therefore, people use mouth rinses in addition to conventional teeth cleaning to control gingivitis (9). Conventional mouthwashes have adverse effects like teeth staining, altering taste and sensitivity from chemical ingredients (10). So mouthwashes with active natural constituents are our target to reach in this clinical study. A pumpkin may be considered as a valuable source for new multi-purpose products for industrial, cosmetic and pharmaceutical utilizations (11). The objective of this study was to determine the anti-inflammatory properties of pumpkin seeds oil for treatment of gingivitis.

**Materials and Method**

**Pumpkin seeds oil was purchased from Amazon website:** In this study 58 healthy male patients were involved their age ranged was (20-30) years. They were diagnosed having gingivitis according to the criteria of Loe and Sillness gingival index. These 85 patients were equally divided into 2 groups; study group, 29 patients, and control group, 29 patients. Gingival tissue around six teeth for each patient were diagnosed (upper right first molar and lateral incisor and left first premolar, for the lower teeth left first molar and lateral incisor and right first premolar). Gingival tissue of selected teeth was divided into four units (facial margins, lingual margins, distofacial and distolinguinal margins) to determine the degree of gingival inflammation. The patients in the study group were instructed to brush their teeth twice daily morning and before the bed time and then apply few drops from the pumpkin seeds oil on the brush and make a gentle massage for one minute to the gingiva. Patients in control group were instructed to do the same protocol but using normal saline (placebo without any active ingredient) instead of the pumpkin seeds oil. All the patients were examined again after one week to evaluate the cases prognosis.

**Results**

Gingival index was developed by Loe and Silness in 1963 for assessing the location and severity of gingivitis by examining the qualitative changes of gingival tissue.

- **GI 0:** Normal, healthy gingiva with sharp non-inflamed margins.
- **GI 1:** Marginal gingivitis with minimal inflammation and edema at the free gingival margins. No bleeding on probing.
- **GI 2:** Moderate gingivitis with a wider band of inflammation and bleeding upon probing.
- **GI 3:** Advanced gingivitis with inflammation clinically reaching the muco-gingival junction usually with ulceration. Periodontitis will usually be present.

**Gingival Index (GI) before treatment**

This table showed the mean, standard deviation and p value for the control and study group after treatment. The mean for the study group was 0.5, the standard deviation was (0.18) and the p value was highly significant.

**Discussion**

Pumpkin seeds oil is an extraordinarily rich source of nutritional, pharmaceutical, and cosmeceutical
properties that exhibited many pharmacological effects and health benefits (12). Pumpkin seeds oil served as an antioxidant (13), antidiabetic (14) antifungal (15), antibacterial, antihypercholesterolemic and anti-inflammatory (16). Anti-microbial activity of pumpkin seeds oil was performed against the pathogenic bacteria S. aureus using disc diffusion method (17). In addition, in vitro, in vivo and clinical studies showed that pumpkin seeds oil had a wide spectrum of amazing biological activities (18).

Pumpkin seeds oil with high content of polyunsaturated fatty acids (Linoleic acid, tocopherols and sterols. Several types of unsaturated fatty acids are the dominant components in pumpkin seeds which can play a role in disease prevention and health promotion (19). High content of these bioactive components were in agreement with an efficient wound healing by the means of an in vivo study. In vivo experiment was conducted by (20) using the cutaneous wound healing rats and revealed that oil from pumpkin seeds extracted by cold pressure was better in macroscopic, morphometric and histological data of rat skin than the untreated rat. Pumpkin seeds are rich in vitamin E as an emerging free radical scavenger, anti-aging and antioxidant. The pumpkin oil could significantly increase collagen production (21).

Conclusion

This study proved that pumpkin seeds oil is a potent anti inflammatory agent that can be used topically for treatment of gingivitis without any side effects.

Relationship between Testosterone and Body Mass Index, Hirsutism, Alopecia, Acne, Type of Menstrual Cycle, and Levels of Interleukin-1β, Interleukin-17, Interleukin-27 and Interleukin-35 for Infertile Women with Polycystic Ovary Syndrome

Sundus Fadhil Hantoosh

Lecturer, Training and Development Department, DNA Forensic Center for Research and Training, AL-Nahrain University, Baghdad, Iraq

ABSTRACT

Background: Polycystic ovary syndrome prevalence among young females is 15%. Sex hormones regulate immunity through hormone receptors on immunocytes. In addition, cytokines, commonly called interleukins, participate in ovarian cycle regulation. Major source of interleukin-17 is T helper 17 cells. Current study was aimed to investigate relationship between testosterone levels with interleukins levels, body mass index and polycystic ovary syndrome symptoms.

Method: Twenty-six infertile polycystic ovary syndrome women were enrolled. Serum testosterone levels and serum levels of interleukin-1β, -17, -27 and -35 were measured on day 2 of the cycle.

Results: There was significant correlation between elevated body mass index and high testosterone levels [p=0.0001]. In addition, recognizable impact of high testosterone concentrations was on incidence of hirsutism, alopecia, acne regularity of menstrual cycle [p=0.0006, p=0.002, p=0.006, p=0.04], respectively. Compared with normal testosterone levels, high testosterone levels caused significant decrease in interleukin-1β levels [p=0.002]; whereas interleukin-17 and interleukin-27 showed comparable results [p=0.36, p=0.09]; and non-significant increase in interleukin-35 in high testosterone levels [p=0.25].

Conclusions: Testosterone levels had significant impact on BMI, PCOS symptoms and serum interleukins levels.

Keywords: Body Mass Index, Polycystic ovary syndrome, alopecia, acne, interleukins, testosterone.
This study was aimed to investigate relationship between testosterone levels and BMI, PCOS symptoms and impact on IL-1β, IL-17, IL-27, and IL-35 concentrations.

**Materials and Method**

This study was conducted with randomly selected twenty-six infertile PCOS females attended consultant clinic of Higher Institute for Infertility Diagnosis and Assisted Reproductive Technologies at AL-Nahrain University in Baghdad, Iraq from January 2016 to April 2016. Information concerning age, type and duration of infertility, hirsutism, alopecia, acne, and menstrual cycle type whether normal or oligomenorrhea (OM) were obtained from patients’ records.

PCOS was diagnosed according to Rotterdam criteria by specialist physician in consultant clinic. Diagnostic PCOS parameters included suffering from two of three criteria: OM or chronic anovulation, clinical and/or biochemical signs of hyperandrogenism, and polycystic ovaries. Conditions excluded before diagnosis were: thyroid dysfunction, hyperprolactinaemia, androgen-secreting tumors, Cushing’s syndrome and congenital adrenal hyperplasia [12]. Also, women having uterine anomalies, endometritis, sexually transmitted diseases, tubal factor infertility and endometriosis were excluded.

Age of participants ranged from 21 to 35 years. Twenty-two had primary infertility with duration from 1 to 10yr [Mean ± SD= 4.04 ± 0.53yr], and four had secondary infertility with duration from 1 to 14yr [Mean ± SD= 5.00 ± 3.02yr].

**Blood Sampling:** Informed and signed consent was obtained from participants. Intravenous blood was obtained on day two of the cycle [CD2]. Blood was centrifuged at 2500rpm for 15 minutes. Serum testosterone concentrations were measured on CD2 using commercially available mini-VIDAS kits [BIOMERIEUX/France]. Normal testosterone levels range is [0.23-0.73ng/ml] according to kit leaflets. Serum levels of IL-1β, IL-17, IL-27 and IL-35 were measured using ELISA kits [CUSABIO/China].

**Statistical Analysis:** Data from current study were analyzed using Statistical Analysis System (SAS; 2012). Chi-squared test was used to compare between percentages and Least Significant Difference (LSD), while t-test was used to compare between means in this study [14].

**Results**

Twenty-six infertile PCOS women were enrolled in current study. BMI was measured and 4[15.38%] patients had normal weight [22.98 ± 0.39kg/m²], 10[38.46%] were overweight [28.06 ± 0.50 kg/m²] and 12[46.15%] were obese [37.74 ± 0.77 kg/m²] (Table 10).

In addition, 17[65.38%] patients had normal testosterone levels [0.42 ± 0.03ng/ml] and 9[34.62%] had high testosterone levels [0.78 ± 0.02ng/ml]. Also, mean testosterone concentration, for 2[7.69%] normal weight patients, was [0.30 ± 0.00ng/ml], for 8[30.77%] overweight it was [0.42 ± 0.05ng/ml] and for 7[26.92%] obese it was [0.47 ± 0.06ng/ml]. For 9[34.61%] PCOS women with high testosterone levels, mean testosterone level for 2[7.69%], normal weight women, was [0.74 ± 0.00ng/ml] and for 7[26.69%], overweight, it was [0.85 ± 0.00ng/ml] and for 5[19.23%], obese patients, it was [0.78 ± 0.02ng/ml].

Moreover, 20[76.92%] PCOS women were hirsute, 20[76.92%] were with alopecia and 11[42.31%] had acne (Table 1).

Discussion

Around 30% of PCOS females have clinical and/or biochemical increase of androgens [15]. Notable condition of PCOS is insulin resistance (IR). Hyperinsulinemia is promoter of hyperandrogenism and chronic oligo-anovulation [16]. The important step in testosterone synthesis is regulation of P450c17 enzyme [17]. Activation of this enzyme in ovary is regulated by insulin and insulin-like growth factors [IGFs], and luteinizing hormone [LH]. Hyperactivity of P450c17 enzyme causes ovarian hyperandrogenism [17]. Luteinizing hormone stimulates androgen production by theca cells [6]. Chronic LH stimulation in PCOS stimulates theca cells hyper production of androgens [17]. Aromatase activity was lessened in PCOD follicles, and androgen increase (caused by this decreased activity) contributes to abnormal development of follicle [18].

Considerable relationship between PCOS and BMI and prevalence of obesity was high [19]. Moreover, abdominal adiposity is prevalent across all weight classes in PCOD [16]. Visceral adiposity is about 30% of normal weight PCOD [18].

In normal weight, severity of hyperandrogenism and IR exhibited strongest relationship in PCOD [20]. Study observed that testosterone levels were significantly elevated in obese and non-obese PCOS groups compared with control healthy subjects. Some PCOS women with normal BMI showed clinical/biochemical hyperandrogenism [15]. Androgen stimulates differentiation of pre-adipocytes to adipocytes, especially in abdominal area, facilitating progress of visceral-type obesity [21]. Insulin working through insulin-like growth factor 1 [IGF1] enhances LH-mediated steroidogenesis in theca cells and increases ovarian androgens [22]. Excessive insulin in obese acts similarly to co-gonadotrophin on theca cells stimulating androgen synthesis and reducing steroid-hormone binding globulin (SHBG) elevating free testosterone concentrations and causing hyperandrogenemia [20].

Adiposity lowers testosterone concentrations [2]. Lower level correlates with higher BMI [2]. A previous study reported significant increase in serum testosterone levels in obese PCOS group compared to non-obese PCOS group [23]. Insulin working through IGF1 enhances LH mediated steroidogenesis in theca cells and increases ovarian androgens [22].

Abdominal adiposity is frequently present even in non-obese PCOD women is IR feature [8]. For elevated weight females, PCOD is associated with IR
and hyperandrogenic [20]. In obesity, excessive insulin acting on theca cells stimulating androgen secretion and reducing SHBG, elevating free testosterone levels and causing hyperandrogenemia [20].

Hyperandrogenism manifestations are hirsutism, alopecia, virilization, acne and seborrhea [15]. Study of 716 PCOS patients showed that the prevalence of hyperandrogenemia, hirsutism, and acne was 75.3%, 72.2%, and 14.5%, respectively. In most cases, hirsutism was caused by combination of increased androgen synthesis compared with non-hirsute females and high skin sensitivity to androgens. Sensitivity of hair follicles to androgen is governed by 5α-reductase activity in skin [15]. For about 20-40% of hirsute PCOs females, analysis of serum androgens failed to reveal elevated concentrations of androgens [24]; maybe, current measurement procedures were not sufficiently reliable, or absence of clear boundaries of normal values in circulation of females. Normal circulating androgens in presence of other clinical signs, does not exclude PCOD diagnosis [24].

Acne prevalence in PCOD was 10%-34% [25]. A study mentioned expression of ARs in keratinocytes within pilosebaceous ducts and documented androgen directly impacted keratinization in acne process [26]. Acne is chronic inflammatory disorder of pilosebaceous unit caused by elevated sebum secretion stimulated by androgen, altered keratinization, bacterial colonization of hair follicles on face, neck, chest, and back, and inflammation [15].

In PCOS, among hyperandrogenism symptoms is alopecia [27].

Females with OM and PCOS have high free testosterone and lower SHBG compared with RMC control women [20]. Insulin resistance and hyperandrogenemia are correlated with having an IMC [20]. Menstrual cycle disorders were present in 90.7% of PCOD [24]. Oligomenorrhea was reported by 69.2%, while 9.3% had normal menses in PCOD [24].

Aberrant regulation of immune system leads to pathological states. Sex hormones regulation of immunity is attribute to hormone receptors present on immunocytes where interaction influences secretion of interleukins which impact proliferation, differentiation and maturation of different kinds of immune cells and consequently outcome of inflammatory disorders. Testosterone is a regulator of immunity [4]. There was an observation that androgen deprivation therapy correlated with elevated concentrations of pro-inflammatory agents and lessened anti-inflammatory interleukins concentrations, while researches indicated that testosterone supplementation reduced inflammatory factors in hypogonadal men [28].

Studies recorded that inflammatory markers were positively combined with androgen concentrations in PCOD [29]. Normal and high testosterone levels decreased IL-1β expression [4]. Interleukin-27 and IL-35 suppress IL-17 release [9,30-31].

Conclusions

Testosterone levels were recognizably increased in high and normal BMI cases. Also, high testosterone levels impacted PCOS symptoms and recognizably affected interleukins concentrations.

Assessment of TNF-a, IL-17, IL-33, TGF-b, and Dopamine in Iraq Depressed Women with Chronic Toxoplasmosis Infection

Maha mahmood shaker¹, Hazima Mossa Alabassi², Sabah A. Hameid A. Rahman¹

¹Biology Department, College of Science, Mustansiriyah University, Baghdad, Iraq; ²Ibn AL-hytham Collage, Baghdad University, Baghdad, Iraq

ABSTRACT

Background: In Iraq, a high prevalence rate of Toxoplasma gondii infection was reported and data about correlation between this infection and major depressive disorders were documented. Therefore, the aim of current study was to evaluate the association between levels of parameters related to chronic toxoplasmosis infection and depression in Iraq women.

Method: In this study, 260 serum samples were collected from Iraqi women and divided into four groups as follow: G1 depressed women infected with toxoplasmosis, G2 women infected with toxoplasmosis but did not have depression, G3 depressed women without toxoplasmosis infection with toxoplasmosis, G4 apparently healthy persons. The following parameters were assessed TNF-a, IL-17, IL-33, TGF-b and dopamine. Statistical analysis was performed by using statistical analysis system.

Results: Data from current study revealed elevated levels of proinflammatory cytokines TNF-a, IL-33, IL-17, as well as there was an increase in concentration of dopamine in G1. The mean ± SE levels for the three cytokines were (2444.69 ± 98.82, 3629.50 ± 61.10 and 1008.88 ± 36.35 pg/ml), respectively and the mean ± SE for dopamine was (387.33 ± 8.09 pg/ml), while TGF-b didn’t show any elevation in its level in this group.

Conclusion: Elevated levels of both proinflammatory cytokines and dopamine in depressed women who had chronic infection of toxoplasmosis may reflect the effect of chronic infection that may alter the expression of dopamine which skew the immune response towered Th17 that affect the expression level of proinflammatory cytokines and neutrophils response.

Keywords: TNF-a, IL-17, IL-33, TGF-b, dopamine, toxoplasma infection, depression.

Introduction

In Iraq, a high prevalence rate of Toxoplasma gondii (T. gondii) infection was reported (¹). Data about correlation between T. gondii and major depressive disorder were documented by (²). Chronic T. gondii infection is characterized by increased levels of host immune activity and neuroinflammation (³). Evidence about correlation between anti-toxo IgG antibodies and depression considered conflicting. Some researchers found a correlation between titer of IgG in pregnant infected women and depression in the USA (⁴). T. gondii infection considered risk factor for schizophrenia, depression and personality disorders in humans. In dopaminergic cells, the parasite increases the level of K⁺ ion, causing 3 times increase in dopamine release. The level of dopamine was also found to be high in the brain tissue with T. gondii cyst (⁵). TNF-a is known to be associated with mood disorders. The IL-33/ST2 axis protects mice from Th1-induced damages in the brain during toxoplasmosis. Cytokines and chemokines are regulated with a delicate balance between a necessary Th1 response for the control of parasite proliferation and a Th2-regulated response to limit the pathology due to an exacerbated deleterious Th1 response (⁶). It was reported that the level of TGF-b was higher in depressed patients as compared with control group.

Moreover, previous data showed that level of anti-inflammatory cytokine TGF-b also showed a significant decrease in patients with major depressive disorder (7). Moreover, it was observed that the level of TGF-b was significantly different in young depressed patients, while there were negative correlations between TGF-b and IL-17, it was observed that the level of TGF-b wasn’t affected by level of dopamine in contrast to level of inflammatory cytokines which was associated with a mood disturbance in toxoplasmosis-infected individuals. Also, IL-17 showed a significant increase. Dopamine was affected in infected rodents. In addition, T. gondii infection may be thought to cause behavioral alteration due to tryptophan metabolism and the effect on the hypothalamic-pituitary adrenal flow (8). There are very few studies supporting toxoplasma infection IgM seropositivity or the development of schizophrenia after the maternal fetal period infection. Toxoplasma induces neuroinflammation and cytokines leading to imbalance in the neurotransmitter metabolism, tryptophan metabolism, host immunity functions and systemic hormone levels. In rodent studies, chronic T. gondii infection increases dopamine concentration through tyrosine hydroxylase encoded in the parasite genome of the brain and nitric oxide-mediated dopamine release occurs in the host (9).

Aim of the study: For many years, the nervous system and the immune system have been seen as two separate systems. In recent years, this situation has begun to be constantly discussed and the point reached in this regard was that: “The fact that the central nervous system, which is supposed to be devoid of the immune system, now harbors the immune system”. These interactions, expressed as neuroimmunity, can be described in two ways; Classical nervous system molecules such as dopamine can act on the immune cells.

Therefore, the aim of current study was to evaluate the association between levels of parameters related to chronic toxoplasmosis infection and depression in Iraq women.

Material and Method

Serum samples were collected from 260 Iraqi women who were selected according to special criteria and the state of depression was diagnosed by special psychologist. Subjects were divided into four groups as follows: G1 depressed women infected with toxoplasmosis, G2 women infected with toxoplasmosis but did not have depression, G3 depressed women without toxoplasma infection, G4 apparently healthy individuals. The following parameters were evaluated: TGF-b, TNF-a, IL-33, IL-17 and dopamine by using ELISA technique. Statistical analysis was performed by using statistical analysis system (SAS, 2010) and excel to find means and correlations.

Result

Table (1) showed that there were increasing levels for proinflammatory cytokines included TNF-a, IL-33, IL-17, as well as there was increasing in concentration of dopamine in G1. The mean ± SE was (2444.69 ± 98.82, 3629.50 ± 61.10, 1008.88 ± 36.35 pg/ml) for the three cytokines respectively, and the mean ± SE for dopamine was (387.33 ± 8.09 pg/ml), while TGF-b didn’t show any rise in this group.

Discussion

Many studies referred to the increased levels of inflammatory cytokines through chronic infection of toxoplasmosis TNF (3), IL-17 (10), and IL-33 (11) and also showed increased level of TNF throughout depression state (12). At the same time IL-33 also showed an association with state of depression. Moreover, (13)
showed an increase in Th17 cells, but lack of association between IL-17 level in blood and severity of disease suggested that IL-17 might promote depression state but not entirely dependent on IL-17 and might promote neurons inflammation and activation of Th17 and other cells might stimulate depressive-like behavior in mice as a result of accumulation of Th17 in brain of mice exhibiting depressive-like behavior. High levels of pro-inflammatory cytokines during course of infection are important to control infection and prevent prevalence of parasite via different mechanisms for example TNF-a has anti-parasitic effect. On the other hand, (3) showed that mice infected with cyst release a high level of TNF and TNF-a produced by different cells during toxoplasmosis infection such as macrophage, microglia and dendritic cells promoting anti-parasitic mechanisms by macrophage. IL-17 also participates in anti-parasitic effect and, during infection, IL-17 is involved in development of neutrophils which were important in eliminating the parasites in addition to contributing in inflammation during parasitic infection (14). IL-33 might regulate information among different types of immune cells during inflammatory response toxoplasmosis, and might regulate immunopathology of ocular toxoplasmosis with its receptors ST2 (14). There were increasing levels of pro-inflammatory cytokines verses decreased levels of anti-inflammatory cytokine TGF-b in three group of our study. However, (15) showed that level of TGF-b was not different among mice infected with toxoplasmosis and also didn’t differ during period of infection.

About dopamine neurotransmitter, current study recorded a low level in (G3) (depressed patients) and this was considered natural result, because of low level of dopamine associated with state of depression and this consisted with previous study. However, its level was high in (G1); might be due to the ability of T. gondii in synthesis of DOPA decarboxylase which is important to convert L-DOPA to dopamine in the dopaminergic cell and this was shown in cyst-containing cells in the brain (16). So in spite of decreasing level of dopamine in (G3) but infection with T. gondii could have modified its level causing increased level in groups (G1 and G2). Toxoplasmosis infection did not increase level of dopamine only, but also might have increased its release. Furthermore, (5) showed that T. gondii infection caused behavioral changes in intermediate host rodents and was considered a risk factor in schizophrenia, depression and personality disorders in humans. In dopaminergic cells, the parasite increases the level of K+ ion, causing dopamine release 3 times more than the normal level. In addition, it was found that dopamine has elevated level in brain tissue with T. gondii cyst. For many years, the nervous system and the immune system have been seen as two separate systems. In recent years, this situation has begun to be constantly discussed, and the point reached in this regard was that: “The fact that the central nervous system, which is supposed to be devoid of the immune system, now harbors the immune system” These interactions, expressed as neuroimmunity, can be described in two ways; Classical nervous system molecules such as dopamine can act on the immune cells. For example, T cells express a few dopamine receptors (DARs). The stimulation of specific DARs on dendritic cells and T cells has been shown to affect the CD4 + T cell differentiation in Th4 or Th17 inflammatory cells. Dopamine receptors are expressed in T cells, dendritic cells (DCs), B cells, NK cells, neutrophils, eosinophils, and monocytes. The best example of these interactions is the cytokine called IL-6. Although its mechanism has not been clearly defined, IL-6 acts in this process as a neutropoetin (stimulator of neuronal growth), TNF-a provides protection during chronic stage of infection (17), this protection is mediated by neutralization of cytokines involved in increasing the susceptibility and higher parasite burdens (18). TNF-a also mediated production of NO. Mice treated with TNF antibody (Ab) showed decreasing NO levels. It was also suggested that the connection between testosterone and dopamine is mediated by nitric oxide as testosterone enhances production of NO by up-regulation of nitric oxide synthase in the medial pre-optic area of the brain (MPOA); subsequently, NO promotes dopamine release in the MPOA and facilitates male sexual behavior (19). NO, TNF-a and other cytokines mediated increased dopamine release (20). Increased level of IL-17 was associated with increased level of dopamine and this appeared in levels of both IL-17 and dopamine in studied groups or through significant positive correlation that was recorded previously. Nonetheless, association between dopamine and IL-17 during human Rheumatoid Arthritis was examined by (20), they showed that cytokine secretion including IL-17 from CD4+ naive T cells, which were stimulated by anti-CD3/CD28 Abs and simultaneously added dopamine. Dopamine markedly increased IL-17 secretion in a dose-dependent manner via IL-6 dependent IL-17 production via D1-like receptors. In addition, D2-
like receptor antagonists induce accumulation of IL-17 T cells and IL-6 T cells, indicating dopamine as an important factor for Th17 differentiation. It was showed that level of TGF-b wasn’t affected by level of dopamine in contrast to level of inflammatory cytokine IL-6 which was associated with mood disturbance associated with toxoplasmosis, and IL17 also showed significant increase. Mast cells are adjacent to the neurons and glial cells in thalamus, hypothalamus and leptomeninges and activate them by cell-to-cell contacts as well as by releasing inflammatory and neurotoxic mediators (21).

Mast cells located at the brain side (more than 95%) of the BBB protect the brain from invading pathogens and toxic substances from peripheral organs (22). Mast cells play a major role in neuroinflammatory conditions including neurodegenerative diseases, by increasing the BBB permeability and activating the brain-resident immune cells microglia and T-cells (23). Stress conditions activate mast cells through CRH, which is activated through activation of HPA axis, and other neuropeptides to release several neuroinflammatory mediators including cytokines such as TNF-α, IL-33 and other inflammatory mediator.

Conclusion

Elevated levels of both proinflammatory cytokines and dopamine in depressed women who had chronic infection of toxoplasmosis may reflect the effect of chronic infection that may alter the expression of dopamine which skew the immune response toward Th17 that affect the expression level of proinflammatory cytokines and neutrophils response.

Down-Regulation of Circulating MicroRNA-205 as a Potential Biomarker for Distinguishing Prostate Carcinoma from Benign Prostatic Hyperplasia

Adel Mosa AL-Rekabi¹, Shoroq Mohammed AL-Temimi²
¹Department of Surgery, College of Medicine, Qadisiyah University, Iraq; ²Department of Pathology, College of Medicine, Qadisiyah University, Iraq

ABSTRACT

Background: MicroRNAs are a sequence of short (~22nt), single-stranded RNA molecules that act as post-transcriptional controllers of gene expression. Circulating microRNAs as the potential minimally-invasive biomarkers for early detection and progression of prostate carcinoma. Therefore, the aim of the study was to find out the potential application of using circulating microRNA-205 to detect prostate cancer among patients with benign prostatic hyperplasia and find its correlation with age and stage of tumors.

Methods: Real-Time PCR was done to demonstrate the gene expression of microRNA-205 in serum sample of patients with prostate cancer, benign prostatic hyperplasia and control groups. The expression levels of microRNA-205 were calculated relative to messenger RNA of Glyceraldehyde 3-phosphate dehydrogenase and determined using the livak method.

Results: microRNA-205 expression level in tissue samples was significantly down-regulated in prostate carcinoma in comparison to normal adjacent tissues and also the serum level was significantly down-regulated in prostate cancer cases in comparison to apparently healthy controls and benign prostatic hyperplasia.

Conclusion: Serum- microRNA-205 gene expression can serve as minimally-invasive biomarkers and standard screening tool for early detection of prostate cancer and for detection of higher stage from early stage of the tumor.

Keywords: MicroRNA-205, RT-PCR, Livak method, Prostate cancer, Benign Prostatic Hyperplasia

Introduction

Prostate cancer (PCA) is the uppermost malignant tumor in males among Western world, with over 40000 cases in the United Kingdom diagnosed per-year, and its control would be significantly better since. Serum Prostate-specific ASntigen (PSA) is a gold standard biomarker for diagnosis of such disease, but it has many limits as a diagnostic marker. Raised serum PSA is not specific to the malignant prostate tumor and 50% of men experiencing biopsy subsequent to a raised PSA, are diagnosed with prostate tumor, an unsatisfactorily high false-positive ratio given the risks of biopsy. The PSA analysis similarly has a false-negative rate of around 15% (1). The PSA has a slight value as a prognostic marker. High percentage of men with prostate cancer mortality due to other causes and the expenses and morbidity associated with over-treating these indolent prostate tumors are considered a significant public health issue (2). The deficiency in sensitivity and specificity of PSA test contribute to a argument over its value in initial diagnosis.

On the other hand, PCa is subject to endocrine stimuli for its growth and survival, therefore, androgen-withdrawal treatment indicated the principal-line of treatment, with important better prognostic result in patient. On the other hand, within 2 years of management, a higher percentage of those patients progress to a castration-resistant form of the disease, which is
MicroRNAs (miRs) are short RNA molecules, on average 22 nucleotides long, they function as post-transcriptional regulators of target complementary RNA (mRNA) usually in the 3’ UTR. which results in mRNA degradation resulting in reduced levels of encoded protein (4). miRNAs play the major regulatory part in different cellular processes comprising cell cycle, proliferation, differentiation and apoptosis (5). Recent revisions had associated various miRNAs in the emergence and progression of many human cancers and also as a potential marker for cancer diagnosis and prognosis (6,7).

Materials and Method

The study was conducted during the period from April 2012 to March 2018. This is a prospective study involved a total of 100 cases; whereby 60 of them were with newly diagnosed PCa, 30 were with Benign Prostatic Hyperplasia (BPH) and 10 were apparently healthy controls. Patients were recruited at the Surgical Department/AL-Diwaniyah Teaching Hospital in Diwaniyah City. Digital rectal examination (DRE) and Ultrasound-guided punch biopsy were performed as a part of the standard diagnostic protocol for patients with prostatic disease in Pathology Department/AL-Diwaniyah Teaching Hospital in Diwaniyah City.

The serum sample was collected from the patients with prostatic disease (n=90) before an operation and apparently healthy controls (n=10) were diagnosed without any tumor or physical illness. After excision of the prostate samples, further tested with the established criterion able to classify as benign or malignant on the basis of miR-205 expression values. Take 90 pairs of fresh tissues from some cases of prostate lesion and normal adjacent tissues (NATs) which is considered as internal control and preserved in Diethylpyrocarbonate (DEPC) water for total RNA extraction and for RT-PCR. Another 90 pairs of specimens from the prostate lesion and normal adjacent tissues for histopathological examination. Pathological sorting was done based on WHO classification and tumor staging was carried out according to AJCC.

MiRNA isolation from serum and tissue: Serum samples were collected between 8:00 and 9:00 a.m. Following centrifugation for 30min at 2,650g, serum samples were stored at 80°C. Tissue samples were homogenized in a denaturing lysis solution and dissolved RNA was stored at -20°C before use. Isolation of total RNA (RNA was extracted from serum and fresh tissues using the Trizol reagent; Bioneer, Korea) was don according to the manufacturer’s instructions. RNA quality was assessed with a NanoDrop 1000 spectrophotometer.

Real-time RT-PCR for miR-205 quantification: miR-205 was evaluated according to “TaqMan miR RT-kit procedure (Applied Biosystems, Foster City, CA, USA)” which involve using miR-specific primer (according to miR- database to design the primers) (19) in addition to essential Taq-Man probes. Reverse transcriptase reactions was prepared to make cDNAs in a volume of 15ml using 10ng total RNA for each sample, 50nM stem–loop RT primer, 1RT buffer, 1mM each of dNTPs, 3.33U/ml and 0.25 U/ml RNase inhibitor. Real-Time PCR was done in triplicate. The volume of 20ml of each sample included; TaqMan Universal PCR Master Mix, 1ml specific miR Assay Mix, and 1.34ml RT product. The reactions were incubated at 50°C for 2min and 95°C for 10min, followed by 40 cycles of 95°C for 15s and 60°C for 1min. All miR-205 quantification data were normalized to house-keeping gene. The messenger RNA(mRNA) of GAPDH gene primers and probe were designed by using NCBI- Gene Bank data base and Primer 3 plus design online. The cDNAs primer of GAPDH design as Random Hexamer primer and the primer used in qPCR was: forward, 5-UCCUUCAUUCACCAGAGUCUG-3 and reverse 5-GACCUCCGUGGAUAGAAAUU-3. Taq-Man probe for mGAPDH was: FAM-CCAGCGAGCCACATCGCTC-TAMRA. The data results of RT-qPCR for miR-205 and GAPDH were analyzed by the relative quantification gene expression levels (fold change) were based on the Ct values by using the Livak method (Fold change = 2-ΔΔCT) that described by (8).

Statistical Analysis: SPSS version 16 and Microsoft Office Excel 2007 were implemented in data analysis. Chi-squared test and Fisher exact test were done to find out the correlations between any two nominal variables. P≤0.05 was considered significant.
Results

Clinicopathological characteristics of patients: Table (1) shown a total of 100 patients, of whom 60 cases (66.7%) with PCa, 30(33.3%) cases with BPH, and the apparently healthy controls were 10 cases.

Comparison of tissue microRNA-205 gene expression of prostate carcinoma and benign prostatic hyperplasia with normal adjacent tissues: Mean cancer tissue of miR-205 was statistically significantly lower than that of NATs (-120 ± 1.5 vs. 1 ± 0.21, respectively, P<0.001; Table 2). Mean fold change of miR-205 in the tissue sample of BPH did not change in comparison with that of NATs and was not statistically significantly different from that of NATs (P>0.05; Table 2). Mean cancer tissue of miR-205 was statistically significantly lower than BPH tissues (P<0.001; Table 2).

Comparison of serum microRNA-205 of prostate carcinoma and benign prostatic hyperplasia with apparently healthy controls: The mean serum miR-205 level of cancer patients was statistically significantly lower than that of apparently healthy controls -80 ± 2.5 vs. 1 ± 0.41, respectively, P<0.001. Mean fold change of miR-205 in the serum of BPH did not change in comparison to those apparently healthy controls and was not statistically significantly different from those apparently healthy controls (P>0.05). Mean fold change of miR-205 in serum of cancer patients was statistically significantly lower than BPH tissues (P<0.001).

The correlation of microRNA-205 gene expression fold change between prostate carcinoma tissues and paired serums: The results showed a statistically significant correlation of miR-205 gene expression in the PCa tissues with those in the paired serums, with r = 0.41 (P<0.001; Figure 1). Also, the results showed a statistically significant correlation of miR-205 gene expression fold change of the BPH tissues with those in the paired serum, with r = 0.31 (P<0.001).

Correlation between serum fold change of microRNA-205 gene expressions with age: Present study presented that there was no significant association between serum fold change miR-205 of PCa, BPH and age of patients in those ≤65 years and >65 years (P>0.005).
Association between serum fold change of microRNA-205 and stage of the tumor: The mean fold change of miR-205 serum levels in PCa patients showed significant statistical difference among stages of a tumor (A, B, C, D) (Table 3).

Predictive value of microRNA-205 in the serum of patients: To evaluate the diagnostic value of serum miR-205 for PCa by using the RT-qPCR technique, a Receiver Operator Characteristic (ROC) curve analysis was done.

A. Comparison of the PCa group and the healthy control group: The best cut-off value for serum miR-205 in PCa in comparison to those apparently healthy control groups was (-50 fold change) with a specificity of 100%, a sensitivity of 87.30% and an excellent accuracy(AUC) (Figure 2).

B. Validity of microRNA-205 folds change as a prognostic marker: To check the cut-off value of fold change for miR-205 expression level, that could assume PCa patient with positive LN and TNM stages C and D (higher stage PCa from patients with earlier stages of PCa (A, B)), an ROC curve analysis was done.

Accordingly, we initiated that miR-205 fold change could guess positive LN and higher stage (C, D). While ROC results established that the AUC values were 100% (excellent) and 96.5% (excellent), when the cut-off value was set to the optimal points (≥-70 and ≥-80), specificity values were 97.2% and 97.1%; sensitivity values were 100% and 100%, respectively (Table 4).

Discussion

The present study focused on tissue and serum levels of miR-205 of same prostate cancer patient samples. The mean cancer tissue fold change of miR-205 was statistically significantly lower than that of NATs. These results were in agreement with results of many studies (9-14). The serum level of miR-205 gene expression was statistically significantly lower from those apparently healthy controls and BPH. Also, the best cut-off value for gene aberration was (-50 fold change) with a specificity of 100%, sensitivity of 87.30% and an excellent accuracy (AUC) from which can detect normal gene expression from gene aberration and also can detect normal and BPH cases from malignant ones. However, it could be helpful for early detection of prostate carcinoma in those cases of highly suggestive and with grey-zone of PSA. These results were in agreement with results of previous studies (9-14).

Early diagnosis has been the key to effective management of many life-threatening illnesses, including prostate carcinoma. Early detection causes the establishment of better treatment of prostate carcinoma at its early stage before it is disseminated and affects other healthy tissues of the body. The expression array of miR-205 could act as a powerful tool for diagnosis of early stage prostate carcinoma (9).

The serum levels of miR-205 gene expression in advanced stages (C, D) and LN metastasis in the present study were statistically significantly lower than those of early stages (A, B) and LN negative, respectively. Moreover, the best cut-off value for gene aberration for stages C and D were (-70) and (-80) fold changes, respectively. Therefore, we can detect gene aberration in advanced stages (C,D) with LN involvement from gene aberration of early stages (A, B). This suggested the possibility of down-regulated miR-205 levels as a prognostic biomarker. These results were in agreement with results of other studies (14-22). In the presented study, there was no statistically significant difference between the age of patients and fold change of miR-205 gene aberration. These findings agreed with those from other studies (9-15).

Conclusion

MiR-205 could be a useful biomarker for early detection of prostate carcinoma, detect the advanced stage of prostate carcinoma. In addition, to the screening of asymptomatic populations and assessment of disease progression in prostate carcinoma.

Investigation of the MEP4 Gene of the Fungalysins Gene Family (MEP 1-5) in Isolated Skin Fungus from Primary School Students

Abbas Abdul Hussein Mohi1, Majid Kazem Al Shibli1
1Faculty of Education, University of AL-Qadisiyah, Iraq

ABSTRACT

Background: Fungalysin MEP 1-5 is a group of genes that encode protease enzymes in skin fungi. Since proteins make up a large part of the weight of mammals represented by collagen, elastin and keratin, accounting for 25% of the weight of mammals. In addition, there are other proteins on the skin are the pillars of the work of protease enzymes; Endoprotease and Exoprotease, which are working to break down protein which is the source of carbon and nitrogen necessary for the growth of these fungi. The aim of current study was to confirm the presence of MEP4 of the Fungalysin gene family in isolates of skin fungal infections.

Method: The study was conducted on isolated samples of primary school students under the age of 16 and included collection of samples from different areas of head palpitations, flexion of the body, hip flexor, mandrel, fingernail and foot band. The fungal infections were distinguished from other conditions such as eczema and hypersensitivity. Several samples were prepared to detect the presence of one MEP1-5 gene (fungalysins) using a known sequence of the 2000bp molecular weight MEP4 gene. After obtaining a primer, a real-time PCR scan was conducted to investigate the differences between the different isolates and their relationship to the virulence of species. The SDA and cycloheximide were used to prevent the growth of fungal fungi and chloramphenicol to prevent the growth of bacteria. The isolates were isolated and phenotypic isolates were included. Trichophyton sp, Microsporium sp, Epdermophytoni sp analyzed data statistically, and analyzed real-time PCR melting curve.

Results: The real-time analysis indicated that 59.25% of isolates did not show the gene expression of this gene, while 40.74% showed expression of MEP 4 gene.

Keywords: Skin fungal infection, Fungalysin gene family, MEP4, PCR, Phenotypic.

Introduction

Fungalysin MEP 1-5 is a group of genes that encode protease enzymes in skin fungi [1]. Since proteins make up a large part of the weight of mammals represented by collagen, elastin and keratin, accounting for 25% of the weight of mammals [2]. In addition, there are other proteins on the skin are the pillars of the work of protease enzymes; Endoprotease and Exoprotease, which are working to break down protein which is the source of carbon and nitrogen necessary for the growth of these fungi. So, it was necessary to find studies on the mechanism of entry of fungus into the skin where the link and the formation of bacterial tube by mechanical forces (contact and friction) and secretion of exoenzymes for lipid analysis and necessary for penetration. A group of these enzymes were identified in fungi by [1]in M. canis and T. rubrum fungi to be a family of five genes known as MEP1, MEP2, MEP3, MEP4, MEP5 and all of the endometalloprotease type in experiments on guinea pigs [1,3,4]. Five specialized genes belonging to the metalloproteases family (MEP), MEP1-5, were identified by the world and [1]‘s described three genes belonging to this family: MEP1, MEP2, MEP3 in M. canis, encoded for three endometalloproteases and MEP2, MEP3 protease in infections of laboratory animals in guinea pigs. The MEP3 gene showed activity with

Keratinolytic, Elastinolytic and Collagenolytic proteins. Two additional genes, MEP4 and MEP5, were then recorded to become a family of five genes in M. canis. Both genes were controlled by endometalloproteases. MEP4, MEP5 in T. rubrum [5].

The authors [1] reported that MEP3 had a molecular weight of 43.5 kilo Dalton and that the gene with MEP2 was produced during the fungus invasion of host cells.

Other researchers [6] found high levels of MEP 3 and MEP4 when developing T. rubrum, while soybeans were high in MEP 2 and MEP5 in T. violaceum [6]. Also, [7] confirmed that MEP4 levels were high in the fungal infection of the host.

The MEP4 gene ensures the following sequences for ATCGTGATTCCTTTAGCACC

And Rev TCGCCCATGGTATAGTCAG

In another study [9], in Egypt, showed that 10% of the isolates contained MEP1-4, while the MEP5 gene had a 20% appearance in T. Verrucosum.

The experiments carried out by [10] using the Agrobacterium tumefaciens-mediated transformation (ATMT) system demonstrated that mutant isolates of MEP4, MEP5 were less virulent than non-mutant isolates, believing that these genes had a significant role in pathogenesis of isolates they contain. The aim of current study was to confirm the presence of MEP4 of the Fungalysin gene family in isolates of skin fungal infections.

Materials and Method

The study samples were collected from people with dermatological diseases and were diagnosed clinically by specialized dermatologists from April 2016 to March 2017. Primary school students in Babylon and Diwaniyah governorates were included through consultation clinics in governmental hospitals or through private clinics for dermatologists. The study included 38 samples of skin flakes, 12 infected hair follicles and 10 samples of infected nails. The patient’s specific information was recorded according to an already prepared form. The samples were transferred by sterile siphon bags prepared for this purpose to the laboratory. Of which 10% were used in direct examination using 10% KOH.

Samples from school children infected with SDACCG were incubated at 28-30°C and observed after day 5. As fungi began to appear in the form of growing colonies, colonies were monitored and changes during the incubation period were recorded.

Insects are passed from time to time to keep them from dying or fungal contamination and subsequent tests [11].

Direct Microscopy: A small sample of the sample was placed on the clean glass slide. A drop of 10% KOH solution was added and cut for 15-30 minutes to allow keratin to dissolve by KOH. Then the test was performed to see the fungal yarn and reproductive spores. If the sample was nail, it was left for a longer period of up to an hour to allow the keratin to dissolve and then examine the samples [12].

Growth of Samples: Samples from infected school children with SDACCG were incubated at 28-30°C and observed after day five as fungi began to appear in the form of growing colonies. Growth of colonies and recording of changes during incubation period are observed. Insects are passed from time to time to keep them from dying or fungal contamination and subsequent tests [11].

Examination and diagnosis of fungal colonies:

Phenotypic examination of colonies: The fungal colonies were examined at the first appearance, as they varied in the number of days needed for growth. The shape of the colony and its edges were also recorded regularly or irregularly. The external appearance was described as granular (cottony) or wooly (wooly). In addition, the color of the dyes produced by each type is recorded on the opposite side and the degree of change of these pigments by the growth progress and the type of medium on which it grows.

Microbiology of colonies: The specific characteristics of each isolated fungal species were investigated using the adhesive tape method. A drop of blue lactiphenol was placed on a clean glass slide. Place the adhesive tape on the surface of the fungal colony and gently press to allow adhesion of the fungus and spores and then lift the tape and place it on the lachninoid drop. The fungal structures are under 10x-20x-40-100x, and parts of the fungal colonies may be taken with fine forceps and placed on the glass slide, then a drop of dye is placed after the lid had been placed and the isolates examined [2,13,14].
Physical tests

1. Hair hole test hair perforation test: This test was used to distinguish between species capable of puncturing hair or not, by taking a strand of blond hair and cut into parts of one centimeter length, sterilized with the catheter and placed in sterile test tubes. Each tube was added to 10-15ml distilled water. The fungus cultivars developed well, with the colony not less than two weeks old. The tubes were incubated at a temperature of 25°C for 1-4 weeks in a dark incubator. The hair was examined a week later by placing the hair on a glass slide and a drop of lactiphenol, Trichophyton spp is repeated every two days of penetration, the results recorded and used to distinguish different types [15,16].

2. DNA extraction of skin fungi: DNA had been extracted as reported by manufacturer FAVORYN BIOTECH CORR. The program was applied to real-time PCR inspection.

Results and Discussion

Direct examination showed 43 positive cases from 51 cases (84%), while results of the transplant showed positive 27% by 52%.

The isolates showed a variable rate of infection with *Trichophyton mentagrophyte* 37.04%, while the second type was *T. soudanense* (14.82%), the *T. rubrum* (14.2%), *M. audouinii* (11.11%) and for *Epidermatophyton floccosum* & *M. canis*, was 7.41% each. Both *M. ferrugineum* and *T. verrcosum* had the lowest infection rate of 3.70% each (Figure 2).
The results showed that there were significant differences between urban and rural populations. Urban injuries were 44.44%, while rural injuries were 55.56% (P= 0.0395). The percentage of male injuries was 62.96%, while females accounted for 37.04%. In terms of age, we found that ages of more than 10 years accounted for 70.38%, while ages less than 10 years accounted for 29.62% (P= 0.0001).
Figure 4: Relationship between age and injury

Amplification chart

Figure 5: PCR real-time analysis and disintegration curve of MEP4 gene.
The real-time analysis indicated that 59.25% of isolates did not show the gene expression of this gene, while 40.74% showed the gene expression as shown in the real-time PCR scan and the MEP 4 disintegration curve.

Laboratory Administration of Clinical Trachoma Cases Caused and Ruled by *Musa domestica* in Mesopotamia

Abdul-Samad Uleiwi Hassan¹, Anaam Mehdi Dawood¹, Zahraa Falah Abd-Alaali¹

¹Medical Laboratories Department, Health & Medical Techniques College, Al-Forat Al-Awsat University, Iraq

**ABSTRACT**

**Background:** Trachoma is an infectious disease carried by bacterium *Chlamydia trachomatis* that roll out by both straight and secondary contact with an infected person’s nose or eye. The aim of current study was to diagnose the main cause of trachoma transferred by houseflies and proves this role through modern analytical techniques used in this study.

**Method:** The current project addressed 12 cases. Clinical treating submitted several modern lab methods incorporated NAAT, culture, antigen detection, genetic probes; and microscopy.

**Results:** Significant difference (P< 0.05) seemed to be obvious in most of the tested variables.

**Conclusion:** Our study provided an explanation of the spread of new cases of trachoma in Mesopotamia and the modern ways for diagnosis applied in biology lab to prove those cases.

**Keywords:** Trachoma, Iraq, Musa domestica, NAA test, demographic map.

**Introduction**

Trachoma is an infectious disease carried by bacterium *Chlamydia trachomatis* that roll out by both straight and secondary contact with an infected person’s nose or eye. This disease causes a jagging of the eyelid’s inner surfaces leading to pain in this organ, collapse of the cornea or the outer surface and at long-last losing vision(1). Universally, more than 80 million persons have an active trachoma. Infections in some states perhaps current in as many as 60–90% of youngsters. Amid grown-up, women more by ordinary influenced than men – likely because their adjacent connection with youngsters. This disease causes declined vision in more than 3 million patients, of whom more than million are formerly blind. It mostly occurs in 53 states of Asia, Africa, and South and Central America, with about more than 200 million persons as at danger cases (2).

Houseflies insects do not perform duties for as a coming after host or act as a container of any germ of medical or veterinary importance, but they do play as mechanical vectors to over 200 microbes, such as Chlamydia. It can travel for several miles from their reproducing places, bearing this microorganism on their body parts; mouthparts, hairs, vomitus, and contaminated feces(4).

Sudden upset of trachoma in Middle East demanded many governmental and private efforts on the research levels to combat, quarantine and eradicate this problem. So many diagnostic techniques were improved and introduced in that manner; i.e. PCR, serological tests, NAD, and others (5).

**The aim of current study was to** diagnose the main cause of trachoma transferred by houseflies and proves this role through modern analytical techniques used in this study.

**Materials and Method**

Models and tests were analyzed in Mesopotamia, particularly in southern regions, Central educational hospitals, while investigations in Baghdad city include serological investigation. NAA applied in LabCorp, headquartered in Burlington, North Carolina.
About 10 cases aged 10 to 24 years who had clinical trachoma diagnosed during the period from July to October 2018.

Diagnostic methods involved applying Direct cytological examination, isolation in cell culture, antigen detection, NAA, Serology.

Demographic map is a mapping technology used to view data on population infected with trachoma in Iraq during 2018.

Statistical analysis of collected and calculated data for clinical variables was scheduled and solved according to (6).

### Results

Diagnostic tests proved that there are mature inclusions appeared as dark purple masses in the cytoplasm of epithelial cells. Culture tests explained a Chlamydial elementary and reticulate bodies can be purified from tissue culture harvests by use of differential renografin density gradients and cushions. Additional antigen diagnostic tests detected elementary bodies in smears. On the same ways NAA assays positive out coming results. The last evidence for trachoma in our study was the positive serological test with IgG: <1:64 and IgM: <1:10 (Table 1).

†Relative to the other assays, NAA and Serological tests are the most sensitive and specific.

Statistical correlation indicated strong and directional relationship between basic research variables (mostly flies) and the trachoma test’s outcomes (Figure 1).

![Figure 1: Statistical bubble diagram explains strong correlation among factors of our research](image)

Demographic survey showed progressive spread of trachoma at the south of state and then it appeared up in Babylon and its neighbor villages of other governorates.

### Discussion

Cytological examining to detect inclusions is particularly beneficial in detecting acute inclusion conjunctivitis of the newborn; the sensitivity of this method exceeds 90%. Cytological testing is relatively insensitive when diagnosing adult conjunctival and genital tract infections. Culture is the only methods that confirms the presence of viable or living organisms (7). Antigens, nucleic acids or antibodies can present in the absence of viable infectious particles. Nucleic acid amplification is a valuable molecular tool not only in basic research but also in application of oriented fields such as clinical medicine development, infectious diseases diagnosis, gene cloning and industrial quality control. Serologic tests support NAAT findings of very
low to zero prevalence of ocular *Chlamydia trachomatis* in this community and have potential to provide objective measures of transmission and useful surveillance tools for trachoma elimination programs (8,9).

Demographic maps data and spatial information technologies have three main advantages here. First: it can be a means of recording and storing information by the governments, the private sector, development agencies and civil society. Second: they can be used to identify and study spatial patterns. Maps draw attention to spatial associations. Third: they are helpful in presenting information and communicating findings. Maps permit us to convey information and conclusion that are difficult to express in words, or to condense messages that would be lengthier to describe in words (10,11).

**Conclusion**

Conclusion of our study states that incidence of chlamydia infection in the populations and communities being served should be monitored. Any unexpected variation from this expected rate should initiate investigation into any variation in laboratory practice, specimen collection and transport procedures, or changes in the population served. Each of the alternate isothermal methods has their own limitations and their mechanisms are relatively complex, they are simple to perform and offer better sensitivity. Incorporation of real-time detection methods such as ECL, molecular beacon made them more competent to be used widely. In the future, some of these methods will be as acceptable and applicable as PCR.

**Ethical Clearance:** Ethical approval was obtained from the Research Ethics Committee at the Directorate of Health in Iraqi Governorate, Iraq.

**Source of Funding:** Self-funded.

**Conflict of Interest:** None to declare.

ABSTRACT

Background: Patients with T2DM are considered as immunosuppressed hence they are at risk of infections. Neutrophils are one of the most important phagocytic cells and have important roles in innate immunity. This study was aimed to detect the type of suppression in circulating Neutrophils function in T2DM blood; either resultant from endogenous or exogenous factor.

Method: A total of 60 blood samples were collected from T2DM adult outpatients, and 30 controls or healthy people were involved. Evaluation of neutrophils activity was accomplished for both patients and controls by testing the abilities of circulating neutrophils in blood samples to engulf and reduce NBT dye. Also, IL-8 ELISA test was used to estimate this cytokine levels in patients and controls.

Results: Data from current study showed significant decrease in phagocytic activity and IL-8 levels in T2DM.

Conclusion: T2DM are negatively affected on peripheral Neutrophils via diminishing phagocytic activity and that was due to endogenous and exogenous factors. Hoever, still need more investigations about other related cytokines because it leads to suppression in innate immunity in T2DM patients which predispose them to various infections.

Keywords: diabetes mellitus, NBT, IL-8, innate immunity, Cytokine, Phagocytosis, neutrophils.

Introduction

Type II diabetes mellitus (T2DM) is a heterogeneous group of disorders characterized by variable degrees of insulin resistance, impaired insulin secretion and increased glucose production. Patients with T2DM are considered immunosuppressed hence they are at risk of infections [¹]. Neutrophils are one of the most important phagocytic cell types. Neutrophils follow chemotactic cues to locate sites of inflammation, migrating to infection sites in response to signals such as chemo-attractants mainly the cytokine IL-8. Phagocytosis is defined as the ingestion of particles by cells and this process involves the binding of particles to the surface of phagocytic cells followed by internalization and destruction of these particles. The coating of a microorganism with molecules that trigger its destruction by phagocytes is known as opsonization. The reduction of nitroblue tetrazolium (NBT) by monocytes and neutrophils can be used as an indirect marker of the phagocytic activity of these cells.

NBT is a dye with low reduction potential that produces an intensely stained product called Formazan Crystals when reduced inside the mitochondria [²].

In patients with T2DM, abnormalities are usually associated with polymorphonuclear neutrophils (PMNs) and monocytes chemotaxis, opsonization, ingestion of bacteria, oxidative burst and intracellular killing. Hyperglycemia or the presence of advanced glycation end products is believed by many researchers to lead to a state of low activation in PMNs [³]. Interlukine-8 is a cytokine produced by macrophages and epithelial cells and acts as powerful chemo-attractant for neutrophils. The effects of IL-8 on neutrophils include chemotaxis, degranulation, trans-endothelial migration and respiratory burst activation and regulation [⁴]. Hence, this study was aimed to detect the type of suppression in circulating Neutrophils function in T2DM blood; either resultant from endogenous or exogenous factors.
Material and Method

Subjects and Samples: A total of 60 blood samples were collected from T2DM adult outpatients at the Diabetic and Endocrine center in Al-Hussein hospital in Al- Muthanna Governorate, Iraq during the period from November 2017 to March 2018. The patients were clinically diagnosed by physicians. Blood samples were collected into two tubes; heparin tubes for NBT test and ordinary tubes to isolate serum. Samples were treated as recommended by [5].

Controls and Samples: The controls were 30 healthy volunteers; 25 males and 6 females. They were adults and healthy with no history of recent infections nor DM. Blood samples were collected similarly from all subjects to compare the results with patients’ results.

Ethical Approval: All ethical approvals concerning DM patients and controls were obtained before starting work.

Phagocytic Activity Evaluation: Evaluation of neutrophils activity was accomplished for both patients and controls by testing the abilities of circulating neutrophils in blood samples to engulf and reduce NBT dye (provided by Segma/USA) and forming formazan particles. This test usually detects the oxidative burst inside neutrophils. Heparinized blood was used and slides were stained by Fleishman’s stain (provided by Segma/USA). Preparation and examination of blood smears were done according to [6].

Interlukin-8 estimation: This cytokine was estimated in serum samples of patients and controls. IL-8 ELISA kit was used for this purpose (provided by R &D/USA), and work was done according to kit leaflet.

Statistical Analysis: Statistical analysis of data was performed using SAS (Statistical Analysis System - version 9.1). Independent t test was used to assess the differences between means.

Results and Discussion

Results are presented in Tables 1 and 2. Parameters used in this study decreased significantly as compared with controls’ results statistically. Concerning NBT test outcomes, there were an obvious suppression in neutrophils activity detected in patients’ neutrophils when compared with controls. Results of current study showed that T2DM has caused a significant decrease (at P<0.05) in neutrophils activity in generating proper phagocytosis. Normal values for this test were also in account and are (55-75%) as recommended by [5].

The obtained results indicated that T2DM patients involved in this study suffered from suppression in phagocytic cells represented by neutrophils in their blood. In addition, the cytokine that is responsible for their activation was in regression of its levels which means less activation and lower function of Neutrophils.

Metabolic disorder and starving cell disease are the description of DM including both type I and type II, because cells don’t get enough energy (glucose) for daily activities. Many authors stated about the effects of T2DM on neutrophils at the cellular level. Decreased bactericidal activity, impairment of phagocytosis and decreased release of lysosomal enzymes and reduced production of reactive oxygen species by neutrophils of diabetic patients have been described by other scientists [7-9].

Other researchers [10] searched about the effects of endogenous and exogenous pro-oxidants trigger of leukocytes activation in DM patients and stated that these mechanisms interact in a cycle responsible for
the control of oxidative/antioxidant homeostasis which were significantly affected in patients with diabetes as in current study.

Other researchers [11] described the causes of diminished phagocytic activity in DM patients from a physiological view and showed for the first time that the chemotactic activity of neutrophils from diabetic patients is significantly lower than in cells from healthy controls and there was an impairment of their functions. Decreased bactericidal activity, impairment of phagocytosis and decreased release of lysosomal enzymes, reduced production of reactive oxygen species by neutrophils of diabetic patients, reduction in leukocyte phagocytosis and bactericidal activity showed a significant correlation with increased blood glucose levels in patients. They explained that due to diabetes mellitus effects on the metabolism of neutrophils, it impaired metabolism of glucose and glutamine and increased fatty acid oxidation then compensate for the reduction in glucose and glutamine utilization to maintain the ATP supply for these cells. That can explain current study result, since NBT test needs the oxidative burst inside phagocytic cells to be efficient in order to reduce NBT dye and form the black formazan particles that deposit and give the positive result. Mitochondrial dysfunction caused impairment of phagocytosis in neutrophils of T2DM, this fact was revealed by [12] and they explained that by less energy supply in diabetic cells including neutrophils.

The present study outcomes were confirmed by suppression of IL-8 levels in T2DM patients, which was reflected on the activity of neutrophils in turn. Since this cytokine plays an important role in activity function of neutrophils as stated by [13], they proved that this cytokine can be used as an indicator for abnormalities of renal innate immunity which leads to renal failure in diabetic patients. Another study [14] supported the fact that recurrent infections in DM patients can be attributed to impaired innate immune response, the first line of defense represented by neutrophils, and that can explain the difficulty in treating infections in DM patients. Moreover, the authors [15] estimated many cytokines in T2DM patients peripheral blood and they concluded that, in general, many cytokines secretion was affected and reflected on their levels and duties in regulation of overall immune system status in patients. Also, they found that IL-8 levels were decreased in a significant manner.

Conclusion

T2DM patients are negatively affected on peripheral Neutrophils via diminishing phagocytic activity and that was due to endogenous and exogenous factors. However, still need more investigations about other related cytokines because it leads to suppression in innate immunity in T2DM patients which predisposes them to various infections.

Ethical Clearance: Ethical approval was obtained from the Research Ethics Committee at the Directorate of Health in Iraqi Governorate, Iraq.

The Effect of the Use of the Self-Programming Method in Cognitive Achievement and Learning the Handling Skills of Football Students

Mohsen Mohammed Hassan¹, Ali Mohammed Jawad Al-Sayegh², Obeis Abed Wahid¹
¹Faculty of Physical Education and Sports Sciences, University of Kufa Iraq; ²Fine Arts Institute for Boys, Al-Najaf Education Directorate, Ministry of Education, Iraq

ABSTRACT
The aim of the research was to identify the effect of the self-programming method in cognitive achievement and learn the handling skills of students. This research was conducted on a sample of students of the first stage in the Faculty of Physical Education and Sports Sciences/ University of Kufa for the academic year 2018-2019. They were divided into two equal groups. The experimental worked in a self-programming and control method. The method was followed by the teacher of the material after performing the homogeneity and equivalence processes, such as the selection of appropriate tests for the research variables affecting the cognitive achievement and learning the handling skills of the football students identified by the researcher (10) students from outside the basic research sample, using the tools and aids in the research. The tribal tests were carried out on the two groups and then the research method was applied within the educational units (8) units within four weeks. (90) Minutes, after which the remote tests were carried out, and then the results of the research were processed using the appropriate statistical methods. The researchers produced several needs, the most important of which is that the self-programming method has a positive effect on learning the skill of handling football and the cognitive achievement associated with this skill, As well as the possibility of using this method in the educational process of football material, and in light of these conclusions recommend that the researchers recommend the use of self-programmatic cognitive achievement and learning the skill of handling for football students.

Keywords: self-programming, cognitive achievement and learning.

Introduction
The teaching methods are an important means of organizing the relations between the learner and the teacher and the educational material during the stages of the educational unit for the purpose of achieving the teaching method that achieves the desired goal. The duties of the teacher are all related to the teaching of the students. All the experiences and attitudes that help to learn the skills of the motor are in the methods teaching and methods¹.

The method that attracts the senses of the learner and develop his mental abilities in the process of obtaining information, which gives him focus throughout the duration of the educational unit, is a good method, as the modern educational process depends on the investment of all the senses of the learner using different methods and teaching methods that address more than a sense of more than Learner achievement in certain situations to receive information about the learning process, and cognitive achievement is an important factor to reach the learner to the learning outcomes of the motor².

Football is a group of games that are practiced at the level of schools, clubs and universities, and contain several basic skills that require learning when teaching methods to achieve the educational purpose, such skills is the handling of football, which is one of the basic skills of football, which requires to style The importance
of research in the use of the method of self-programming and its application in the educational situations associated with attracting the learner’s attention and focus towards the process of learning this important skill(3).

The method of self-programming is one of the technological methods in the field of teaching and learning, motor and psychology, which provides the effort and time for the teacher to explain the educational material, and depends on this method to determine the general objectives of the self-programmatic style, which contains behavioral goals (same kinetic, cognitive, emotional) Age and individual differences among learners, as well as the adoption of the organization of educational material, which includes instructions and guidance and provide expressions that are exciting and suspense and the distribution of the framework of the article (preface, linking, frames of re-review, distinction) and serial drawings to illustrate the technical performance of the kinetic energy to be learned(4,5).

Research Methodology and Field Procedures:

Research Methodology: The researchers used the experimental approach to design the two groups with pre-test and post-test as appropriate to the nature of the research problem.

The research sample: The sample of the research was selected from the original research society of the students of the first stage in the Faculty of Physical Education and Sports Sciences - University of Kufa for the academic year (2018-2019), the number of (71) students, randomly and a number of (30) students, were divided into two equal groups and (15) Is a student for each group. Thus, the percentage of the research sample is (42.25%), which is appropriate to represent the research community as a real and honest representation, as shown in Table (1).

<table>

</tr>
</tbody>
</table>

Homogeneity of the sample and the equivalence of the two research groups: To verify the homogeneity of the research sample in the variables of age, height and weight, the researchers measured these variables and extracted the arithmetic mean, the standard deviation, the mean and the spline coefficient, as shown in Table (2).

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table (3) shows that the values of (t) calculated are less than the tabular value of (2.04) at the level of significance (0.05) and the degree of freedom (28) which means that there are no significant differences between the two research groups in the search variables affecting learning handling skills And cognitive achievement of
football, in which shows the equivalence of the two groups in the tests under consideration.

Means, tools and devices used in research:
- Arab and foreign sources and references.
- Observation
- Personal interviews
- The exams
- Football field and legal football balls (10).
- Metal measuring tape for measuring length and medical balance for weight measurement.
- Hand Scientific Calculator and Pencils.
- Evaluation form for technical performance tests for handling skills.
- Evaluation form for tests of variables of research affecting the learning of handling skills.

Selection of tests: The researchers selected the tests in question * by looking at the scientific sources of tests, measurement and football, and the tests were selected machines:

1. Test the skill of technical performance and accuracy of handling football.

2. The cognitive achievement test in line with the research objectives the researchers used the cognitive achievement scale of the research sample as well as the comparison between the two research groups in the extent of mastery of the cognitive achievement of the skills of football. It is a tool to measure the learning outcomes of the first stage students in the Faculty of Physical Education and Sports Sciences. For this purpose, the researchers prepared and formulated the cognitive test score and developed it in a format that covers the basic aspects of some of the basic skills of football taught to students through the self-programming method.

Pilot study: The pilot study was conducted on 15/1/2019 on the sample of the exploratory survey consisting of (20) students and outside the basic research sample. The aim of this experiment is to know the following:
- Time taken to perform tests.
- Method of using tools, instruments and tests.
- Organize the test sequence to facilitate the transition from one player to another to save time and effort.
- Finding scientific tests.

Conducting the main experiment: The experimental tests were conducted on 9/2/2019, after the implementation of the first two teaching units, in which the handling skills were explained after using the ideal living model in the skill presentation. The research sample applied this skill during the two educational units. At the end of the second unit, The tests were conducted on the tribal variables of research affecting the learning of the skills of handling and achievement of knowledge of football, and took the educational curriculum (4) weeks, two units per week, and the total units of the skill handling (8) Hydrating 90 minutes, as the researchers apply the vocabulary of the educational curriculum according self-style programmatic style, and after the completion of the college educational units, posttests of the first and second of the two groups on 13/4/2019 and the circumstances of the same as they were tribal tests for this skill was conducted.

Results

Table 4: Shows the statistical results of the value (t) calculated between the tribal and remote tests in the booklet style programmed in learning the skill of handling football and cognitive achievement

The researchers attributed the reason for these differences in the learning of handling skills and the development of cognitive achievement among the learners of this group to the ability of the material teacher to control and invest the time of the unit in the implementation of teaching tasks and duties using
the explanatory method that helped to understand and understand the learner and his understanding of the parts of the skill, In its three parts (preparatory, president, final). The use of illustrations, which have been included in the curriculum, with the help of the presentation of the living model of skill, has enabled the learner to understand and understand the nature of the movement\textsuperscript{6-8}.

Table 5: Shows the statistical results of the value of (t) calculated in the tests and the distance between the two groups of the first research (manual programmed) in learning the technical performance of the skill of handling cognitive achievement

</tbody>
</table>

Table (5) shows that the calculated values (t) were greater than the tabular value of (2.04) at the level of significance (0.05) and below the degree of freedom (28) indicating that there are significant differences between the two sets of the programmed manual and the demonstration in cognitive achievement tests and performance The researchers attribute the cause of the differences between the two methods and the superiority of the programmatic method that the use of technological development in the process of learning may achieve the objectives required in the teaching process and attract the learner and develop his attention throughout the duration of the unit and this is confirmed study, which indicated that the self-programmatic approach strengthens motivation and stimulates the learner and increases his attention and concentration in comparison with traditional methods\textsuperscript{9,10}.

The use of the method of self-programming has helped to effectively learn this skill because it is a modern scientific methods in which the learner is the focus of the educational process, which increases the motivation for the learning process, as well as it provided sufficient time to apply and provide information and correct errors, A greater opportunity for skill training\textsuperscript{11}. As well as the development of cognitive achievement related to the skill of dealing with football in the research, which resulted in this method is the sources of interest and motivation and suspense to the process of learning and attention and automatic work and active as the behavior of the learner in this method independent behavior as an individual and a member of his group and provide him with sufficient instructions to ensure it on the experience of value and ensure that the trends in the use of his abilities to identify the principles and detailed parts of the skill and focus on it and represents an educational method that allows the learner to develop his knowledge through practical experience directly\textsuperscript{12}.

**Conclusion**

1. The method of self-programming have a positive impact in learning the skill of handling and development of cognitive achievement for football students.

2. Learning in a self-programming way. In learning the skill of handling and developing the cognitive achievement of football students.

3. The possibility of using this method in the educational process of football for students.

The Level of Ambition and its Relation to the Cognitive Achievement of Students in Volleyball

Hussein Abdel-Zahra Abdel-Yamah¹, Khalil Hamid Mohammed Ali², Hassanein Jabbar Rahi Asadi³
¹,²,³The College of Physical Education and Sports Sciences, University of Kerbala, Iraq

ABSTRACT

The research consisted of two axes, namely the identification of the level of ambition and cognitive achievement and comparison among students in the fourth stage/Kerbala University, Faculty of Education and Sports Sciences, where the standards of the level of ambition and cognitive achievement were prepared and the descriptive method used in the comparison method to suit the nature of the research. The research sample included (90) students, and the extraction of associative relations using statistical means.

Keywords: Ambition and cognitive achievement.

Introduction

As a result of this development, the countries of the world began the programmed and precise planning of the educational process, which called for the discovery of many modern scientific theories which led to the interpretation of many phenomena and helped to find the best solutions to many of the problems and topics that aim to improve the level of technical and digital performance and various sports competitions.

Believing in the effective and influential role that can be played by the psychological side, which did not take the appropriate share of it, considering that the psychological factor complemented the aspects of the general numbers of the individual and is an important axis of the integrated development of the athlete and also confirmed scientific studies in the field of physical education importance, During the study of personality theories and analysis and identify the drivers of the behavior of sports and the diagnosis of important social and psychological phenomena affect the cognitive and mental aspects and the extent of the individual’s possession of the cognitive and informational aspects of skill or effective practice and this is called the side Cognitive or cognitive achievement, which is the result of previous experiences and knowledge,¹ and the extent of their understanding and interpretation within the mental abilities related to the inherent fact and the act of locomotion and its relevance to the skill aspect of volleyball. The extent to which the individual has a knowledge of the various skills of volleyball and knowledge of offensive formations is necessary to reverse the optimal performance And the extent of success achieved as the extent of the student’s abilities and possibilities qualify him to perform his duties towards the game of volleyball and to improve the level of student in the game of volleyball and its relevance to the level of ambition required and built On the basis of his real abilities is necessary and this explains the extent of success and athletic excellence of it, and hence must be studied their behavior during the performance in the fulfillment of their ambitions in the practice of various volleyball skills and all formations offensive and the accompanying acts of conduct during the behavior of students when playing volleyball, And this is all related to the cognitive aspect of the student and the extent of his awareness of the skill and offensive formations and the level of ambition desired, and hence the drawbacks of the importance of research lies in the identification of the correlation between the variables of the study and the (level of ambition, cognitive achievement) Of the volleyball.²

Methodology

Field research procedures: The researchers used the descriptive method of surveying methods and comparative
studies because of its suitability and the nature of the research. The researchers chose the research society from the students of the fourth stage - Faculty of Physical Education and Sports Sciences - Kerbala University for the academic year (2018 - 2019) and 90 students.

**Scale Level of ambition:** The researchers built the scale of the level of ambition according to the scientific steps followed in building the measurements. A total of (36) paragraphs of the scale were distributed in (5) areas. As shown in table (1).

<table>
<thead>
<tr>
<th>Table 1: The fields and the number of paragraphs and their sequence of the measurement of communication skills</th>

<tr>
<td>Total</td>
</tr>
</tbody>
</table>

The substitutions were used to answer the paragraphs of the scale and reached three alternatives for each paragraph (always 3 degrees), sometimes (2 degrees), never (1 degree).

**Coherence coefficient:** Pearson correlation coefficient was used in this and for all of the measures of the scale (35). The results showed that all the paragraphs have a statistical function in a sample of (90) students below the level of significance (0.05) of (0.205) and freedom degree (88). Table (2) the correlation between the degree of the paragraph and the sum.

**Volleyball Cognitive Achievement Scale:** The researchers constructed the cognitive achievement scale for volleyball for the fourth stage, and 40 knowledge questions were distributed in the scientific fields of the offensive plan without the crushing beating, the offensive plan (4-2), the offensive plan (3-3) 4), offensive plan (1-5), rules of play, each question (4) one choices are the correct choice.
Correction of cognitive achievement test: The questions of cognitive achievement are of (40) question, where the researcher assigned one (one) to the question his answer is correct and (zero) for the question his answer is incorrect and all of them included multiple choice.

Statistical analysis of cognitive achievement test questions:

First: coefficient of ease and difficulty paragraphs: After the statistical analysis of the cognitive test subjects in the fourth stage students of the Faculty of Physical Education and Sports Sciences - University of Kerbala, the researchers found that there are questions of an appropriate level and the difficulty and ease of each question was found to be between 67% - 33% This shows.

Parameter discrimination coefficient: The results showed that all the paragraphs were distinct and were limited between (0 - 0 - 63.0). The researcher adopted the questions that had a discrimination index (40.0) and higher according to the Ebel standards. (40) Question that it has a very good discrimination index and is able to distinguish between tested individuals.

Relationship of the paragraph to the overall degree of the test (internal consistency): The researchers used the Pearson correlation coefficient between the scores of the sample on each question and their total score on the test to extract the correlation and then rely on the sample of the building sample. It ranged from (219.0 - 768.0) to the statistical correlation coefficient with the values of the correlation coefficient (205.0) In the light of this criterion, all the paragraphs were function with a degree of freedom equal to (N -2), equal to (88) and a significant level (0.05).

Results

After the process of measurement of variables through the application of the measurement measures and access to data and to achieve the objectives of the study, which includes recognition of the reality of the
level of ambition and cognitive achievement of students, and then sought to extract the values of the computational and standard deviations of the sample of the sample of the basic experiment of the search of (90) And then the mean value of the investigated variables was calculated as shown in Table (4).

</table>

Table (5) shows that the difference in favor of the arithmetical mean achieved, and this indicates that the reality of the level of ambition for students of the fourth stage volleyball is above the middle level and this indicates their high level of ambition and have the ability to achieve their goals. The student is always seeking to obtain a job that is appreciated and respected social status, although the motivation for this job is not related to the economic needs, the student seeks respect and needs to be appreciated, proud of his qualifications and achieving his professional ambition and satisfaction of this need is achieved for the student mental health and the ability to face pressure this confirms their positive attitude toward volleyball. The researchers attribute this to their high confidence in themselves and have the ability and ability to excel in performance and in line with the development of sport because the student received knowledge and learning of the skills of sports and its various laws and methods of playing and teaching various and how to manage competitions and competitions gave him a scientific background and formed a culture of sports highlights its role in the service of the community and the specialization of sports education as a stand-alone science no less than the other educational disciplines because it contains many sciences and knowledge and at the same time have a common knowledge with the Other educational and scientific disciplines. The researchers believe that the students of the faculties of physical education and sports sciences must have a cognitive and academic aspect that makes them a glorious teacher in the success of the educational process, especially the levels of knowledge and culture. This in itself shows that there are levels of knowledge and culture that vary from teacher to teacher. The professional, educational and educational attitudes that require high interpretation and analysis require knowledge capabilities that are characterized by rapid response without hesitation, as well as the extent of experience and excellence that reflect teacher intelligence, because knowledge is “a variety of preparations and strengths The mind, the mind, the mind, the mind, the mind, the mental aspect of the human personality”.

The researchers believe that the control of mental and psychological behaviour and relaxation associated with the performance of the study sample members plays an important role in their attitudes and responses, as (relaxation and psychological calm of the player and the stimulation of the nervous system within the environment works to make positive behaviour and develop processes of perception and improvement of memory and imagination).

Collective achievement is positive and affects the psychological variables as it is an indicator of positive thinking and behaviour that the player in a particular position, whether that educational and training situation and linked to the positive and direct behaviour or performance, which occurs during the movement through the rapid translation of the thinking plan to Different movements, responses and behaviours.
On the other hand, «how to think and types, and the replacement of negative ideas to positive ideas and good behavior of the priorities of the performance of the volleyball team by having the correct thinking and adjustment to the path of positive behavior, so that the athlete can solve the tactical duties and to be skilled performance at the level of high level of development must work on the development of various aspects of thinking has such as the correct cashability and speed of thought and flexibility and thinking ability and the ability to visualize and the speed of reaction and perception and development of the thinking of the player must take its place prominent and influential by mastering technical skills and that are preparing the basic conditions for the development and raise the level of tactical thinking of the player and this is shown by the positive behavior of the player and the achievement of its objectives.8

View and analyze the relation between the level of ambition and cognitive achievement in the research sample: The researchers used the method of studying correlational relationships in the investigated variables and in order to achieve the objectives of the study (the nature of the relationship between the level of ambition and cognitive achievement).

### Table 6: Shows the level of ambition and its relation to the cognitive achievement of students in the fourth stage

<table>
<thead>
<tr>
<th>Variables</th>
<th>Calculate the values of (t) of the significance of the correlation coefficient</th>
<th>Moral significance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Cognitive Achievement</td>

</tbody>
</table>

Table (6) shows that the value of the correlation coefficients of cognitive achievement in calculating the value of (T) calculated as an indication of the significance of the correlation coefficients reached (1) either at the correlation coefficient between the cognitive achievement variables, at the degree of freedom (2) and below the level of significance (0.05). The researchers see that physical education and sports science is one of the areas that affect the human being as an important element in the building of the individual, and prepared in an integrated manner on scientific grounds, the ability of the individual to exert effort depends on many of the variables which come in the forefront variables level of ambition and cognitive achievement.9

Some studies believe that the true success of the sports educator is to emphasize the combination of practice with activity and knowledge. It is essential that every sports educator learns the knowledge and knowledge of the sport and the psychological and social skills that enable him to transfer his knowledge and culture to others. It is not reasonable for an individual to exercise activity and trust without a repertoire of knowledge to help him.10

### Conclusion

Develop a scientific research tool to measure the level of ambition among students in the fourth stage Faculty of Physical Education and Sports Sciences Kerbala University; The development of a scientific research tool on the cognitive achievement test of students in the fourth stage Faculty of Physical Education and Sports Sciences Kerbala University.; results showed that there are differences in the level of ambition among students in the fourth stage Faculty of Physical Education and Sports Sciences Kerbala University., and results showed that there are differences in the cognitive achievement test among the students of the fourth stage, Faculty of Physical Education and Sports Sciences, Kerbala University.

The Effect of Stopping Training in Some Physical and Functional Variables and Sending Table Tennis

Marwan Abdulhamed Yousif1, Zeyad Mishaal Farhan2, Aarif Abdul Jabbar Hussain3

1,2,3The College of Physical Education and Sport Sciences, University of Anbar, Iraq

ABSTRACT

The aim of the study is to track the changes due to the cessation of training for a period of one week, two weeks and three weeks on the strengths of the muscles, the functional variables and the skill of transmission in the face and back of the tennis racket. While the hypothesis confirmed there are differences of statistical significance in the strengths of muscle and functional variables and skill of transmission in the face and the back of the racket as a result of the cessation of training between the level and after the cessation of the period (one week and two weeks and three weeks).

The researchers used the descriptive approach in a sequential manner to suitability and nature of research. The results of the study included (6) players representing the Anbar University table tennis team for the academic year 2018-2019. The researchers concluded that there were negative effects in the reduction of all functional variables, but diastolic pressure maintained its level for the duration of the period of cessation of training either the technical and physical variables recorded a significant decrease Stop training altogether. The researchers recommended that periodic tests of the fitness, functional and skill level of tennis players be consistently confirmed.

Keywords: stopping training, physical and functional variables.

Introduction

The continuation of the training process is one of the most important basic principles that reach the athlete to the highest levels and must be scientifically determined according to the age and level of the athlete and the effectiveness exercised by both the individual or the individual as the scientific basis of the training process is one of the most important factors to ensure the correct orientation of the athlete Maintain its level and climb to the top. Therefore, the cessation of the training process is considered a negative indicator affects the level of performance of the athlete, whether in physical, functional or skill, although the cessation of a short period or long.

The sudden interruption of training can lead to disruption of the athlete’s health condition, and difficulties arise when the training is resumed. Therefore, it is necessary to know what changes occur to the athlete when the physical training is stopped for a period of time, whether due to injury or the end of the sports season, resulting in a decline in the level of performance sports for most sports events.

Among these activities is the game of ping pong, which has reached a level of performance and play. All the games that require its practitioners to prepare well physically, skillfully, strategically and psychologically. This preparation must be based on scientific bases, with the necessity of continuing the training without interruption through the above The importance of research in the knowledge of the scientific facts resulting from the impact of the cessation of training in some physical and functional variables and the skill of transmission in the game of table tennis in order to provide the stakeholders (trainers, players, teachers and researchers) in this sport scientific information and indications of the impact of the stop training to be
helpful to them when training curricula or research on the players drop-volitional training or forcibly for their access to the physical and skill level required action.³

**Research Methodology**

The researchers used the descriptive approach in a sequential manner to suitability and nature of research.

**The research sample:** The study sample consisted of (6) players representing the Anbar University team in table tennis for the academic year 2018-2019. The players were excluded for the pilot experiment and the sample number reached (4) players.

Standards and tests used in the search:

**Functional Benchmarks:**

- Blood pressure measurement: Blood pressure is measured by a ready-made blood pressure measurement type.
- Pulse measurement: Pulse is measured by an electric type device.

**Tests used in research:**

**Muscle strength tests:**

**Explosive power test for the muscles of the arms:**⁴

**Purpose of the test:** Measure the explosive force of the arms.

**Measuring instruments:** measuring tape, medical ball weighing (3) kg, throwing circle space area.

**Description of performance:** The laboratory takes the position of standing in front of the position of throwing, and holds the ball in the hands together and then bend the knees and swing the hands with a medical ball and throwing forward as far as possible.

**Registration:** Calculates the distance to the nearest name from the rim of the circle throwing to the nearest trace of the ball from the edge of the circle.

**Test the strength of the muscles of the legs:**⁴ Jump to the maximum height bend and extend the two men from the knee joint and to the maximum number of repetitions until the exhaustion of the effort.

**Test the strength characteristic of the speed of the muscles of the arms:** Test the propulsion in front position for 10 seconds.

**Purpose of the test:** Measure the speed characteristic of the muscles of the arms and shoulders.

**Serve test:** Testing the difficulty scores for the high and low transmission reception areas of the side and back of the hand.

Areas were divided into five regions as follows:

- The area (1) located at the right of the table surface is 112 cm x 15 cm wide.
- Area (2) located in the right corner of the table at a distance of 25 cm.
- Area (3) located in the left corner of the table with a distance of 25 cm.
- The area (4) to the left of the tabletop is 112 cm x 15 cm wide.
- Area (5) confined to the lines of the former regions.

**Machines and tools used in research:**

- An electrical device to measure blood pressure and heartbeat type (beurer).
- Stopwatch type (any time).
- Line pen for dividing and numbering table areas.
- (5) Table balls.
- Table tennis rackets (4).
- Legal toys table with accessories number (1).

**Field research procedures:**

**Pilot study:** The researcher conducted the pilot study on Sunday, 24/2/2019, on players from the total research community, through which it was recognized the efficiency of the sample in the tests and the occurrence of some errors that were avoided in the main experiment.

**Main experience:** The researchers conducted the test for the first week on the research sample on Thursday, 28/2/2019 at the student activities hall of Anbar University and included several tests that included the research variables. After the second week, researchers conducted the second test on Thursday 7/3/2019. The third test was conducted three weeks after the discontinuation of the training respectively on 14/3/2019 and 21/3/2019 for all the variables of the research. The researchers took into account the sequence, date and place of the tests.

Table (3) shows the significance of all the studied variables because the value of the error ratio is less than the significance level of 0.05, while the lack of morality in the variables to maintain the athlete at the level and this is shown by the level of significance for being less than the error rate.

**Discussion**

It is evident from the tables (3.2.1) that there are statistically significant differences for some variables between the test of determining the level and the first week and in favor of the test of the level. This is evidence that there is a decrease in the level of strength and pulse due to leaving the training in the period after the cessation of training. Which is confirmed by several studies, especially with regard to functional performance where it can begin to appear with indicators attributed to the low level in the absence of touching any activity, especially the pulse rate and this is confirmed by Fleck (Fleck1994) that the dropout of training leads to change the physiological and physical adaptations of the body Lack of physical achievement and, The improvement in the level of the individual resulting from physical activity and skill is an improvement can be increased and decreased in the case of the fallout of training, the ability of the individual decline and the degree of development previously acquired functionally and physically and skillfully, and this experience has shown that many Of physical and skill traits decrease in the event of discontinuation of training. “While there are no differences between some of the physical, functional and skill capabilities of the players and these variables can be retained by the player even in the absence of activity, but this retention is for a limited period."

Table (2) shows that there are differences for all variables between the test of the level and the second week and for the test of the level determination because of the lack of practice of the players training level gradually decreased in all functional variables, physical and skill, except the variable diastolic pressure was maintained below the level of low and normal for the players, and stresses that the sudden interruption of
training can lead to disruption of the health condition of the athlete and create difficulties in the resumption of training. While athletes at the level maintained the level of diastolic pressure and explosive power, both of which can be maintained in that period.9

Table (3) shows that there are differences between the test of the level and the third week and for the test of determining the level in all variables except the variable diastolic variable where the level was maintained below and under normal condition of the players. The researcher attributed this decline to the lack of physical activity and skill in the post-competitive period and this is because of the low level of performance of the players, which confirms that the discontinuation of training, whether complete or partial, it leads to the loss of anatomical and physiological and achievement related. The greater the period of discontinuation of training, the greater the quality and quantity of physiological and physical adaptations lost.10 While the athletes maintained the level of pressure in the period, although the effect may be induced if the period exceeded one and a half to two months due to lack of exercise. This is confirmed that diastolic pressure is not affected by the absence of physical or physical activity, but that for a specified period may last from two to three months.11

Conclusion

1. There is a negative effect on the low heart rate and the pace of force between the first two weeks
2. There is a positive effect of some physical, functional and skill variables for the period between the first two weeks and the second in the case of non-exercise training.
3. There is a negative effect of all the variables studied between the results of leaving the training for three weeks except the diastolic pressure variable maintained its level during that period.
4. There is a negative impact of all the variables studied between the results of leaving the training for four weeks except the diastolic pressure variable maintained its level during that period.

Study of Variables in the Ratio of Creatine in the Blood of Short, Medium and Long Distance for Runners

Zaid Samsam Turki Sulyan¹, Mahmood Dawood Salman², Saddam Mohammed Fareed Rageh³
¹²³The College of Physical Education and Sport Sciences, University of Babylon, Iraq; ²Al-Mustaqbal University College, Department of Physical Education and Sport Sciences, Iraq

ABSTRACT

The study of the effect of training on jogging on serum creatine levels is important to identify the level of developmental and functional development, as well as understanding the process of developing appropriate training programs for short, medium and long term effectiveness.

Creatine is an important indicator in the human body by calculating the blood quantities in the day following the race or training in order to know the work of the kidneys or any damage in them, and to establish a sound path and right to our coaches and our players relying on the analysis that helps them in the development of their achievement.

The aim of the study was to study the variables in the ratio of creatine in the blood of short, medium and long distances of 10 players.

The experimental approach - equal groups due to its relevance to the subject of the research.

The researchers concluded:

1. The presence of effects of significant significance for the athletes in the various energy systems in the ratio of creatine in the blood of the players and according to the high intensity and effort in the functional work of the two kidneys.

2. Short-range athletes were more susceptible to high blood creatinine, as they needed higher voltage than medium and short hips.

Keywords: Creatine, blood and distance.

Introduction

The study of the effect of training on different types of jogging on the blood creatine ratio is important and necessary to know the level of development and functional as well as the understanding of the development of training programs suitable for the events of short, medium and long, which has received great attention by researchers and trainers in the world, where the largest number of The medals in the games because the awards are characterized by individuality in addition to attracting large numbers of athletes and the public because of the skill, excitement and suspense⁷. Laboratory analysis has been used to determine changes in creatine levels of short-, medium- and long-term athletes due to the effect of exercise with different training doses on them. It is therefore necessary to identify the physiological and chemical laws on which functional changes occur during sporting events and which help to improve the body’s response when controlling and working on them⁴.

In view of the specificity of jogging by regulating the production of different energy and the development of the physical and functional capabilities of the players in order to achieve advanced achievements, the importance of research in the study of the impact of jogging the various energy production systems in the proportion of creatine in the blood according to modern scientific
bases in order to raise the level of players to reach them achievements to reach the level of players in developed countries in this important and vital\(^3\).

Creatine is an important indicator of the metabolism of proteins in the human body. This is done by calculating its quantity and its value in the blood because it is one of the energy-rich chemical compounds to measure the metabolic remains that indicate tiredness and recovery. However, some trainers did not give enough importance to this vital and influential aspect. The development of training curricula that are affected by the type of effort given to the short, medium and long distance runners who need proper nutrition, especially the quality of the meat and the quantity of power generation according to the type of intensity and training load of each and the impact of this on the proportion of creatine ratio in the blood in order to develop a sound track and true in front of our coaches and players by relying on sound scientific results that are useful in the development of their achievement\(^3,4\).

**Research aims:**

1. Knowledge of the effects of energy systems at different levels of creatine blood in the players.
2. Knowledge of the differences in the ratio of creatine blood runners according to the energy systems used in each of the variables investigated.

**Research hypotheses:**

1. The short, medium and long circuits of different energy systems have a real effect on the blood creatine ratio of the players.
2. There are differences in the proportion of creatine blood between the groups of the research sample in the variables investigated.

**Research methodology and procedures:**

**Research Methodology:** The experimental method is used as an equal group due to its relevance to this research. Experimental approaches examine the problems and phenomena based on the experimental method or the scientific research method based on observations, hypotheses and precise experiments to verify hypotheses (Mahmoud Al-Rubaie et al. 2018, p. 30).

**The research sample:** The research sample consisted of 10 (10) advanced runners in the field and the field were chosen by random method and those who practice activities ran (100 m and 3-1500m and the number of (4 – 5000 m and the number 3) distributed to three groups and depending on the type of game.

In order to identify the characteristics of the sample members and the extent of their representation in the research community, the researcher found some variables as shown in Table (1).

**Pilot study:** For the purpose of adjusting variables for the main experiment, the researcher conducted a reconnaissance experiment on 15/2/2018, the purpose of which was to:
1. Ensure that the task force can apply duties.
2. Identify the time of the experiment to benefit from the main experiment.
3. Identify the requirements of conducting the main experiment in terms of materials used and others.

Field research procedures

Measurements and tests:

1. Anthropometric measurements (length, weight, age, training age)
2. Measurement of some biochemical variables (measuring the concentration of urea in the blood)

Method of testing: The assistant team drew blood samples from the eye in order to conduct tests on them and to identify some biochemical variables (serum creatin concentration). The blood was withdrawn after the athlete had been out of food for at least six hours. The laboratory temperature (37 degrees).

The main experience: The assistant team drew blood samples from the resting position, six minutes before the race and for all the sample of the research during the first day of the official championship period corresponding to 18/2/2018. On 20/2/2018, another sample was drawn from the blood of runners running 100 m. After the official race for them, and draw the blood for the contestants 1500 m, 5000 m on 21/2/2018 also after the completion of the race immediately after the transfer of a special portfolio to the laboratory where the measurements there until 3/3/2018 were processed statistically, as stated in the door the fourth.

The first group (ran 100 m) shows that \(^{(2)}\) for the creatinine test, Phosphokinase, the mean (125.333) and the standard deviation (45.742) in the pretest, the mean (136) and the standard deviation (45.177), \(^{(2)}\) which indicates that the difference is significant between the pre and post tests and for the benefit of the post-test.

The mean of the calculation of creatine phosphokinase was (98.650) with a standard deviation (17.051) in the pretest. In the post-test, the mean (109.175) and the standard deviation (18.821), the calculated value (t) (3.985), which is the largest of the value of the table (2) is (3.182) by line (0.05) and the degree of freedom (3), indicating that the difference is significant between the pre-test and the post-test and for the post-test.

That (5000) meter as in Table (2) shows that the computation of the test creatine phosphokinase (92.766) and the standard deviation (20.952) in the post-test. The calculated value (t) is 0.196, which is smaller than the total value of (4.352) and a score of error (0.05) and degree of freedom (2), which indicates that the difference is not significant between the tests pre and post.

Knowledge and the difference between the groups in the post tests the researcher sought to test the analysis of variance as in the following table (3).

Table 3: Shows the results of variance of the three groups in the post-test creatine test

</table>
Table (3) shows that the calculated value of $(f)$ is (1.585), which is smaller than the $(f)$ tabular value of (4.74) and by mistake (0.05) and freedom degree (7.2). This indicates that the differences between the averages Groups are not significant.

**Discussion of Results**

Creatine is an important indicator of the metabolism of proteins in the human body. This is done by calculating the quantity and value of blood in the day following the race or training to measure the residual metabolism following the race or training, which indicates tiredness, recovery and removal of metabolic residues.

In the three groups (short-, medium- and long-term), the ratio of creatine in the blood was normal, where it was limited to (1-2-6), as shown in Table 2. Although the ratio increases during short- May lead to a relative increase even though they are within the normal range. In our observation of Table (2) we find that after the effort there is an increase in the ratio of creatine in the blood for the spindles (100) m, which can be explained by the high effort in this sport and reliance on the phosphate creatinine stored muscle in burning energy\(^{(5,6)}\), which leads to increase the proportion of blood availability and delay The rate of removal by the kidneys due to the relative discontinuation of kidney function, as is the case in runners (1500 and 5000), since the dependence on phosphogenic storage is not the burning of energy (Divix-1988- p. 59)

Table (2) shows that the results are significant for the three groups in the post tests in the pre. The researcher attributed this to the fact that the rider of these events controlled the rate of effort through the appropriate speed, which makes the creatine phosphate and the metabolism is not exhausted before the time, indicating that it allows the most efficient use of phosphate metabolism and creatine during the full competition\(^{(6-9)}\).

On this basis, we did not see any significant differences between the three tests of the three groups as shown in Table (3). The reason is that the metabolic process is responsible for the energy used during these activities, but it is emptied less quickly than the phosphate creatine during these activities and during the physical effort, Because the metabolic process is done by other devices, so the impact of the exercise of sporting events will be delivered on all the organs of the body, which shows us that the body and its functional mechanism works as a unit\(^{(10-12)}\).

**Conclusions**

1. The long range (5000 m) group was less affected by the high blood creatinine ratio because it required more long-term training than short and medium training.
2. Effect of kidney function towards elimination of excess ktnine due to delay in removal rate by kidneys in running (100 m)
3. There is an increase in creatine in the blood for spasticity (100 m) due to high stress and dependence on muscle creatine phosphate in the muscle to burn energy
4. Do not rely on the reservoirs in the burning energy (1500 m) and (5000 m), which leads to removal by the kidneys
5. Control the runners in the rate of effort through the appropriate speed makes phosphate creatine and the metabolism is not exhausted before the ozone
6. No significant differences of the three groups because the metabolism is responsible for the energy used during the pharmacology, to be discharged less quickly than phosphate creatine.

Molecular Investigation of Aminoglycoside Modifying Enzyme among Aminoglycoside-Resistant Uropathogenic Escherichia Coli Isolates from Najaf Hospitals, Iraq

Khadeeja Obaid Alm’amoori¹, Zainab Jaber Hadi¹, Ali Muhsin Almohana¹
¹Faculty of Medicine, Kufa University, Iraq

ABSTRACT

Background: E coli is the most common uropathogen for uncomplicated UTIs (75-95%). Plasmid-mediated AMEs were reported to be the widespread among Gram-negative isolates resistant to aminoglycosides. The purpose of this study is to investigate the occurrence of genes encoding AMEs in aminoglycosides resistance UPEC isolates.

Method: A cross sectional study of the participate patients their approval for direction usage their specimen. The susceptibility test by disk diffusion for UPEC were isolated from urine and thirteen plasmid–mediated AMEs aac(3’)-I, aac(3’)-II, aac(3)-III, aac(3’)-IV , ant(2′′)-I, ant(3″)-I, ant(4′)-IIa, acc(6’)-Ib, acc(6’)-IIb, aph(3’)-I, aph(3’)-IIa, aph(3’)-Ib, and aph(3’)-VI were screened by mono- and tri-plex PCR.

Results: 298 was significant bacteruria, there were 132 clinical isolates of uropathogenic E. coli, among these 60(45.5 %) co resistant to at least two aminoglycoside antibiotics were selected varied from (100%) kanamycin to (53.3% (amikacin. It was found that 98.3%, 95.0%, 90.0%,86.7%, 51.7%, 36.7%, and 10 % of isolates were harbored aac(6’)-Ib, aph(3’)-I, aph(3’)-IIa, aph(3’)-Ib, ant(3″)-I, (aac(3)-II, and aac(3)-IV, respectively.

Conclusion: AME genes were present in all of the UPEC isolates and the first aph(3’)-I, aph(3’)-Ib, aph(3’)-IIa and ant(3″)-I determinants in Iraq.

Keyword: Plasmid-mediated AMEs, uropathogenic E. coli, aac(6’)-Ib, aph(3’)-I, aph(3’)-IIa, aph(3’)-Ib, ant(3″)-I, (aac(3)-II, and aac(3)-IV.

Introduction

Urinary tract infection is the most prevalent infectious diseases, and very problematic worldwide[1]. UPEC is the most frequently causes of UTIs in humans[2]. Three methods to aminoglycosides resistance in human bacterial pathogens (i) reduced uptake[3], drug trapping[4], active efflux[5] (ii) aminoglycoside-modifying enzymes (AMEs)[6](iii) changed ribosomal binding positions by mutation[7]. AMEs are a most family of enzymes containing of three sub-class classified based on the type of chemical alteration,(AACs)-N-acetyltransferase, which using acetyl-coenayme A for acetylate an amino set, (ANTS)-O-nucleotidyltransferases, which transmission an adenyl set from ATP to a hydroxyl set of the antibiotic; and (APHs)-O-phosphotransferases, that phosphorylate a hydroxyl set as well used ATP[8].

Nowadays no epidemiological assessments have described the prevalence of AMEs genes in E. coli clinical isolates in Iraq. The aim of this study is to investigate the occurrence of genes encoding important AMEs in aminoglycosides resistance UPEC isolates from Najaf hospitals.

Method

Collection of specimens: This a cross sectional study of the participate patients their approval for direction usage their specimen was conducted in in two main hospitals in Najaf and during the period of six months from March to
September 2018 in patients clinically suspected to have UTI. The inclusion criteria for the volunteer patients were attended or admitted in the two hospitals.

**Isolation and Identification of *E. coli* isolates:** Identification of bacterial pathogens was made based on Gram reactions, culture characters, routine standard biochemical tests, culture on EMB agar plates to confirm that there is no mixed and using commercially API 20 E kit.

**Antibiotic Susceptibility Test:** Susceptibility to antimicrobial was accompanied by Kirby–Bauer method based to the guideline suggested by the Clinical and Laboratory Standards Institute(9).

**Screening Test for aminoglycosides resistance:** The disk diffusion test was made to identify aminoglycosides resistance by using gentamicin (10µg), tobramycin(10µg), Kanamycin (30 µg), netilmicin (30 µg) and amikacin (30 µg) disk.

**Screening Test for AMEs genes:** The reaction carried out by multiplex PCR for aac(3′)-II, ant(3′)-I and aac(6′)-Ib and monplex PCR for aac(3′)-I, aac(3′)-III, aac(3′)-IV, aph(3′)-I, aph(3′)-IIa, aph(3′)-Ib, aph(3′)-VI, ant(2″)-I, ant(4′)-IIa, and aac(6′)-II in aminoglycosides resistance using T3000 thermocycler and Go Tag Green Master mix [Promega (USA)]. The sequence of primers targeting AMEs genes were published in another place(10,11,12,13,14,15,16).

**Results**

A total of 1072 urine samples were randomly collected from clinically suspected to have UTI. Overall results revealed that 298 of urine specimens were significantly positive for uropathogens. The mixed bacterial infections were not found. 132 (44.3%) isolates were recognized as *E. coli* followed by other Gram-negative and Gram-positive bacteria as shown (Figure 1).

**Screening test for Aminoglycosides Resistance:** Overall, 45.5% (60/132) of the UPEC were no susceptible to at least two of the aminoglycosides tests varied among the isolates at the 100%, 98.3%, 80.0%, 65.0%, and 53.3% for kanamycin, tobramycin, gentamicin, netilmicin and amikacin, respectively. Furthermore, the 22 (16.7%) bacteria were resistance to all aminoglycosides agents.

**Screening Test to AMEs genes:** AMEs determinants were found in 60 isolates (100%). ACCs were the most prevalent type of AME was detected in 98.3% of the isolates. The most frequently was aac(6′)-Ib (59 isolates; 98.3%), followed by aac(3′)-II (22; 36.7%), and aac(3′)-IV (6; 10.0%). The second types was APHs genes, aph(3′)-I (57 ;95.0%), aph(3′)-Ib (52 ; 86.7%) and aph(3′)-IIa (54 ;90.0%). ANTs genes was also investigated, ant(3″)-I (31 ;51.7%). While aac(3′)-I, aac(3′)- III and aac(6′)-II, aph(3′)-VI, ant(2″)-I and ant(4′)-IIa were not identified. All the 60 UPEC harbored several AMEs genes for at least three genes, and a total of 20 different combinations. One isolates (1.7%) harbored seven aminoglycoside resistance genes.

**Discussion**

**Frequency of *E. coli***: UPEC isolates (44.3%) were the major causative agent of significant bacteriuria in Najaf. The more frequency of the *E. coli* could be attributed to the enteric flora and the way of transmission is by fecal contamination because of poor hygiene and the anatomical nearness to the genito–urinary tract in females(17).The rate of UPEC isolated is agreement with study done in Iraq(18), documented that rate of *E. coli* was 38.9% in urine specimens from patients suffering from UTIs. Many authors have the same findings, which *E. coli* was accounting for more than 40% of UTI(19,20). The variations of the rate of UPEC isolation may be due to the geographical variation, method of collection of urine samples, passage of time, various personal, genders, educational, and general socioeconomic status and availability of medicinal services.

**Resistance to the Aminoglycosides**: All isolates exhibited resistance to older aminoglycosides, kanamycin as compared with resistance to tobramycin (98.3%), gentamicin (80.0%), netilmicin (65.0%), and amikacin (53.3%). Amikacin could still be considered the gold standard in treating the extra resistant UPEC isolates. In Iraq, proportions of resistance of UPEC to kanamycin and gentamicin were perfectly high and

![Figure 1: Prevalence of bacterial uropathogens identified of patients with significant bacteriuria](n = 298)
resistance proportions to netilmicin and amikacin were perfectly low\textsuperscript{(21)}. Low resistance was reported against amikacin antibiotic in other studies\textsuperscript{(22,23)}. The low resistance of amikacin may be attributed to the presence of the aminohydroxybutyryl group, that often stops the enzymatic alteration of amikacin at multiple sites without interfering with the A position of Rma\textsuperscript{(24)}. Other study have identified higher occurrence of resistance to amikacin in Turkey (49.7\%)\textsuperscript{(25)}. Resistance to gentamicin varies in different countries with rats (94.5\%) described in Turkey\textsuperscript{(25)}. In Iran, South Africa, Latin America, and Europe revealed perfectly high frequencies of amikacin resistance (14%-92\%) and very high netilmicin resistance (25%-90\%)\textsuperscript{(26,27,28)}. The different resistance profile in diverse geographical areas may be connected to variances in consumption regimens. \textit{E. coli} resistance to aminoglycosides is increasing over time, depending on situation of antibiotics consumption in the society.

**Dissemination of genes encoding AMEs:** AME genes were present in all of the UPEC isolates. In other studies, the AME positive rates were 85.0% in Baghdad\textsuperscript{(21)}, 95.2\% in China\textsuperscript{(29)} and 79.5\% in Poland\textsuperscript{(28)}. ACC [\textit{aac(6)\textprime }-\textit{Ib}, \textit{aac(3)-II}, \textit{aac(3)-IV}] genes were the most prevalent AME genes in isolates. \textit{aac(6)\textprime }-\textit{Ib} gene was found in 98.3\% of the isolates. This result is in accordance with Spain\textsuperscript{(30)}, Poland\textsuperscript{(28)}, where presented \textit{aac(6)\textprime }-\textit{Ib} as the one of the most frequently detected gene encoding ACC in \textit{E. coli}. \textit{aac(3)-II} gene (36.7\%), which associated with highly resistant to gentamicin but may only exhibit low-level resistance to tobramycin, and netilmicin\textsuperscript{(31)}. The prevalence of \textit{aac(3)-II} gene is lower than those previously reported in China (40.0\%), Iran (40.0\%), and Egypt (47.88\%)\textsuperscript{(28,29,32)}. Other reports in Iran and Poland\textsuperscript{(33,28)} showed low rates of \textit{aac(3)-II} in UPEC isolates. However, \textit{aac(3)-II} gene present on mobile molecular elements can facilitate the spread and transfer of resistant genes among bacteria\textsuperscript{(34)}. \textit{AAC(3)-VI} enzyme produces resistance to gentamicin, tobramycin, apramycin and netilmicin and has been identified rarely among clinical isolates of \textit{E. coli} and Enterobacteriaceae\textsuperscript{(35)}. The rate of the \textit{aac(3)-IV} gene was low (10.0\%). The low rate (14.3\%) of \textit{aac(3)-IV} gene was obtained in Ethiopia\textsuperscript{(36)}. In Iran, \textit{aac(3)-IV} gene were not detected in aminoglycoside resistance \textit{E. coli} isolate\textsuperscript{(33)}.

ABSTRACT

Metallic bio-conjugated nanoparticles are known to be a common example for these characteristics, out of which gold NPs (AuNPs) in particular are heavily exploited due to their inert nature and high electron density. Coating the AuNPs with albumin proteins is useful due to their biocompatibility and their ability to bind many drug molecules. Among carrier proteins, human serum albumin (HSA) is considered one of the major transporter proteins in the blood plasma. It constitutes approximately half of the protein found in human blood. Curve fitting method allow you to create, access, and modify curve fitting objects. It also allows, through method like plot and integrate, to perform operations that uniformly process the entirety of information encapsulated in a curve fitting object. The results are appeared that describe the variation of the NPs concentration with time, the fluoresce spectrum with nanoparticles. The analytical data are corresponding with experimental information.

Keywords: drug-binding ; Simulation; serum albumin

Introduction

In recent days nanotechnology has induced great scientific advancement in the field of research and technology with developing interest for its various applications ranging from information technologies to medicinal applications. The applications of nanotechnology to biomedicine, especially in cancer diagnosis and treatment, promises to have a profound impact on healthcare [1]. The exploitation of the unique properties of nano-sized particles for cancer therapeutics is most popularly known as nano-medicine.

The unusual properties of nanoparticles (AuNps) are on the basis of their great expansion due to their potential applications in different areas (energy, food, health, clothing, cars, etc.). This situation has led to an increase in the release of different nanomaterials into the environment and their potential effects on the ecosystem and human health are becoming a major concern [2,3]. As a consequence, there is a pressing need to fully characterize the toxicological effects that Nps could have when they are released into the environment or come into contact with the human body.

The high surface-area to volume ratio of the NPs is advantageous for uploading drugs and enhancing their concentration. Metallic bio-conjugated nanoparticles are known to be a common example for these characteristics, out of which gold NPs (NPs) in particular are heavily exploited due to their inert nature and high electron density. This, along with the non-toxic nature of gold, makes NPs a useful system that can be utilized in transporting and delivering a wide range of endogenous and exogenous substances in the biological medium [4-8].

The importance of protein-conjugated NPs as drug carriers is inherent due to their target septicity and biocompatibility which are believed to reduce drug resistance in cells. These unique properties have led to promising applications of NPs in clinical treatments and disease diagnoses through high contrast NPs imaging, tracking and sensing. Extending the applications to include NPs as precursors to maintain and monitor the binding properties of protein–ligand systems would be useful. In this regard, any modification in the binding properties is important to examine. A direct effect on the kinetics of drug release is encountered if binding is too

Email: hassantuhmaz@yahoo.com
On the contrary, it may contribute to inefficient drug transportation and distribution if binding is too weak. This can be achieved by studying the behavior of the protein with ligands/drugs under biologically relevant conditions when this protein is free in solution, compared to when the protein is adsorbed on the surface of NPs.\textsuperscript{9-14}

Scientific Study: Many drugs are bound to proteins within the body. There is marked variability in the extent to which the drugs bind to the proteins. The degree of drug-protein binding might affect a drug’s efficiency. Drugs can be bound to plasma proteins as well as tissue proteins. Plasma protein binding can have multiple effects on the pharmacokinetics (PK) of a drug. The binding of drug to plasma proteins is a major determinant of drug disposition. When a drug is bound to the plasma proteins, it is not actively distributed to the site of action to interact with the target tissues. Moreover, the bound drug is kept in the blood, while the unbound (free) fraction may be metabolized or excreted. The binding has a very important effect also on drug pharmacodynamics (PD). Only the free drug interacts with receptors, therefore only the free drug can produce therapeutic effect. Common blood proteins that bind drugs are human serum albumins, lipoproteins, glycoproteins, and globulins. Albumin is the most abundant protein in the blood plasma. Many medications extensively bind to the albumins. Protein binding interactions are displacement reactions, which have been implicated as the causative mechanisms in many drug-drug interactions. Competitive displacement interactions are predominant ones among protein binding reactions. The competitive protein binding drug-drug interactions result in increased the free plasma concentrations of the displaced medications. Clinically displacement reactions acquire importance when the displaced drug is highly bound to plasma proteins. In this case the displacer drug produces a very rapid and significant increase in the plasma concentrations of the displaced medication. The result of this interaction can be dramatic if the second drug is a drug with narrow therapeutic index. Such type of interactions can lead to enhanced pharmacological effects and, possibly, toxicity of the displaced medication. A simple, generalized guideline for the evaluation of the clinical significance of protein binding interactions frequently cannot be applied. Instead, a careful analysis of protein binding effects must be made on a drug-by-drug basis. Free, unbound concentrations should always be measured rather than estimated, and used as the primary input for PK/PD correlations, as well as for statements on the safety and efficacy of drugs.\textsuperscript{9}

Method

Comparison between the experimental data and theoretical analysis, also mathematical analysis is known as progression analysis, is used to find the “top appropriate” line or curve for a chain of statistics points. Most of the time, the curve adequate will yield a calculation that can be used to bargain points anywhere lengthways the curve. In approximately cases, you may not be disturbed about result an equation. Instead, you may just want to use a curve acceptable to smooth the data and develop the appearance of your scheme.

Results and Discussions

Fluorescence change of HSA as a function of the concentration of AuNPs, extracted from the data with simulation curve matching. The equation which describe the effect of increasing for Au NPs with time as shown in figure (1) where it gives femtosecond dynamics of Au NPs. Figure (2): The effect of NPs increasing on spectrum curve under simulation of data. Fluorescence of sample concentration of AuNPs (Wavelength = 330nm). The effect in figure (3) is estimated by using the relation:

\[ F(a, \lambda) = 2.1 \times 10^{-22} \lambda^4 - 1.7 \times 10^{-5} \lambda^3 + 0.011 \lambda^2 - 1.7 \lambda + 30 \]

Figure 1: Femtosecond dynamics of Au NPs
Conclusion

We examined the spectroscopy of HSA-bioconjugated AuNPs as a model drug carrier in order to illuminate the effect of the protein on the properties of the NPs and the constancy of the protein arrangement on the metallic surface. From the results we catch that the behavior of system variables can be founded by speculating the relations which are designated the deviation of euller implementation by improved the TNPs concentration is changed with time. The fluorescent marker is affected by the increasing on NPs concentration. Thus, the simulation process leads to link between the variables of system.

\[
F (a. u) = 2.1 \times 10^{-22} \lambda^4 - 1.7 \times 10^{-5} \lambda^3 + 0.011* \lambda^2 - 1.7* \lambda + 30
\]

The Creative Leadership of the Heads of Sports Clubs in the Middle Euphrates from the Point of View of its Members

Ahmed Faris Hadi Abd Ali, Saddam Mohammed Fareed Rageh

The Faculty of Physical Education and Sport Sciences, University of Babylon, Iraq

ABSTRACT

The sports clubs are witnessing a clear and growing interest in developing their managerial abilities in various fields. Perhaps their first step is to take care of the creative leadership and develop it to increase the efficiency of these sports clubs, which is an exceptional importance in our Iraqi society as the main framework through which the movement activates sport and improves its position in the society that suffers from various crises affecting various aspects of life, and the success of these clubs will be a direct and vital contribution to the progress of the sports movement.

The objective of the current research is to identify the reality of the creative leadership of the heads of the sports clubs in the Middle Euphrates from the point of view of the members. The research society also determines the heads of the 58 sports clubs and the members of the governing body in the sports clubs, numbering (429) of the research community (487). The sample of the application was randomly selected, consisting of (100) members of the administrative bodies of the sports clubs in the Middle Euphrates. After the completion of the process of building the measure of creative leadership by following the scientific procedures, and to achieve the goal of the research collected data on the scale, and for the purpose of facilitating the procedures presented in the form of tables and forms and then interpreted. The most important conclusions that provide for the reality of the creative leadership of the heads of sports clubs was reflecting a perception and a satisfactory perception of the administrative bodies of sports clubs clearly and accurately expressed through their answers on the scale of creative leadership.

Keywords: Creative leadership and sports clubs.

Introduction

Sports clubs are currently striving to adapt to the complex and interrelated global and local variables in order to achieve sustainable competitive advantage. In order to achieve this, we must rely on human resources and employees cannot participate constructively in achieving the objectives of sports clubs efficiently and effectively without prior planning. They even exchange it for their confidence by doing their best to achieve their goals.

Which leads to creativity and excellence in the administrative aspect, as creative leadership plays a role and an impact in building the confidence of working individuals and their reflection in their commitment to their clubs and the commitment of sports clubs to individuals did not mean the study and analysis and remained underpinning, especially as their importance increases to deepen the ability of sports clubs to meet the challenges In order to achieve and instill a culture of individuals’ commitment to their clubs, contemporary sports clubs should consider human resources as the most valuable resources and assets to be able to achieve survival, growth and sustainability. Therefore, creative leadership is one of the most important pillars of the progress of countries and their development in various fields: economic, social, educational and sports. Studies have shown that creative leadership leads to improving the general climate of decision making, breaking down barriers and stimulating new and useful ideas. Solutions and get rid of normal thinking, and produce the largest number of ideas in the least time and effort because they are produced from special mental processes.
Hence the importance of research in the attempt of the researchers to identify the creative leadership of the heads of sports clubs in the Middle Euphrates from the point of view of its members, in order to improve the level of sports clubs through the study of the reality of this variable and the impact of clubs in the development of the game through the tournaments that they hold between clubs inside and outside the country and its impact on providing Iraqi sports with outstanding players to reach the highest levels. The sports clubs are witnessing a clear and growing interest in developing their managerial abilities in various fields. Perhaps their first step is to take care of the creative leadership and develop it to increase the efficiency of these sports clubs, which is an exceptional importance in our Iraqi society as the main framework through which the movement activates sport and improves its position in the society that suffers from And the success of these clubs will be a direct and vital contribution to the progress of the sports movement, and can summarize the problem of research through the following question:

Is there a creative leadership of the heads of sports clubs?

The aim of this research is to identify the reality of the creative leadership of the heads of sports clubs in the Middle Euphrates from the point of view of the members.

**Research methodology and field procedures:**

**Research Methodology:** The researchers used the descriptive approach in the survey method and the correlation and comparison relationships, due to its relevance and the nature of the current study.

**Community and sample search:** The research community determines the heads of the sports clubs (58) members and members of the governing body in the sports clubs (429), thus the total number of the research community (487). The sample of the application was randomly selected, consisting of (100) members of the administrative bodies of the sports clubs in the Middle Euphrates.

**Search Tool:** After reviewing the scientific sources and research related to the scale of creative leadership and its fields, the innovative driving scale was adopted, consisting of (50) paragraphs divided into (5) fields, as follows: The first field (gravity and influence) consists of (11) paragraph and the second area The problem consists of (11) paragraphs and the third area (fluency - flexibility - originality) consists of (10) paragraph and the fourth area (encouragement and adoption of creativity) consists of (10) paragraph and the fifth area (initiative) consists of (8) items.

Alternatives to the answer for each paragraph include five alternatives to the answer given that the alternative is very large (5), large (4), medium (3), low (2) and very low (1) degree.

To indicate the validity of the paragraphs were presented to the experts and specialists in educational and psychological sciences and sports psychology and sports management, as well as if you need to delete or modify or merge some similar paragraphs.

**Results**

**View, analyze, and discuss search results:** After the completion of the process of building the measure of creative leadership following the scientific procedures, and to achieve the goal of the research collected data for the scale, and for the purpose of facilitating the procedures presented in the form of tables and forms and then interpreted the following results have emerged:

<table>

</table>

Table (2) shows that the computational mean of the application sample in the results of the problem solving area was (46.84), the standard deviation (5.68), and the torsion coefficient (0.282), indicating the absence of extreme values in their results. The mean medium of the adult field (33) indicates that the value of the arithmetic mean is greater than the value of the mean medium and the field order in their responses (I) with the relative weight of (85.16).

The ability to solve problems as the basis of creative work, and we mean the diagnosis of many problems within the same situation, by identifying the dimensions and aspects and shortcomings in them to reach creative solutions in respect of them, and that is what the importance of this area is increased in administrative work because it is the means by which the way to solve problems and overcome obstacles and work for the future and the decisions become more difficult as we climb to the top of the administrative pyramid.6

The mean of the results of the field of encouragement and adoption of creativity was (39.61), the standard deviation (4.51), and the torsion coefficient (-0.161) indicating the absence of extreme values in their results. Comparing the arithmetic mean with the mean medium of the adult fields (30), where the most important factors that stand in the way of creativity can be summarized as follows:8 Personal obstacles, obstacles from childhood, constraints by the leader may paralyze creativity,9 organizational constraints, social constraints may be due to a defect in the promotion of excellence and creativity and to overcome obstacles and distractions between the president of the club and the members of the administrative bodies of sports clubs in a manner that ensures the maximum possible degree of efficiency to achieve the goals.10

Conclusions

In light of the researcher’s findings from the current research findings, the following can be inferred:

1. The field of ability to solve problems ranked first, which is the highest area of encouragement and adoption of creativity ranked fifth, the lowest in the measure of creative leadership.
2. The club leaders have a good level of creative leadership in most sports clubs.
3. The reality of the creative leadership of the heads of sports clubs was reflecting a perception and a satisfactory perception of the administrative bodies of sports clubs clearly and accurately expressed through their answers on the scale of creative leadership.

Inter-Pregnancy Interval and its Association with Autistic Children

Hajir Salem Muhsen¹, Sijal Fadhil Farhood Al-Joborae¹

¹College of Medicine, Babylon University, Iraq Ministry of Higher Education and Scientific Research

ABSTRACT

Background: Autism is a life-long developmental disorder that causes considerable amount of health loss during the life of affected people. Despite the role of environmental factors in its development, but a single factor is not sufficient to cause it, and a combination of several factors is more likely to be responsible.

Aim of the Study: To determine the risk of autism with short, adequate and long inter-pregnancy intervals.

Methodology: This study is a cross sectional study conducted in centers for autistic children in three governorates (Karbala, Babil, and Wasit) in addition to the psychiatry unit in Al-Zahraa Teaching Hospital in Wasit. The data collection was performed from January 2019 to April 2019.

Results: Mean age of autistic children was (6.12 ± 2.25) ranging from (3-15) years old, most of them being males (73.7%) who were born term (70.0%). Almost two-thirds of them were born via cesarean section. Three-quarters of children were either second birth order or third (33.2% and 43.7%) respectively. One-third of mother did not have regular antenatal care, and 17.0% of them had bleeding in pregnancy, mostly in first trimester. There was significant association between inter-pregnancy interval and the gestational age at birth (p-value=0.034). Also, there was significant association between inter-pregnancy interval and both of maternal age at child birth and antenatal care, p-value=0.008 and 0.001, respectively.

Conclusion: Certain maternal and child factors are associated with inter-pregnancy interval, including gestational age, maternal age, and antenatal care. Some of these are known risk factors for autism. Almost half of the patients had inter-pregnancy interval of less than 2 years.

Keywords: autism; inter-pregnancy interval; neurobehavioral disorder.

Introduction

Autism is a life-long neuro-developmental disorder that typically has three aspects: communication impairment, impairment in social relationships, and stereotyped patterns of behaviors[1]. The term autism spectrum disorders (ASD) refers to 3 disorders: autistic disorder, Asperger’s disorder, and pervasive developmental disorder (PDD)[2]. This term describes a category of brain disorders that occur in childhood and leads to severe functional impairment and associated problems affecting learning ability and language[3].

ASD are responsible for significant health loss during life[4], and it affects 15 per 1000 persons in developed countries, giving a prevalence of 1.5%[5]. ASD is higher in males than females, with approximately 4 males affected for each female. This was explained by several theories; one of them suggests that sex chromosome genes play a key role in molecular mechanisms involved in autism occurrence[6], another theory is the role of testosterone in the occurrence of ASD[7].

A single factor is not sufficient to cause ASD, and a combination of several factors is more likely to affect disease occurrence[8]. Risk factors are classified into prenatal, perinatal, and postnatal[9]. Both paternal age and maternal age were suggested as risk factors for

Scientific Research
Email: qaisajam1981@gmail.com
autism[10,11,12]. Physical and mental health of the mother are also possible risk factors for ASD[9,13], as well as prenatal medication use by the mother[11].

It has been suggested that both short and long inter-pregnancy interval (IPI) are associated with higher risk of developing autism spectrum disorder[14]. This has a significant importance in clinical and public health settings, since it affects families from both developed and developing countries, while being a possibly modifiable risk factor[15].

The number of women who delay their first pregnancy is rising globally. And to overcome the negative effects of having children at older ages; those women tend to have their second child after a short duration from the birth of the first one, or within a short inter-pregnancy period[15]. This shorter period may increase the chance that the second child develop autism[9].

In Iraq, a study in Baghdad in 2011 had shown that autism patients constituted more than 15.0% of psychiatric patients[16]. Another study in 2016 targeted the identification of risk factors for autism in Iraqi autistic children in Baghdad city. The most important of the risk factors identified was unhappy emotional state of the mother during pregnancy, abnormal gestational age, neonatal jaundice, as well as bottle-feeding, which is a highly modifiable risk factor that was not described in many other studies worldwide[17].

This study aims to determine the risk of developing autism in children born after short, adequate and long inter-pregnancy intervals.

Aim of the Study

To determine the risk of autism with short, adequate and long inter-pregnancy intervals.

Patients and Method

This is a cross-sectional study conducted in centers for autistic children in governorates (Karbala, Babil, and Wasit) in addition to the psychiatry unit in Al- Zahraa Teaching Hospital/Wasit. Data collection was performed from January 2019 to April 2019.

Children younger than 18 years who were diagnosed with autism spectrum disorder who were not the first born child in their families were included in the study, while children who were the first born for their families were excluded. Data was collected by interviewing families of children using specially designed form, and statistical analysis was performed using SPSS® 24.

Results

Distribution of child’s socio-demographic factors: table 1 shows that the mean age of autistic children was (6.12 ± 2.25) ranging from (3-15) years old. The mean birth weight was (2.79 ± 0.64) Kg ranging from (1000-5000) gm.

Most of the children with autism included in the study were male (73.7%) and they were born term (70.0%). Those autistic children who were born preterm had a history of either extreme prematurity (42.6%), or moderate prematurity (48.9%).

Distribution of variables related to delivery: table 2 shows that up to two-thirds of children with autism included in the study were born via normal vaginal delivery (60.7%) and (48.0%) of vaginal deliveries were induced.

Three-quarters of children were either second in birth order or third (33.2% and 43.7%) respectively. Likewise; three-quarters of autistic children had a cephalic presentation during delivery.

Distribution of maternal obstetrical history:

Regarding obstetrical history, table 3 shows that about one-third of mothers have either irregular or a total lack of antenatal care (26.7% and 7.3%) respectively. Seventeen percent gave a history of bleeding in pregnancy and over half of those mothers who bled during pregnancy, this event occurred in the first trimester. An absolute majority (78.9%) did not use contraception prior to the current pregnancy.

*P-value ≤ 0.05 was significant
Discussion

Mean age of children of autism was (6.12) years, which is approximately (1.3) years younger than the findings in the US National Survey of Children’s Health (NSCH) in 2013 described by Sheldrick et al. in which the mean age at disease identification was (7.4) years[18].

Low birth weight is an important perinatal risk factors for ASD[19]. Mean birth weight for autistic children was (2.79) kg, which was lower than the birth weight of (3.197) Kg reported by Darcy-Mahoney et al. in their study conducted at the Pediatric Neurodevelopmental Clinic (PNC) in 2010[20].

Male children constituted almost three-quarters of children with autism in the present study, giving a male-to-female ratio of (2.8:1). This ratio is close to the ratio of (3:1) reported by Loomes et al.[21]. Autistic children born preterm constituted (19.1%) of the total autistic children. This is close to the finding by Schende et al. in their study who described a proportion of (14.6%) of their study population[22].

Regarding antenatal care of mothers of autistic children, two-thirds (66.0%) had regular antenatal care while the remaining had no regular antenatal care. This is lower than the proportion of Iraqi women with regular antenatal care of (72.7%) reported by Hussein et al. in Al-Hilla city during 2014-2015[23]. This suggest a protective role for antenatal care regularity against ASD development. Bleeding during pregnancy was found in (17.0%) of cases, more than half of them being in the first trimester. This is consistent with the meta-analysis by Gardener et al. who described a significant elevation in risk of autism, reaching up to 81.0%, in pregnant women who are exposed to bleeding during their pregnancies[11].

Inter-pregnancy interval of less than 2 years was observed in almost half of the cases (45.4%), a possible link between short inter-pregnancy period was suggested by Zerbo et al. in 2015[24].

Birth asphyxia was present in more than (25.0%) of study cases, this proportion was substantially higher than what was described by Fezer et al. in their study conducted during 2008-2015, which found proportion of (8.0%) of patients suffered birth asphyxia, and could demonstrate MRI abnormalities in them, concluding that birth asphyxia is one of the modifiable risk factors for autism[25].

Gestational age was found to be significantly associated with inter-pregnancy interval. Darcy-Mahoney et al. demonstrated a 2-fold higher risk of ASD among children with less than 33-weeks of gestation[20], which suggests that this is one of the mechanisms through which inter-pregnancy interval affects the risk of ASD. Two maternal factors were also found to be significantly associated with inter-pregnancy interval, these are maternal age at child birth, and regularity of antenatal care. This may further clarify the role of inter-pregnancy interval in development of ASD.

Conclusion

The study concludes that certain maternal and child factors are associated with duration of inter-pregnancy interval, including gestational age, maternal age, and antenatal care. Some of these factors are well established risk factors for development of ASD. It also concludes that almost half of the patients had inter-pregnancy interval of less than 2 years.

The Role IL-16 rs11556218 T/G Gene Polymorphism with the Risk of Osteoporosis in a sample of Iraqi Postmenopausal Women

Mohammad Shakir Atiya¹, Da’ad Ali Hussain¹

¹Institute of Genetic Engineering and Biotechnology, University of Baghdad, Iraq

ABSTRACT

Background: Interleukins (ILs), a multifunctional cytokines. It’s play a fundamental role in inflammatory diseases, as well as in the development of osteoporosis and there are data about the role of IL-16 polymorphism in development of postmenopausal osteoporosis.

Patients and Method: In this study, we investigated about the IL-16 rs11556218 T/G polymorphisms and the risk of osteoporosis among 50 patients with osteoporosis and 40 healthy controls. Serum IL-16 level and its correlation with the IL-16 rs11556218 T/G genotypes were analyzed.

Results: Significant differences of genotype distribution were observed between osteoporosis patients and controls at the IL-16 rs11556218 T/G genotypes. Compared with the IL-16 rs11556218 T/G homozygote TT, the heterozygous TG genotype was associated with significantly increased risk for osteoporosis (X²= 13.25, OR = 5.52, p = 0.00048); the GG genotype was not significantly different from controls, this may be due to the number of samples collection or samples ethics. But the odds ratio appear a high risk factor (O.R.) of osteoporosis among people who having GG genotype (X²= 1.35, OR = 2.59, p = 0.292). In addition allele frequency for G allele associated with significantly increased risk for osteoporosis (x²=16.78, OR=3.94, p=<0.0001). TG and GG combined variants were associated with increased risk for osteoporosis compared with the TT genotype (X²= 10.98, OR =4.33, P = 0.0013). Moreover, in patients with osteoporosis, there was a correlation between the serum IL-16 and rs11556218 T/G genotype.

Conclusion: our study provided the evidence of association the polymorphisms of IL-16 rs11556218 T/G genotype and the risk of osteoporosis and found the IL-16 rs11556218 T/G genotype was associated with increased risk for development of osteoporosis in Iraqi postmenopausal women.

Keywords: IL-16, Osteoporosis, Single-nucleotide polymorphism Susceptibility.

Introduction

Osteoporosis in Postmenopausal women is a common disorder characterized by decreased bone mineral density (BMD), changes in bone microarchitecture and thus causing increased fracture risk. Osteoporosis is a disease occurs by the interaction of genetic and environmental factors. The environmental factors can roles play in control gene expression and therefore occur the process of the disease [1]. The risk factors among women include lower height, race, low-calcium diet, body mass index, use of corticosteroids for over six months and menopausal status. Earlier, studies showed that environmental effects and genetic control affected bone turnover [2]. Pro-inflammatory cytokines are among the important factors involved in bone turnover, they are the stimulants of bone resorption by acting directly on osteoclasts and osteoclast precursors. Recent studies propose that osteoclasts and immune cells share a number of regulatory molecules, including cytokines, signaling pathways, receptors, growth factors, and transcription factors [3]. Therefore, cytokines that are produced by immune cells and regulate adaptive responses may also influence osteoclast function through common receptors, signaling pathways, and transcription factors. This hypothesis is propped by
evidence gathered from experimental animal models and human observations with autoimmune diseases \([4,5]\). Recent studies have investigated Interleukin-16 gene polymorphisms in relationship to risk of osteoporosis \([6]\) and other disease such as colorectal cancer and gastric cancer \([7]\), prostate cancer \([8]\), glioma \([9]\), and osteosarcoma \([10]\). Interleukine-16 (IL-16) is produced by activated CD8-positive (CD8+) T cells and activates CD4+ T cells, macrophages, monocytes, and dendritic cells by binding to the CD4 molecular. In addition to the activation of CD4+ T cells, IL-16 can stimulate the secretion of inflammatory cytokines such as α-interleukin-1β, tumour necrosis factor (TNF), and interleukin-6 (IL-6) \([11]\). So IL-16 share in the inflammatory disorder through the activation of T lymphocytes and the secretion of inflammatory cytokines \([11,12,13]\) that increases osteoclast formation by promoting bone marrow stromal cell production of M-CSF and RANKL, and by enhance the responsiveness of osteoclast precursors to RANKL \([14]\).

### Material & Method

**Study population:** This study was conducted with 50 osteoporosis patients with postmenopausal Iraqi women who attended Baghdad Teaching hospital in Baghdad/Iraq between December 2018 and March 2019. Osteoporosis was defined according to the conventional World Health Organization (WHO) definition. Subjects with a history of bone disease, metabolic or endocrine disorders such as diabetes mellitus, hyperthyroidism, hyperparathyroidism, renal disease, liver disease, medications known to affect bone metabolism (e.g. anticonvulsants, corticosteroids, heparin sodium) were excluded. The control group comprised 40 healthy volunteers for the general health checkup in our hospital during the same period. After obtaining written informed consent, 5 mL of peripheral blood was collected for DNA extraction and ELSA test. Each participant was interviewed using a standard questionnaire by a trained nurse, to collect demographic characteristics and medical histories. All the specimens we recruited were of Arabic/Iraq ethnicity and were filtered based on their clinical characteristics. Before the assay, we obtained a written informed consent from each participant in our study.

**DNA extraction and genotyping:** Genomic DNA was isolated from EDTA anticoagulated peripheral blood with a commercially available extraction kit (Zymo, USA) according to the manufacturer’s instructions. Genotype determination for one SNP in the IL-16 gene (rs11556218T/G) was performed by real-time polymerase chain reaction (RT-PCR). The polymorphisms within IL16 rs11556218 T/G were genotyped with TaqMan genotyping assays using the Roto-Gene Q apparatus Real-Time (Roto-Gene Q, Germany). probes and primers designed for RT-PCR shown in Table 1.

**Serum level measurement of IL-16:** The interleukin-16 (IL-16) level were determined by enzyme-linked immunosorbent assay (ELISA) using a commercially available ELISA quantitative kit (R&D systems, USA) according to manufacturer’s instructions.

**Statistical Analysis:** Genetic analysis was performed by using Chi-square (χ2) test. P <0.05 was considered significant. Statistical analysis was performed by using Graphpad Prism6 (Graphpad Software Inc., La Jolla, CA). Data were expressed as (mean ± SD). The normality of the distribution of all variables was assessed by the student’s ANOVA test and Pearson correlation analyses that have been used to determine the significant difference between the groups.
Result

This study included 50 osteoporosis patients and 40 healthy controls, the mean ages of osteoporosis patients and healthy controls were 59.46 ± 7.217 and 53.55 ± 5.007 years, respectively. The genotype and allele frequencies of the IL-16 rs11556218 T/G polymorphisms for all the studied variations are shown in Table 2. All genotype frequencies of the control group conformed to the Hardy–Weinberg equilibrium.

Serum IL-16 level and its correlation with the IL-16 rs11556218 T/G genotypes. Given the observed notable association between the IL-16 rs11556218 T/G genotypes and osteoporosis risk, we further investigated the serum IL-16 levels in controls and patients with osteoporosis as well as the potential regulatory effects of the IL-16 rs11556218 T/G genotype on serum IL-16. We examined the serum IL-16 levels by ELISA in 50 osteoporosis patients and 40 healthy controls. The serum IL-16 of patients with osteoporosis significantly increased compared to controls (P =<0.0001). Moreover, in patients with osteoporosis, there was a correlation between the serum IL-16 and rs11556218 T/G genotype (P = 0.0001). The rs11556218 G allele-carrying patients had a higher serum IL-16 than the non-carriers (P =<0.0001, Table 3).

Discussion

In the present study, we selected, one SNP IL-16 rs11556218 T/G to evaluate their association in patients with Iraqi postmenopausal women with osteoporosis and healthy controls. The SNPs rs11556218 T/G, are located in an exon region, and their single-nucleotide changes would result in an amino acid substitution.

Genetic variation in the DNA sequence of the IL-16 gene may lead to altered cytokine production and/or activity variation may modulate an individual’s susceptibility to osteoporosis. The present results revealed that the IL-16 rs11556218 T/G polymorphism, representing an asparagine (Asn) to lysine (Lys) substitution in exon 6 of the IL-16 gene, has a significant effect on the risk of postmenopausal osteoporosis.

Inflammatory processes and cytokines play fundamental roles in the pathogenesis of women osteoporosis. Variations in cytokine levels, among individuals are a plausible explanation for differences in disease susceptibility and severity, and are principally attributable to single nucleotide polymorphisms (SNPs) in cytokine-encoding genes.

Interleukine-16 as a proinflammatory cytokine whose functions include: chemo-attraction and modulation of T cell activation, and it’s important mediator in inflammatory and autoimmune diseases. The IL-16 gene is located on chromosome 15q26.3, and is initially translated into a precursor protein consisting of 631 amino acids, which is cleaved by caspase-3 to form the active C-terminal domain containing 121 amino acids. IL-16 is a CD4-specific ligand required for the initiation of CD4 bioactivity. Through binding to the CD4 molecule, IL-16 can selectively activate CD4+ T cells, monocytes, eosinophils, macrophages, and dendritic cells. In addition, IL-16 can increase the stimulate and produce of inflammatory cytokines, such as TNF-α, IL-1β, IL-6, and IL-15, leading to inflammatory response. Thus, it is biologically reasonable to hypothesize a potential relationship between IL-16 gene polymorphisms and osteoporosis risk.

Conclusion

Our study provided the evidence of association the polymorphisms of IL-16 rs11556218 T/G genotype, G allele, and the risk of osteoporosis, and found the IL-16 rs11556218 T/G genotype and G allele, was associated with increased risk for development of osteoporosis in Iraqi postmenopausal women.

The Impact of the Educational Program on the Woods Model in Learning the Skills of Serve and Receiving Volleyball Students

Sahira Mohammed Abdulameer¹, Luma S. Hamoodi¹, Intisar Owaid Ali¹
¹College of Physical Education and Sports Science for Girls, University of Baghdad, Iraq

ABSTRACT

The problem of research is that there is a weakness in the performance of some basic skills in volleyball (transmission and reception) in the educated and not reach the desired level that we aspire to. This may be due to the lack of use of some modern educational strategies and models that make the learner a key focus which could negatively affect performance skill. The aim of the research was to identify the effect of the Woods model in learning the skills of transmitting and receiving volleyball students.

The experimental method was used and the research was conducted on a sample of second grade students in the middle school of Yarmouk for girls. The number of female students was 31 divided into two experimental groups. The number of female students was 16 and the number of female students was 15. The tool was used to measure, the most important results of the research indicate that the Woods model does not play an important role in learning the skills of transmitting and receiving volleyball transmissions in the research sample. The group that learned the two skills studied by using the Woods model is better than the group that learned the same skills using the technique of the lesson. One of the most important recommendations is that the Woods model should be used to learn volleyball skills, especially the skills of serve and receiving in schools, under consideration.

Keywords: Educational program, Woods model and skills of serve and receiving.

Introduction

One of the bright signs that play a role in life is the issue of learning and education. It is a goal and goal for every educational institution, whether sports or non-sports, to bring out learners capable of being role models for their peers at all levels.

Because of the importance of the intermediate stage in building the personality of the learner in general, and the development of his abilities, especially the mental ones in particular, and to be meaningful learning, it was necessary to use models and strategies, such models Woods model, which stems from the theory of construction, which confirms three consecutive mental processes in the educational process, Prediction - observation), prediction is the first stages of the Woods model through which the learners predict the skill to be learned to know what happens in the future based on previous information and the second stage is the learners note the skill to be learned and applied and access the results are through the experiment and the learner begins to receive new information that was not previously available to him. The third stage is the explanation in which the learners reach the correct interpretation of the questions and ideas presented during the educational unit.¹

The volleyball game is characterized by its popularity and ease of use by different age groups as well as the technical and planning development of its various skills including (skill of serve and receiving the serve). It is also necessary to pay attention to this class of middle stage as they face different pressures that require effort to face them.
Through the experience of female researchers in education and their observation of female students’ performance, I found that there are weaknesses in the performance of some basic skills in volleyball, especially the skill of transmitting and receiving the students. This may be due to the lack of use of some modern educational strategies and models which make the learner a key focus, which may adversely affect the performance of skills. As the adoption of the learner on a strong basis based on the attitudes of education need to address, thinking and some mental processes that contribute to improving performance.²

All of this called on the researchers to use an educational model that may play a role in making the learner predict, observe and interpret the two skills under study, so that his role is not the recipient of the information but rather strives to achieve the objectives of the educational process, studying.

Research aim: Identify the effect of the Woods model in learning the skills of serve and receiver of volleyball for female students.

Research Hypothesis: The Woods model does not have the effect of learning the skills of serve and receiver of volleyball for female students.

Research Methodology and Field Procedures

Research Methodology: The experimental approach was used to design the two groups (control and experimentation) with pre-test and post-random selection to suit the problem and subject matter of the research.

Research community and design: The research community is represented by the second grade students in the Yarmouk Middle School for Girls, which belong to Al-Rusafa School for the academic year 2017-2018. The number of students is divided into (4) people, and the selection of the sample must be representative of the original society, the researchers randomly selected the two groups (A - C) randomly and in a lottery manner to represent the sample of the main experiment (40) female students. The students were dismissed, who had health problems and absenteeism. The number of female students reached (9) And a percentage (38.75%) of the total community of origin divided into two groups, one of them (16) students who learn the two skills under study using the Woods model and a control group (A) of 15 students who learn the two skills under study using the teacher style.

Means, tools and devices borrowed:

- Arab and foreign sources.
- Registration and unloading forms.
- International Informatics Net.
- Volleyball court Legal.
- Legal plane balls (15) Micasa type.
- Colored adhesive tape No. 2.
- Metal measuring tape - Flex.
- Camera (2) Type Sharp.
- Discs (CD).
- No-Beat Type Calculator (DELL).

Measurement tools:

Serve test: Purpose of the test: Measuring the skill of the serve of the volleyball player in a position similar to the match.

Instruments: legal volleyball court, legal volleyball.

Performance specification: The player stands in the middle of the end of the pitch (the half facing the half of the planned plot 9 meters from the net), from this place and the player holding the ball is serve to cross the ball network to half of the planned stadium.

Registration: Each time you send the correct number of the area in which the ball falls in the half of the planned pitch, and since the player has ten attempts on this test, and because grades are distributed on the regions of (1) to (4) degrees, the great degree of this test is (40) degrees. Note that in the case of the fall of the ball on the line separating the two areas calculated for the player the top zone.

Receiver reception test: Purpose of the test: measuring the skill of the player in receiving the serve.

Tools:

1. Draw two circles (A - B) in the corners of the stadium, so that the distance between the center of the circle and the side line (1.5) m, while the distance between the center and the end line (3 meters).
2. A sign (x) shall be placed in the opposite half of the stadium and at a distance of (3 meters) from the finish line, (4.5) meters from the side line.

3. Divide the area (3 meters) into three equal areas.

**Performance specifications:** The laboratory stands within the circle (A) and is facing the network, and the teacher to send the ball to him in this place to receive them to be directed into the area (1), and so on in the following five balls to go to the area (2) As well as with the five balls of the third so that he went to the area (3) repeat the same work with the same number of attempts of the circle (B).

**Registration:** The laboratory records the total points obtained from the 30 attempts granted to it (15 attempts from each department) according to the following method:

- Falling ball within the specified area gives the laboratory (3) degrees.
- Falling ball outside the specified area and within the vicinity of the laboratory gives two degrees.
- The ball falls outside the specified area and inside the stadium the laboratory gets one score.
- Except for the above, the laboratory receives zero.

**Pre Tests:** The researchers gave two introductory units on the two skills under study after which the pretests of the two skills were conducted on 27/2/2018 in the external arena of the Yarmouk Middle School for Girls. The researchers also carried out the equivalence of the two groups of research in the pretests of the volleyball and volleyball skills, as shown in Table (1).

5. The educational program was implemented on 29/2/2018 until 2/5/2018

6. The experimental group learned the skill of serve and receiving volleyball transmissions using the Woods model. The control group learned the skill using the technique.

7. The Woods model was implemented during the educational unit agencies:

A. The students were divided into groups of 4 groups. Some questions were asked by the school of the subject to the learners and they were allowed to
think and predict the correct answer. Then, a student from each group was randomly selected to answer the question after consultation with her group.

B. Apply the exercises for the skill under study with a Flex presentation that is close to the place of performance as a feedback feed to correct the performance, and that the application is within the totals themselves to cooperate among themselves to correct the mistakes to achieve the correct performance.

C. Give a game of relaxation or relaxation exercises in the closing section as well as the school to explain the correct questions raised in the educational aspect.

**Posttests:** The researchers conducted post tests for the technical tests on 3/5/2018 in the external arena of Yarmouk medium for girls.

**Results**

**Table 2:** Shows the results of the pre and posttests of the research variables and the two groups

Table (2) shows that there are significant differences between the pre and posttests of the technical tests (serve - receiving serve) and the experimental and control groups and for the tests of the dimension.

The researchers attributed this to the fact that the Woods model and the style followed by the teacher played an important role in learning the two skills under study. This indicates that the Woods model was appropriate for the sample level as well as that they were prepared according to the correct scientific basis. Do not forget the role of the teacher in planning and implementation, which played an important role in learning the two skills under study. That the natural phenomena of the learning process is to have a development in learning as long as the teacher follows the steps of sound foundations of learning and education, which is the correct performance of the explanation and presentation and then focus on it until the consolidation of performance. The educational process should also be a training organization for beginners to learn motor skills, whether one skill or two skills, to facilitate the learning process.

**Table 3:** Shows the results of the post tests of the research variables and the two groups

At the level of error < or = (0.05)

Table (3) shows significant differences between the experimental and control groups in the post tests of the two skills under study and for the benefit of the experimental group.

The researchers attributed this to the fact that the Woods model was better at learning the two skills under study than the teacher’s approach. This is because the Woods model makes the learner predict, observe and explain. This in turn makes the learner think and invest his mental processes during the lesson. The study must be provided on the basis of careful observation and practical experimentation and self-activity based on desire and attention to what the student studies. It also requires...
and the prediction of learners of what can happen in the future and the expectation of things requires mental learners to reach the correct solutions and interpretations, correct interpretation and scientific and this in turn helps learning and mastering the new skill. Previous experiences affect the speed and ease of learning and mastering the new skill. And that the opposition of opinions between learners requires the help of the teacher in giving the correct interpretation and scientific and this in turn helps learners to reach the correct solutions and interpretations, and the prediction of learners of what can happen in the future and the expectation of things requires mental perception and this also contributes to learning the skill better. Previous experiences affect the speed and ease of learning and mastering the new skill. And the existence of cooperation among members of the same group easy to acquire the information and skills required, and indicates (Ismail) that the learner who is the process of teaching his colleague and provide him with explanations and advises him mistakes directly in any educational situation helps to acquire and develop advanced skills of the learner. 

The researchers also attribute this to the role of feedback through a flex presentation that represents images of motor performance as well as explanation of skill details, which contributes to correcting the wrong performance of learners. This is expressed, the use of feedback is one of the factors determining the effectiveness learning of motor skills and the development of motor performance. Most research has shown that feedback increases performance improvement in the first stages of learning. This will lead to the use of more than one sense in the performance of the skill and this in turn leads to better learning as a general principle, the more possible use of the senses during mental perception the better.

Conclusions

1. The WDS model has an important role in learning the skills of transmitting and receiving volleyball transmissions in the research sample.

2. The method adopted by the teacher has a positive effect on learning the two skills under study.

3. The group that learned the two skills under study was able to use the Woods model on the group that learned the same skills using the technique of the lesson.

Capability of Diffusion-Weighted Magnetic Resonance Imaging in Differentiating between Atypical Hemangioma and Malignant Lesions

Ashwaq Khalil Hashim¹, Osamah Ayad Abdulsattar¹

¹College of Medicine, University of Babylon, Ministry of Higher Education and Scientific Research

ABSTRACT

Background: Despite its high sensitivity in detecting spinal intramedullary changes; conventional MRI has limited specificity for distinguishing between benign and malignant lesions. Diffusion-weighted MRI is a promising method that can assist in the identification of atypical hemangiomas and differentiating them from malignant lesions of the spine by assessing the molecular function of the body and its micro-architecture.

Aim of the Study: To evaluate the value of diffusion-weighted magnetic resonance imaging in the diagnosis of and differentiation between atypical hemangioma and malignant lesions of the spine.

Methodology: This study is a comparative analytical study conducted from May 2018 through May 2019 and included patients from Al-Hilla teaching hospital who underwent both diffusion-weighted magnetic resonance imaging (DW-MRI) and computerized tomography (CT) scan for the spine in order to identify and diagnose atypical hemangioma and malignant lesions.

Results: Mean age of study participants was (58.4 ± 15.5) years with a mean body mass index of (24.09 ± 3.76) Kg/m². Males comprised (66.7%) of study population. Magnetic resonance imaging of cases with atypical hemangioma of spine had shown hypointense T1-weighted image, hyperintense T2-weighted image, and no restriction of diffusion, with mean ADC value of (1.24×10⁻³ mm²/s), while in cases of metastatic bony lesions of spine there was hypointense T1, hyperintense T2, and restriction of diffusion with mean ADC value of (0.81×10⁻³ mm²/s).

Conclusions: diffusion weight magnetic resonance imaging is an effective diagnostic tool for differentiation between atypical hemangioma of spine and malignant bony lesion of spine.

Keywords: diffusion-weighted MRI; spine; hemangioma; malignancy

Introduction

High sensitivity of magnetic resonance imaging (MRI) in the detection of intramedullary changes in the spine had led to consider it the technique of choice regarding spinal cord imaging[1]. However, conventional MRI has limited specificity for certain abnormalities especially distinguishing between benign and malignant lesions[2].

Malignant tumors of the spine pose a challenge for clinicians both in diagnosis and in treatment. The majority them are metastatic tumors, forming more than 90% of spinal tumors[3]. In fact, the most common site for bone metastasis in the body is the spine[4]. Spinal metastatic tumors may arise from breast, renal, lung, thyroid, and colorectal cancer[5], with increasing incidence every year[6].

Several diagnostic modalities are employed for the diagnosis of spinal tumors, including plain X-ray, computerized tomography (CT) scans, and MRI[3]. MRI is considered one of the most successful diagnostic techniques in diagnosing the malignancies of spine[7]. Its ability to visualize both bone involvement and
neural compression allowed the clinicians to gain more information about the diagnosis, including the detection of the extent of involvement and the assessment of any compressions of the spinal cord\cite{8}.

However, some benign spinal lesions may falsely be diagnosed as malignant, which will expose the patient to unnecessary intervention\cite{9}. Hemangioma is one of the benign lesions of the spine that typically appears hyperintense in T1-weight images and T2-weighted images of the MRI, with intense enhancement in post-contrast T1-weighted images with fat suppression\cite{10}.

However, some hemangiomas have atypical features, and may appear hypointense on T1-weighted images while keeping the same appearance on both T2-weighted images and fat suppressed images. This may mimic malignant lesions in conventional MRI, especially when the hemangioma extend indistinctly over the entire vertebral body\cite{10}. This necessitate utilization of certain techniques to differentiate between benign and malignant lesions.

Diffusion-weighted magnetic resonance imaging (DW-MRI) is a promising method that can significantly impact the ability of identifying atypical hemangiomas and differentiating them from malignant lesions of the spine\cite{9, 11}. It can assess the molecular function of the body as well as its micro-architecture, thereby help identify malignant lesions and distinguishing them from benign ones\cite{12}.

Diffusion of water molecules occurs in a pattern influenced by tissue components and properties. This pattern is sometimes modified due to certain pathological conditions, and this modification can appear as changes in diffusion pattern\cite{13}. Restriction in water diffusion reflects the cellularity of the tissue and the integrity of the membranes, since water molecules are more restricted when there the tissue is highly cellular with several cell membranes of good integrity (such as the tissue of a tumor), while less restriction is seen when cell membranes are broken or when the environment is less cellular\cite{14}.

In solid tumors, diffusion is typically restricted, and diffusion-weighted images can effectively limit the false positive findings acquired by conventional imaging techniques, by showing hyperintense signal for certain tumor regions. This has rationalized the utilization of DW-MRI in oncology as a major diagnostic approach, combined with conventional MRI sequence for the diagnosis of malignancies within various tissues\cite{13}.

**Aim of the Study**

To evaluate the value of diffusion-weighted magnetic resonance imaging in the diagnosis of and differentiation between atypical hemangioma and malignant lesions of the spine.

**Patients and Method**

This study is a prospective analytical study conducted from May 2018 through May 2019 and included 300 patients from Al-Hilla teaching hospital who underwent both diffusion-weighted magnetic resonance imaging (DW-MRI) and computerized tomography (CT) scan for the spine in order to identify and diagnose atypical hemangioma and metastatic lesions. Those patients were included for further analysis regarding the efficacy of diffusion-weighted MRI in diagnosing their atypical hemangioma or metastatic bony lesions, while patients who have contraindications to CT scan or MRI were excluded from the study. Statistical analysis was performed using SPSS® version 23 (For Linux operating system). P-value of less than 0.05 was considered statistically significant.

**Results**

The study included 300 patients categorized into 3 groups: Group (A) included 18 patients with atypical hemangioma, Group (B) included 42 patients with metastatic bony lesions, and Group (C) included 240 patients with typical hemangioma. Groups (A) and (B) were included for further statistical analysis.

Age of patients ranged from (30-86) years, with a mean of (58.4 ± 15.5) years. Significant difference in age was observed between group (A) with atypical hemangioma (41.5 ± 8.6 years) and group (B) with metastatic bone lesion (65.6 ± 11.6 years), t-test=7.92, P-value<0.001. Figure(1) illustrates the age groups of study participants by study group. Two thirds (66.7%) of study participants were males while one-third (33.3%) were females.
Patients had their diseases for a median duration of (3) years, with a range reaching up to (5) years. The most prominent symptom was backache radiated to the lower limbs, which was present in (71.7%) of the cases. Parasthesia and numbness were present in (25%) of cases. Symptoms of malignancy such as osteopenia and compression fractures were present only in metastatic bone lesions group and affected (59.5%) of them.

Atypical hemangioma in group (A) had hypo-intense T1-weighted image in (81.25%) of the cases, and hyper-intense T2-weighted image in all of the cases. Figure(2) shows the MRI of a 54 years old female with hemangioma.
No restriction of diffusion was observed in any of the cases with atypical hemangioma (diffusion is free). The DW-MRI imaging of a 69 years old female with spinal hemangioma is shown in Figure(3).

Figure 3: DW-MRI imaging of a 69 years old female patient with spinal hemangioma

Metastatic cases in group (B) similarly had hypo-intense T1-weighted image and hyper-intense T2-weighted image in all of the cases. However, all cases with metastatic lesions shown a restriction of diffusion. Figure(4) shows the MRI of a male aged 49 years with bone metastasis to the spine.

Figure 4: MRI imaging of a 49 years old male with bony metastasis to the spine

Mean ADC value for atypical hemangioma was \((1.24 \times 10^{-3} \text{mm}^2/\text{s})\) with a standard deviation of \((0.32 \times 10^{-3} \text{mm}^2/\text{s})\) and a 95% confidence interval of \((1.08 \times 10^{-3} - 1.40 \times 10^{-3})\), while in metastatic bone lesions the mean ADC value was \((0.81 \times 10^{-3} \text{mm}^2/\text{s})\) with a standard deviation of \((0.91 \times 10^{-3} \text{mm}^2/\text{s})\) and 95% confidence interval of \((0.53 \times 10^{-3} - 1.09 \times 10^{-3})\) as in Table(1). Figure(5) shows the ADC map of a 30 years old patient of hemangioma of the spine.

**Figure 5: ADC map of a 30 years old patient of hemangioma of the spine**

**Discussion**

Typical hemangiomas can be differentiated from metastasis to the spine with relative ease utilizing conventional MRI. Those typical hemangiomas appear on MRI as hyper-intense lesions on T1-weighted images and T2-weighted images, which is distinctive from the surrounding vertebral bone marrow that appears normal. While in bone metastasis the lesion appears as hypo-intense on T1-weighted image and either hyper-intense or hypo-intense on T2-weighted image[10]. In contrast, certain atypical hemangioma lesions may show different appearance on conventional MRI, with a hypo-intense appearance on T1-weighted image, giving a radiological finding similar to that of bone metastasis[15].

Mean age of the cases with atypical hemangioma enrolled in the present study was (41.5) years, which was lower than the mean age of (60.6) for the patients with hemangioma reported by Shi et al. in their study conducted from 2013 to 2015 in China[15], while the mean age of metastatic lesions in the present study was (65.5) years which was higher than the age of (54.33) years among metastasis patients reported by Shi et al.[15]. This may reflect a variation among the two populations regarding the age of incidence of each condition.

Two thirds of the patients included in the present study were males. However, patients with atypical hemangioma showed a female predominance, which is consistent with the typical demographic characteristics of the hemangiomas[16]. While metastatic bone lesions in the present study had shown a male predominance, which is consistent with some types of tumors, but other types generally have equal gender prevalence[16].

Back pain was the commonest symptoms among both groups of patients in the present study, with radiation to the lower limbs. This finding is endorsed by the study by Aich et al. who reported in their study that the most common symptom reported by patients with vertebral hemangioma was back pain[17]. Lawrie I. had
also described that back pain is a frequent symptom in spinal bone metastasis\(^{[18]}\).

Although compression fractures and osteopenia were present only in metastatic bone lesions group, and could be considered as distinctive features for this condition in comparison to hemangiomas; but the late presentation and high morbidity of both compression fractures and osteopenia impose considering them as complications rather than symptoms, rendering them useless for the diagnostic distinction between metastatic bone lesions and atypical hemangiomas.

Regarding the radiological findings of the study groups, the majority of patients with atypical hemangioma had shown hypo-intense lesions on T1-weighted image, while all of them had shown a hyper-intense lesion on T2-weighted image. This finding is supported by the finding by Matrawy et al. in their study, who observed a hypo-intense lesion on T1-weighted image and hyper-intense lesion on T2-weighted image in all patients with atypical hemangioma of the spine\(^{[9]}\).

Interestingly, patients with metastatic bone lesions in the present study had also shown similar radiological findings, with hypo-intense lesions on T1-weighted image while being hyper-intense lesion on T2-weighted images, which was similar to the radiological findings described by Matrawy et al. in their study\(^{[9]}\). This similarity in the presentation of T1-weighted and T2-weighted images of malignant metastatic lesions of the spine and benign atypical hemangiomas of the spine reflect the diagnostic difficult between those two lesions of the spine experienced with conventional MRI.

However, on DW-MRI, all the cases of atypical hemangioma were observed to have free diffusion, while all cases of metastatic bone lesions were observed to have restriction of diffusion; giving a high sensitivity and specificity in distinguishing between them. A similar observation was reported by Matrawy et al.\(^{[9]}\)

The value of apparent diffusion coefficient (ADC) value was found to be higher among cases with atypical hemangioma compared to cases with metastatic bone lesions, with means of \(1.24\times10^{-3}\text{mm}^2/\text{s}\) and \(0.81\times10^{-3}\text{mm}^2/\text{s}\), respectively. These values are closely similar to the ADC values described by Taskin et al. who observed an ADC mean value of \(1.80\times10^{-3}\text{mm}^2/\text{s}\) for atypical hemangioma and \(0.94\times10^{-3}\text{mm}^2/\text{s}\) for metastatic bone lesions\(^{[19]}\).

Another result that support this findings was observed by Leeds et al. who observed a higher value of ADC in patients with benign spinal lesions than the value of ADC observed in patients with malignant spinal lesions\(^{[10]}\). Combination of DWI technique with ADC mapping can provide a better differentiation between benign and malignant lesions of the spine.

This is similar to what was demonstrated by Herneth et al. in their study that demonstrated a significantly different levels of ADC between cases of vertebral metastases, with a mean of \((0.69\times10^{-3}\text{mm}^2/\text{sec})\) and cases of benign lesions, with a mean of \((1.62\times10^{-3}\text{mm}^2/\text{sec})\), suggesting an increase in the specificity when using ADC values in magnetic resonance imaging\(^{[20]}\).

Conclusions

The present study concludes that diffusion weight magnetic resonance imaging (DW-MRI) can be utilized as an effective diagnostic approach in the identification of cases with spinal hemangiomas (whether typical or atypical) and cases of metastatic bony lesions of the spine, and the differentiation between them when conventional MRI shows a similar findings.

ABSTRACT

Background: Many study had tried to investigated the gene that associated with coronary heart disease and its complication, the danger of atherosclerosis and complication may increase as result of oxidization of low density lipoprotein by lectin-like oxidized low density lipoprotein receptor-1 (LOX-1) which found as cell surface endocytosis searcher receptor, the aim is to explore whether or not the LOX-1 gene and its 3’UTR C188T (rs1050283) polymorphisms were a genetic risks of ACS in sample of Iraqi population.

Method: A case control study in which 3’- UTR188 C/T single nucleotide polymorphism (SNP) of LOX-1 were studied in 100 Iraqi subjects: 35 with ACS, 30 have chronic stable angina, and 35 control subjects without CAD. DNA amplification refractory mutant system polymerase chain reaction method was performed the genotyping.

Results: significantly not associated between 3’-UTR188 C/T SNP and the prevalence of ACS among the study groups.

Conclusion: 3’- UTR188 C/T SNP polymorphism in the clinical practice not useful to evaluate the risk for ACS.

Keywords: acute coronary syndromes, Lectin-like oxidized low-density lipoprotein receptor-1 polymorphism, soluble LOX-1, 3’-UTR188 C/T (rs1050283) polymorphism.

Introduction

Coronary artery disease (CAD) is the major cause of morbidity and disability in the world 1. It is almost always due to atherosclerosis the pathogenesis of which is complex. Several risk factors have been identified: age, male sex, smoking, hypertension, diabetes mellitus, dyslipidemia, obesity, sedentary life and heavy alcohol intake myocardial infarction, stroke. Modification of these traditional risk factors has consistently shown a 30% to 40% reduction in mortality and morbidity.

3. Epidemiological studies have shown that genetic predisposition accounts for 40% to 60% of the risk for CAD 4. genetic background of CAD and ACS provide knowledge about the pathogenesis of the illness and the groundwork to build up therapeutic approaches and prevention. Modification of native LDL, particularly its oxidation, is essential for cholesterol accumulation in macrophages and foam cell formation 5. LOX-1 receptor is involved in endothelial dysfunction 6 also known as OLR-1, monocyte union ox-LDL-mediated upregulation of MCP-1 and monocyte adhesion to HCAECs both were suppressed (P<0.01, the migration, proliferation, and apoptosis of fibroblast/smooth muscle cells 7–10 oxidatively (ox-, platelet stimulation 11, as well as plaque unsteadiness 12, all of above are significant in the pathogenesis of atherosclerosis and its complications. Study done in USA was firstly documented the oxidized LDL-receptor
1. LOX-1 is a 50-kDa type II membrane glycoprotein belongs to the C-type lectin family. The lectin-like oxidized LDL receptor gene encoding for LOX-1 receptor is mapped on chromosome 12p13.2-p12.3 and consists of 6 exons interrupted by 5 introns designated lectin-like oxidized LDL receptor-1 (LOX-1). The 3' UTR is an untranslated region found on the 3' side of the coding sequence on mRNA strand immediately following the translation stop codon and plays a critical role in translation stability, termination, as well as post-transcriptional gene expression. It is the non-coding regions of the genome that are responsible for regulation, facilitating complex temporal and spatial gene expression through the combinatorial effect of numerous mechanisms and interactions working together to fine-tune gene expression. The major regions involved in regulation of a particular gene are the 50 and 30 untranslated regions and introns. In addition, pervasive transcription of complex genomes produces a variety of non-coding transcripts that interact with these regions and contribute to regulation. This review discusses recent insights into the regulatory roles of the untranslated gene regions and non-coding RNAs in the control of complex gene expression, as well as the implications of this in terms of organism complexity and evolution. © 2012 The Author(s). Numerous polymorphisms most certainly been documented inside the LOX-1 gene, including a C-to-T substitution inside the 3'untranslated region (3' UTR-C/T; rs1050283) located 188 base pair downstream of the stop codon. This site appointed the binding of ox LDL. The binding of an allele-specific manner with nuclear proteins may be affected by this polymorphism 1820% to 49% stenosis (24.9%). Human being relationship research of various populations have not significant association between gene polymorphisms and CAD and/or its complications, regarding whether polymorphisms within this gene were connected with CAD and/or its complications. Therefore the purpose of study is: evaluation of the prevalence of the single nuclear polymorphism (SNP) of the LOX-1 gene: the 3'UTR C188T in a group of Iraqi population and investigate whether variation in the 3'UTR188 CT (1050283rs), genetic cause of Acute coronary syndrome was LOX-1 gene.

Patient and Method

Study design: This is a case control study conducted at Al-Imamain Al-kadhimain medical city and involved 100 participants (63 male and 37 female). Diagnosis of the clinical syndromes of CAD was ascertained by the attending cardiologist on the basis of history, ECG, hs-Troponin according to American College of Cardiology (ACC) clinical data standard 19.

Study Subjects:

1. Group I: included 35 patients with ACS (20 male, 15 female, mean age 58.77 ± 12.66) admitted to the CCU.

2. Group II: The non-ACS group consists of 30 patients with chronic stable angina pectoris (CSA: 19 male, 11 female, mean age 62.07 ± 10.6) controlled by medical treatment or planning for elective revascularization (25 of them did coronary angiography).

3. Group III: Control group consist of 35 non-ischemic individuals (24 male, 11 male, mean age 46.51 ± 12.54) i.e. those without symptomatic CAD or any significant luminal narrowing on coronary angiography (20 of them).

Detailed personal information (age, gender, body mass index, smoking status, family history, hypertension and diabetes) of all patients collected using a structured questionnaire.

All participants were eligible to give consent and being above 18 years of age. A written consent was taken by all participants.

Exclusion criteria included patients with: peripheral vascular diseases, and stroke.

SNP genotyping: genomic DNA was isolated from fresh blood by using ReliaPrep™ Blood gDNA Miniprep System kit (promega USA). The Polymerase chain reaction (PCR) - amplification refractory mutant system (ARMS) method was used to genotype the 3'UTR188CT (rs1050283) by using two outer primers for amplification and two inner primers for detection of the SNP depending on their melting temperature.; forward inner 5'-TATGTCAACATTTTGTCACTAGGAC-3', reverse inner primer 5'-ACAAGCTAGGTGAAATAATACCGA-3', forward outer 5'-TGGAAGAAAAGAAAAATCTTTGAGTT-3', reverse outer 5'ATGAGGTTAAAGAGACTGAGTTCAGAGG-3'. Melting curve detection for each genotype is done by computerized software according to melting
temperature. The melting range for each genotype is: 82 ± 1 °C for CC, 85 ± 1 °C for TT, and 82 °C ± 1, and 85 °C ± 1 for CT. equilibrium was done at the SNP locus in the entire example. Used chi-square to evaluate allele and genotype frequencies. P < 0.05 reflected statistically significant. Statistical analysis done by SPSS 23.

**Results**

**Clinical characteristics of the study subjects:** The demographic parameters of the study groups were not significantly different except for age and total cholesterol (table 1)

Genotype distribution and allele frequencies of 3’UTR188CT polymorphism were within equilibrium of Hardy-Weinberg (p > 0.05).
Relation of genotype polymorphism with ACS in comparison with other study groups: There were no significant differences in LOX-1 genotype between the study groups, neither in dominant nor recessive model. It seems that the effect of polymorphism is more probably through recessive model (P value 0.09). The frequency of wild type (allele C) and mutant type (allele T) did not differ significantly.

HWE: Hardy – Weinberg equilibrium
Discussion

Many studies have tested the relations between LOX-1 (1050283rs) polymorphisms and CAD or ACS, this study is the original study in Iraq to report the relationship of with CAD and with ACS in particularly and LOX-1 gene polymorphism. Comparison of genotypes (CC, CT, TT), dominant and recessive model and allele frequencies all show no significant association neither for CAD nor for ACS. logistic regression of T carrier to CAD and to ACS in whole population (not shown in results), there was significant correlation to ACS only (P value0.016), but the OR and 95% confidence interval for T carrier was 0.0548 and (0.0051,0.5826) respectively in which the null value (OR=1) is not contained within 95% confidence i.e. the probability that the null hypothesis (rejection of the presence of disease) is more than 5%. However, this can tell that T allele is one of the markers that need to be investigated by a large size study to look for its possible role in clinical practice in connection with ACS risk assessment. This result was in agreement with Sentinelli et al 2006 20 who found no association with CAD in Italian patients (351 patients with CAD and in 215 person as control) , Kurnaz et al 2012 21, in a group of Turkish patients (83 CAD patient vs. 99 healthy control), Wang et al 2010 22, and Trabetti et al 2006 (a total of 677 Italian subjects, 327 CAD-free, 350 CAD, of which 190 with AMI and 160 AMI-free) 23. In contrary Mango et al 2003 24 and Chen Q et al 2003 25 20% to 49% stenosis (24.9% founded an association of the SNP with the threat of MI. samples in Mango research was comparatively small like in our study (150 MI cases and 103 control cases), restricting the research that detect LOX-1 and effects on coronary artery disease and myocardial infarction. while the later research study included 589 white and 122 black women used coronary angiography for diagnosed ischemia. These differences occur due to control group had absent of stenosis after angiography, as in this study (20 out of 35) and sentinelli study (54 out of 215). Thus, undiscovered CAD might be present in the control group. In the study by Mango et al, angiography used to diagnosed controls group (103), and the disease properly evaluated. as a result, chance in a study and small numbers of control cases lead to this no association. another possible explanation for the result divergence is that the different populations and different geographic distribution on which these studies are done, so that ethnic diversity of polymorphisms and environmental factors may play a role.

Conclusion

In this study, relation of the 3'-UTR188 C/T SNP polymorphism with the occurrence of ACS in patients of CAD is still doubtful and need more study on large size population in multi -centers using standardized unbiased methods, enrolling precisely defined CAD patients and well-matched controls to make benefit of the results in the clinical practice to evaluate the risk for atherosclerosis and its related disorders.

Oxytocin Level and Depression Risk in Elderly Iraqi Population

Noor K. Habash¹, Meena M. Abdul–Hussain¹, Khalid M. Jasim², Ammar L. Khazaal³
¹Medical Laboratory Techniques, Dijlah University College, Iraq, ²Al Rashad Training Hospital, Iraq, ³Ibn-rushed Training Hospital, Iraq

ABSTRACT

Depression is a global problem across the world with high morbidity.

Abnormalities in the neuroendocrine, neurohypophyseal system and immune systems have been reported in depression. The possible connection of Oxytocin in psychiatric disorder might predict the risk of depression.

Aim of the Study: Estimation of Oxytocin level in individual could be at risk of depression according to their lifestyle as a resident in nursing home and age compared with currently depressed patients and control volunteers and identify the correlation of Oxytocin concentration with the severity of depression.

Patients and Method: Thirty three patients diagnosed with depression (21 male and 9 female). Thirty five normal control subjects (19 male and 11 female) and seventy volunteers who reside at nursing home (45 male and 25 female). ELISA technique used to measure the Oxytocin levels.

Results: The study found that the Oxytocin value is reduced in patients with depressive disorder compared with control group and similarly values of the third group included in this study to depressive patients levels in which reduction of Oxytocin level. There is a significant association of decreased oxytocin with the severity of depression.

Conclusion: Low concentration of Oxytocin in both patients of depression and tested subjects as group at depression risk compared to normal control reveals that estimation of Oxytocin can be used for prediction of early onset of depression particularly in population with increased other risk factors of development of depressive disorders.

Keywords: depression risk ; elderly Iraqi population ; Oxytocin level.

Introduction

Oxytocin (OXT) is a neuropeptide produced by the hypothalamus, involved in a broad range of physiological and behavioral processes (¹). Recent biological studies are confirming that OXT has also extra-hypothalamic cerebral sites of production and could be involved in many other central processes related to psychiatric conditions such as depression, autism, anxiety or schizophrenia (²). Depression is associated with substantial deficits in quality of life, it is considered the leading cause of disability globally due to nearly about 350 million people worldwide is affected (³,⁴). It is well known that the diagnosis of depression is based exclusively on clinical criteria, particularly there is no currently biological diagnostic marker for assessment and management of this disorder (⁵,⁶). There is a rising number of studies related to the OXT to psychiatric processes and particularly to mood disorders (⁷). Also many human studies revealed that plasma OXT levels are reduced in patients suffering from major depression. (⁸). Among risk factors of depression is the life style and the quality of relationships among families and individuals and the stressful life events, thus the study aimed to evaluate the oxytocin level as a prediction procedure of development of depression in population at risk of this life threatening disorder and may provide the ability of induction the preventable strategies of therapy or improvement of life quality.

DOI Number: 10.5958/0976-5506.2019.03207.8
Patients and Method

Thirty three participants with depressive disorder diagnosed as mild, moderate, and severe depression according to the criteria of ICD−10 (International Statistical Classification of Diseases and Related Health Problems 10th Revision), the samples are collected from Ibn-rushed training hospital for psychiatry, Baghdad, Iraq, from February 2019 to June 2019. The written consent obtained from all the patients and the approval and ethics consideration approved by Ethics Committee of Ibn-rushed training hospital. The exclusion criteria were bipolar disorder, hormonal therapy, pregnancy and lactation for females or using hormonal contraceptives, the patients were 21 male and 9 female mean age 62.71 ± 8.18. The control group were thirty five, 19 male and 11 female mean age 58.42 ± 7.75. Seventy residents in nursing home, 45 male and 25 female mean age 63.67 ± 9.07 with sadness mode and loss of appetite, the information taken by interviews with the volunteers included in this study and reported in the questionnaire. Morning blood samples were collected and centrifuged at 3000rpm, the resultant serum of centrifugation is stored at −40 C°. Serum concentration measured by competitive Enzyme Linked Immuno Sorbent Assay (ELISA) technique. The laboratory measured data are presented as mean ± standard deviation for mean (SDM) to compare the means between the different three groups by using ANOVA.

Receiver Operator Characteristic (ROC) curves used to plot sensitivity and specificity and determine the cut off value. All analyses data were statistically analyzed using Statistical Package for Social Sciences (SPSS), software program version 17.0. A P value less than 0.05 considered statistically significant.

Results

Concentration of OXT in both depressive patient and in subjects at depressive risk group lower than controls, there was a significant difference (P=0.001) as shown in table 1.

Discussion

Understanding the role of OXT level alteration in development of depressive disorders may be useful in correction the reduced levels by different procedures targeting the enhancement of normal OXT. A significant correlation was found in this study of the low level of OXT in patients in comparison with healthy controls \(P\)-value= 0.001) this was similar to that found by Yuen et al. study\(^9\) and Ozsoy et al. study\(^10\). A similar study identified the role of OXT receptor variability in stress resilience for people with AA OXT receptor genotype which found that low level of peripheral OXT is positively correlated with dopamine transporter availability\(^11\). These results suggest that the involvement of OXT in the
organism reacts to stressful conditions may be explained by the correlations between OXT and the dopaminergic system\(^{(2)}\). These studies confirm that the variability in OXT receptor may increase the risk for depression, by favoring a specific biological pattern of increased sensitivity and reactivity to stress\(^{(5,6)}\). The cut off value was found 695.97 in which below show probability for depression with 82.9 and 66.5 for sensitivity and specificity respectively, these results near to a results demonstrated by Abd ElNasr M. Omar et al.\(^{(13)}\) which found 81.82 for sensitivity and 85.7 for specificity. When compared the control group with inhabitants of nursing home the cut off value was 805.002 in which below may indicate increase the risk for depression particularly in population with a number of other risk factors related to their age, attachment and life style, these finding could classify this group as at risk of depressive disorder. The association of OXT level with the severity of depression was statistically significant\(^{(p =0.001)}\). Yet no studies evaluate the correlation of serum Oxytocin and severity of depression.

Study the Activity of 14-3-3 Eta Protein among Ankylosing Spondylitis Patients

May Yahya Al- Ma’amouri

1Department of Medical Laboratories Techniques, Technical Medical Institute of Mansur, Middle Technical University, Iraq

ABSTRACT

Background: Ankylosing spondylitis (AS) is an immune disorder that influence on spine and may affect on other joints. Ankylosing spondylitis occurs in patients under the age of 45 years, and result in disability and reduce the activity of patient if not treated sufficiently.

Objective: Measuring serum level of 14-3-3 eta protein among ankylosing spondylitis patients and evaluate its effectiveness in the diagnosis of disease.

Materials and Method: The study conducted in Al-Yarmouk teaching hospital and involved 40 patients with AS, 40 patients suffer from rheumatoid arthritis (RA) and 20 healthy control. Mean ages were 38 ± 2, 43 ± 2 and 37 ± 2 for healthy control, rheumatoid patients and ankylosing patients respectively. We used ELISA test to estimate 14-3-3 eta protein levels and anti-citrullinate antibodies (ACP) in serum of ankylosing patients in addition to rheumatoid patients and control.

Results: Among 40 ankylosing patients, there were 18 females and 22 males, while rheumatoid patients there were 20 females and 20 males and control there were 10 females and 10 males. There was no significant in age and gender among studied groups, but there was highly significant in both ACP among rheumatoid patients higher than both ankylosing and control.

Conclusion: There is a relationship between 14-3-3 eta protein and both ankylosing spondylitris and rheumatoid arthritis, but with (RA) more than (AS), also there is relationship between ACP and (AS) and (RA), but also with (RA) more than (AS).

Keywords: Ankylosing spondylitis, 14-3-3 eta protein, ACP, Rheumatoid arthritis

Introduction

Ankylosing spondylitis, an inflammatory condition that can cause grouping of bones of joints. Causes of AS is unknown but ecological and hereditary elements may be played a crucial role in this disease which is considered an autoimmune disease (1). It is the main cause of continuing back pain (2)(3). The medical indicators of (RA) and (AS) are different. AS is beginning in the youth phase compared with RA over the age 40 years, and with a male more than female compared with the female prevalence in RA. HLA-B27 antigen plays important role in AS diagnosis while HLA DR4 or DR 1 positives for RA, with 60%. The type and localization of arthritis is the spine and sacroiliac joints with an oligo arthritis of the larger joints such as hips, knees and shoulders in AS, while peripheral polyarthritis in RA, especially hands and feet (4).

Human 14–3-3eta protein is an abundant intracellular protein that plays a role in regulation of cellular practices such as protein production, cellular indicating and the whole biochemical process that occur within a living organism(5).

This study discusses recent advances in 14-3-3 eta protein and its autoantibodies among AS patients and compare with rheumatoid arthritis patients.
Materials and Method

Patients and Samples: We conducted this study in Al-Yarmouk teaching hospital and involved 40 patients with ankylosing spondylitis, 40 patients suffering from rheumatoid arthritis and 20 healthy control. Mean ages were 38 ± 2, 43 ± 2 and 37 ± 2 for healthy controls, rheumatoid patients and ankylosing patients respectively.

Diagnosis: ELISA test was used to estimate 14-3-3 eta protein levels and anti-citrullinate antibodies (ACP) in the serum of ankylosing patients in addition to rheumatoid patients and controls.

Statistical Analysis: Statistical analyses were performed using Least significant difference –LSD test (Analysis of Variation-ANOVA) to significant compare between means of difference groups in study parameters. P-values less than 0.05 were statistically significant (6).

Results

Among 40 ankylosing patients, there were 18 females and 22 males, while rheumatoid patients there were 20 females and 20 males and control there were 10 females and 10 males as shown in table 1.

Means having with the different letters in column differed significantly

Discussion

The result of this study showed that levels of 14-3-3 eta protein in the serum of RA patients were high and highly specific RA more than AS patients and this result agreement with (6) who explain the presence of this protein in the joints of patients with rheumatoid arthritis (RA) (7). Said that serum levels of 14-3-3η is high in RA patients, but not in another disorder. Also there are few studies about using 14-3-3 eta protein with AS such as (8) who clarified in his study that 14-3-3 eta protein was higher than control also these could be a novel biomarkers associated with inflammation in AS.

ACP (anti-citrullinated protein) is raised with high specificity in rheumatoid arthritis (RA), this result agreement with many studies as (9) and (10) who demonstrated that ACPA occurrence has a high analytical exactness for RA And associated with bone loss. In spite of ACP is used especially with RA, but in our study we observed elevated level of this protein in the serum of AS patients and there was any study which explain this result.
Conclusion

From this study we concluded that 14-3-3 eta protein is important for RA more than AS and we recommended other studies to evaluate the activity of ACP and 14-3-3 for AS.

Prevalence of Endodontically Treated Teeth in Baghdad Sub Population

Nadeen Jamal Abdulredah¹, Farah Salahaldeen Abbas¹
¹Department of Conservative Dentistry, Dental College, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

Aim: To determine the pattern of demand for endodontic treatment among patients attending Aleulawih dental speciality center in Baghdad, Iraq.

Method: A retrospective review of the patients’ dental records who attended the Conservative Dental Clinic of Aleulawih dental speciality center in Baghdad, Iraq from January 2018 to October 2018 for root canal therapy (RCT) was done. The demographic and clinical data were retrieved from the patients’ records and analyzed using the SPSS version 20. The data were categorized as follows: 1- The total number of maxillary and mandibular teeth. 2- The number of each individual tooth group treated. 3- The number of teeth treated in age groups (10-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70 and above) years. 4- The total number of treatments performed in males and females patients.

Results and Conclusion: The maxillary teeth showed higher percentage (56.3 %) of root canal treatment than mandibular teeth (43.7 %), while mandibular 1st molars show higher percentage (56.2 %) in the treated cases than other teeth. The highest incidence of root canal treatment was found in the age group twenty to twenty-nine (29.2 %). The male patients were more frequent (50.3 %) than female patients.

Keywords: Endodontic epidemiology, Patient demands, Retrospective study, Root canal therapy.

Introduction

Bacteria and their by-products can spread into periapical tissues after ingression dental pulp by dental caries and trauma (1). Tooth preservation is the ultimate goal of modern dental care and endodontic treatment is one of the most technically demanding procedures and a very specialized aspect in restorative dentistry requiring high level of technical skills (2, 3).

It is important to acknowledge that diseases, apical periodontitis included, are in addition influenced by more distant causes such as dentists’ skills and attitudes, behavior and priorities among people and characteristics of their social environment. These factors form causal patterns by interacting in complicated ways and they may be even more important causes of disease than more directly related cause the pathogens (4). Epidemiological studies are the only scientific approach to enlighten such interactions and thereby broaden our concept of health and disease.

Different epidemiological studies have been done on prevalence and conditions of the periapical periodontal tissues of root-filled teeth in population. Some studies assessed the total number of endodontically treated teeth, while others concentrating on the number of persons with endodontic treatment in the population and finally presence and absence of periapical periodontitis in endodontically treated teeth (5-8).

The rate of dentate individuals has increased over the last decades and the prevalence of root-filled teeth has also increased with age. This change in frequency of dentate individuals in the population may be due to the new and better restorative materials and methods also a declining tendency amongst dentists to extract teeth (9).

There are limited epidemiologic studies relating to the pattern of demand of Root Canal Therapy in
Iraq. Information on pattern of demand for treatment is necessary for understanding disease pattern also for devising optimal preventive and management strategies\(^{(10)}\).

Considering the importance of epidemiological investigations, the aim of this study was to determine the prevalence of endodontically treated teeth in relation to age and gender in Baghdad sub population.

It is important to identify the most frequently involved tooth and pattern of tooth surfaces involvement in caries, to identify the location of the tooth and to reinforce oral hygiene measures from the time of eruption of the tooth. These measures might prevent pulpal exposure and the need for endodontic therapy in the future\(^{(11)}\).

**Aim of the study:** To determine pattern of demand for endodontic treatment among patients attending Aleulawih dental specialty center in Baghdad, Iraq.

**Material and Method**

A retrospective review of the patients’ dental records who attended the Conservative Dental Clinic of Aleulawih dental speciality center in Baghdad, Iraq from January 2018 to October 2018 for root canal therapy (RCT) was done. The demographic and clinical data were retrieved from the patients’ records and analyzed using the SPSS version 20.

The data were categorized as follows: 1- The total number of maxillary and mandibular teeth. 2- The number of each individual tooth group treated. 3- The number of teeth treated in age groups (10-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70 years and above) years. 4- The total number of treatments performed in males and females patients.

**Results**

There were 1594 patients comprising 801(50.3%) males and 793(49.7%) females. A total number of 1594 teeth were treated.

The age range of patients was 10-70 years old while median age was 40 years. The highest incidence of root canal treatment 29.2% was found in the 20-29 years age group, this was followed by 30-39 years age group which constituted 26.4%. The 70 years and above had the least number of patients as shown in table (1).

Maxillary teeth underwent higher percentage of root canal treatment (56.3%) as against mandibular teeth were treatment was done in (43.7%) as shown in table (1).

Discussion

The results of our study reported a higher incidence of root canal treatment were in males, this is in agreement with studies of Osama et al (12), Oginni (13) and studies done by Kamberi et al (1) and Tareen et al (14), they reported that the prevalence of endodontically treated teeth was significantly higher in males than the females. One explanation for our results may be related to socio-psychological aspects of females and they are more passionate and interested about their oral health, though they attend dental clinics for various treatments more frequently than males (15).

Most of the patients that presented were found in the 20-29 years age group. This can be partly attributed to the location of dental specialty center and high prevalence of dental caries often reported among young adults (16). Our results are in agreement with that of Farrel & Burke (17) which reported a higher incidence between twenty one & thirty years age group.

In this study molars, then premolars required significantly more frequent endodontic treatment than anterior teeth and this is in agreement with studies (11,18) and in agreement with study of Oglah et al (13). The most probable reason was that molars are more susceptible to food stagnation than the anterior teeth.

The percentage of endodontic treatment was higher in premolars than incisors in both arches. This could be related to the anterior position of the incisors in the oral cavity; hence the caries can be easily detected by the patient in the early stage (13).

Our study reported that there was a higher incidence of root canal treatment in the mandibular first molar; this could be related to that it is the first tooth to erupt in the oral cavity; hence it was more prone to caries (3,19).

In our study the maxillary teeth were the most frequent treated than mandibular teeth. This could be related to the aesthetic reason, as the upper teeth appear more prominent than the lower teeth during smile, making the patient more interested to preserve the upper teeth (13). This pattern was in agreement with that of Scavo et al (18) and Al-Negrish (20) who reported that 55.69% and 77.7% of their RCTs were performed in maxillary teeth.

Information about frequency and distribution of endodontically treated teeth may help predict future needs for dental treatment in the growing dental population (11).

Conclusion

Maxillary teeth showed higher percentage of endodontic treatment than mandibular teeth with higher incidence in lower molars than other teeth groups. The age between twenty to twenty-nine years have higher percent of root canal treatment than other ages with higher frequency in male than female patients.

Study the Inflammatory Biomarkers of Acute Coronary Syndrome Patients in Wasit Province

Sama Ali AL-Rubaie¹, Mohammed R.S.AL-Attabi¹, Alaa A. AL-Kinani²

¹Department of Biology, College of Science, Wasit University, Wasit, Iraq; ²Al-Zahraa Teaching Hospital, Wasit Health Office, Ministry of Health and Ecology, Iraq

ABSTRACT

This prospective study was performed in the coronary care unit at AL-Zahraa teaching hospital in Wasit Governorate during the period from January 2018 to June 2018. This study explained the role of inflammatory biomarkers in proper diagnosis, risk stratification and prognostic evaluation of patients with acute coronary syndrome (ACS). A total of 100 patients with ACS, 77 men aged 25-90 years and 23 women aged 45-85 years. They were divided into three age groups. The first group was <45 years old, the second group was 45-60 years old and the third group was >60 years. The risk factors for ACS include gender, age, HT, diabetes, smoking, and dyslipidemia through a questionnaire. Our study revealed that male to female ratio was 3:1 and demonstrate that male gender and HT were most prevalent risk factor for ACS. Regarding white blood cells and the rate of Erythrocyte sedimentation rate, the results showed a significant increase in white blood cells, neutrophils and the rate of red blood cell deposition at P≤0.05. The results of our study showed a significant increase in the markers of the acute phase protein, which showed a significant increase in the value of fibrinogen and C-reactive protein(CRP) at P≤0.05. Regarding biomarker of myocardial ischemia, there was a significant increase in troponin and creatinine kinase at P≤0.05. There was high 30 day mortality among patients with high level of inflammatory biomarker (fibrinogen and CRP), biomarkers of myocardial ischemia(troponin and CK-MB) and those with markedly elevated WBC count.

Keywords: ACS, Inflammatory, Biomarker

Introduction

Coronary heart disease (CHD) is the leading cause of death in developed countries¹. CHD can affect individuals at any age, but becomes significantly more common with progressive age. Males are affected more often than females. Atherogenesis refers to the development of atheromatous plaques, which is characterized by arterial remodeling and fatty accumulation in subendothelia. As atherosclerosis develops, myocardial ischemia leads to myocardial hypoxia and myocardial death². ACS includes unstable angina (UA), non-ST elevation myocardial infarction (NSTEMI), and ST elevation myocardial infarction (STEMI). Diagnosis of ACS based on history, ECG finding, Echocardiography and inflammatory biomarker³.

Inflammation is essential to the initiation, development, and progression of atherosclerosis⁴. Acute-phase response proteins markers include serum C-reactive protein (CRP), pentraxin 3 (PTX3), amyloid A, homocysteine, and fibrinogen⁵⁶. CRP is an inflammatory biomarker directly participates in atherogenesis and useful in short-term prognosis and long-term risk assessment for cardiovascular disease patients⁶. Fibrinogen (factor I) is a glycoprotein during tissue and vascular injury, it is converted enzymatically by thrombin to fibrin and subsequently to a fibrin-based blood clot⁷. Troponin, is a complex of three regulatory proteins (troponin C, troponin I, and troponin T) that is integral to muscle contraction in skeletal muscle and cardiac muscle, but not smooth muscle and troponin often usefull as a diagnostic and prognostic marker. Its highly specific marker for myocardial infarction⁸. Creatine kinase (CK) is an enzyme assayed in blood tests as a marker of damage of CK-rich tissue⁹. So the aims of the study was to determine the Role of inflammatory biomarkers in proper diagnosis, risk stratification and prognostic evaluation of patients with ACS.
Material and Method

Study design: A total of 100 patients in the coronary care unit at AL-Zahraa teaching hospital from “January 2018 - June 2018”, with age ranged between (24 to 90 Year). Patients presented with chest pain, ECG and Echo findings of myocardial ischemia. Risk factor for IHD were evaluated. Biomarker of myocardial ischemia (Troponin and CK-MB) and acute phase proteins (CRP and Fibrinogen) were tested for all patients.

Blood sample: 8 ml of venous blood were withdrawn and 2 ml was placed in a tube containing Ethylene diamine tetra acetate for checking the complete blood count and ESR. 1.8 ml was placed in a tube containing sodium citrate to obtain the plasma for measurement of the first coagulation factor level (fibrinogen), and 4.2 ml in a tube containing gel and clot activator for check the level of troponin, CK-MB and CRP. White blood cell differential and ESR testing was done using a complete blood measurement Device Cell-DYN Ruby. Hemostat Fibrinogen testing is based on the most commonly used method first described by Clauss. The CRP-latex is a slide agglutination test for the qualitative and semi quantitative detection of CRP. High sensitive troponin I (TNHS) was evaluated by a one-step enzyme immunoassay sandwich method with a final fluorescent detection (ELFA). CK enzyme was assessed by Immunological UV assay.

Statistical Analysis: The descriptive statistics analyzed by using one-way analysis of variance (ANOVA) were performed using means and standard deviations (SDs) with LSD test for continuous variables (p ≤ 0.05) was considered to be significant, and independent–sample T Test for woman group (P-value ≤0.01) was considered to be significant. All analyses were performed with computerized SPSS program (statistical program for social sciences).

Results

A total of 100 patients with ACS were included in this study, Male to Female ratio was 3:1. The most predominant age group in Male patients was 45-60 years (second age group) 39:77 (50.65%) and in women was >60 years (Third age group) 17:23 (73.91%).

There was no clear significance in p-value (p≤0.05) of WBC count between age group in men. On other hand there were significant p-value (p≤0.05) of WBC, Neutrophil, Monocyte and ESR in women age group.

Table (1) and (2) show the acute phase proteins in both gender. There were no clear significant of Fibrinogen in men regarding age group while there were significant P-value (p≤ 0.05) in women. On other side results showed that there were high number of positive CRP in the second age group in men while the highest number was found in the third age group of women.

Discussion

This study focused on clinical study of patients with ACS intermingled with role of inflammatory biomarker for risk stratification. In this study, it was found that males to females distribution was (77%: 23%) respectively and these results was similar to result of Jordanian study (78.3%: 21.7%)9, but not similar to Qazvin population (50.2%: 49.8%)10and Tehran studies (41%: 59%)11. The mean age of male patients was (56.23 ± 12.89 year) similar to that in Tehran study (54 ± 12 year) and the mean age of female patients was (65.65 ± 10.16 year) that is near to Arab and Jewish women study (68 ± 9 and 63 ± 9 year)12. Advancing age is the most powerful independent risk factor for cardiovascular disease among both gender 13. Our study revealed that CAD was more common in postmenopausal women because endogenous estrogens delays the manifestation of atherosclerotic disease in women by its regulating effect on lipids, inflammatory markers and the coagulant system and direct vasodilatory effect 14.

Regarding WBC count, leukocytosis was observed in 41% of patients. Neutrophil count was increase in 52% of patients. Monocyte count was increased in 26% of patients and ESR was increased in 55% of patients. Our results agreed with Yayan J et al15. Correlation of the leukocyte count with CAD was consistent with current concept that atherosclerosis is an inflammatory disease and the utility of the leukocyte count as a risk factor and prognostic indicator16. Monocyte-derived macrophages produce oxidants that can induce endothelial cell injury and subsequent thrombus formation 17.
Regarding the acute phase proteins, 91 patients (91%) had elevated fibrinogen level, 70 patients (76.92%) was male and 21 patients (23.07%) was female. The result agreed with Ajeed A. M.\(^2\) 90 %. The fibrinogen form individual fibrin strands that cross-linked by blood factor XIIIa to form a mature fibrin clot\(^3\).

The results of CRP revealed that 64 patients (64%) had positive CRP, 46 patients (59.74%) was male and 18 patients (78.26%) was female. These are consistent with the findings of the researchers Li. H \(et\ al\) \(^19\). The CRP increased in the condition of injury, infection, and other inflammatory stimuli. There were agreement with the previous study by Zebras \(et\ al\)\(^20\) who showed that CRP levels are higher after AMI and unstable angina. They also showed that CRP was strongly predictive of long-term death from MI for patients presenting with ACS\(^20\).

We found no correlation between inflammatory marker CRP and CK-MB cardiac enzyme in these patients. These are in agreement with that of Auer \(et\ al\)\(^21\), this may be explained by the fact that CRP levels peaked around 50 hours after the onset of pain, a time when CK-MB which peaked after about 15 hours, had already returned to normal.

Through our survey 71 patients (71%) had positive troponin, 54 patients (76%) was male and 17 patients (24%) was female. Our result of troponin percentage agreed with Melanson \(et\ al\)\(^22\) 64% and Nicholas \(et\ al\)\(^23\) that show troponin positive in 68% of the patients. The increase in troponin results from the erosion and rupture of a fibrous cap containing a lipid-rich atherosclerotic plaque\(^23\). Troponin are released during myocyte damage and necrosis, and represent the cornerstone of the diagnosis of ACS\(^1\). CK-MB enzyme is elevated in patients with myocardial infarction, as a result of damage to myocardial cells\(^23\). The result of CKMB revealed that 56 patients (56%) had positive CKMB, 48 patients (85.71%) was male and 8 patients (14.28%) was female and these agreed with Patel S \(et\ al\)\(^26\) that show Troponin I and CK-MB levels in STEMI patients were statistically highly significant with ‘p’ value of <0.0001. This is consistent with the studies conducted by previous researchers Joarder \(et\ al\) reported that Serum cTnI is better and more characteristic biomarker than CK-MB for risk prediction and prognosis in AMI patients. Cardiac troponin-I has high specificity for cardiac injury because it is not found in skeletal muscle\(^27\). Previous studies have supported the prognostic value of the WBC as a predictor of heart failure and death in both short term and long term following ACS\(^29\). In our study the CRP and fibrinogen were separately associated with increased risk of 30 days mortality independent of conventional cardiovascular risk factors. Steinberg \(et\ al\) found that elevated troponin-I levels greater than 1 ng/ml in patients with acute MI to be positively correlated with death within 30 days and correlation between elevated troponin-I and death was independent of CK-MB levels\(^29\). MISSION Trial and GUSTO IIa trial showed that peak troponin T levels are a good estimate of infarct size, left ventricular function and was significantly predictive of 30-day mortality in patients with acute MI\(^30\).

**Conclusion**

CAD was more common in male patients of all age group, male to female ratio was 3:1. One or more risk factors patient had more CAD developed. Acute phase protein, biomarker of myocardial ischemia and leukocyte count are important parameter for proper diagnosis and risk stratification of patients with ACS.

The Impact of Nd-YAG Laser on Salivary Streptococcus Mutans and Lactobacilli in Vitro

Khamal IM. Al-Hasnawi1, Nada Jafer MH. Radhi1
1Pedodontic and Preventive Dentistry Department, Collage of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Laser has an antibacterial action on dentine and enamel through the vaporization of cariogenic bacteria (Streptococcus mutans and Lactobacilli). Many investigations related to the application of Neodymium doped yttrium–aluminium–garnet (Nd:YAG) laser in preventive dentistry have been proposed as caries prevention therapies.

Aim of the Study: The aim of the study was to investigate the antibacterial effect of Nd-YAG laser on the viable counts of salivary mutans streptococci and lactobacilli.

Materials and Method: Standardized suspensions of bacterial growth of Streptococcus Mutans and Lactobacilli that each one were inoculated in seven sterile screw capped bottles, one of them was control and the other six were the study bottles (study groups) exposed to Nd-YAG laser beam at different powers and different exposure times.

Results: The results of Streptococcus mutans and Lactobacilli, which exposed to Nd-YAG laser, showed a heavy bacterial growth in the control group, but after radiation, there was a reduction in the mean values of CFU/ml for Streptococcus Mutans, while heavy reduction in the mean values of CFU/ml for Lactobacilli, with the maximum reduction was in the group that was exposed to (80mj for 30s) for two bacteria.

Conclusion: The Nd-YAG laser was represented antibacterial effect on Lactobacilli with minimal exposure time and energy, while less effect on Streptococcus mutans with maximum energy and exposure time.

Keywords: Nd:YAG laser, Streptococcus mutans, Lactobacilli.

Introduction

Dental caries is a localised chemical dissolution of dental hard tissues that is caused by acidic by-products of the metabolic processes of the biofilm (dental plaque) covering an affected tooth surface. When fermentable foods are eaten frequently, the low pH in the plaque is sustained and a net loss of mineral from the tooth occurs. This low pH selects for aciduric organisms, such as S. mutans and lactobacilli. Mutans streptococci and lactobacilli are strong acid producers and hence cause an acidic environment creating the risk for cavities. Lactobacilli are considered secondary invaders rather than initiators of the caries process. The presence of these microorganisms is also dependent on the size of the cavity: they are more numerous in medium and large cavities. Many studies showed a positive association between Streptococcus mutans and initiation of a carious lesion, such studies demonstrated that these bacteria can be isolated from dental plaque adjacent to a carious tooth surface.

LASER is the acronym of the words ‘Light Amplification by Stimulated Emission of Radiation’. The Nd: YAG laser is classified as solid-state laser because it contains a solid lasing medium (Neodymium-doped yttrium aluminum garnet). Nd: YAG laser (1064 nm) is one of the laser systems that have many applications in the dental field. Irradiation with Nd: YAG laser is absorbed by protein (high affinity to melanin) and mineral structures, such as phosphates and carbonate hydroxyapatite, as well as water (low affinity). Utilizing thermal stresses created inside the tissue, Nd:
YAG disorganizes the skeleton of bacterial cells. In this process, protein denaturation takes place and the bacterial cells die \(^{(9)}\).

**Materials and Method**

In this study, Nd-YAG laser radiation effect was tested at different times and powers on the viable counts of *Streptococcus Mutans* and *Lactobacilli*. Fresh clinical isolates of *Streptococcus Mutans* and *Lactobacilli* were retrieved from saliva samples of patients with dental caries using: *Mitis Salivarius* Agar Base and LBS Agar (*Lactobacillus* Selection Agar). Pure isolates of the bacteria were preserved in nutrient agar in the refrigerator until required for the study. *Streptococcus Mutans* and *Lactobacilli* isolates were inoculated in 10 ml of the nutrient broth (pH 7.0), then incubated anaerobically in anaerobic jars containing a range of atmospheric concentrations of CO\(_2\) of about 5%. at 37°C for (18- 24) hrs for activation before the conduction of the experiment in the study \(^{(10)}\). Standardized suspensions of bacterial growth that contained 108 (McFarland Standard 0.5) were inoculated in seven sterile screw capped bottles near the burner in aseptic conditions, one of them without irradiation of Nd-YAG laser (as a control group) and the other six were the study bottles (study groups) exposed to Nd-YAG laser beam. The beam of Nd-YAG laser was directed perpendicularly to a mirror that reflects the beam directly to the opening of the bottle, in a pulse mode \(^{(11)}\). Samples were subjected to laser irradiation at different energies (40mj, 80mj) and different exposure times (5sec., 15sec., 30sec.) \(^{(12)}\). After exposure to laser radiation, 0.1ml of the irradiated suspension was spread over the surface of brain heart infusion agar plates for each isolate. Then plates incubated aerobically at 37 °C for 24 hrs according to the nature growth of bacteria until the growth was visible \(^{(7)}\). The irradiation experiments were done in sterilized hood. The microbiological assay was carried out by counting the CFU for all tubes \(^{(13)}\). Using the following formula, the CFU/ml can be calculated: CFU/ml = No. of colonies x 1/dilution factor x 10 \(^{(14)}\).

**Results**

Many tubes of the broth of *Streptococcus Mutans* and *Lactobacilli* exposed to Nd-YAG laser at different energies and exposure times. Results showed a heavy bacterial growth in control group, but after radiation, there was a reduction in the mean values of CFU/ml for *Streptococcus Mutans*, while heavy reduction in the mean values of CFU/ml for *Lactobacilli*, with the maximum reduction was in the group that was exposed to (80mj for 30s) for both bacteria. Finding showed that there was a highly significant difference regarding both of bacteria at different energies and times between them \((p> 0.01)\), but Levene test of homogeneity showed non significancy because the control group non irradiated with laser, so Dunnett test was used (2-sided) that treat one group as a control, and compare all other groups against it as shown in Tables (1) and (2) that there was a statistically highly significant difference \((p> 0.01)\), except in *Streptococcus Mutans*, in (40mj-5s), the result was non significant \((p>0.05)\), and in (40mj-15s), the result was found significant \((p>0.05)\).

By using pairwise Adjustment for several comparisons (Bonferroni) as shown in Table (3), at energy 40mj (5s, 15s) non significant difference \((p<0.05)\), but the other groups of the same energy (5s, 30s), (15s, 30s) with energy 80mj (5s, 15s), (5s, 30s), (15s, 30s) were highly significant difference \((p> 0.01)\).

In Table (4), showed that there was non significant difference between times (5s, 15s and 30s) within energy (80mj) \((p< 0.05)\), while the energy group (40mj) was revealed to be highly significant \((p>0.01)\).

In Table (5) the result revealed that there was a highly significant difference, in bacterial number between time within each power group \((p>0.01)\).

Table (6) revealed that there was a highly significant difference, in bacterial number between time within each energy group in group (5s) \((p>0.01)\), and in groups (15s, 30s) the result was shown to be significant \((p>0.05)\).

Discussion

The present study showed a heavy bacterial growth in control group, but after radiation, there was a reduction in the mean values of CFU/ml for *Streptococcus Mutans*, while heavy reduction in the mean values of CFU/ml for *Lactobacilli*, with the maximum reduction was in the group that was exposed to (80mj for 30s) for both bacteria. Thermal reaction deals with biological properties related to different temperatures inside the cells, depending on the kind of irradiated cell and laser parameters chosen. Therefore thermal effect of Nd:YAG laser radiation on the bacterial cell result multiple biological effect such as decrease in enzyme activity, cell immovability, disintegration of protein, increase the permeability, evaporation, and thermal breakdown (i.e. great damage and burst cell) that may happen at elevated temperature (15). The Nd:YAG laser is absorbed selectively by definite pigment, comprising melanin, hemoglobin and probably the pigments found in bacteria and microorganisms, which might consider it as a perfect bactericidal (16). The blood or blood contents in a natural situation might increase the counting of porphyrins and melanin pigments in the bacteria in which the bactericidal outcome is enhanced by Nd:YAG laser (17). Additional remarkable feature is the dentin, which was observed more carefully in a study of Jalil (18). An evaluation of studies searching the antimicrobial influence of laser light is not simple to understand because the reports about energy density or experimental circumstances are almost deficient. Elevated cell density and the existence of extracellular matrix, also, nonpigmented bacteria describes the reduced effect of Nd:YAG laser on agar dishes and bacterial broth. Multiple readings have presented that the bactericidal effect of the Nd:YAG laser in the dental structure is reinforced over enamel prisms and dentinal tubules as this effort considered as a bright guide, on the other hand, more studies in vivo are necessary (19).

Dentine with carious lesions absorption 1064 nm extra wavelength in relationship to sound dentin, which rise the preferred bactericidal outcome. The decrease in the number of bacteria (CFU/ml) are established by Jacobs, in their work, the Nd:YAG laser effect on *Lactobacillus*, in vitro (20).

The depth of penetration in dentin influenced by many absorption of wavelengths. The bacteria establish in deeper dentinal tubules had a lesser influence by Er:YAG laser, while the Nd:YAG laser was really higher (18). This clarify the smaller influence of Nd:YAG on *Streptococcus mutans* with higher energy and additional exposure time, that used in present study. The different bacterial species could have dissimilar susceptibility to laser, besides might be because of multiple experimental techniques and materials (21).

The Activity of 5-Flurouracil Metabolizing Enzyme Dihydropyrimidine Dehydrogenase (DPD) and its Association with Tumor Progression and Markers (CEA, CA19.9) in Patients with Colorectal Cancer

Hadel Kareem AL-Rubaiawi¹, Raid J. Mohamed¹
¹Department of Chemistry and Biochemistry, Collage of medicine, Al-Nahrain University, Iraq

ABSTRACT
For the last seventy years, the fluoropyrimidine 5-fluorouracil (5-FU) has been placed as the first line chemotherapy in the treatment of various cancers including colorectal. DPD mediated conversion of 5-Flurouracil to dihydrofluorouracil (DHFU) is the rate-limiting step of 5-Flurouracil catabolism. The response rates of the 5-Flurouracil for advanced CRC is less .5-FU causes severe toxic effects with deficiency of DPD enzyme. The aim of this study was to Evaluate the kinetic and concentration of DPD in tissue with different stage of CRC, as well as Correlation between enzyme concentration and biomarker (CEA.CA19.9).

Method: By using an ELISA kit for level of DPD and spectrophotometer for activity, in serum and tissue we measured The level and the activity of DPD enzyme in 60 subject in Iraq includes: 30 patients with advance stage of CRC, 30 patients with early CRC and 30 healthy control We also measured serum CEA19.9 and CEA levels.

Results: The result of the current study showed that serum and tissue activity of DPD in Advance CRC patient very high relative activity compared with early CRC patients and control. Moreover, the activity of DPD in early CRC patient higher than control. Level of tissue DPD shown a significant different between Advance and early CRC patient tissue and normal tissue. While no significant difference in mean serum level of DPD between CRC patient (advance and early) and healthy control. Moreover, DPD showed a moderate correlation with CA19-9 in CRC patients (early and advance) which was close to significant.

Conclusions: In patients with advanced CRC, there is a hyperactivity of DPD in serum and tumor tissues.

Keywords: Colorectal cancer, Dihydropyrimidin dehydrogenase, 5- Fluorouracil, Elisa

Introduction
Colorectal cancer (CRC) it is the second leading cause of the cancer-related mortality in the world, with around 655,000 deaths worldwide in every year.(1,2)

The majority of this cancer-related deaths could be stopped by applying existing knowledge about cancer prevention, can increasing the use of recommended checking tests, and ensuring that’s the all patients timely received the standard treatment.(3) In the past decade, there has been wonderful progress in reducing both the incidence and mortality average of the colorectal cancer in the world. Largely due to the prevention and the early detection of CRC through the screening (4)

CRC usually develops so slowly, over a period of ten to twenty years, with most starting as non-cancerous growths develops on the inner layer of the colon or the rectum. The most current kind of polyp is called an adenomatous polyp or the adenoma these adenomas grow from glandular cells, which secrete mucus to the lubricate the colorectum. An evaluated one-third of patients will eventually develops one or more adenomas progressing to the invasive cancer. As the adenoma becomes bigger and larger, there is an increasing

If found in patient early colorectal cancer can be successfully treated. The current treatment of the colorectal cancer at most depends on surgery, radiotherapy, chemotherapy and the targeted therapy.\(^{(5)}\) Depending on the stage of cancer growth, gathering of two or more treatments are often recommended to achieve the best result.

The Surgery is the main treatment option for the CRC wherein the tumor surround healthy tissue and adjacent lymph nodes must be removed. The 5 year relative survival rates of patients with CRC metastasis to distant organs is much minimize than CRC patients at the earlier stages. The current pharmacotherapy, such as chemotherapy, and the targeted therapy act on the cancer cells principally through the cell apoptosis, cell senescence and autophagy.\(^{(6)}\)

The existing therapeutic compounds for treatment of the CRC are several. They include cytotoxic agents (oxaliplatin, 5-fluorouracil, capcitabine and irinotecan), targeted therapies (the anti-vascular endothelial growth factor-A antibody \([\text{bevacizumab}]\), and the anti-epidermal growth factor receptor antibodies \([\text{cetuximab, and panitumumab}]\)).

For the last seventy years, the fluoropyrimidine 5-fluorouracil (5-FU) has been placed as a first line chemotherapy in the treatment of various cancers including colorectal, neck, head and breast cancers.\(^{(7,8)}\) This combination has multiple mechanisms of the cytotoxicity including the inhibition of the enzyme thymidylate synthase, which is improve overall and disease-free survival of the patients with resected stage III CRC.\(^{(9)}\)

The response rates of the 5-Flurouracil for advanced CRC is less than fifteen percent, and the bioavailability is also limited.\(^{(10)}\) Furthermore, 5-Flurouracil causes severe toxic effects on gastrointestinal tract, hematological, cardiac, neural and dermatological reactions.\(^{(10,11)}\) Hence, there is a need to identify a possibility drug delivery system for 5-Flurouracil to achieve better therapeutic activity with fewer side effects.

5-Flurouracil is converted to the fluorodeoxyuridine monophosphate (FdUMP), which forms a stable complex with the enzyme thymidylate synthase (TS), and thus inhibits the deoxothyimidine mono-phosphate (dTMP) production. dTMP is essential for the DNA replication and repair and its depletion therefore causes the cytotoxicity.\(^{(12)}\) Dihydropyrimidine dehydrogenase (DPD)-mediated conversion of 5-Flurouracil to dihydrofluorouracil (DHFU) is the rate-limiting step of 5-Flurouracil catabolism in normal and tumor cells. Up to eighty percent of administered 5-Flurouracil is broken down by DPD enzyme in the liver.\(^{(13)}\)

**Materials and Method**

**Study Subjects:** The present study included 90 subject includes: 30 patients with advance CRC, 30 patients with early CRC and 30 healthy control. Serum and tissue was collected. The tumor tissues were surgically removed from colorectal tumor patients by either mastectomy or lumpectomy and the other from normal surrounding tissues. samples collected between September 2018 and April 2019. Patients were divided into three groups; control, Advance CRC patients and early CRC patients. All sample collected before chemotherapy.

**Measurement level and activity of DPD enzyme in serum and tissue:** Level of DPD in serum and tissue by using Elisa technique. while method for determination the activity of DPD enzyme in sera and tissue by using spectrophotometer according to Podschun et al. (1993)\(^{(14)}\)

DPD activity was measured at room temperature \((25^\circC)\) 1 ml of the total reaction volume contained phosphate buffer \((35\text{mM, P7.4}),\) dithioerythritol \((20\text{mM}),\) MgCl\(_2\).H\(_2\)O \((280\text{mM}),\) Uracil \((1500\text{ µM})\) and NADPH \((600\text{µM})\). The Activity was measured by monitoring the lowering in the absorbance at 340nm due to oxidation of the NADPH to NADP+. One enzyme unit is defined as the oxidation of one mmol NADPH per min under the assay conditions.

**Statistical Analysis:** The data that obtain could be analyzed using SPSS version Analysis of variance will be used to compare means between the different groups and person’s correlation will be used to find out any correlation between serum concentrations of enzymes and tumor marker.

**Result**

**Levels of DPD Enzyme in serum and tissue:** Median serum level of DPD enzyme in healthy control groups (1.7 ng/ml, range 0.16-9.95 ng/ml) was slightly higher than that of early CRC patients (1.63 ng/ml, range 0.16-10 ng/ml) or advance CRC patients (1.61 ng/ml, range 0.16-8.4 ng/ml)
Data regarding tissue concentration of DPD enzymes were found to be normally distributed and therefore were expressed as mean ± SD. (Mean tissue concentration of DPD in advance CRC patients (0.32 ± 0.063 ng/mL) was far much higher than either healthy controls (0.065 ± 0.041 ng/mL) or early CRC patients (0.14 ± 0.042 ng/mL) with highly significant differences. Moreover, early CRC patients differed significantly from healthy controls as shown in (figure 1).

Figure 1: mean PDP activity in tissue and serum in CRC patients and controls

DPD Activity in Serum and tissue: Mean serum activity of DPD enzyme in advance CRC patients was 3.22 ± 1.27 U/mL compared with 0.43 ± 0.194 U/mL in early CRC patients and 0.189 ± 0.08 U/mL in healthy controls with highly significant differences. Although early CRC patients had higher DPD activity than healthy controls, the difference was not a significant (Figure 2).

As in case of serum, DPD showed a very high relative activity in tissue in advance CRC patients (3.61 ± 0.44 U/mL) compared with 1.64 ± 0.36 U/mL in early CRC patients and 0.8 ± 0.15 U/mL in healthy controls with highly significant differences (Figure 2). Moreover, there was a significant difference between early CRC patients and healthy controls in DPD activity in tissue.

Figure 2: mean PDP activity in tissue and serum in CRC patients and controls

Correlations between Enzymes and Tumor Markers:
Generally, there were positive non- significant correlations between DPD with each of CA\textsubscript{19,9} and CEA on the other side DPD showed a moderate correlation with CA\textsubscript{19,9} in CRC patients (early and advance) which was close to significant (p= 0.08).

Discussion
ELISA technique was employed to measure serum and tissue level of DPD. The current study revealed no significant difference in mean serum level of DPD between CRC patient (advance and early) and healthy control. This is the first study in Iraq measuring serum concentration of DPD and compared with stages of CRC patient and healthy control before chemotherapy. In tissue DPD enzyme shown a significant different between Advance and early CRC patient tissue and normal tissue, which was level of DPD enzyme was approximately 4 fold higher in colorectal tissue compared with normal colorectal tissues. The DPD in advance CRC patient tissues was approximately 2 fold higher than that in early CRC patient tissue.

The study suggests increasing DPD level in tissue with differential of tumor because large amount of tissue and specimens for determination are always contaminate by lymphocytes which have the highest DPD activity in the many types of tissue measured (15)

This is consistent with the result of a study of Ishibashi, Keiichiro, et al. (2009) (16) who compared...
DPD level in primary CRC and metastasis stage of CRC in 103 individuals. Level of DPD was determined by enzyme-linked immunosorbent assay (ELISA).

The result of the current study showed that serum and tissue activity of DPD in Advance CRC patient very high relative activity compared with early CRC patients and control. Moreover, the activity of DPD in early CRC patient higher than control.

The result is totally agreeing with the result of study of Mizutani, Y., et al. (2001) (17), who investigated the activity of DPD in 74 bladder cancers and studied the relationship between the DPD activity and stages of cancer. The activity of DPD was approximately 2-fold higher in bladder cancer tissues compared with normal bladder tissues. DPD activity in invasive bladder cancers was approximately 2-fold higher than that in superficial cancers.

This high DPD activity in the CRC tissues compared with normal tissues may contribute to the unfavorable differential between anticancer effect and adverse effect of 5-FU. Thus, the high 5-FU degradation may occur in cancer tissues, compared that with normal tissues. this finding suggest that DPD may play role in 5-FU resistance through increase inactivation of 5-FU cancer cells of (17)

The present study also agrees with Nagakawa, et al. (2002) (18) The DPD activity in tumor tissue was two- to threefold higher (p < 0.01) than that in normal tissue

The present data suggest that DPD enzyme activity might play an important role in the protecting tumor cells from the effect of anticancer (5-FU) in situ, as both concentration and activity of this enzyme are higher in malignant tissue which is accompanied by rapid degradation of 5-FU in these tissue. This effect does not only facilitate tumor growth, but also may increase the opportunity for metastasis. The DPD activity of CRC tumors may be a useful clinical marker of the responsibility of a Fluorinated pyrimidine dosing in colorectal cancer.

DPD activity may help to classify tumor in stages (advance and early)

Conclusion

The concentration of DPD enzymes in tumor tissues raised considerably in CRC patients especially in those with advanced stages.

In patients with advanced CRC, there is a hyperactivity of DPD in serum and tumor tissues. The DPD activity of CRC tumors may be a useful clinical marker of the responsibility of a Fluorinated pyrimidine dosing in colorectal cancer.

ABSTRACT

The study was carried out in Tikrit city from January 1st to July 1st 2018. These patients admitted to Sallah Al-Deen general hospital and primary health care centers in Tikrit city. The number of patients with urinary tract infection was 300 patients whom their ages ranged from 2 months to 70 years. The control group included 100 individuals who appeared healthy with no history of UTI. Urine direct and indirect examination was held for all the patients and control. 210 samples of cultured specimens gave positive results in culture media. Most isolates were Staph. aureus with 25%, Staph. saprophyticus 24%, E. coli 16%, K. pneumoneae 5%. Pseudomonas aeruginosa, Proteus and Citrobacter frundii were present in about 2%, 5% and 7% respectively. Yeast-like fungi, Candida albicans and Candida spp. was also found 7% and 2% respectively. All samples have been subjected to complete blood count with emphasis on platelets; platelet count, distribution width (PDW) and mean platelet volume (MPV). Platelet count showed a significantly higher values in patients with UTI in comparison to control group. Platelet count and parameters showed a significant increase in gram positive bacteria specifically higher for Staph. saprophyticus. which means there is maybe a correlation between platelets and the type of the causative agent of infection.

Keywords: Urinary Tract Infection; Patients; Blood Count

Introduction

Urinary tract infection (UTI) is considered as one of the most common bacterial diseases in men and women of all ages. The early diagnosis of the infection and suitable treatment are significant to reduce renal complications and in extent kidney failure. Bacteria are the main reason of infection among humans but we cannot overlook the role of certain viruses and fungi as a causative agents. However, the role of viral and fungal UTI is considered to be an infrequent phenomena. Though the infection may seems to be harmless in the onset of infection, the patient may show a variety of symptoms as the stage progresses and it may lead to death in rare cases where the infection is sever.

Urine analysis is one of the most important and essential tests used in clinical laboratories in the diagnosis and follow up of UTI (1). Microscopic urine sedimentation test has been the most used methodology for examining urine cells and microorganisms. Screening test with dipstick reagents is mostly used as complement to urinalysis examination tests.

CBC is monotonously ordered in some patients with UTI, including blood cells and platelet parameters (2). Platelets are very complex enucleated cells. They are the derivatives of bone marrow megakaryocytes. Platelets activity can stimulates inflammatory process by promoting recruitment of leukocytes and suppressing the apoptosis of monocytes, neutrophils, and eosinophil (3,4).

Mean platelet volume (MPV), is a parameter usually asserted by complete blood count (CBC) analysis. It is the indication of the average size of platelets which subsequently reverberates the stimulation and production rate of platelet (5,6). As for platelet distribution width (PDW), it is an indicator of variation in platelet size.

Email: marwan.walady@yahoo.com
which reflects platelet activation. A high MPV values is an indication of increased platelet activity which means there is a very intense inflammation (7-9).

**Aim of study:** The aim of this study was performed in order to inspect platelet counts and platelet parameters in patients with culture positive UTI to determine if there are organism specific responses.

**Method**

This cross sectional study was conducted through the period of 1st January 2018 to 1st July 2018 on the patients admitted to Sallah Al-Deen hospital and health centers in Tikrit city. their age ranged between two months and seventy years old. Our study included 300 patients with 210 culture positive UTI and one hundred sex and age matched healthy individuals as a control group.

Urine samples were collected by either midstream urination or by using sterile urine bag for infants. The samples were examined within 30 minutes of collection. After direct urine culture (physical appearance, rabid urine dipstick and microscopic examination) the samples were conducted to culturing on blood agar, MacConkey agar, Cled agar and sabroud dextrose agar. Positive plates were subjected to gram stain, biochemical tests and API 20 strip for identification.

Five ml of blood samples were drawn under sterile conditions in different blood differentiation tubes for presumed tests.

Complete blood count was performed by (Genex count 60 automated hematology analyazer) counter for measuring CBC. Data analysis and statistics by The Mann-Whitney U test, The Pearson’s correlation test were used. P <0.05 was considered statistically significant.

**Results**

300 sample of urine were collected from patients with UTI. 100 healthy individuals were included as a control group. The age ranged between two months and seventy years whom were distributed into five age groups according to age and gender as shown in table (1). The results revealed that 210 (70%) of UTI samples gave positive result in culture. That leaves 90 (30%) of samples registered as a negative in culture media.

Out of the 210 culture proved UTI, 130 of them were females and 80 males distributed into five age groups, table (1) The mean age of the UTI group was 26.004 ± 22.663 years, compared to the control group 20.236 ± 20.126 years (P= > 0.05) as it shown in table (3). Gram positive culture bacteria were found in (52%) of the cases with UTI; while Gram negative bacteria was found in (25%) while yeast was found in (11%) of the cases.

Table 2 reveals that *Staph. aureus* was the most common bacterial species isolated from urine of about (25%). In the second place comes *Staph. Saprophyticus* in about (24%) of samples and most of them came from female patients. *E. coli* was found in (16%) of samples as well as *K. pneumonia* and *Citrobacter frundii* of about (5%) and (7%) respectively. *Pseudomonas aeruginosa* and *Proteus* species were also found, (2%) for *Pseudomonas aeruginosa* and about (2%) and (3%) for each of *Proteus vulgaris* and *Proteus mirabilis* respectively. *Strep. epidermidis* was also found in (4%) of samples. In addition to that (1%) of samples were found to be positive for *Salmonella typhimurium*. Also about (12%) samples showed a positive result for yeast, specifically *Candida albicans* 16 (7%) and Candida spp. 9 (2%) on culture media.

**Discussion**

Results showed that UTI infection samples gave about 210 positive bacterial culture. By urinary culture those 210 culture positive cases was found to give (52%) gram positive bacteria; while Gram positive bacteria was found in (36%) of the cases. As for yeast, it was found in (11%) of all the cultured samples.

Study groups of patients with urinary tract infection were divided into five age groups according to age and gender. The infection was more frequent at the age between 5 and 30 years old and was more frequent in females as it shown in table 2.

UTI is more common in women than men. The reason of this difference is not significantly clear but there is important risk factors in those age groups that may be considered valuable. Those risk factors includes physiologic and anatomic factors, such as estrogen deficiency, obstructing lesions and genetic factors, such as blood group status and antibiotic consuming or functional statuses (10).

Platelets is part of the innate immune system, it can be considered as a part of acute phase response during inflammations. The increase in thrombocytes may affect the bone marrow cell production as a response to pro-inflammatory cytokines, such as IL-1 and IL-6 (11-13).

Activating the platelets lead to some morphological changes in shape and size which may lead to changes in platelet numbers and subsequently an increasing in mean platelet volume and platelet distribution width (14).

Our current study showed that patients with UTI had a statistically higher platelet count and parameters (MPV & PDW) than healthy control group as shown in table 4. In addition to that, there was an increasing in platelet parameters (MPV & PDW) but none was noticed in platelet values in patients with gram positive UTI compared to those with gram negative infection, table 5.

Tekin et al. (15) had reported an elevation in platelet values and its parameters (MPV & PDW) in patients with UTI in comparison to the control group. The results showed that there was no difference in platelet counts in children who are suffering from upper or lower UTI, also there was no significant difference in mean platelet volume among patients with Gram positive and Gram negative UTI. Some previous studies showed that early
responses to the presence of endotoxins have been positively correlated with the release of thromboxane, which elicits platelet aggregation. Both thrombocyte hyperaggregability and peripheral damage might cause a positive feedback to the bone marrow over twenty four hours, which may result in the secretion of larger and more active platelets (16).

In Addition to that, some bacteria could have evolved mechanisms to block the process of platelet activation and cause platelet aggregation, perhaps to evade host defense mechanisms. Rowe et al (17), they examined ninety three postoperative pediatric patients and found that seventy one percent of the patients infected with gram negative sepsis had thrombocyte counts less than 100,000 whereas thrombocyte counts in the nonseptic or in gram positive sepsis patients were higher than 150 thousand. They also noticed an elevation in thrombocyte count in patients whom treated for sepsis. In another study by Scheifele et al (18), they examined endotoxinemia and thrombocytopenia during the infection of necrotizing enterocolitis. In their study, they detect E. coli in about 49% and 28% of them had a platelet value less than 100,000 mm3. In our study, the results were compatible with these evidence, patients infected with gram positive bacteria usually had statistically higher platelet counts values than patients infected with gram negative bacteria (19).

The volume of the platelet is positively correlated with the function of the platelet which means that larger platelets are evidently more active than smaller ones. Platelet distribution width is a marker of platelet size, which may be an indicator of active thrombocyte release. Mean platelet volume has been reported to be an indirect sign of deflection in the production of platelets and the response of bone marrow activity to UTI in children and adult studies (20).

ABSTRACT

Colorectal cancer (CRC) is one of the common malignant tumors of gastrointestinal tract (GIT). The incidence rate of this cancer increased in frequency in the last few years. This study was carried out to investigate the possible association of some risk factors with CRC such as (age, gender, smoking, inflammatory bowel disease, and ulcerative colitis). In this study we analyzed using immunohistochemistry technique of the following markers for 30 selected cases: cytokeratin 20 (CK20), and cytotoxic T-lymphocyte (CD8), the results showed that CD8 and CK20 are positive immunostaining markers.

CD8 expression: Results indicated that CD8 levels were positive in the all cases studied. In term of scores, CRC patients with the score ++ (moderate) represented the highest percentage 14 (46.67%) compared with patients with score+ (weak) 10(33.33%) and score+++ (strong) 6(20.00), the statistical analysis showed increase significant in percentage of patients with score++ as compared with score+ and score+++ at (P<0.05).

CK20 expression: In this study the positive immunohistochemical expression of CK20 was significantly higher in CRC patients with score ++ (moderate) 16 (53.33) in comparison with CRC patients with scores + (weak) 9 (30.00) and score +++ (strong) 5 (16.67) at (P<0.05).

Keywords: Colorectal cancer, Immunohistochemistry, Cytotoxic T-lymphocyte, Cytokeratin 20.

Introduction

Cancer is a disease that occurs when control is lost on cell division and growth as well as on the metastasis of abnormal cells. Reasons for cancer are both intrinsic, i.e. infections, smoking, radiant sources, and pollutants, and extrinsic, i.e. genetic and metabolic mutations, along with abnormal immune responses and hormone levels (1). The abnormal growth of colon and or rectal epithelial cell is known as bowel and or colorectal cancer (CRC)/tumor that can attack other organs of the body and consequently turns into a cancerous growth, most tumors are classified as adenocarcinomas (2). CRC is more prevalent in the rectum, then sigmoid, cecum, transverse colon, flexures, ascending colon and descending colon (38, %, 29%, 15%, 10%, 10%, 5%, 3% respectively) (3). Among cancer cases in the world, women have CRC as the second cause whereas men have it as the third cause (4). Stool blood, altered movement of bowel, continuous tiredness, nausea, vomit, malaise, anorexia, abdominal distension and losing of weight are among the main symptoms of CRC (5). In patients with colorectal cancer, the clinical presentation depends on the location, size, as well as the presence or absence of metastases (6). CRC pathogenesis is of high degree of complexity, with different factors interacting with each other, these factors include somatic alterations that accumulate in the epithelial layer of the colorectum, germ-line features that determine susceptibility to cancer, as well as effects from the environment (7). Invasive CRC results from

DOI Number: 10.5958/0976-5506.2019.03214.5
a sequence of multiple events, starting from genetic changes being accumulated and giving the advantage to the epithelium to grow in a selective manner, stimulating its transformation to adenomatous polyp (8,9).

**Aims of study:** The current study was proposed to meet the following aims:

1. To evaluate and diagnose CRC according to the risk factors.
2. To study the roles of some immunohistochemical markers (CD8, and cytokeratin 20) in the diagnosis of CRC.

**Materials and Method**

Detection of CD8, CK20 Expression in Paraffin Embedded Tissue by Immunohistochemical Technique (IHC): We selected a total of 30 cases of colorectal adenocarcinomas. All the tissues which used in this study were archival tissue blocks collected from histopathological laboratories of Gastroenterology and Liver Diseases Teaching Hospital, Baghdad.

**Immunohistochemical scoring:** Immunostained slides were scored after the entire slide was evaluated by light microscope. Results were interpreted by a pathologist in the Iraqi Specialized Lab.

**Scoring of CD8:** CD8 infiltration was scored as the number of CD8 leukocytes per tumor area. They were assessed as:

1. No/sporadic/weak (score 1).
2. Moderate (score 2).
3. Abundant/strong (score 3).
4. Highly abundant infiltration (score 4). (9).

**Score of CK20:** CK20 expression was based on intensity of cytoplasmic staining as following:

1. No staining (0).
2. Weak intensity (score 1), up to 5% of cells.
3. Moderate intensity (score 2), up to 10% of cells.
4. Strong intensity (score 3), greater than 10% of cells (10).

**Results**

**Immunohistochemical Evaluation of Tumor Tissues:** The tissue expression of CD8 and CK20 markers was evaluated in patients with colorectal cancer. The data related to the effect of age (Table 1) demonstrate that the age stratum of more than 60 years was the most affected group with CRC (14: 46.66%), followed by the age stratum of 40-60 years (12 : 40%), then the age stratum of less than 40 years (4: 13.34%). As related to the effects of gender, the percentage of the males with colorectal cancer was higher (16, 53.33%) than the percentage of the females (14, 46.67%), but the statistical analysis showed non-significant difference. The results also showed a significant increase in the percentage of smoker (17, 56.67%) as compared with non-smoker patients (13, 43.33%) at P<0.05. Increase significant was observed in the percentage of patients with CRC in T3 (18: 60.00%) as compared with T1, and T2 (4: 13.33%, and 8: 26.67%, respectively) at P<0.05. While, the percentage of patients with CRC in G2 of moderate differentiated adenocarcinoma (20, 66.67%) was higher than the percentage in patients in G1 (4, 13.33%), and G3 poorly differentiated adenocarcinoma 6 (20.00%), there are increase significant in percentage of patients with G2 compared with G1 and G3 at (P<0.05). Regarding to the diseases that is most related to colorectal cancer, the highest percentage of CRC patients was recorded in the patients with diabetes mellitus type II (12, 40%), followed by ulcerative colitis (11, 36.67%), then polyp 5(16.67%), and lastly the lowest affected group was those with genetic factors (2, 6.66%). In addition, percentage of patients with colorectal cancer was higher in the rectosigmoid region (12, 40%), followed by rectum (8, 26. 68%), sigmoid colon (6, 20%), and the lowest percentage was in both right colon and transverse colon (2, 6.66%)

**Immunohistochemical diagnosis:** We investigated the expressions of CK20 and CD8 in 30 cases of colorectal carcinoma in this study of immunohistochemical technique as shown in Figures 1 and 2.
Figure 1: A- Anti-CD8 Antibody immunostaining in normal colon. IHC (10x). B- Moderate differentiated colonic adenocarcinoma with Weak reaction to CD8 (Score +). Anti-CD8 Antibody immunostaining. IHC (40x). C- Poorly differentiated colonic adenocarcinoma with Weak reaction to CD8 (Score +). Anti-CD8 Antibody immunostaining. IHC (40x). D, E- Moderate differentiated colonic adenocarcinoma with Moderate reaction to CD8 (Score ++). Anti-CD8 Antibody immunostaining. IHC (40x). F- Moderate differentiated colonic adenocarcinoma with Strong reaction to CD8 (Score +++). Anti-CD8 Antibody immunostaining. IHC (10x).

Figure 2: A- Anti-CK20 Antibody cytoplasmic staining in normal colon. IHC (10x). B- Well- differentiated colonic adenocarcinoma with Weak reaction to CK20 (Score +). Anti-CK20 Antibody immunostaining. IHC (40x). C- Well- differentiated colonic adenocarcinoma with moderate reaction to CK20 (Score ++). Anti-CK20 Antibody immunostaining. IHC (40x). D- Moderate differentiated colonic adenocarcinoma with Weak reaction to CK20 (Score +). Anti-CK20 Antibody immunostaining. IHC (40x). E- Moderate differentiated colonic adenocarcinoma with moderate reaction to CK20 (Score ++). Anti-CK20 Antibody immunostaining. IHC (40x). F- Moderate differentiated colonic adenocarcinoma with strong reaction to CK20 (Score +++). Anti-CK20 Antibody immunostaining. IHC (40x).
Interpretation of immunohistochemical reactions focused primarily over highlighting the chromogen on the antigenic targets and the number of positive tumor cells. Thus, if no cell has been immunohistochemically staining, we considered an absent reaction; if the reaction was positive in less than 10% of examined cells with a microscope, we considered a poor response (weak, score +), if they were positive in 10% to 25% of the cells, we considered a moderate reaction (score ++), and if it was positive in more than 25%, we have found that the reaction was intense (strong, score +++).

Discussion

IHC is often a diagnostic tool used to support easier and more precise classification of the gastrointestinal tumors. Thus, diagnostic tissue biomarkers are important sources for complementary information to those of clinical colonoscopy.

CD8: CD8+ cytotoxic T cells in particular have received attention not only because of their known role as cytolytic agents and demonstrated reactivity to tumor-derived self-epitopes, but also their prevalence and apparent positive prognostic effect in colorectal cancer as well as other tumor types (11). Tumor-infiltrating cells were shown to be able to recognize and remove tumor cells, but also to enhance immune evasion by these cells, thus affecting progression and metastases of the disease (12). More recent studies propose an essential function of tumor-infiltrating lymphocytes (TILs) in enhancing anti-CRC immune response with similar function in other malignancies (13). The proportions of T cells and T cytotoxic cells in the tumor center (TC) and the invasive margin (IM) were used to build up an immunoscore (IS) (14). The IS value was suggested by some scientists to be more useful than that of the currently used TNM staging system, particularly in relation to colon cancers (15), while others showed that this benefit is only valid in diseases stages I–III (16). The major active components of the adaptive immune response such as cytotoxic T lymphocytes (CTL) have essential roles in the regulation of growth and metastasis of the tumor. The first report of the value of infiltrating CTLs in CRC prognosis was provided by Naito et al (17). The elevated numbers of TILs in CRC was frequently correlated with a favorable prognosis (18).

CK20: The cytoskeleton in mammals consists of three families of proteins. These include the microfilaments mainly made of actin, the microtubules mainly made of tubulin, and the intermediate filaments that is composed of various types of proteins, including cytokeratins (CKs) that are involved to differentiation mechanisms of the cell (19). The expression of this cytokeratin in the colon is restricted to epithelial cells with later stages of differentiation in comparison with those cells in the bases of the crypt which are usually at earlier stages of differentiation (20). However, in spite of this pattern, the expression of CK20 in CRC maintains its high level of conservation and is highly uninfluenced by the fundamental genetic changes accompanying malignant transformation. A rare and significant exception is when CK20 expression is lost in a number CRC patients with deficiency of the process of mismatch repair (21). CKs, during their secretion by the cells undergoing proliferation or apoptosis, they confer good markers to recognize the malignancies of the epithelium, clearly indicating a continuous cellular activity (22). Presence or absence of different CKs is facilitated by staining with antibody panels, while its interpretation at clinical level must be confirmed via morphological and other diagnostic examinations A CK-specific antibody can identify a type of epithelial cells through its binding to protein epitopes (23).

Conclusions

1. In our study, we found that elderly age, male gender, smoking, and other infection, appeared to be the most possible association factors for colorectal cancer.

2. Immunohistochemistry for CD8 and CK 20 help differentiate colorectal adenocarcinoma. The most widely used immunohistochemical markers for colorectal adenocarcinoma are cytokeratin (CK) 20, and CD8. The most common immunophenotype of colorectal adenocarcinoma is positivity for CK20 and CD8, which is a relatively specific staining pattern for colorectal origin.

Detection of Tn917 Carrying \textit{erm}(B) Gene in a Clinical Isolates of \textit{S. pyogenes}

Hanan Raheem Hassooni\textsuperscript{1}, Hameed M. Jasim\textsuperscript{2}, Abbas Aboud Farhan\textsuperscript{1}, Adil Hassan Alhusseiny\textsuperscript{3}

\textsuperscript{1}Department of Biology, Faculty of Education for Pure Science, Diyala University, Iraq; \textsuperscript{2}College of Biotechnology, Al-Nahrain University, Baghdad, Iraq; \textsuperscript{3}Department of Internal Medicine, Faculty of Medicine, Diyala University, Iraq

\textbf{ABSTRACT}

\textbf{Background:} This study was conducted to investigate the genetic organization of \textit{erm}-carrying Tn917 in clinical isolates of \textit{Streptococcus pyogenes}. Tn917 is a nonconjugative transposon which is responsible for the spread of erythromycin resistance in bacterial isolates. Over the past two decades, erythromycin resistance rates have increased in \textit{S.pyogenes} in many countries, To obtain information that may be useful in solving the spread of antimicrobial resistance, antibiotic-resistant genes can be identified as well as their association with mobile genetic elements.

\textbf{Material and Method:} A total of 22 isolates of \textit{S. pyogenes} isolates collected from the infection of upper respiratory system were examined, first by detecting their antibiotic susceptibility against three different antibiotics groups (Macrolides, Tetracycline, and lincosamides) then genomic DNA was extracted from each isolate for detection Tn917 by using specific primers to amplify \textit{erm}(B) gene carried by this transposable element.

\textbf{Results:} Results showed that there is a high level of resistance to erythromycin, (90.9%), then to Minocycline (68.1%), Lincomycin (59%), Tetracycline (54.5%), Clindamycin (50%), Azithromycin and Clarithromycin (36.3%), Doxycycline (31.8%) and then to Oxytetracycline (27.2%). Results also showed that five of \textit{S. pyogenes} isolates were harboring Tn917 transposable element carrying \textit{erm} gene. On the other hand, results showed that there are another isolates resistant to erythromycin that may possess a chromosomal or plasmid copy of the erythromycin resistance gene, or may the resistance caused by another structural erythromycin gene carried by other type of transposable elements rather than Tn917.

\textbf{Conclusion:} Our findings suggest that the isolates of \textit{S. pyogenes} are harboring chromosomal copy of Tn917 conferring erythromycin resistance. One possible explanation for the presence of genes at different isolates is due to \textit{erm} gene, which was most likely located on Tn917.

\textbf{Keywords:} Tn917, Erythromycin resistance, \textit{Streptococcus pyogenes}, \textit{erm}(B) gene

\textbf{Introduction}

\textit{Streptococcus pyogenes} is the major human pathogen connected with local or systemic infestation and post-streptococcal immunologic disorders\textsuperscript{16}. These bacteria colonize the throat or skin and cause several purulent infections involving pharyngitis, necrotizing fasciitis, impetigo and streptococcal toxic shock syndrome\textsuperscript{12,13}. Besides, \textit{S. pyogenes} may stimulate autoimmune diseases like rheumatic fever, acute post-streptococcal glomerulonephritis and rheumatic heart disease\textsuperscript{14}. When penicillin use is inappropriate among patients with \textbeta-lactam allergy, macrolides represent the best solution for treating respiratory infections, leading to increased resistance in \textit{S.pyogenes} \textsuperscript{15}. In \textit{S. pyogenes}, macrolide resistance probably due to several mechanisms: post-transcriptional target site modifications caused by rRNA methylases [\textit{erm}(B) or \textit{erm}(A) genes] which modify an adenine remains in the 23S rRNA, target mutations such as mutational alterations in 23S rRNA or ribosomal proteins and acquisition of active efflux

[mef (A) gene] which is associated with resistance to 14- and 15-membered macrolides \cite{6,7}. Since the 1990s, the global increase in resistance to erythromycin in the \textit{S. pyogenes} has led researchers around the world to conduct more epidemiological and molecular studies, which have helped to identify mechanisms, determinants and genetic components that cause resistance \cite{8,9}. Tn917 is a nonconjugative transposon which is responsible for the spread of erythromycin resistance \cite{10}. Originally, Tn917 was determined on a non-comparative plasmid in the \textit{E. faecalis} bacteria, and the transfer of this transposon is stimulated when the cells are exposed to low concentrations of erythromycin, making it transferable to a plasmid-free recipient of the same type \cite{11,12}. According to the importance of Tn917 in spreading erythromycin resistance between bacterial isolates, this study was aimed to explore the presence of Tn917 in \textit{S. pyogenes} isolated from upper respiratory tracts.

**Material and Method**

**Bacterial Isolates:** Clinical samples were collected (January/2018 to April/2019) from patients (adults and children) complain from tonsillitis, pharyngitis and otitis media, who attends the Consulting clinic at Baquba Teaching Hospital, Al-Batoul Teaching Hospital, Private clinics in Diyala governorate, the Consulting clinic at Central Child Teaching Hospital, Medical City Teaching Hospital in Baghdad governorate, Private clinics in Erbil governorate, and American University of Beirut Medical Center/Lebanon. To ensure the viability of pathogens, samples were sent directly to the microbiology in a sterile transport medium. Several factors have been relied upon in this study to identify \textit{S. pyogenes}, including colonial morphology, gram staining, and biochemical tests by using Vitek 2 system.

**Susceptibility testing:** Susceptibility of \textit{S. pyogenes} isolates against Macrolides group (Erythromycin, Azithromycin, and Clarithromycin) Tetracycline group (Tetracycline, Minocycline, Doxycycline, and Oxytetracycline) and Lincosamides group (Clindamycin and Lincomycin) was examined on β- selective \textit{S.pyogenes} agar with the addition of 5% of fresh blood according to the standard disc diffusion method, these antibiotics were supplied by Bioanalyse/Turkey.

**Amplification experiments:** Amplification of chromosomal DNA was performed by using specific primer ERMB1: 5’-GAAAAGGTACTCAAACCAATA-3’ and ERMB2: 5’ AGTAACCGTACTAAATTGTTAC-3’, which targeting \textit{erm(B) gene} \cite{13}. This primer was provided in lyophilized form and was dissolved in sterilized distilled water to give a final concentration of 10 picomole/µl. PCR master mix supplied by Intron, Korea. The optimum conditions for amplification of Tn917 were described in table (1).

After PCR amplification, agarose gel electrophoresis (2%) was used to detect the amplified products. Aliquot of 5 µl of pure DNA solutions were mixed with 2 µl of 6x loading dye, then DNA samples were loaded into the wells. DNA bands were visualized under a UV-light transilluminator.

**Nucleotide sequence:** Sequencing of the amplified gene product was performed by national instrumentation center for environmental management (nicem) online at http://nicem.snu.ac.kr/main/?en_skin=index.html.

**Results and Discussion**

Results indicated in table (2) showed that the bacterial isolates of \textit{S. pyogenes} were highly resistant to erythromycin, twenty isolates (90.9%), then to Minocycline (68.1%), Lincomycin (59%), Tetracycline (54.5%), Clindamycin (50%), Azithromycin and Clarithromycin (36.3%), Doxycycline (31.8%) and then to Oxytetracycline (27.2%).

In recent years, treatment for *S. pyogenes* has become difficult owing to the global rise in the prevalence of antibiotic resistance, particularly against first-line antibiotics such as erythromycin and penicillin [14]. Increasing of antimicrobial resistance in *S. pyogenes* that cause infectious diseases is a global problem, although resistance significantly varies between geographical regions [12]. In a local study, *S. pyogenes* resistance to erythromycin was 33.33%, while tetracycline was 52.38% [15].

Globally, most studies have shown a frighteningly high increase in antibiotic resistance ratios between *S. pyogenes* within the macrolide group, particularly erythromycin, and the tetracycline group. A study conducted in Spain between 1986 and 1997 showed that the percentage of resistance to erythromycin in Madrid in 1987 was 0.0%, then the percentage increased in 1989, 1992 and 1997 to 3.0%, 8.1%, 31.8%, respectively [16]. In Finland, the resistance of *S. pyogenes* to erythromycin recorded the highest rate of 44% [17]. On the other hand, study conducted in the United States reported that the resistance ratio of *S. pyogenes* isolates to erythromycin was 6.8%, Azithromycin 6.9%, Clarithromycin 6.6%, and Clindomycin 0.7% [18]. Also, another study carried out in Turkey found that from a total of 127 isolates of the *S. pyogenes*, the resistance to erythromycin was 9% and tetracycline 18% [19]. Furthermore, results indicated in the table (3) showed that the multi-drug resistant was spread among the isolates of *S. pyogenes* as they give a different resistant pattern to antibiotics of different groups.

### Table 3: Pattern of antibiotic susceptibility of *S. pyogenes* to different groups of antibiotics

AZM : Azithromycin; CLR : Clarithromycin; E : Erythromycin; TE : Tetracycline; DO : Doxycycline; MI : Minocycline; T : Oxytetracycline; DA : Clindamycin; L : Lincomycin; R : Resistance; S : Sensitive
Results also showed that the isolate *S. pyogenes* H6 was resistant to all antibiotics used in this study (100%), while the isolates H14, H15, H19, and H22 were resistant to seven antibiotics (77.7%), then the isolate H8 who was resistant to six antibiotics (66.6%). Common bacterial pathogens can be resistant to all known antimicrobial agents; *Streptococcus* has special genetic elements structures called conjugative transposons. These structures can transport large-range of resistance genes and have the ability to capture other resistance elements to form composite structures allowing them to spread multi drug resistance between different bacteria \[12\]. To identify the resistance gene and resistance determinants a PCR-based approach by using specific Primers (ERMB1 and ERMB2). Results illustrated in figure (1) showed an amplified product of 639bp appeared after electrophoresis on agarose gel (2%), represents the presence of Tn917 conferring erythromycin resistance in many isolates of *S. pyogenes*, this result confirmed other study carried by Sutcliffe *et al.* \[20\] who detected Tn917 in *S. pyogenes* using the same primers. This transposable element was detected in five isolates of *S. pyogenes* out of the total isolates (22 isolate). All these isolates (H1, H2, H3, H4, and H7) were resistant to erythromycin as indicated in table (3).

In addition, results indicated in table (3) showed that there are another 15 isolates resistant to erythromycin symbolized H5, H6, H8, H9, H11, H12, H13, H14, H15, H16, H17, H18, H19, H21, and H22 which may that may possess a chromosomal or plasmid copy of the erythromycin resistance gene, or may the resistance caused by another structural erythromycin gene carried by other type of transposable elements rather than Tn917 in these isolates. Results also showed that there are two isolates of *S. pyogenes* (H10 and H20) were sensitive to erythromycin among the total isolates and were unable to grow on enrichment medium containing this antibiotic.

Nucleotide sequence of the amplified product of Tn917 was illustrated in figure (2). This sequence was 100% identical to the nucleotide sequence of Tn917 recorded in the NCBI database under the accession number M11180. Which supports the results concluded in this study that the five isolates of *S. pyogenes* are harboring chromosomal copies of Tn917 conferring erythromycin resistance. One possible explanation for the presence of genes at different isolates is due to *erm* gene, which was most likely located on Tn917 \[21\].

ABSTRACT

This study is the nucleus of an information and data base for scientific research trends in the field of physical education and sports sciences. “The process of surveying and publishing the research heritage is one of the first contributions in activating the scientific research movement and advancing the vision of researchers. This is not an easy matter. Scientific messages in the individual and differential games according to the specialties of the departments of the Faculty of Physical Education for Girls/Alexandria University for the period (2000 - 2017).

The research society and its sample included the letters of (Masters/PhD) for graduate students which were granted from the Faculty of Sports Education for Girls/Alexandria University for the period from (2000 to 2017) in the library of the college with a total of (941) M.Sc. After collecting the necessary data and analyzing them and conducting the appropriate statistical treatments on the sample of the study, the percentages of the number of scientific letters based on their directions and scientific sections were determined, the number of scientific thesis for the master’s program (612), while the doctoral program (329).

Keywords: Analytical study, individual and secondary games.

Introduction

The need for scientific research in the present time is more severe than ever before. The world is in a race and competition to reach as much accurate and fruitful knowledge as possible, which ensures the superiority of man over others. After realizing the importance of scientific research and the great role which he performs in progress and development, gave him much attention and provided him with all the requirements he needed as the mainstay of the economy and development.

The research carried out by universities and institutions of higher education plays an essential role in any country seeking advancement and advancement. Scientific research is one of the most important functions of the basic universities, which is the center of scientific innovation, the development of knowledge and enriching it and seeking to employ it in solving problems. The MA and PhD are not only research exercises, but are a scientific production and a real beginning for researchers coming, please innovation and innovation to contribute to the progress of science and human development and the accumulation of scientific knowledge of humanity.¹

The importance of documentation by the adoption of scientific research on what is a stock of information, and the use of this information and good use requires documentation and provision in a way that can be used in the inventory of problems and analysis and choice of solutions, and these documentation services are the pillars of scientific research and the reasons for success, it helps researchers to know what was published On the subject of their interest, and make them in constant

DOI Number: 10.5958/0976-5506.2019.03216.9
contact and knowledge of all developments on the emergency and what is new.2

Despite the existence of the specialization of Physical Education at the University of Alexandria, which grants the Master’s degree and PhD several years ago, but there is no study on the documentation of scientific thesis in this specialty. Hence the idea of this study to highlight these thesis in order to know them and then to come up with proposals that would contribute to the development of a vision for a research map of these scientific thesis and accordingly contribute to guide future studies and research to the priority fields of research with the identification of areas that have not received attention. Sufficient. It is an attempt to document and analyze the master’s and doctoral dissertations. This study is an important workshop in the information cycle between those who produce it and those who need it. And analyze those trends with an attempt to interpret them. This study may be the nucleus of an information and data base for scientific research trends in the field of physical education and sports sciences. The process of surveying and publishing the research heritage is one of the first contributions to the revitalization of the scientific research movement and the development of insight among researchers.3

Research Aim
The aim of the research is to analyze the trends of the scientific thesis in the individual and differential games according to the specialties of the departments of the Faculty of Physical Education for Girls/Alexandria University for the period (2000 - 2017).

Research Methodology and Procedures:
Research Methodology: The descriptive method was used by the researchers in a descriptive manner to suit the nature of the study.

Society and sample research: The research society and its sample included the letters of (Masters/PhD) for graduate students which were granted from the Faculty of Sports Education for Girls/Alexandria University for the period from (2000 to 2017) in the library of the college with a total of (941) M.Sc.

The number of letters of study in mathematics was (310) letters (Master/PhD), which represents a percentage of (32.94%). The number of scientific thesis in individual games (218) letters (Master/PhD), which represents a percentage of (23.18%). While the number of public letters sporadic (413) letters (Master/PhD), a rate of (43.88%). The research sample consisted of all the items of the study, ie the comprehensive survey, because it was based on the study of the research community. The following table shows the numbers and percentages.

Table 1: Shows the percentage of thesis and percentage according to the scientific sections in the Faculty of Sports Education for Girls Alexandria University for the period 2000 – 2017

Search procedures: The researchers conducted a comprehensive survey of all masters and doctoral dissertations at the Faculty of Sport Education for Girls at Alexandria University, and a special table was prepared to prepare the students and their attitudes in the research according to the scientific departments in the college and the percentage of the period (2000 - 2017).

Conted…
Discussion of Results

The researchers attributed this preparation to the students’ perception of the importance of postgraduate studies in human life at the present time. It is an important tool that leads to a distinguished future and opportunities to secure a source of earning and enjoying a higher status.4

The higher education is one of the important and advanced stages of the educational ladder. The university is the institution through which higher education, especially the postgraduate stage, is scientifically prepared to become highly qualified. Needs of economic and social development.7 The superiority of the master’s program in postgraduate studies in this college is also evident in terms of the number of scientific thesis. The researchers explain this superiority that the study of the Master in particular is a conclusive certificate in the life of the human being, it gives the university student many advantages that make it one of the most important goals after studying at the university.6

As for the superiority of the individual games to the individual games in the interest and orientation of postgraduate students, researchers explain that the reason for this is the popularity of the large enjoyed by these games in the communities, because of the enjoyment of the enjoyment of the mixture of competition and by all groups, in addition to not need most of those games To the many tools and equipment. «Telephony games have been and still are the field of attracting viewers, practitioners and researchers to the events of these games of high development in the level of technical performance, skill and plan.»7

Table (3) shows the distribution of letters and their directions for the games according to the division of the scientific sections, and it became clear that the game of football came at the forefront of interest of graduate students and targeting them to research and study. The researchers attributed the reason to the nature of the game and its attractiveness and it is the most popular and popular sport, it is at the forefront of sports activities that swept the hearts of many fans. Therefore, researchers attribute this great interest by graduate students in this game is the ambition of the researchers to upgrade the level of this game locally and then simulate the level of Arab or global through the follow-up weaknesses and try to find solutions to them according to the scientific methods followed in a step to develop important rules to develop This game avoids random solutions.8

The results show that the track and race games ranked first in the scientific thesis, and the researchers attribute this progress to these games in the possibility of obtaining medals in tournaments by the number of Less players as well as they include more effectiveness and do not need many tools to practice.

In terms of the scientific departments found in the college, the results showed in Table (2) of the distribution of Master’s and PhD thesis according to the departments. The sports training section was in the forefront of the interests and orientations of postgraduate students among the rest of the departments. The researchers attribute this interest to the scholars’ belief in the importance of science Sports training, and that the development of most sports is mainly due to specialists to the development of sports training methods. Given the certainty of turn as an important means of increasing productivity efficiency.9

It is clear from the above that there is a discrepancy between the students’ desires towards the theoretical approach. A move away from proper planning leads to the lack of good space for all games to be covered and covered by research and development.10

The researchers attributed the reasons for the variation in trends among postgraduate students to the availability of the sample, the popularity of sports and their impact on the society, which is reflected in the possibility of providing playgrounds and tools for games, as well as the scientific specialties of the supervisors of the Faculty of Sports Education for Girls, Alexandria University, 2000 -2017 AD). In view of the presentation, analysis and discussion of the results of the survey of the variables of the research, the researchers were able to reach the results and information that would achieve the goal of the current study.

Conclusions

After completing the research procedures, the researchers reached the following conclusions:

1. The number of scientific thesis for the master’s program (612), while the doctoral program (329).
2. Different trends in sports, as the most detailed games dealt with research and study is the game of football, while the game of hockey ranked in the final trends. As for the individual games came track games and race in the forefront of individual games, while the game came wrestling last place.
3. The Department of Sports Training came in the forefront of the interests and attitudes of postgraduate students among the rest of the scientific departments in the college.

Effect of Closure of Peritoneum on Early Postoperative Outcome and Operating Time During the First Cesarean Section

Suaad Rodan Shoelef

1Specialist Gynecologist and Obstetrics, F.I.B.M.S. Gyn. & Obs., Bint Alhuda Teaching Hospital, Thiqar, Iraq

ABSTRACT

Background: Effect of closure of parietal peritoneum during the first cesarean section on early postoperative outcome including postoperative pain, fever, wound infection, postoperative distension, regain of intestinal mobility and hospital stay days.

Objective: To compare closure versus non closure of parietal peritoneum during first cesarean section regarding operative time and early postoperative time.

Methodology: This was a prospective study conducted in Bint Alhuda teaching hospital in Thiqar on 200 patient who were get their first cesarean section in a time period between September 2018 to April 2019. The patients divided into two groups; closure group (patients group who underwent closure of parietal peritoneum), and non-closure group (patients who didn’t underwent closure and we compare between 2 groups regarding operative time and early postoperative outcome.

Results: Non closure of parietal peritoneum during the first cesarean section result in reduction of the mean operating time and better early postoperative outcome.

Keywords: first cesarean section; early postoperative; closure of peritoneum

Introduction

Cesarean delivery is defined as delivering the fetus through surgical incision made through the abdominal wall (laparotomy) and the uterine wall (hysterotomy) (1). The most common indication for primary cesarean section including labor dystocia, abnormal or intermittent fetal heart rate tracing, fetal malpresentation, multiple gestation and fetal macrosomia (2). Peritoneal closure is no longer recommended as it is associated with increased adhesion formation and may increase surgical time and postoperative hospital stay (3). Furthermore these surfaces reapproximate within 24-48 hours and can heal without scar (4).

In cesarean section complication such as fever, wound infection, postoperative pain and bleeding occurs more frequently than in normal vaginal delivery and these conditions effect the postnatal care of the newborn infant. Traditionally; suturing of parietal peritoneal layer in cesarean section have been done, but in many randomized clinical trials, this stage could be easily eliminated since it doesn’t increase the rate of morbidity (5-8).

Reasons noted for closure of peritoneum include restoring anatomy and re approximating tissue, reducing infection rate by reestablishing the anatomical barrier, decreasing wound dehiscence, reducing hemorrhage and minimizing adhesion. Reasons cited for non-closure of perineum include reduction of operative time, shortening of hospitalization, early return of bowel function, reduction in the risk of bladder adhesion following next cesarean section and immediate postoperative recovery. It would also reduce the number of stiches which is the preferred option given that the body responds to stiches as if they were a foreign material (7-9).

Postoperative pain can cause unpleasant psychological responses including retention of secretion in respiratory system, ileus, increase need for analgesia, increase postoperative hospital stay and delay breast
feeding. Reduction of postoperative pain may improve mothers comfort and eventually the outcome of newborn infant. Therefore reduction of pain and use of fewer analgesics while still providing more comfort for patients is one of the important issue following cesarean section.

A series of studies evaluated the effect of leaving the peritoneum open and compared it with closure after cesarean section. Some studies reported lower incidence of postoperative febrile morbidity, shorter hospital stay and as early return of bowel function following non-closure of peritoneum compared to closure (7,9).

Other studies have not showed significant difference about wound infection, postoperative febrile morbidity and stay in hospital in hospital (10,11).

Patients and Method

This is a prospective study conducted at Bint Alhuda teaching hospital during the period from September 2018- April 2019. The study performed on 200 women who underwent primary lower segment cesarean section.

Inclusion Criteria: Patients underwent primary cesarean section for obstetrics causes.

Exclusion Criteria:
- Any previous abdominal surgery.
- Medical disorders e.g.; diabetes mellitus, hypertension, heart disease, renal disease, and hepatic disorders.
- Any febrile morbidity before the cesarean section.

The same technique was performed in all cesarean section operations. All surgeries done under general anesthesia. Pfannestiel incision followed transvers lower segment uterine incision that was closed in two layers using continuous absorbable suture (Vicryl No 2). Both layers of peritoneum were not closed in group 1 (100 patients) and was closed in group 2 (100 patients) using continuous absorbable sutures (Vicryl No 0). The rectus sheath closed by non-absorbable sutures (Nylon No 1) while the subcutaneous tissue sutured using continuous absorbable sutures (Vicryl No 1) and the skin closed using subarticular suture (Nylone No 0) and the time of operation was recorded.

All patients received the same intra operative prophylactic antibiotics (ceftriaxone vial 1gm I.V. and metronidazole vial 500mg), the dose repeated every 12 hours for 48 hours. The patients were followed up in the hospital for 24 hours and routinely discharged after 24 hours.

The patients divided were divided into 2 groups as follow:

Group 1: 100 women performed a lower segment cesarean section with non-closure of visceral and parietal peritoneum.

Group 2: 100 women performed lower segment cesarean section with closure of parietal peritoneum.

Postoperatively the patients the patients followed up by
- vital signs
- abdominal laxity
- uterine contraction
- vaginal bleeding
- Operative time
- Postoperative pain (Postoperative pain was roughly measured by the need for postoperative pain killers).
- Postoperative fever: temperature more than 38 degree C.
- Intestinal movement was assessed by hearing of bowel sound by stethoscope at right iliac fossa (ileocecal junction).
- Postoperative hospital stay.

Results

Comparative analytic study between the 2 groups was carried out regarding
- Operative time
- Need for postoperative pain killer
- Postoperative fever
- Return of intestinal movement
- postoperative hospital stay

As showed in the table there is no significant difference between both groups regarding postoperative stay.

**Discussion**

When the parietal peritoneum left non closed in primary cesarean section there was reduction in operative time and postoperative pain with no difference in the incidence of pyrexia and postoperative duration of hospital stay (12).

In hospital based interventional study done by Avantika Sharma, Nupur Hooja, Apoorv Shastri, Brijesh Dadhich and Richa Manish in a tertiary care hospital over they found that if parietal peritoneum left open in primary cesarean section lead to less postoperative pain, the duration of surgery is less resulting in better patient outcome. This is also significantly cost effective (13).

When the mean duration of surgery is less this reduces the duration of anesthesia and exposure of wound to external environmental contamination, thus reducing risk of anesthetic complication, wound infection and thromboembolic complication (14).

There was improved short term postoperative outcome if the peritoneum was not closed (15). On other hand there are studies showed that closure of peritoneum protect against adhesion formation (16).

Doppler Finding in Renal Parenchymal Disease Correlated with Histopathological Finding

Jinan Hussein Mohammed, Talib Atiyah Salman

1Nephrology and Transplant Center, Medical City, Baghdad Iraq

ABSTRACT

A study was conducted between 1st Dec – 2016 to 1st Oct- 2017 at radiological department of Al Shaheed Ghazi Hospital in the renal disease and transplantation center (Baghdad Medical city complex) 84 patient who are suffering from renal disease manifestation in both native and transplanted kidneys. Doppler blood indices (RI, PI and AT) were measured at same day before renal biopsy. Renal biopsy finding and Doppler blood indices were compared to asses’ whether there were a correlation between chronic renal changes and the Doppler indices changes.

RI, was significantly higher in patients group with renal diseases in comparison to control group (0.70 ± 0.07 vs. 0.55 ± 0.04), the accuracy was 72.9%, while PI and AT show less significant changes PI was (1.61 ± 0.25 vs. 1.47 ± 0.06) and AT (0.086 ± 0.023 vs. 0.024 ± 0.058). PI accuracy was 59.9 % and for AT was 54.2%. as consequence the mean value of RI was significantly differed among different renal pathologies (p=0.001) but the PI and ACT were not differed significantly (p<0.05 for both).

Conclusions: Our results suggest that Renal Doppler indices (RI) was significantly increased in patients with chronic renal disease which confirmed by pathological examination and higher accuracy than other indices PI and AT so we can use it as good marker for chronic renal disorders while other indices (P.I and A.T) can use as complimentary.

Keywords: histopathological finding; renal disease Doppler; disease

Introduction

Gray –scale renal ultrasonography (US) is still performed as a matter of course during the initial evaluation of both native and transplanted renal dysfunction[1]. Despite major technological advance, gray –scale renal (US) has remain largely unchanged since the 1970s[2]. Ultrasonography finding are often normal in spite of the presence of sever renal dysfunction in some cases [3]. it is not always possible to distinguish between obstructive and non obstructive pelvicaliectasis on the basis of gray-scale alone[4).

Doppler ultrasound obviates the need for ionizing radiation and intravenous contrast material administration in situations in which they may be undesirable, such as pregnancy, allergy and renal insufficiency [5].

Doppler ultrasonography examination of vascular structure is a fundamental diagnostic technique in determine changes and pathology in these vascular organs. Doppler ultrasonography examination of the kidney, as particularly highly perfused organ[6]

Four major indices are used in clinical practice: the Systole-Diastole(S/D) ratio, the pulsatile index (PI), acceleration time (AT) and the Resistive index (RI)[7,8].

They are also used for analysis of pathological blood flow pattern and may possibly be used to discriminate among various pathophysiological conditions of the kidney. Resistive index is more widely used than S/D ratio, AT, and PI[7].

The rationale of choosing these topics because Renal Doppler ultrasound is increasingly used in our practice for assessment of renal parenchymal diseases
as investigation and for evaluation of Reno vascular disease and allograft

Dysfunction so we need to compare intra renal Doppler indices measurement to biopsy findings

**Aim of the study:** To see how much Doppler useful in assessment renal parenchymal disease and allograft dysfunction compared to renal biopsy and could be good alternative method in patient refuse biopsy or contra indicated to it.

**Subject and Method**

An observational cross sectional study performed from 1st Dec – 2016 to 1st Oct- 2017 at the radiological department of nephrology and transplantation center (Baghdad Medical city complex).

A convenient sample of 84 subject with age ranged from 12 to 65 year (83 female, 51 male), 50 normal control (group A) and 84 patients with renal parenchymal disease (group B), 14 from (84) patients have allograft dysfunction post kidney transplantation surgery.

Full information are taken from all patients through well-developed questionnair

Inclusion criteria include all patients who referred to do renal biopsy as part of their diagnostic maneuver for renal problem Ex (generalized body edema, resistant hypertension, increase serum creatinine and proteinuria without definite diagnosis and the previously B-mode exam not demonstrate any clear pathology,

Patients who are excluded from study include those who are contra indicated for renal biopsy either due to low GRF less than 30 ml/min,or malignant hyper tension that exceed systolic 20 hg and diastolic of more than 14 hg,or small size kidney.

A real-time ultrasound device with color Doppler capacity using (Philips HD 11XE – DS) to estimate both B-scale and Doppler measurement, by trans abdominal approach in supine and oblique positions. All. After taking the reading the ultrasound system parameters will calculate RI, PI, AC time automatically. We use a single measure of each indices for each patient as average of both kidney, Then the patient sends to small theatre room in same day in order to taking renal biopsy

**Statistical Analysis:** Discrete variables presented using there number and percentage, chi square test used to analyze the discrete variable, two samples t test used to analyze the differences in means between two groups (if both follow normal distribution with no significant outlier), while one way ANOVA used to analyze the differences between more than two groups (if they follow normal distribution with no significant outlier) after that in the results is significant post Hoc Tukey test used to find which pair is significant. Receiver operator curve used to see the validity of different parameters in separating active cases from control (negative cases) and area under the curve i.e. AUC and its p value prescribe this validity (if AUC ≥ 0.9 mean excellent test, 0.8 – 0.89 means good test, 0.7 – 0.79 fair test otherwise unacceptable). Trapezoidal method used for calculate the curve. In a ROC curve the true positive rate (Sensitivity) is plotted in function of the false positive rate (100-Specificity) for different cut-off points. Each point on the ROC curve represents a sensitivity/specificity pair corresponding to a particular decision threshold.

A test with perfect discrimination (no overlap in the two distributions) has a ROC curve that passes through the upper left corner (100% sensitivity, 100% specificity). Therefore the closer the ROC curve is to the upper left corner, the higher the overall accuracy of the test

**Results**

Discussion

Doppler study done for both groups, we found that all group (A) was totally normal indices, while Doppler indices of patients (the group B) who have histopathological diagnosed of renal parenchymal disease show significant correlation with R.I were the sensitivity of R.I was 78.6% and less significant correlation with other 2 indices, P.I were the sensitivity was 69.3 % and sensitivity of A.T was 58.8%

The positive predictive value of elevation R.I in renal parenchymal disease was 68.3%, and the negative predictive value was 65.9% made the resistive index have agood value in predict renal parenchymal disease while the other indices, P.I and AT with their PPV 61 %, 58 % and NPV 51.8%, 50.1% resespectivly made them less accurate in prediction to renal parenchymal diseases.

Series of articles published from the University of Michigan, patients with isolated glomerular disease had normal R.I, where subject with vascular or interstial disease had elevated R.I value\(^9\). finding compatible with our study results

Authors Sugiura T et al \(^{10}\), Study by Mostbeck G H et al \(^{10}\), confirmed the same correlation (our study).

A However our result are not consistent with the finding of another study that conducted by ;Ikee R et al \(^{11}\) which not proved the correlation of Doppler ultrasound indices with chronic renal diseases.

Hypertension and age are two well-known factors that influence renal resistance\(^{12}\). In our study, age represent an independent factor of increased R.I; but it may cause RI to be within normal in young age, conversely, hypertension showed mild influence on renal resistance and R.I in study of

Ikee et al. \(^{4}\) who demonstrated that increase R.I may be attributed to vascular lesion and systemic hypertension. The authors Mostbeck G H et al \(^{4}\) and Riehl J et al \(^{5}\) linked the changes in RI to aging process rather than to renal disease.

Galesic K et al study show that RI can provide diagnostic information in several renal diseases\(^{13}\) where The RI value exceeding 0.80 is associated with a reduced likelihood of improved renal function after the correlation of renal artery stenosis and The RI value exceeding 0.80 is also associated with poor allograft survival after renal transplantation \(^{14}\). RI increases in diabetic nephropathy when the kidneys start to shrink and micro albuminuria occurs \(^{15}\).

In a study parbahar mr et al showed that RI allowed the early identification of patients with chronic tubulointerstitial nephritis \(^{16,17}\). Doppler ultrasonography, providing information about tubulointerstitial and vascular lesions, should predict renal prognosis \(^{18}\).

Conclusion

In our study we find a good relation for ultrasound Doppler indices which are the resistive index, pulsatility index and less significant acceleration time with changes in renal vascularity that occur in renal parenchymal diseases correlated with histopathological result. the segmental glumeriosclerosis was the higher percentage (38% of patients) and the interstitial nephritis had the lower percentage (6.%) of patients.

Changes in Freet3;T4 Thyroxine and Thyrotropin in Hemodialysis and Non-Dialysis Chronic Renal Failure Patients

Yasamin Abdul-Amer kadhum¹, Dalal Abd Al-Sattar Asaad¹, Ali Shalash Sultan¹

¹Biology Department, College of Science-Mustansiriyah University, Iraq

ABSTRACT

The metabolism, degradation and excretion of thyroid hormones is associated with renal function. The study was aimed to evaluate the serum urea, creatinine and thyroid function in hemodialysis and non-dialysis patients. The levels of creatinine increased in non-dialysis. T3, FT3 and FT4 decreased in hemodialysis chronic renal failure, but T4 and TSH were within normal values.

Materials and Method: The serum urea, creatinine, (TT4), (FT4). (TT3), (FT3) and Thrytropin (TSH) levels were estimated in serum 60 subjects with hemodialysis and non-dialysis in Baquba Teaching Hospital. They were divided into 2 groups as : Group 1 Containing 30 hemodialysis subjects (15 males, 15 females) and Group 2 containing 30 non-dialysis patients (15 males, 15 females). The levels of urea were measured by Urea- Kit called end point enzymatic method of urea concentration. Creatinine levels were measured by using creatinine kit methods.

Results: Hemodialysed subjects showed significant (P< 0.05) reduction in T3, FT4, FT3 and creatinine in comparison with non-dialysis subjects group. While Urea, TT4 and TSH value showed non significant difference (p>0.05).

Conclusion: Total thyroxine and TSH don’t effected in both groups of subjects.

Keywords: Chronic renal failure (CRF), Thyroid hormones

Introduction

CRF is a more slowly disease of the renal function progressing upon a period of months and years (¹) The disease is characterized by lower glomerular filtration rates (GFR) and special modified treatment of renal system such as dialysis is recommended for its treatment. (²) The rate of CRF occurrence involved 1 of every 5000 and impacts middle-ages with older people mostly (³). The kidneys has many functions in the metabolism, degradation and thyroid hormones excretion with related substances (⁴). The most commonly abnormality recorded is low serum FT3 level. Generally, thyroxine levels were normal or slight reduced in dialysed subjects (⁵,⁶). Subjects with of CRF always show clinical signs suspected of thyroid dysfunction, such as dry pale skin, reduce temperature, intolerance for coldness, reduced basal metabolic rate, inactivity, exhaustion and edema. Many studies of of uremic subjects for thyroid functions showed different conflicting results. Hyperthyroidism, hypothyroidism and euthyroid condition were recorded by many researchers (⁷). Serum (T3) levels were recorded to be reduced with CRF. Serum total and Free thyroxine levels were seen may be low, normal or elevated. Serum (TSH) levels were noticed to be normal in overall subjects of CRF characterized by low T3 levels. (⁸,⁹). CKD impacts the hypothalamus-pituitary thyroid axis and circulatory thyroid hormone. Low T3 is found in subclinical hypothyroidism common thyroid dysfunction in CKD subjects (⁹). Levels of TSH are usually normal (⁷,⁸). In CRF there is an continuous high decline in (GFR) which leading to the accumulation of urea, creatinine and other substances in the blood. GFR less than 15 mL/minute as stage five of CKD (¹⁰). Serum creatinine level in men is more than 5.0 mg/dl in stage five, and in women more than 4.0 mg/dl (¹¹). Hypertensive state causes renal failure affecting renal blood vessels, may further increased the blood pressure eventually leading to ESRD (¹²,¹³).
Materials and Method

60 patients (30 men and 30 females) with CRF were in rolled in this study. Their ages ranged from 20 to 50 year. A full clinical evaluation was performed in those subjects including history of disease and physical examinations. This evaluation revealed that all the subjects have no history of thyroid dysfunction and with different stages of chronic renal failure were involved in this work. 30 subjects who suffering renal failure hemodialyzed regularly and 30 subjects with conservative managements (non-dialysis). Requested 5 ml of blood were drawn from anterior cubital vein and were used to estimate serum FT4 and total thyroxine (TT4), Free and total triiodothyronine (TT3), TSH, urea and creatinine. Urea levels were measured by standard methods Urea- Kit.\(^{15,16}\)

Creatinine kits were used for creatinin estimation, creatinine in alkaline solution reacts with picrocaine to form complex color \(^{17}\). Thyroid hormones were estimated by radio immune assay techniques by hormonal Kit provides by BioMerieux, France.\(^{18}\)

Statistical Analysis: Data procession software package was used SPSS 20. Information were expressed (M ± SE). The means difference of two groups analyzed by t-test; the significance was tested at two-tail P value. The P<0.05 value of differences considered significant.

Results

Table (1) shows results:- Urea did not show any different significant (p>0.05) between non-dialysis and in hemodialysed subjects (23.28 ± 1.52 mmol/l; 23.10 ± 1.59 mmol/l) respectively. Creatinine levels reduced significantly (p<0.05) in hemodialysis subjects (297.93 ± 31.44) in comparison with non-dialysis subjects (350.166 ± 37.03 µmol/l). T3 (Figure 1), FT4 (Figure 2) and FT3 (Figure 3) decreased significantly in hemodialysis patients (0.63 ± 0.06 nmol/L; 9.44 ± 0.35 nmol/L and 2.32 ± 0.17 nmol/L) when compared with non-dialysis patients (0.86 ± 0.06 nmol/L; 10.87 ± 0.56 nmol/L and 2.99 ± 0.17 nmol/L) respectively. T4 and TSH showed no any different significant (p>0.05) between two groups (82.52 ± 4.29 nmol/L and 2.29 ± 0.42 mlu/ml) in non-dialysis and (82.39 ± 4.49 nmol/L and 2.03 ± 0.36 mlu/ml) in hemodialysis. As shown in table below.

Figure 1: Shows the level of T3 in nondialysis and hemodialysis

Figure 2: Shows the level of FT4 in nondialysis and hemodialysis
The regulating metabolism is done by thyroid hormones that affecting development, protein synthesis. Triiodothyronine (T3) and thyroxine (T4) are two hormones of thyroid gland. These hormones effecting significantly on renal disease that related to chronic kidney disease (CKD) (8). CKD has been shown to affect the pituitary-thyroid axis and the peripheral metabolism of thyroid hormones. Reduce T3 concentrations found commonly in laboratory tests by subclinical hypothyroidism in CKD subjects. Gupta et al (19) as recorded in present research. Low T3 syndrome is the most common disturbance in CKD subjects. The decline of serum T3 levels in CKD subjects may be due to impaired conversion of T4 to T3 results from the reduction of iodothyronine deiodinase because of malnutrition and/or chronic metabolic acidosis. From other side the decline in conversion of T4 to T3 peripheraly comes from the low clearance of inflammatory cytokines like TNF-a and IL-6 had been reported in CKD (20,21).

FreeT3 and FT4 in our study showed a decline in HD group while T4 showed normal levels but Merza and Hasson, (22) reported non significant difference. That Free and total T3 and T4 levels were usually normal or decrease in subjects of CRF (23). Which their levels may be normal or little decline, from otherwise free T4 may be elevated caused by heparin effects used in anticoagulation during hemodialysis (HD), inhibiting T4 binds to its thyroid globulins (24). Serum TSH levels are always normal as noticed in the present study. The present study suggest pituitary disturbances related to uremia (22). Clinically the renal function is estimated by serum creatinine and the blood urea nitrogen (BUN). The decline in the GFR caused by increasing in values of serum creatinine and urea nitrogen values in CRF (27). The laboratory haemodialysis is used for kidney therapy (30). In this technique urea, creatinine and free water removing from the blood. (25, 26) From above definition the levels of Creatinine increased in HD group in comparing with non dialysis group that hemodialysis lower creatinine concentration. Hence;the evaluated pre-dialysis and post-dialysis referred to levels of serum renal biochemical markers in CRF patients to elucidate the impact of dialysis on CRF subjects. That urea and creatinine levels in serum showed a significant fall in post-dialysis group in comparison with the pre-dialysis group (3). The amount of creatinine in serum depends on their generation, GFR and it’s secretion by renal tubules of serum creatinine. It was measured about 2% of the body’s creatine is transformed into creatinine daily, causing proliferation of creatinine at (male: 20 to 25 mg/kg/day; female 15 to 20 mg/kg/day) (28). Males revealed higher serum creatinine levels than females due to muscle mass. Our study included male and females.

Conclusions: - Low TT3 and Free T4 are seen in euthyroid chronic renal failure patients while TSH values within normal range. This normal TSH revealed functional euthyroid status in CRF.

The Culture of Terrorism Da’ashi and its Implications on Iraqi Society Medical Anthropology Study

Salwan Fauze Abed AL-Aobide¹, Habib Hashim Abid Ali¹
¹Department of Sociology, College of Art, University of Babylon, Iraq

ABSTRACT

The main theme of the research is the culture of terrorism and its implications in the Iraqi society - a study of medical anthropology in Tikrit. The most important cultural, social, psychological and health effects of the terrorist organization on the residents of Tikrit during the period of occupation. To reach the most important of these effects, and by staying in the study community for an appropriate period, and to reach important results.

Keywords: Culture, Terrorism, SIS, Society, Religious extremism.

Introduction

The concept of culture refers to the total social heritage of the human race. In other words, the history of culture is the history of man as a human being. For thousands of years it has passed through generations and in its transmission from generation to generation, some of its elements have been lost, Culture is the sum total of ways in which human beings live, moving from generation to generation through acquisition and learning. This culture has its historical political and religious roots. Wahhabism has spread various militant movements such as al-Qaeda in Afghanistan, which have taken Wahhabism ideologically and systematically.

Chapter I/The first topic/main elements of the study

First: Study problem:

Second: The importance of the study: Scientific importance: The scientific importance focuses on the theoretical framework of the study, which is reflected in the collection of scientific knowledge, clarifying the theoretical and reference features of the school’s functional structural direction, and the impact of role and function on the culture of thought and its impact on the culture of Iraqi society.

III. Objectives of the study: The study aims to achieve the following:

1. Identify the cultural factors that led to the spread of Da’ash thought in some areas of Iraqi society.

2. To identify the manifestations and images of the Da’ash thought by studying the institutions that they created.

3. To recognize the social changes made by the Da’ash thought in some parts of Iraqi society that he controlled.

Fourth: Study Questions: The study’s questions are:

1. What cultural factors have helped to control the flourishing and spread of its culture in some of the parts of Iraq it occupied?

2. If there is a culture of Da’ash, what are the factors leading to this culture?

3. What are the images, forms and symbols of this extremist da’is culture?

First: Culture: British anthropologist Edward Taylor has defined a “culture” as a “culture” of the broader ethnological meaning, which is the composite of knowledge, beliefs, art, ethics, law, customs and all other abilities and customs acquired by man as a member of society.(1) «Harry Shapiron «is» culture «as the whole of the manifestations of acquired behavior that are shown and practiced by individuals in a society of human societies.»(2)
Second: Terrorism: Terrorism is a set of anti-social and anti-social motives and actions by individuals, groups or organizations with the aim of changing existing social systems in society, undermining political security within society and causing terror and intimidation to humanitarian units. (3)

Fourth: Religious extremism: Extremism is defined as a set of beliefs and ideas that transcend politically, socially and religiously. (4) Extremism is always linked to what is essentially intellectual. Extremism may refer to a context in which an individual produces or reshapes extremist ideas, as well as political ideologies that oppose the very essence of values and principles and reject democracy and human rights. (5)

Chapter Two: Reference Framework for the Study

The first topic: the theory of cultural communication:
The theory of cultural communication arose from some of the questions posed by the School of Culture and Personality. (6) The analysis is based largely on some isolated cultural features, despite the fact that the anthropologists of the School of Culture and Personality. (7) since culture is all integrated because culture is an organized and structured unit. (8) The selection of aspects that are supposed to be positive in a particular culture to be combined with positive aspects of another culture in order to reach a better cultural system, apart from the value judgments that raise a series of issues involved in this proposal, seems simply untenable. On the other hand, there is a focus by some authors, (9) including “Hershkovitch” on what they call cultural survival, which elements of ancient culture, which can lead to a culture that leads to the continuity of culture despite the apparent changes. (10)

The second topic: the theory of functional structure:
(Durkheim) in the writing of the “Preliminary Forms” refers to how members of society exert control over each other through religious beliefs and rites. (11) He also argues that the distinguishing characteristic of religion is the division of the world into two essentially opposing kingdoms. (12) the first containing all that is holy and the other containing all that is profaned. (13) After his analysis of religion in writing functionally, he tried to prove that the function of religion is to strengthen the bonds that bind the individual to the society to which he is a member. (14) Since the forms of practice and religious beliefs may vary, they achieve the same functions everywhere and specifically (Durkheim) used social phenomena and the distinctive concept of sociology should be the study of social phenomena. (15)

Chapter Three:

Terror in the city of Tikrit: The first topic: factors and the spread of thought Da’ashi in parts of Iraq. It has become the talk of “the preacher” is the modern world, but it is not a modern one. (16) but several conversations in several languages and dialects and not only that, but several perceptions based on several approaches and ideas, and all claims to be the right talk with most of them a modern building to think. (17) He says that the establishment of the foreign intelligence industry and supported by the state to achieve the interests, including the saying that it is an adult caliphate on the methods of prophecy. (18) which is the duty of allegiance to it, and there are those who believe that “” urged “century Kharaj in this era, who said the Prophet. (19) The more they come out of them, the horn will be cut off until the antichrist comes out in the sight of them. (20)

This terrorist organization has carried out many terrorist operations in parts of Iraq. (21) In order to achieve sustainability, survival and expansion, the organization has adopted a dual-track strategy:

First: the expansion and expansion of the territory surrounding the areas controlled by Syria and parts of Iraq through its military capabilities. (22)

Second: global expansion and expansion must be achieved through the system of states in locations where jihadist movements, followers and supporters exist, to accept and accept the allegiance of other jihadist movements, and to motivate al-Qaeda groups to split; and to encourage different and independent jihadist groups to join an advocacy organization. (23)

1. genocide “Spyker massacre”: The massacre took place in Tikrit, Salah al-Din province, and this massacre took place after the capture of the Air Force students at Spyker Air Base in the Iraqis on 12 June 2014. (24) after the arrest of a preacher On Tikrit in Iraq and one day after their control of Mosul. (25) where they captured “2200-2000” student from the Iraqi Air Force and led them to the presidential palaces in Tikrit and killed them there and in other areas shot dead and some of them were buried alive, and have filmed
a supporter of the course of this massacre.\(^{26}\) In which some of the clan members participated And some of the students succeeded in escaping to the area of science, which was steadfast at the time did not fall by the organization of an advocate of the terrorist until 24 June 2014. \(^{27}\)

2. Recruitment: The recruitment of individuals that was followed by a call was based on the propaganda discourse of the organization of the state, which is based on direct action on the Internet, and the organization was closely linked to the speech of propaganda.\(^{28}\) whether the speech images or evidence transferred through traditional and digital social media, as the organization knows well that The organization’s war is primarily a media war, in which it uses all available means to achieve its propaganda objectives.\(^{29}\)

3. Persecution of the Yezidi minority: The Yezidi minority has been subjected to the most severe attacks on minorities in the history of the region, so that what is happening to them is called the genocide.\(^{30}\)

The results of this terrorist act are an indication of the security breach and a violation of the military and security sectors. \(^{31}\)

1. Explosive devices
2. Assassinations by light weapons
3. Demolition and detonation of the graves of the righteous
4. Stealing Antiquities.\(^{32}\)

The third topic: The results of the culture of terrorism Da’ashi on parts of Iraq Da’ash’s organization represents an unprecedented threat to international peace and security.\(^{33}\)

The organization has sought to advocate through a media strategy in achieving limited goals

1. Recruitment and publicity to attract large numbers of those interested in organizing.
2. To establish authority as the manifestation of power in northern Iraq and Syria by establishing it intellectually and juristically.
3. Support the armed organizations that are close to the organization intellectually and morally.\(^{34}\)

The study reached the following results:

1. The results of the study showed that the sample of the study according to the sex variable of the respondents indicated that the highest percentage of males included their percentage (80%).
2. The results of the study showed that there are no cases of the imposition of a polygamous system for the respondents, and according to the percentage indicated (100%), which included all members of the total study community.
3. The results of the study show that those who do not force one of the girls to marry their Mujahideen, where they accounted for 60%.
4. The results of the study show the situation of those who do not force widows to marry their Mujahideen, and their percentage (60%).
5. According to the results of the study, there are no cases of female captivity, according to the percentage of the percentage (100%), which is the highest percentage of the total study community.
6. The results of the study showed that the sample of the study according to the imposition of men’s and women’s clothing, which represented all the sample that does not impose uniforms on clothes, and by (100%).
7. The results of the study show that the sample of the study according to the variable nature of the relationship between the terrorists and the public and the people, where the type of relationship is good, the proportion of (60%).
8. The results of the study show that if the relationship is good with terrorists, according to the opinion of the respondents, those who answered the index (fear of not giving them the freedom to work), and by (27%).
9. The results of the study show that it is difficult to tolerate some special things, Those who responded to the (no) index and (67.6%).
10. The results of the study show that the opinion of respondents who answered (no) not to give an opportunity for tolerance, and those who answered the index (the fact that the other parties have an intellectual and religious approach) by 25%.
11. The results of the study indicate that there is an important role for the weakness of the means of
social control, which works on the spread of the culture of terrorism Daheshi, while the proportion (69%).

12. The results of the study show that the private economic sources to finance the terrorist advocate, according to the respondents, who answered the index of all methods and methods, and by (80.6%).

13. According to the results of the study, the type of currency of the gangs of the supporter of the terrorist according to the opinion of respondents, a number of respondents answered the index (all types of currencies mentioned), and by (100%).

14. The results of the study show that the highest percentage (87.4%) is the highest percentage of the total sample, which supports the state monopoly of resources and good things lead to increase the culture of terrorism Da’ashi, and the lowest percentage was (12.6%) is the proportion of less than.

15. The results of the study indicate whether terrorists are forced to compel people to perform religious duties such as prayer. The highest percentage of those who responded to forcing terrorists to perform prayer duties was 92.2%, which indicates that the culture of terrorists.

Conclusion

There are many influences of a provocative occupation for parts of Iraq, including the intellectual impact, where this culture has planted the ideas of violence and atonement and the murdering among children and young people.

An important aspect of the culture of terrorism is the healthy a psychological impacts. This period of occupation has affected the spread of diseases among women, children and the elderly due to lack of food and health, as well as psychological diseases through the suffering of the people of the occupied territories.

The Effect of Using Competitive Exercise in Motor Fitness and Speed of Transition for Football Players (Junior Class)

Majid Mohammed Mukhli†, Fouad Hammad Asil‡, Mustafa Hapeep Shallal§
†Secondary Almithaq for Boys, Directorate of Education Province of Anbar, Ministry of Education, Iraq; ‡The College of Physical Education and Sport Sciences, University of Anbar, Iraq; §Department of Physical Education and Sports Sciences, Al Maarif University College, Iraq

ABSTRACT

The aim of the research was to identify the effect of competitive exercises in the special numbers stage on physical abilities such as motor agility and the transition speed of the emerging football players. The study assumed that there is a positive effect of competitive exercises on the research variables. The research was carried out on a sample of young players of the Ramadi football club for the 2018 sports season. The researchers used the experimental method for two equal groups.

The study found that competitive exercises had a positive effect on the development of motor fitness and the transition speed of football players. Competitive exercises in the special numbers stage because of their role in the development of search variables, so that the player to perform the skills of motor used throughout the match in the competition. The researcher concluded that the competitive exercises introduced and applied to the experimental group had an effective effect in the development of the physical variables of the members of the research sample.

Keywords: Competitive Exercise, Motor Fitness and Junior Class.

Introduction

The field of sports training is one of the areas that have witnessed the recent development of remarkable.... Every day is witnessing the development of a fast pace amazing both in terms of information on the numbers of the athlete or the results of these numbers, which appear in the achievement of athletes to high levels.

Football is one of the most popular games in the world. It is the reason for the high level of excitement and excitement that this game has. The complex nature of soccer with its physical, muscular, mechanical, planning and high skills requires skills and abilities. Especially to achieve a high level of performance during the time of the game and pressure affecting, so you need to make a great effort of the player throughout the game and a high ability to perform skill efficiently to face the tremendous development in the defense methods of the competing teams, as in the requirements of bribes The motor of the transition and the speed with which the players must be owned by the attackers or defenders.

One of the requirements of the development of football players is their numbers in many areas as any sport activity is determined by the general framework through skills, performance, space and the law of the game, and uses this development a similar development in ways of training the players to prepare their numbers in an integrated. Therefore, the researchers’ tendency to highlight the importance of their research in the experience of numbers of players in the stage of special numbers, using competitive exercises and knowledge of the impact on the agility and speed of the transition of football players.

Through the experience of researchers in the field of football and the fact that they are players and coaches in their field and by watching some of the club’s youth group games, the researchers noticed that there is a lack or
a clear failure in the training status and performance of the players in the team, especially when the opposing team to click on the team winning the ball command Which led to the formation of the burden and fatigue of physical and mental consumption of the ability and efficiency of the team, resulting in frequent mistakes of players during the course of the game and lack of focus in most of the times of the game and the performance. Therefore, the researchers decided to go into the experiment of introducing competitive exercises in the special numbers stage, which is similar to the cases of play and its impact on the members of the research sample.3

Research aims: Identify the effect of the use of competitive exercises in motor fitness and the speed of transition of football players (beginner’s category).

Hypothesis:
1. There are statistically significant differences between the results of the pre and posttests of the motor agility and the transitional speed of the control and experimental groups of the research sample.

2. There are statistically significant differences between the results of posttests in motor fitness and the speed of the transition of control groups and experimental football for the members of the research sample.

Research Methodology and Field Procedures:

Research Methodology: “The choice of the appropriate approach is determined by the nature of the research problem in order to reach the appropriate solutions within the assets of scientific research and on this basis the researchers used the experimental method (the two sets of control and experimentation with pre and posttests) because it is one of the most sufficient means to reach a reliable knowledge “.5

The research sample: The sample of the research consisted of the players of the football club Ramadi football season 2016/2017, the number of (37) players were chosen by the random method of irregular then divided into two groups by lottery, one control and the other pilot and the reality of (16) player for each group after the exclusion of the researcher Number of sample players for the purpose of homogeneity.

Devices and tools used in the search:
1. Medical balance.
2. Measuring device length.
5. Legal football balls.
6. Burke for planning test areas.
7. Metric measuring tape.
8. Round hoops.
9. Arab and foreign sources.
10. Internet Information Network.
11. Tests and measurement.

Description of the tests used in the research:

Motor fitness test:5

Test Objective: Measure the ability to change direction while running (Fitness).

Tools: measuring tape, stopwatch, number 4 chairs, burke, registration form.

Procedures: Draw the starting line length of 1.80 m and thickness of 5 cm and four chairs will be placed in front of the starting line where the first barrier at a distance of 3.60 m of this line and the distance between each line and the last 1.80 m and determine the points on the ends of the beginning and end, Let it be (A, B).

Performance description: When the laboratory is given the starting signal starts running between the chairs in the form of (8) and then the laboratory revolves around the
last barrier, and continue running between the barriers in the same way the other end at the point (B).

**Method of recording:** Calculate the time taken and give the laboratory only one attempt, adding to the time it takes the laboratory 10/1 of a second only when touching any of the four chairs.

**Transition speed test:**

**Test Objective:** Measure the transition speed of young footballers.

**Tools and possibilities:** Yard or playground marked by distance (60 m) set with start and end line, stopwatch, pistol launch.

**Method of testing:** The player stands behind the starting line (high position), and when the start signal is heard, the player runs as fast as possible until he passes the starting line.

**Method of registration:** The player is counted as the time spent in the distance (60 m), and gives the player only one attempt.

**Pilot study:**

1. **The first pilot study to test physical abilities:**
   The first pilot experiment was conducted on Sunday (1/10/2018) on a sample of (4) players from the research community. The objective of the experiment was:
   - Ensure the validity of the devices and tools used.
   - The adequacy of the working group and their understanding of the work process.
   - Ensure that tests are easy to apply and suitability to the sample level.
   - Determining the time required for the tests.
   - Know the obstacles that may appear to avoid errors.

2. **The second pilot experiment of competitive exercises:** The researchers, with the help of the team coach, conducted an exploratory training unit on (4) players who are the same players of the first pilot experiment on Monday (2 - 10 - 2018)
   - Ensure that the training modules are implemented in a timely manner.
   - Ensure the times set by the researchers when conducting competitive exercises in the training module
   - To distribute work duties to the assistant working group and to determine the sequence of measurements and tests.

**Field research procedures:**

**Pre Tests:** The tests were carried out on the Ramadi football club, where the researchers tested the spatial and temporal conditions and the method of conducting the test and the auxiliary team. Achieve the same conditions as possible when performing post-tests.

**The main experience (competitive exercises):** The researchers prepared competitive exercises within the period of special numbers on some physical variables of the players of the youth category for the period of (8) weeks by forming (2-1) of the training units and by (3) training units per week and in the form (2-1) of the week’s where the length of the unit (60 - 90) minutes. The main section consisted of the competitive exercises prepared by the researchers and the share of the competitive exercises from the time of the training unit was (60) minutes. The researcher took care of the training level, age and physical and skill abilities of the research sample members, Owned M sports training as well as the opinions of specialists in football, where he began to implement the vocabulary of competitive exercises on Saturday (7 - 10-2018) and continued until Wednesday (29 - 11-2018).

**Posttests:** The researchers carried out post tests for the members of the research sample on Saturday (2 - 12 - 2018) following the same conditions and controls in the pre tests and the auxiliary team under the direct supervision of the researcher.

**Results**

</tbody>
</table>

*The value of t (tabular) (2.04) below the level of significance (0.05) in front of freedom degree (16 + 16-2 = 30)

The table shows (4) there is a significant difference in the results of the post tests of two experimental and control in agility motor and transition speed for the benefit of the experimental group, which showed the value of (t) calculated and both tests is greater than the value of (v) Tabulated at the level (0.05) and the degree of freedom (16 + 16-2 = 30).

Discussion of Results

The results showed that there were significant differences in both the pre and post tests for both groups. This indicates the positive effect of both methods. The control group used in its distance learning method To acquire fitness elements, and the experimental group that used competitive exercise to acquire fitness elements, as demonstrated by the search results. “Organized physical training develops public and private fitness. It gives the player agility, flexibility, mobility and durability, and gives them plenty of fun”.

Table (3) shows that the experimental group was better than the control group in the development of fitness and speed, which resulted from competitive training, which included a set of competitive exercises that correspond to the real competition conditions of the game. Competitive training is of great importance at the end of the special number stage. These exercises are an important place in training and are increasingly influenced by the use of other training methods. At the same time, in the exercise of competition exercises, all aspects of the athlete’s training situation are clear and cannot be replaced by any means other training, especially during the direct construction phase of the sportswear “.

Therefore, the exercises used close to the direct activities of the competitions, and the use of methods and methods of training are in a manner that leads to the establishment of rules that lead to the development of physical qualities of the specific and directly determine the success of competitions.

Conclusions

1. The use of competitive exercises in the stage of the number of young footballers has a positive impact on the development of motor agility and the speed of transition, as shown by the results of the research.

2. The results show that there are significant differences between the pre and posttest of the control group in motor agility and transition speed.
3. The results of the pre-test and post-test experimental group in motor agility and transient speed show that there are significant differences.

4. The results showed that there were significant differences between the post-test of the control and experimental groups in motor agility and transition speed.

Effectiveness of Electromedian Exercises to Develop Visual Attention, Perception of the Environment and Reaction of Football Players

Asaad Ali Safih¹, Saba Shaker Farhan¹, Raafat Abdulhadi Kadhim¹

¹The College of Physical Education and Sport Sciences, University of Al-Qadisiyah, Iraq

ABSTRACT

The research and the importance of the research included: The importance of mental abilities in the field of physical education in general and football in particular. The research problem was to identify the possibility of electro-exercise in the development of visual attention and awareness of the environment and reaction to football players. The goal of research is

The aim of the research is to use electromedian exercises to develop visual attention, awareness of the environment and reaction to football players.

The imposition of research is

There were statistically significant differences in favor of the group using electro medians exercise.

The fields of research were:

1. Human Field/Clubs Players of Qadisiyah Governorate
3. The spatial field/the laboratory of sports psychology and the football field in the Faculty of Physical Education and Sports Sciences - University of Qadisiyah

The research method and its field procedures were also used. The researchers used the experimental method and discussed the sample of the research, which are football players in the clubs affiliated with Qadisiyah Governorate, and discussed the tools used in the research, the testing used and the statistical means.

The results of the research were presented and discussed in the form of tables and then discussed, conclusions and recommendations were the most important

Conclusions: There is an evolution of the post tests of both control and experimental groups.

Keywords: Electromedian exercises, visual attention and reaction.

Introduction

Modern technology has been introduced in all areas of life, especially in the field of psychology, as many systems have been developed to measure and develop psychological and mental abilities such as the testing system, the Cogni Plus system, the Rihacom system and others. Some of the systems allocated tests that athletes can use such as Veena sport. This interest in mental abilities and how they are measured and developed as a result of the development of the players’ abilities and their physical and technical abilities, which required them to develop their mental abilities to keep pace with the speed of the game. One of the capacities that the system has been concerned with is attention in all its forms. “The independence of the psychological factors and the abilities of each other is a fundamental pillar in dealing with all variables that affect attention”.

DOI Number: 10.5958/0976-5506.2019.03222.4
The system also focused on the cognitive variable and its types, including the perception of the ocean, which is characterized by “the process in which the stimuli are organized or is the awareness of the ocean and the absorption of relations between the parts of the situation in the ocean.” Hence the importance of research in harnessing the electronic system and field exercises together in the development of visual attention and awareness of the environment and reaction to football players.²

Research Aim: The use of electromedian exercises in the development of visual attention and awareness of the environment and reaction to football players.

Hypothesis: There were statistically significant differences in favor of the group using electromedian exercise.

Method and Procedures

The sample: The research society included football players in Qadisiyah governorate clubs and the participants in the first division of (6) clubs and the number of (192) player either the sample of the search was chosen by random method, was a draw between the clubs in the search community and was selected clubs (Diwaniyah and Al-Ittifaq) and were divided into two groups, (Al-Ittifaq Club) and Experimental Club (Diwaniyah Club) and (25) players for each group. The sample rate was 27.08%. The homogeneity and equivalence between the individuals and the sample groups were carried out in the variables under study.

Table 1: Shows the number of the society and the sample of the research

Study design: The researchers used the experimental approach in the same way as the two groups to suit the nature of the problem studied.

Tests used in research: The researchers used the Vienna Test System to obtain the results of the search variables. The tests used in this system are:

Visual attention test (FVW):³ The researchers also identified the variables measured by the test of attention (number of strikes, number of false positives, reaction time, ability to discriminate, tendency to answer, time of work)

Test description: The test consists of a set of images, numbers, words, syllables or drawings that show the stimuli either once or twice, and the laboratory must make a decision by pressing the red button or the green button on the keyboard as in picture 1, the test phase begins once the laboratory presses the green button. The program starts displaying the elements one by one and one element only for each screen page. The test should be determined in the form (new or old) and after each operation the items are automatically displayed.

Figure 1: Shows the keyboard for the test of attention

Test duration: The time required to test (15) minutes (including instructions and exercise stage) means that the training time is (5) minutes and the actual test time (10) minutes.

Ocean perception test (pp.):⁴ The researchers selected the ocean perception test after direct access to the Vienna system and its equipment, including the Ocean Recognition Test. Using the test literature, researchers were able to identify the exact shape of the device, how to conduct the test and the reliability of the results obtained. The researcher also found the possibility of applying this Testing on football players because the variables measured by the ocean perception test are (the field of total vision, divided attention, visual concentration, visual reaction, emotional maturity).
Pre Test: The researchers carried out the pre-test on 24/7/2018 for both experimental and control groups at 9 am.

Exercises used in research: After the pretest, the curriculum was prepared by the researchers on the experimental group, which depends on the division of the module into the first two electronic system using the cogniplus system and the second field using a group of motor exercises that develop the variables under study on completion of the training module on the same day. Completion of the electronic exercise Players go to the field to perform the exercise. As for the control group, it remains on the motor exercises given by the trainer. The training modules lasted six weeks. The following table shows the details of the method used. The researchers used the level of difficulty for electronic exercises and intensity of exercise.

Post-test: The researchers conducted the pre-test on the study sample on 30/9/2018 for both experimental and control groups at 9 am.

Analysis and discussion of results: The results of the pre and posttests as shown in Table (2) and Table (3) indicate that there are statistically significant differences between the pre and posttests and for the benefit of the post-test and the variables of the study. The researchers found that the nature of the exercises in the experimental group, which depends on mixing electronic and field exercises in a single training module, which makes the player to benefit from the capabilities practiced on the electronic side and applied in practice in the field and thus be installed and developed faster and more. In the exercise of attention, the distribution and distribution of stimuli in a way that facilitates the installation of the sample and the result of continuing these exercises and the integration of stimuli (audio and visual) led to an increase in the level of attention and confirms The athlete has the ability to quickly draw attention from sexy (And) that the football player needs attention in its different forms and more than one source, as his attention to the ball and the player and fellow player and the competitor and the voice of the coach and other stimuli and is intended to choose the most suitable
to respond to him, so the nature Exercises used within the system Cogni Plus, which focuses on each type of attention (auditory attention, and visual attention), has an effective impact on the development process.⁸

In the perception of the ocean, electronic exercise has an effective effect in stabilizing the development of the sample, the subsequent physical exercise of the exercise of the dancers is an increase in the effectiveness of the awareness of the surroundings of the player,⁹ which makes him aware of the surrounding players and colleagues and competitors and spaces and the boundaries of the stadium at the same time and without This is what makes the player able to move on the pitch and execute the play plan with ease and smoothness, thus achieving what the coaches aspire to. “Batting believes that the high environmental interference practice results in higher retrieval and better learning transition.”¹⁰

**Conclusions**

1. There is a difference in the level of attention and awareness of the environment and reaction to football players.
2. Electromedian exercises have an effect on the development of the studied variables.
3. The overlap of electronic and field exercises in one exercise has an impact on the development of the ability of football players and thus raise the level of attention and perception of the ocean and react to them.

AgNps as Antibacterial Agent Against *Klebsiella pneumoniae* Isolated from Wound Infection

Khamael H. Obaid

*University of al Zahraa for women, Kerbala, Iraq*

**ABSTRACT**

One hundred wound swab samples were collected from wound patients who visited the Teaching Hospital wound unit, Hillah, Babylon province, Iraq. *K. pneumoniae* was identified morphologically and biochemically. Total of 10 (10%) from total samples exhibited positive culture for *K. pneumoniae*. Antibiotic susceptibility was tested for 12 antibiotics. *K. pneumoniae* isolates showed high resistance rates to penicillins including ampicillin, amoxicillin (100%) and piperacillin (90%). The present study indicated that resistance to β-lactamase inhibitors including amoxicillin-clavulanic acid, ampicillin-sulbactam and ticarcillin-clavulanic acid were 100%, 90% and 70% respectively. This investigation also indicated that *K. pneumoniae* had high rates of resistance to the third generation of cephalosporins including cefotaxime (80%) followed by ceftazidime (80%), ceftriaxone (80%) and Cefepime (60%). During the study period, 4 (40%) isolates were found resistant to both imipenem and meropenem. Anti-bacterial activity of silver nanoparticles (AgNps) against *K. pneumoniae* displays excessive widespread spectrum antibacterial action against established bacteria with increased zone of inhibition diameter that is proportional with the increase in nanoparticle concentration. The (MIC of AgNps ranged from 50-100μg/ml and the MBC ranged from 100-200μg/ml.

**Keywords:** Ag Nanoparticles, *K. pneumonia*, wound infection.

**Introduction**

This genus was described for the first time by Trevisan in 1885 [1]. The genus *Klebsiella* sp. are rod shaped, 0.3-1μm in diameter and 0.6-6μm in length, Gram-negative, non-motile, non sporulating, it is among the oldest known genera in the family bacteria that are encased by a prominent polysaccharide-based capsule.

The *Klebsiella* are found in different habitats including water, soils, sewage and mucosal surfaces of mammals. In humans, *K. pneumoniae* can be present in the nasopharynx and in the intestinal tract [2]. This microorganism is responsible for (3%-9%) of community and hospital acquired pneumonia and septicemia, especially in immune compromised individuals. Carrier rate (1% to 6%) found in healthy individuals rise to 20% in hospitalized patients. Higher incidence was recorded in urinary tract in specific groups of patients at risk [3]. Most *Klebsiella* are ampicillin resistant, but acquisition of plasmid-encoded resistance led to nosocomial infection outbreaks as in 1970s and 1980s due to gentamicin and tobramycin resistance [4]. *K. pneumoniae* reported resistant to cefuroxime, ceftazidime and cefotaxime. This was chromosomally encoded, but subsequently plasmid-encoded ESBL caused outbreaks of infection in intensive care units [5]. The increasing antimicrobial resistance among ESBL producing *K. pneumoniae* strains. Besides, they have acquired plasmid-mediated AmpC enzymes, unlike ESBLs, AmpCs are poorly inhibited by β- lactamase inhibitors and are less active against cefepime and cefpirome than ESBLs [6]. That makes therapy very difficult and use of expensive broad spectrum drugs like carbapenems which are the most effective antibiotics against these bacteria [7].

**Materials and Method**

**Culture media:** Ames transport, Blood agar base, Muller-Hinton agar, Nutrientagar, Nutrient broth and Brain heart agar (Himedia, India).
Antibiotics discs were purchased from (Bioanalyse, Turkey) and are listed in table 1.

Specimen Collection and Isolation: Bacterial isolates were acquired from the patients who stay in the Teaching Hospital wound unit in Hillah, Babylon province, Iraq. Total of 100 specimens were collected using Ames transport media then inoculated into brain heart infusion broth (BHI) and incubated at 37°C for 24 hr. Isolated colonies were purified on nutrient agar (NA). K. pneumoniae (10 isolates) were identified depending on the morphological feature on culture media and biochemical tests according to Bergey’s manual [8].

Antimicrobial Susceptibility Test by Disk Diffusion Method: In this test, the antibiotics names and its standard inhibition diameters were used as recommended by [9]. The Inhibition zone diameter was measured using a caliper and compared with those determined by the Clinical Laboratory Standards Institute (CLSI) to conclude the resistance (R) or sensitivity (S) to each antibiotic.

Antibacterial activity of AgNPs: AgNPs (60nm) was acquired from (US research nanomaterials Inc USA). The antibacterial action was handed out as designated by the CLSI. Bacterial sensitivity to AgNPs is tested by disk diffusion assay as mentioned earlier [15]. Triplicates of AgNPs in dilutions of (400, 200, 100, 50, 25 and 12.5µg/ml) in sterile deionized water were prepared and ready sterile discs were emerged in each dilution. The bacteria isolates were initially incubated for 15min at 4°C then incubated at 37°C for 24hr. The Positive results were documented after a zone of inhibition was noticed [10].

Minimum bactericidal concentration (MBC determination) and Minimum inhibitory concentration (MIC): Bacterial isolates were incubated overnight at 37°C that were used to mark 0.5 McFarland. About 10ml tubes of nutrient broth medium was prepared with five dilutions of AgNPs (400, 200, 100, 50, 25 and 12.5µg/ml) in triplicates with a negative control (without AgNPs). Each tube was inoculated aseptically with 1ml of the bacterial suspension (about 10⁹CFU/mL). The inoculated sets were incubated at 37°C overnight. The lesser concentration with no turbidity is represented as the MIC. Tubes with no turbidity were cultured on nutrient agar plates and incubated at 37°C overnight. Bacterial colonies growth was checked and the concentration that displays no growth is represented as the MBC [9,10].

Results and Discussion

Present results showed high resistant rates to penicillins including ampicillin, amoxicillin (100%) and piperacillin (90%). This result is in agreement with the results being reported by Al-Najaf [11] who found that 100% of K. pneumoniae isolates were resistant to ampicillin, amoxicillin and 92% were resistant to piperacillin. Resistance of K. pneumoniae to penicillin’s is not surprising, because K. pneumoniae has chromosomal encoded resistance to several penicillins [12]. The present study indicated that resistance to β-lactamase inhibitors including amoxicillin-clavulanic acid, ampicillin-sulbactam and ticarcillin-clavulanic acid were 100%, 90% and 70% respectively. This investigation also indicated that K. pneumoniae had high rates of resistance to cephalosporins including cefotaxime (80%) followed by ceftazidime (80%), ceftriaxone (80%) (and Cefepime (60%). These data agrees with [11]. In another similar study carried out by [13], 96.7% resistance was noted for cefotaxime and 85% resistance for ceftazidime among isolates. The resistance to third generation cephalosporins is mainly due to mutations in the common group of class A β-lactamases, consisting of TEM, SHV and CTX-M β-lactamases that has extended hydrolytic spectrum activity on cephalosprins, but also a number of other rare enzymes that often exhibit ESBL activity. During the study period, 4 (40%) isolates were found resistant to both imipenem and meropenem. In other study [14], reported the rate of resistance to imipenem in...
During three years K. pneumoniae elevated from 1.3% to 11.1% in US. Carbapenem resistance K. pneumoniae is an emerging phenomenon threatening the public health. As carbapenems have long been considered the antibiotic class of last resort to treat severe infections caused by pathogens that produce ESBLs as in table 2 [15].

Antibacterial activity of AgNPs: AgNPs showed powerful broad spectrum anti-bacterial activity against the tested bacteria and it is concentration dependent, (table 3). The 400 µg/ml concentration showed the highest zone of inhibition. The MIC of AgNPs ranged from 50-100 µg/ml and the MBC ranged from 100 -200 µg/ml. AgNPs cause sudden decline in bacterial cell membrane integrity in addition to the release of reactive oxygen species (ROS) where superoxide species is generated and contributing in the degradation of biomolecules [16].

Figure 1: MIC and MBC of AgNPs of K. pneumoniae
Conclusion

The results showed that the isolated *K. pneumoniae* have high rate of resistance to Penicillins, Penicillins+β-lactamase Inhibitors, Cephalosporins and Carbapenems antibiotics. AgNPs proved its efficiency and highly recommended as safe and economic alternative antibacterial agent with significant inhibitory and antibacterial effect.

Study of Hepatitis C Virus (HCV) Genotypes in Al-Muthanna Governorate, Iraq

Salam Allawi Hassan¹, Wisam Salih Abbood¹
¹College of Medicine, University of Al-Qadisiyah, Iraq

ABSTRACT

The current study aimed to determinate the genotypic prevalence of hepatitis C virus (HCV) at Al-Muthanna province – Iraq. Then determine which genotype is predominant. The prevalence of HCV genotypes in this province was unknown. The genotypic study is important for the selection of the best antiviral drugs of the disease. This study was conducted in the health institutes of Al-Muthanna Governorate for the period from October 2018 to April 2019. The study included collection (5 ml) of the blood sample for the total number of persons (2842) from (thalassemia patients, blood donors and renal dialysis patients). Then, they were examined by the initial test using ELISA technique, where it was found that 81 (2.85%) people were positive for this test. Then, the PCR technique (RT-PCR) was carried out for serum samples which were positive for ELISA test. Results showed that 60 (74.07%) of the 81 (2.85%) samples were positive in the PCR test. DNA sequencing technique was used to determine which genotype is prevalent in Al-Muthanna Governorate, 30 samples were tested from 60 samples of positive samples in PCR. The results showed that three genotypes of HCV were detected in patients, genotype 1a 16 (53.33%), genotype 2a 9 (30%) and genotype 2b 5 (16.66%) with significant differences (p<0.05). Genotype 1a was the predominant.

Keywords: Hepatitis C Virus, Genotypes

Introduction

Hepatitis C, a serious viral disease of the liver and caused by hepatitis C virus (HCV) infection is a major health issue of global concern (¹). Hepatitis C virus (HCV) belongs to the Flaviviridae family and it is the only member of the Hepacivirus genus (²). HCV is an enveloped positive-strand RNA virus (sS RNA). Six main HCV genotypes and over 100 subtypes have been therefore recognized (³). HCV genomic RNA composed of a single open reading frame (OFR) flanked by 5' and 3' untranslated regions (UTRs), which encodes for a single large polyprotein, processed by cellular and viral proteases to form a structural and non-structural proteins (⁴). In most developing countries, transmission of HCV occurs through exposure to infected blood and blood products at various healthcare facilities and localities. Such contamination usually occurs through unsafe injection, blood transfusions, organ transplants and sometimes through mother to child transmission or the sharing needles among Intravenous drug uses (IDUs) while Unlike the developed countries, where the mode of HCV transmission is mainly through intravenous drug uses (IDUs) (⁵³⁸). A recent study shows that, HCV genotypes 1 and 3 are the two most prevalent genotypes globally and account for about 76.3% cases of HCV in the world. However, most cases of HCV caused by these two genotypes are found in East and South Asia respectively. East Asia is also burdened with genotypes 2 and 6 and the two collectively account for about 14.5% cases of global HCV infections. The global cases of HCV due to genotypes 4 and 5 are approximately 8.3% and less than 1% respectively. Africa and Middle East have the most cases of genotypes 4 and 5. However, genotype 5 is considered as the least prevalent globally but most endemic in sub-Saharan Africa regions (⁷).
Materials and Method

Patients and Study Location: This study was conducted in the health institutes of Al-Muthanna Governorate, including (Al-Hussein Teaching Hospital- Al-Amal Center for renal dialysis, Teaching hospital for gyniatrics and pediatrics -Thalassemia Unit, Al-Rumaintha General Hospital, Al-Khader General Hospital, Main Blood bank and Public Health Laboratory for the period from October 2018 to April 2019, the study included collection of blood samples from suspected people of HCV infection (blood donors, thalassemia patients, renal dialysis patients).

Blood Samples: Venous blood sample (5ml) were collected from suspected people with HCV by using sterile disposable syringes then placed in gel tube (free of anticoagulant) and allowed to coagulate at room temperature for (15-20) minutes then centrifuged at 3000 rpm for 10 min for separation of serum. Then the serum is placed in a plane tube without gel and frozen in (-20 °C) until use.

Method

1. Investigation of anti HCV antibodies (IgG) in serum by ELISA technique: All the samples 2842 were tested by enzyme linked immune sorbent assay (ELISA) technique for detected of Anti-HCV antibody (IgG) in serum by using (Fortress company test Kit/USA) using the manufacturers protocol.

2. Investigation of HCV infection by using polymerase chain reaction (PCR) technique:
   - A. Viral RNA Extraction: Viral RNA was extracted from serum samples by using AccuZol™ total RNA extraction kit (Bioneer, Korea) and done according to company instructions.
   - B. Estimation of extracted RNA: The extracted RNA were estimated by using Nanodrop spectrophotometer that used to measurement the RNA concentration and purity at absorbance 260/280 nm at ratio 1.8 as pure RNA.
   - C. Nested RT-PCR: Nested RT-PCR was performed for molecular detection of Hepatitis C Virus based on core protein gene that amplified with specific primers that provided by (Macrogen. Company, Korea) by nested RT PCR method (8).

   Nested RT-PCR was done by two step :
   - First Step: First reaction RT- PCR master mix preparation: RT-PCR master mix was prepared by using (NEXpro™ RT-PCR Master Mix, Genes Laboratories company, Korea) and done according to the company instructions.
   - Second Step: Second reaction Nested PCR master mix preparation: Nested-PCR master mix was prepared by using (AccuPower® PCR PreMix, Bioneer company, Korea) and done according to the company instructions.

   D. Nested RT-PCR product analysis: The PCR products were electrophoresed in 1% agarose gel stained with ethidium bromide and observed under gel documentation system (Wised, Korea).

3. DNA sequencing: Nested RT-PCR products of positive Hepatitis C Virus core protein gene were sent to Macrogen Company in Korea for performed the DNA sequencing by (AB DNA sequencing system) where (30) samples were tested from (60) samples of positive samples in PCR products with in mind that equal numbers of both genders and study groups were send.The DNA sequencing analysis for HCV genotyping was conducted by using phylogenetic tree UPGMA method (MEGA 6.0 version), Multiple alignment analysis based ClustalW alignment analysis, and NCBI-BLAST for homology sequence identity.

Results and Discussion

For the purpose of studying the genotyping of the hepatitis C virus, positive samples of RT-PCR products were confirmed by gel electrophoresis method (Figure -1). Then, DNA sequencing performed by (AB DNA sequencing system), the DNA sequence analysis of HCV was performed by using phylogenic Tree UPGMA method (MEGA 6.0), Multiple alignment analysis based ClustalW alignment analysis (Figure -2), and NCBI-BLAST for homology sequence identity (Table -1).
Figure 1: Agarose gel electrophoresis image that show the Nested PCR product of core gene in hepatitis C virus serum samples. Where M: Marker (3000-100bp), lane (1-15) some positive and negative Nested PCR amplification of core gene at 405bp Nested PCR product size

Figure 2: Multiple sequence alignment analysis of core protein gene HCV partial sequence for local HCV isolates and NCBI-Blast HCV genotypes isolates (from NCBI-BLAST online). The multiple alignment analysis was constructed using ClustalW alignment tool in (MEGA 6.0 version). That showed the nucleotide alignment similarity as (*) with substitution mutation core protein gene HCV nucleotide sequence

The genotyping analysis results showed that the genotype (1a) was the most to give significant (P<0.05) positive results. The ratio of positive records of (1a) genotype was (53.33%) out of (16) examined samples. On the other hand, genotype (2a) showed significantly (P<0.05) lower ratio of infection comparing to that of the genotype (1a), with (30%) out of (30) total samples. Finally, genotype (2b) was the lowest to show the relation with the prevalence of the disease. Genotype (2b) revealed significant (P<0.05) decline in the ratio of the positive results when compared to genotype (1a) and genotype (2a), with (16.66%) out of (5) examined samples (Table -2).

Hepatitis C virus (HCV) infection is a major health problem in developing countries. Geographical distribution of various genotypes of HCV is useful for
understanding the epidemiological status, detection of mode and source of infection, designing the program of control, evaluating the response to treatment and development of diagnostic methods and vaccine production, this study was the first in Al-Muthanna province, which included the search for genotyping of hepatitis C virus among patients by using DNA sequence.

In Iraq, the results of the current study are in agreement with results of previous studies as follows: In Sulaimani province, A study showed that the genotype (1 and 2) were the most common among other genotypes in different study groups by percentage (87.5%), (8.3%) respectively (9) and In Basra province, A study has shown that the genotype (1a) were of the most common genotyping among patients in percentage (37.25%) (10) but there are other studies in Dhi Qar province, Baghdad province and another study in four Iraqi provinces are (Najaf, Babylon, Karbala and Qadisiyah Provinces) showed that genotype (4) was predominant among other genotypes with patients in Percentage (86.27%), (89.4%), (41.38%) and (84.6%) respectively(11-14).

In other countries, many previous studies agreement with the results of the present study in genotyping as follows: In Jordan, A study found that HCV genotype 1a (73.3%) is the most prevalent genotype in Jordanian patients, this genotype is also predominant in Jordanian blood donors and in hemodialysis patients of some Middle Eastern countries including Lebanon, Turkey, Cyprus and Syria (15). In Turkey and Israel, A study showed that genotype (1) was the predominated (16). In Iran, A study showed that HCV genotype (1) was the most prevalent genotype (17, 18). In Lebanon and Saudi Arabia, There are studies showed that the highly prevalence of genotype (2) in dialysis patients (19).

The molecular epidemiological studies have shown marked differences in geographical distribution by geographical regions and among patients groups, genotypes (1, 2 and 3) are widely distributed throughout USA, Europe, Australia and East Asia, genotype (4) is largely confined to the Middle East, Egypt and central Africa, genotype (5) and (6) are found predominantly in South Africa and South East Asia (20).

To discuss the results in this study, it is believed that transmission of the genetic pattern occurs from one region to another during migration or travel for medical purposes or tourism and others, Where many of the residents of the province go to treatment in the neighboring provinces or for treatment outside Iraq, for example in India, Iran, Turkey, Jordan, Syria or Lebanon where previous studies have reported that epidemiological profile of genotype 1 was linked to injection drug use, patients who acquired HCV through blood transfusion or use non-sterile needles (21).

Conclusions

The present study showed that three dominant genotypes in Al-Muthanna province/Iraq, which is 1a 16 (53.33%), 2a 9 (30%) and 2b 5 (16.66%) respectively.

The Impact of an Educational Field for the Development of Perceptual-Kinetics and Skill of Passing Cub’s Football

Aban Abdul Kareem Mezher¹, Diaa Gaber Mohammed¹
¹The college of Physical Education and Sports Sciences, University of Babylon, Iraq

ABSTRACT

The researcher used the experimental method to design two equal groups (control and experimental) for the sample of (20) players for the season 2018-2019, and the researcher prepared an educational field. The researcher designed a device to measure the perceptual-kinetic perceptions, the researcher conducted a pilot exploration to ensure the safety of devices and tools, and the researcher conducted pre-tests, as well as the implementation of special exercises for motor compatibility and skill passing football through the field prepared for a period of (8) (3) units per week A, then the researcher conducted post-tests and processing data statistically and then presented and analyzed and the researcher concluded the effectiveness of the educational field of perceptual-kinetics and also recommends the use of the educational field during the educational units for players to develop other football skills.

Keywords: Educational field, perceptual-kinetics and passing.

Introduction

To reach the level of outstanding athlete in any event or sports game must have rules and fundamentals to help achieve, and most notably the multiplicity of duties and activities that are used in the context of education and preparation to achieve the optimum level. The game of football is one of these sports events, which receive increasing attention from all developed and developing countries and that of all ages and races of all kinds. This has made people with experience and competence and workers in the field of the game, always thinking about finding the best methods and methods that work to develop and refine the talents of the players to the highest levels.¹

The field of educational play is an important educational methods that have been used to develop the players skills and motor skills, as well as the use of devices and tools. Sensory-kinetics, which is an important variable for the interconnection of body parts during skill performance, is a process associated with the nervous system to regulate the work of forces.²

The use of various means and tools in the process of education and training have the greatest impact in the development and upgrading of the players in terms of mental and skill where the process of performance development becomes more effective and exciting for the players. This shows the weakness in the skill of passing football, which represents the process of learning and mastery of the utmost importance when teaching age groups, so the researcher considered the study of this problem through the preparation of an educational field that includes exercises (physical - skill) that the researcher is supposed to work to develop the perception. The mobility and skill of passing football using this special educational field to develop those variables.³

Passing is also a key skill in terms of the interdependence of internal forces with external forces, which play an important role in offensive situations. From this point of view came the importance of this research in the preparation of a modern playing field containing exercises and equipment and tools and aids to develop the perceptual sense of mobility and skill passing football for young people.
Research Aims:

1. Preparation of an educational field for the development of perceptual-kinetics and kinetics and skill passing of the cubs football players.

2. Design a special device to measure perceptual sense-kinetics of the football of the Cubs.

Research Methodology and Field Procedures

Research Methodology: The researcher used the experimental method in the two group’s equivalent method to suit the nature of the problem and research objectives. Experimental research is one of the types of scientific research through which the relationship between research variables can be measured.

Research Community: The researcher identified the players of Al-Zawraa Sports Academy in Babil Governorate, the junior category for the ages (12-14) years and the number (25) players, the researcher chose a random sample of (20) players representing a percentage of (80%) of the original community, And randomly divided them into two groups (experimental and control) and the way of even and odd numbers by (10) players in each group for the sports season 2018-2019.

Means, tools and devices used:

1. Survey of experts and specialists.
2. Arab and foreign sources.
3. Legal football field.
4. Footballs (20).
5. Stopwatch number (2).
6. Suppression number (20).
7. Counting colored rings (12).
8. Medical balance to measure weight.
9. Measuring tape type linen length of 50 meter.
10. Camera type (Sony).
11. CD for photography.
12. Electronic calculator type (dell).

Device design for perceptual-kinetics: The researcher designed a device to measure the perceptual-kinetics (distance, direction, time) and presented the researcher to a group of experts and specialists in the specialty (sports training, motor learning).

The mechanism of work of the device: It is a device emulator for the sensors-kinetics of football cubs used to measure the speed of response and determine the direction and distance of the exciter in milliseconds (ms) (1/1000) of a second and this high accuracy that enables us to get real results when performing the test. Each player consists of the original board that contains the generators in different colors (green, red, blue), which work alternately. The laboratory cannot finish the flashes (9). The LEDs illuminate (9) times for each laboratory and must put his foot in a dedicated space similar to the color of the LED lighted as quickly as possible to calculate the time of each laboratory. Note that each laboratory sees Seek a total distance of (13.5) meter. It is not possible to know which LED will work.

Identify the tests used in the search: In the field of identifying tests and measurement and for the purpose of identifying the best tests, the researcher used the sources and scientific references as well as presented to the experts for the purpose of determining the most suitable tests of skill passing football for cubs.

Football Passing Test: Objective of the test: to measure the accuracy of the scroll.
**Tools:** markers, target (1 \times 1) m, footballs, tape measure.

**Method of performance:** The laboratory stands with the ball at a distance of (10) m from the target and when you hear the signal the laboratory handles the ball and is fixed towards the target.

**Method of registration:** Each laboratory is given (5) balls to perform five attempts as follows:

- Degree for successful attempt.
- Zero for failed attempt.

**Pilot study:** The researcher conducted the pilot study on 1/9/2018 at 4:00 pm on Saturday and on a sample of 5 players from Al-Zawraa Sports Club academy aged (14) years to find out the suitability and validity of the instruments of the test.

**Scientific basis of the tests:** A scientific evaluation of the tests was carried out before the start of the implementation of the main experiment in order to determine the validity, reliability and position as applied to the survey sample.

**Validity test:** In order to ensure the validity of the test, the researcher used the content honesty through a questionnaire distributed to a group of experts and specialists in the field of physical education and football for their opinions.

**Test stability:** In order to ensure the validity of the test, the researcher used the mid-split method.

**Objective testing:** The researcher calculated the objectivity of the test by finding the Spearman Brown correlation coefficient of two arbitrators, after statistically processed.

From Table (3) which shows the median and the deviation, for the pre and post tests and for the total tests under consideration (perceptual-kinetics-passing) and for the control group, we find that the results of perceptual-kinetics test in the pre-test achieved a median of (9.78 Sec.) and a spring deviation of (1.11), either in the post-test for the same skill The median reached (8.72 Sec.) with a deviation of 1.01 below the level of (0.05) and a degree of freedom (9), while the results of the passing test and in the pre-test achieved a median of (19) and a deviation of (1.5), and in the post-test for the same skill, the median reached (19.5) with a spring deviation of (0.988) below the level Z (0.05) and degree of freedom (9).

Table 4: The mean and deviation of the pre- and post-tests and the value of the calculated Wilcoxon and its statistical significance are shown for the results of the tests under investigation (experimental group) under the level of significance (0.05)

</tbody>
</table>

By looking at Table (4), which shows the median and deviation of the pre- and post-tests and the total tests under consideration (sensory-kinetics-passing) and for the experimental group, we find that the results of the test of perceptual-kinetics and in the pre-test achieved a median of (8.85 Sec.) In the post-test for the same skill, the median reached (8.23Sec.) With a deviation of (1.01) below the significance level (0.05) and the degree of freedom (9). We find that the results of passing test and in the pretest test achieved a median of (18) and a deviation of (1.5), but in the post-test for the same skill, the median reached (19) and a spring deviation of (1) under the level of significance (0.05) and the degree of freedom (9).

Discussion of the Results

Through what has been presented in table (3) and (4), which shows the presence of significant differences and statistically significant for the benefit of the post-test of the control and experimental groups, as for the control group and attributed the researcher attribute this reason to the commitment of players to the units of the curriculum prepared by the coach for the skills that Included in the vocabulary of special exercises in the school of football, which helped to develop the level of players through the appropriate repetitions, as well as training is the key factor in the interaction of the learner with the skill. The tests attribute this development to the effectiveness of the exercises that helped the experimental group in developing the ability of the perceptual kinetics, which is an important motor abilities that must be available in the performance of basic skills reel Foot and especially the skill of passing and is the common denominator in most events and sports. 

In order to explain the findings of the researcher to test the passing skill, we highlight the details of table (4), through these results shows the impact of training clearly in the level of performance of passing skill and this development came in the performance of this skill, as a result of continuous training in the training units of the game, which requires precision and perfection in performance and focus by the coaches all plays a continuing important role in reaching the player to the high level of technical performance of the skill in terms of accuracy, integration and installation of high technical performance. Therefore, the researcher considers that the continuous training on the performance of passing skill and clarify the correct performance and correct errors lead to its performance become automatic and accurate without thinking about its parts, that is, the player’s performance reaches a high degree of mechanism and automatic when the training is inherent to the player ball and repetition and continuous practice and without interruption as well Focus on exercises of a variable and diverse nature.

As for the experimental group, the researcher attributes the significant differences between the pre and post tests and in favor of the post in the development of the skill of passing football to introduce these exercises and aids and the interaction of players with them positively during the educational units and their response to all the requirements of motor performance.
required of them, as well its important role in the development of the experience gained by the players from the educational units of compatibility exercises and skill football biography, as well as these exercises led to the diversity of forms and uses to the development of accuracy of performance, as well as the researcher attributes the reason for this development to the use of A variety of auxiliary tools during the educational modules, which have been important in the development of the perceptual sense and the skill of passing football, To increase the excitement of the learner must diversify the methods and tools used to make the learning process more clear and easy.11

Conclusions
1. The field of training has the effectiveness and impact in the development of motor passing of the players in the implementation of some basic skills of football.

2. There are differences in impact in favor of the curriculum applied in the field of training and in each (perceptual-kinetics, passing) football.

3. The device a great effectiveness in measuring perceptual sense-kinetics of football players Cubs.

The Impact of Compound Exercises in the Development of Some Perceptions of The Environment for Football Youth

Hussein Hamzah Najm¹, Diaa Gaber Mohammed¹, Hussein Salih Najm¹
¹The College of Physical Education and Sports Sciences, University of Babylon, Iraq

ABSTRACT

Complex exercises work to develop and refine talents for football and young ages and from the beginning of the training age of the player to reach the highest levels, and that the level of good performance of the player is reflected by a set of basic skills and abilities possessed in the face of different perceptions of the ocean and make the right decision and proper within the competition and the conditions of the game. The researchers aims to be the preparation of composite exercises (skill - planning) through the use of different training methods and a variety of football beginners and to identify the impact of these composite exercises in the development of these perceptions as they used the experimental method For a sample of (30) players, and the implementation of harmonic exercises installed in the main section only by (24) training units and we showed the results of the research that was presented and analyzed for the tests before and after the research group there were significant differences in the development (field of vision).

The researcher’s conclusions show that the combined exercises affected the effectiveness of the performance of football’s youth in the face of the diverse perceptions of the environment offensive play positions.

Keywords: compound exercises and environment.

Introduction

Specialized in the field of football to teach young people to invest play plans and integrate the educational skill with the planning side and complete other physical and psychological aspects in addition to the development of skill and plan and attention to the conditions of competition as there are several different circumstances that occur to the player and must learn and experience before entering them, including Perceptions of the ocean as many perceptions such as field of view, attention and control, the power of concentration and perception of isolation, which the player must train and adjust and try to reduce the impact on him to reach optimal performance.¹

The researchers noted the weakness of the football players and attention to the open ocean conditions faced by the player, which generates a weakness in the face of offensive and scoring in these various situations, so teaching them and training them to face different perceptions during the game is very necessary, especially In the junior stage, which is one of the most important stages as the player is in a crucial stage to move to the advanced stage, which is the stage of youth, where the planetary learning is late and there is a great loss of effort and time.²

The importance of the research is that the impact of these exercises in the development of emerging players and the link between the performance of tactical planning with control and awareness of other variables of perceptions of the ocean in order to develop the players to make the right decision Attacking Attitudes During Competition It is a simple attempt by the researcher to develop the skillful and tactical performance of football youth.³

Research aims:

1. Identify the impact of compound exercises in the development of some perceptions of the environment for young football in the specialized school - Babylon.
2. Identify the preference of the two groups in the development of environmental perceptions of the youth football in the specialized school - Babylon.

Research hypotheses: Combined exercises (skill - planning) have a positive impact in the development of some perceptions of the environment for young people football.

Research Methodology and Field Procedures

Research Methodology: The researchers used the experimental method to design the two equal groups with pre- and post-test to suit the nature of the problem to be solved.

Research community and its samples:

Research community: The researcher identified the research community of the emerging players in the specialized schools for the care of talented football in the province of Babylon and the ages of (15.16) years and the number of (38) players.

Search samples:

1. Sample of the pilot: This sample consisted of (8) players randomly selected from the research community representing the specialized school.

2. Main sample (sample application): This sample consisted of (30) players representing the emerging players in the specialized football school in Babil province.

Homogeneity of the sample and equivalence of the two research groups:

Homogenization of the research sample: The researcher investigated the homogeneity of the research sample in variables related to morphological measurements (length, mass, age, training age) as shown in Table (1).

Table 1: Shows the homogeneity of the research sample in variables (length, mass, age, training age)

The results of Table (2) show that the sig values in the pretest tests of some environment perceptions between the control and experimental groups were greater than the level of significance (0.05), which indicates the equivalence of the two groups in all pretest tests.
The means and tools used in the research:

1. Arab and foreign references and sources.
2. Interview.
3. Observation.
4. Tests and measurement.
5. Legal football field.
6. Legal footballs type (PUMA) German origin number (20) balls.
7. Plastic signs (10).
8. Legal goals.
10. Computer (laptop) type (Dell) Korean origin number (1).

Field research procedures:

Identify environment perceptions: A game of football in which there are many variables and different conditions during the game and competitions and at all times of their time and these conditions may be natural or artificial and there are many perceptions that the player must sense and the ability to change in decision-making through the rapid perception and distinctive interpretation of these Environmental perceptions, which the learner must master and apply during learning or practice exercises and before entering the competition must be prepared for them, however fast and changing perceptions, and include the audience and players colleagues and competitors and the ball and the correct expectation of all these There are also perceptions pertaining to the law of the game, which must be carefully observed and not violated, all these are perceptions of the periphery faced by the player during the game, therefore, the player must be taught to develop the face of these perceptions and attention to them through various exercises and thus reflected on the development of performance The player during the competition, including the development of the face of different offensive positions and accuracy of scoring, especially in this stage junior stage where learning is very important at this stage in order to install this learning before moving to the youth stage and the development of the skill side etc. Fold through a variety of exercises to help the players to make the right decision and appropriate, according to the offensive position experienced by the player.

Characterization of environmental perception test:

Test application: The examiner sits and looks at the computer screen and focuses his attention to the center of the screen, which should be a distance between (40 - 60 cm), and when the examiner moves less or more than the allowed distance will appear an alert on the computer screen to alert the examiner to return within the standard range of the examination And then the device measures the angle of field of view of the total examiner.

Stages of the test: It goes through three main stages, which can be summarized as follows:

1. Instructions Phase Instructions are given here, step-by-step instructions and information about the test and what will be the subject of the stimulus or questions and so on. And how to use the comprehensive keyboard as well as how to use the foot pedals and so. Also can use the keyboard or foot pedals by hand and right foot, or hand and left foot and according to the desire of the examiner.

2. The Practice Phase: This is the stage that follows the instruction phase, where the examiner is trained on how to respond to the test through some actual illustrative examples. If the examiner made three mistakes or if he did not make any definitive response within 5 minutes, the exercise phase will stop and the program will ask the examiner to refer to the examiner for further instructions. The test applicant can then take the appropriate action, either to return the entire phase back to the instruction phase and so on, thus ensuring that the actual test is performed only after it is found that the examiner has understood and understood the instructions accurately.

3. Test Phase: This is the phase immediately following the exercise phase, in which the rotary knob in the overall response plate should be used with the left or right foot pedal as desired, provided that the examiner is warned not to use both pedals simultaneously. One.

After the test is completed, a help screen is displayed asking us to either show the scan results directly on the computer screen or print them on the printer. Rank for each paragraph with the time taken to answer the test, with Profile showing the detailed test based on the standard scores.
Test duration: The time required for the test is about 15 minutes (including instructions and exercise phase). The variables selected by the researcher are measured within the test of environment perceptions measured by a peripheral perception system within the Vienna test system can be illustrated as follows:

1. The field of vision.
2. Control (focus force).
3. Divided attention.

The main experience: The researcher relied on the following steps after all variables and circumstances of the research were stopped in order to conduct the field experiment.

Pretests of the research sample: The pre-test was conducted on Sunday 30/7/2018.

Implementation of the contents of the combined exercises (skill - plans): The researcher presented models of educational units that include these positions and in order to be accurate results were implemented educational units on the research sample with the assistance of the team and under the direct supervision of the researcher.

The vocabulary of the content of the combined exercises are as follows:

1. It took (8) weeks to carry out the combined exercises (skill - plan).
2. The number of educational units per week (3) units.
3. The total number of units (24) educational units for the experimental group.
4. Time per unit of education (120) minutes.
5. The application of compound exercises in the main section only and time (80) minutes.

The researcher started the implementation of composite exercises prepared on Friday, 3/8/2018 at five o’clock in the housing stadium in the province of Babylon and until Wednesday, 26/9/2018.

Posttests for sample search: Tests were conducted for some environment perceptions of the members of the research sample on Sunday 30/9/2018 at nine in the morning at the University of Babylon - College of Basic Education.

**Results**

In order to compare the results of the post-test of some environmental perceptions between the control and experimental groups and to find out which is better, the researcher used (t.test) test for asymmetric (independent) samples, as shown in Table (3).

**Table 3: Shows the mean, the standard deviations and the value (t) calculated in the post-tests of cognitive flexibility and some environmental perceptions between the control and experimental groups**

* The value of (t) tabular and amounting to (1.70) indicative level (0.05) and the degree of freedom (28).

The results of Table (3) show differences and differences in the values of the computational media in the dimensional tests of some environment perceptions (field of vision, concentration, divided attention) between the control and experimental groups of the experimental group. On the significance of the differences, the researcher used the test (t.test) for the independent samples, Experimental.

Discussion of the results of the differences between the pre- and post-tests of some environment perceptions of offensive play positions and accuracy of scoring between the control and experimental groups: 
Through the results presented in Table (3) which show the existence of significant differences in the dimensional tests of some environmental perceptions between the control and experimental research groups and better for the experimental group, the researcher attributes the
reason for these differences to the combined exercises and tools used by the researcher in developing some environment perceptions. 6

For the experimental group in all educational units of the main section in addition to explanation and clarification for the players in how to make the best decision after watching the best model and this helped to attract the attention of the players during the performance of composite exercises in the main section of the educational units and The following is easy to encrypt and save information in the mental memory of the players and easily summoned in different offensive situations in similar situations of play and the reality of competition as he stressed to reach the player to achieve a good level in the game must focus on the good choice of targeted exercises and put the player in Training conditions especially close to the conditions of the game. 7

All this has a great impact on the development of players also to the perceptions of the environment faced by the player during the combined exercises and its reflection in the reality of competition and games, as well as to watch these situations and offensive situations before the application It helps the player to develop the perceptions of the environment, 8 which includes the field of vision, focus and divided attention and this is confirmed by Attention is indispensable part in training during the games occur situations and situations require the player constant observation and constant alertness and permanent focus so that he can overcome These sudden situations and unexpected difficulties that often appear in real playing conditions, 9 as the field of vision of the football player is very important in order to expand his vision to competing players as well as fellow players in order to pass the ball to them or receive them in addition to focus is important The divided attention that the researcher deems very important for football players because the divided attention helps players in making the best decisions during the games to pay attention to the opponent and colleagues and follow their movements and create opportunities to score in the team’s goal. 10

Conclusions

1. Complex exercises (skill - tactical) have an active role in the development of some perceptions of the environment for the offensive play positions and accuracy of scoring for football beginners.

2. Players of the experimental group achieved noticeable differences in the post-tests of some environment perceptions of the offensive play positions and accuracy of scoring, but less than the players of the experimental group.

Serum Levels of Lipocalin-2 and Prostate Specific Antigen in Patients with Prostate Cancer; A Comparative Study

Karwan A. Muhammad¹, Khudhiar A. Khudhiar², Salam S. Ahmed³

¹B.Sc. Medical Laboratory Technology, Main Blood Bank, Kirkuk Health Directorate, Iraq; ²Ass. Prof. in Biochemistry, ³Professor of Clinical & Medical Biochemistry, College of Medicine, Tikrit University, Iraq

ABSTRACT

Background: Prostatic cancer is a common disease, increasing dramatically with age. Over one million men are biopsied annually in the United States, making this a major public health problem. Approximately one in nine men with prostate cancer the median age at diagnosis is 66 years, and the median age at death is 80 years. Lipocalin 2 has been identified as an adipokine. It is expressed in liver, lung, kidney, macrophages and epithelial cells. Lipocalin 2 function involves in a variety of physiological activities, which is an important factor in innate immune responses. Prostate-specific antigen (PSA) is the most reliable tumor marker available and is widely used for the diagnosis and management of prostate cancer, and it is another commonly test used to screening for prostate carcinoma.

Material & Method: This is a cross sectional, hospital based study, this study was carried out from Jan 2019 to July 2019. Forty – eight men with prostatic cancer were screened to participate in the present study. Men ages were between 50 - 88 years old, and they were from center and the periphery of Kirkuk city. Forty – two apparently health men without prostatic cancer and with negative family history for the first and the second degree relative of prostatic cancer were considered as a control groups, their ages were from 50 to 80 years. A serum level of Lipocalin 2 was measured by ELIZA and prostate specific antigen by VIDAS.

Results: The mean serum level of lipocalin 2 was significantly elevated in prostate cancer men compared to control men (37.03 ± 3.71 vs. 18.19 ± 2.94 ng/dl) respectively at a P 0.05. This study showed that there is the significant difference between the patients and the control group concerning PSA level, which was higher in sera of the patients (23.53 ± 8.34 vs. 2.47 ± 1.40).

Conclusion: Both of lipocalin 2 and PSA were higher in the sera of the patients with prostatic cancer, and were positively correlated with each other.

Keywords: Prostate Cancer, lipocalin 2, and prostate specific antigen.

Introduction

Prostate cancer (PCA) is the leading type of most common diagnosed urological cancer in men, and its prevalence is continuously increasing.(1) It is more common in men over the age of 65 years. There are 15% cases with positive family history of prostate cancer worldwide.(2) Prostate cancer is one of the solid cancers that is also the second leading cause of cancer death among males.(3) It is occurs when the cells in the prostate gland grow out of control and form lumps, called tumor. Prostate cancer shows that more than 95% of malignancies in prostate are adenocarcinoma (the medical term for a cancer that starts in gland cells is adenocarcinoma). Other types of cancer can also start in the prostate gland, including sarcomas, small cell carcinomas, neuroendocrine tumors, and transitional cell carcinomas.(4,5)

Lipocalin 2 (LCN2) also known as neutrophil gelatinase associated lipocalin (NGAL), Lipocalin 2 is a small protein which belongs to the superfamily of lipocalins, was identified originally as a 25 KDa secreted...
protein. It has become of interest to cancer researchers because its expression changes in colorectal, breast, and pancreatic cancers, and highly expression of LCN2 in hepatocellular carcinomas (HCC). Hypothesized that the serum NGAL may act as a diagnostic biomarker of early acute kidney injury (AKI). It has been documented that LCN2 can also bind to soluble siderophores of mycobacteria, namely carboxymycobactins, and that LCN2 can inhibit the in vitro growth of M. tuberculosis, and have a role in reducing bacterial outgrowth and mortality.

Members of the lipocalin protein family are characterized by their ability to bind small hydrophobic molecules (such as retinoids, hormones and fatty acids). They often bind to specific cell-surface receptors and form macromolecular complexes. Lipocalin 2 have role in iron-homeostasis: impact on cell proliferation, differentiation, and as modulator of the inflammatory response, several studies highlight the increased production of LCN2 upon diverse pro-inflammatory stimuli.

Prostate-specific antigen a member of the kallikrein gene family, is a serine protease synthesized by prostate epithelial cells, with a molecular weight (MW) of 30 KDa glycoprotein and containing 261 amino acids, the gene encoding for PSA is located on chromosome 19. It is secreted into seminal fluid in high concentration (mg/ml) that is primarily involved in liquefying human sperm through a proteolytic mechanism, which appear normally in serum from the healthy males at low concentrations (μg/L).

Patients, Materials, and Method

The patients were collected from Azadi Teaching Hospital, Kirkuk General Hospital and Kirkuk Oncology Center, that approved by Kirkuk Health Directorate, to collect the samples from the patients. This study was carried out from Jan 2019 to July 2019, in Kirkuk City-Iraq. A verbal consent was taken from each men included in this study whether considered as a case or control. A total of 48 patients with prostate cancer were enrolled in this study, their ages were from 55 to 88 years. An apparently health men without prostatic cancer and with negative family history for the first and the second degree relative of prostatic cancer were considered as a control groups, their ages were from 50 to 80 years.

By using a sterile disposable syringe 5 mls of blood sample were taken by vein puncture from each subject enrolled in this study. Blood samples were placed into disposable gel test tubes, after 20 minutes blood clotting, centrifuged at 3000 rpm for 15 minute and the obtained serum were aspirated using mechanical micropipette and transferred into clean test tubes which labeled and stored in deep freeze a - 20 until the time of estimation. Serum of the patients and controls had assay: levels of Lipocalin 2 and prostate specific antigen. Lipocalin 2 was measured by ELIZA, while prostate specific antigen by VIDAS. The correlation of lipocalin 2 to prostatic specific antigen was also estimated.

Statistical Analysis: All the date collected in this study was analyzed by using the student t-test, the mean, standard deviation, and P-value was also considered. The significance was considered at a P value of less than 0.05.

Results

This study recorded the highest rate of prostate cancer (42%) was within the age group 70 - 79 years, followed those within the age group 60 - 69 years (35%), then age group 50 – 59 years (15%). least rate of prostate cancer in this study was (8%) within the age group ≥ 80, as evident in figure (1).

Discussion

This study recorded that the highest rate of prostate cancer was within the age group of 70 to 79 years, while the lowest rate was for those of equal or less than 80 years, also the result showed that the prostate cancer risk was increase with age. In this study only 4 patients were ≥ 80 years of age; this little number was related to the limitation of the participants of the old ages. The result of study was in agreement with Bashir et al, (143) who recorded that the age was positively associated with prostate cancer risk. It is rare before the age of 40, but the chance of developing prostate cancer rises rapidly after the age of 50 years. Crawford ED, et al, (18) reported that prostate cancer is associated with aging, they recorded that in the United States of America, that 70% of all cases of prostate cancer were diagnosed in men of 65 years of age and over. It is relatively rare for prostate cancer to be diagnosed in men below 50 years of age. The probability of developing prostate cancer increases from 0.005% among individuals aged below 39 years to 2.2% for those aged 40 to 59 years and 13.7% for those aged 60 to 79 years.

Measurements of BMI in this study showed that the mean of BMI was higher in men with PCa when compared with healthy men. Although the precise etiology of prostate cancer is unknown, several lines of evidence suggest that environmental and/or lifestyle factors may have an important role in the development of clinically significant disease. However, even though lifetime dietary fat consumption and obesity are clearly linked, the association between obesity and PCa risk in epidemiologic studies has been inconsistent, Amling et al, (19) showed that the obesity was one of several potential risk factors like the obesity that might be related to the development of clinically significant PCa.

This study showed that there was a significantly higher mean serum level of LCN2 in prostate cancer men compared with that of the control groups. Lipocalin 2 has an important role in the regulation of cellular oncogenesis and apoptosis. The identification of biomarkers involved in the proliferation, migration, and invasion of prostate cancer cells can help create new therapies for treating this type of cancer. (20) Lipocalin 2 may have roles in prostate cancer through its effect on intracellular iron; LCN2 can either deliver or remove iron from the cell, depending on the context. The iron-bound form of LCN2 is internalized after binding to the 24P3R receptor. This leads to the release of iron and subsequent increase of intracellular iron. In contrast, when the iron-free form binds the 24P3R receptor, LCN2 is associated
with the intracellular siderophores, resulting in iron chelation and iron transfer to the extracellular medium, leading to reduced intracellular iron. Iron is critical in regulating cellular proliferation, invasion and cancer metastasis. Thus, LCN 2 may play important roles in prostate carcinogenesis and progression via regulation of iron homeostasis. The higher serum level of LCN2 in patients with prostatic cancer in the current study, these results were in agreement with Sicheng BI et al, (22) suggesting that levels of serum LCN2 in PCA patients depending on the type of prostatic tumor whether benign or malignant, and LCN2 may be a potential serum marker for the diagnosis of PCA. Combined detection of LCN2 and PSA contributes to the early diagnosis of PCA. Muşlu N, et al,(23) Turkish study showed that the increased serum LCN2 levels, when sensitivity fixed to 80% specificity of LCN2 was better than PSA indicate a relation with PCA diagnosis.

The results of this study indicate that the serum level of PSA significantly increased in sera of patients with prostatic carcinoma as compare with control group, the elevation in serum level of PSA was > 20 ng/ml. The elevated PSA serum levels more than 4 ng/ml and abnormal digital rectal examinations are signs that a malignant prostatic lesion might be present and warrant multiple prostatic biopsies that put the diagnosis. However, PSA serum levels below the threshold of 4 ng/ml do not guarantee the absence of disease, the prevalence of prostate cancer in these patients being as high as 15%, of which a significant percentage are high grade tumors. Increase serum levels of PSA above threshold can be determined by a multitude of other factors besides prostate cancer, including benign prostatic hyperplasia, prostatitis, atypical small acinar proliferation, and prostatic intraepithelial neoplasia. (24, 25) The significantly increased serum level of PSA in sera of patients with prostatic carcinoma, these findings correlated with the studies by, Armstrong et al, (26)

Conclusion

This study showed that there is positive correlation between LCN 2 and PSA among PCA men. This finding was in agreement with the result of Sicheng BI et al, (22) who found a positive correlation between serum LCN2 and PSA levels in PCA men. And who reported that the lipocalin 2 may be a potential serum marker for the diagnosis of PCA. Combined detection of LCN2 and PSA contributes to the early diagnosis of PCA.

Practicing, Attitudes and Beliefs of Physicians at Al-Emamain Medical City towards Seasonal Influenza Vaccination

Nibras Alaa Hussain1, Berq J. Hadi Al-Yasseri1

1Family &Community Medicine Department, College of Medicine, Al-Nahrain University, Baghdad, Iraq

ABSTRACT

Background: Influenza viruses are the causes of influenza epidemics in human. The virus has the characteristic of antigenic drift with a continuous emergence of new antigenic variants which are responsible for seasonal epidemics. Thus, the available vaccines should be annually adjusted in order to give the required protection level. Most health associated international organizations recommend annual vaccination of almost all people ≥ 6 months old, particularly those at high risk.

Objectives: The study is an attempt to display the practicing, attitudes and Beliefs of physicians at Al-Emamain Al-Kadhumain medical city towards Seasonal Influenza Vaccination.

Method: A cross-sectional study was conducted at Al-Emamain Al-Kadhumain medical city, from February to end of April, 2018. A total of 306 physicians were interviewed using semi constructed Questionnaires especially prepared for this purpose.

Results: The rate of vaccine uptake among this sample was (29.7%). 79.9% of them believed the Flu-vaccine was safe, 69%of them see it needed and 71% of whom take the vaccine, regard it effective in preventing Flu and it's complications. There was significant relation between Flu-Vaccination and gender and also with the wards where the physicians work.

Conclusion: Flu-vaccination rates among the physicians was low, despite most of them were think the vaccine was safe, needed and effective. About two third of them disagree to give the vaccine to pregnant women.

Keywords: Influenza vaccine, attitude, physicians

Introduction

The two types of influenza virus, A and B, are responsible for influenza epidemics in human. Influenza A viruses are further classified into H1N1 and H3N2 subtypes according to hemagglutinin and neuraminidase; two surface antigens. On the other hand, there are two genetic lineages of influenza B viruses with no subtypes. However, the antigenic drift occurs less frequently in this type than influenza A virus. Beside these subtypes, new variants of influenza viruses continuously emerge due to the recombination and some point mutations that occur during viral replication. As such, antibodies formed against certain type or even subtype of influenza virus confer little or no protection against the other types or subtypes. It is this antigenic drift which is responsible for seasonal epidemics and requires the readjustment of the vaccine each season. (1) Despite the fact that the vast majority of individuals infected with influenza virus will recover without serious sequelae, severe illness and even death may occur especially among older patients, infants, pregnant women, patients with chronic diseases, and healthcare workers. Thus, influenza vaccine is an utmost necessity to protect those patients. (2) Influenza shots is a commonly used vaccine which is undergoes two-time a year development to pace with the rapid antigenic change in the virus. Although the vaccine varies from year to year, it provides moderate to high protection level against the virus. (3,4) The efficiency of the vaccine in children below 2 years, and in adults with 65 years or older is not known, mainly because the low quantity of research. (5,6,7) The WHO, CDC and European Center for Disease Prevention and Controls recommendations emphasize annual vaccination of almost all aged six
months or older, particularly those at high risk. (3,8,9,10). Generally, influenza vaccines contain either as inactivated or attenuated virus, and given as trivalent, quadrivalent injection, or nasal spray. Vaccines that are given as trivalent injection contains inactivated virus; while nasal spray vaccine contains attenuated virus (11). According to CDC recommendations, this latter form of the vaccine should be avoided in children below 2 years, adults over 50 years, individuals with known hypersensitivity to any component of the vaccine, patients with asthma, children and adolescents using long-term aspirin, immunocompromised patients, and pregnant women. (12) Generally, the vaccine is safe, although some adverse reactions may occur. For example, fever may develop in 5-10% of vaccinated children. Similarly, myalgia and tiredness may occur less frequently. Moreover, there some reports which linked the vaccine with increased incidence of Guillain-Barre syndrome in elderly people to reach about one case per million doses. (3) 85 percent of the children who died were not have been vaccinated during the 2017–2018. (13,14)

The Method

A cross-sectional study was adopted at Al-Emamain Al-Kadhumain Medical City/Baghdad. The data collection was carried during February to the end of April, 2018. A total of 306 physicians were interviewed by undergraduates medical students, using a semi-constructed questionnaire especially prepared for this study. The questionnaire involved the Sociodemographic information like age, gender, specialty, history of smoking and chronic diseases, the ward of practicing and attitudes and beliefs questions about the vaccine. Statistical package for social science version 20 computer software and Microsoft Excel 2010 were used for analysis. Verbal consent was taken from all the participants before they answered the questionnaire.

The Results

A total sample of 306 physicians with mean age (± SD was (34.7 ± 8.7) year and range from (25-60) years. Among this sample 91(29.7%) of physicians received seasonal influenza vaccine and remaining 215(70.3%) were not receive it. Figure (1).

**Discussion**

Influenza is the most common illnesses that is associated with annual epidemics worldwide. Several lines of evidence support the potential transmission of the virus from infected healthcare workers, whether symptomatic or asymptomatic, to their susceptible patients. Therefore, immunization of healthcare workers is expected to potentially reduce the risk of viral transmission. (9). Despite the availability of immunization guidelines in many countries, the uptake of influenza vaccine among health care workers was low, (11) and this like what was found in this study, as the rate of influenza vaccination among physicians was 29.7%, this nearly the same to the studies conducted in United Arabian Emirates, Lebanese general population, and one of US hospital setting, the vaccination rate among health care workers were 24.7%, 27.6%, 28%, respectively. (14,15,16). Most of physicians involved in the current study believed the Flu-Vaccination was effective and safe and half of them think mandatory vaccination of the health workers should have implemented like what found in USA studies. (11,17). Regarding the cause of non-vaccination, this study found most common cause of it was lack of time and this nearly like previous studies in French and Australia (12,18), and this one of the causes prevent vaccination which may be due to overload that the Iraqis’ physician suffering from. The current study found decrease agreement to give a pregnant or a child less than 5 years Flu Vaccine like a study done in Jordan. (19) And this may be due to lack of information and education about influenza vaccine, and the fear from their family if any side effect developed especially in our society. Concerning the statistical significance found in this study, it found significant association between intake vaccine and the gender like which found in previous study in Turkey. (20). This study also found a significant relation between vaccine intake and the wards that physician worked in, like what was found in a UK hospital setting (21) and this may have related to more contact with patients in internal medicine or whom suffering from series diseases also physicians in medical ward may had more accurate information about the importance of this vaccine. Finally, there was no significant association between residence, history of smoking and chronic diseases and uptake of flu vaccine, like which found in Lebanese general population. This may be due to small percent of physicians having history of smoking and chronic disease. (15).

**Conclusion**

Flu-vaccination rates among the physicians was low, despite most of them were think the vaccine was safe, needed and effective. About two third of them disagree to give the vaccine to pregnant women.

The Effect of Learning Style by Playing Directly in Learning the Skill of Passing Football at the Age of (13-14) Years

Ali Qais Habeeb Majeed1, Samer Abdulhadi Ahmed1, Ahmed Murtada Abdulhussain1

1The College of Physical Education and Sports Sciences, University of Kerbala, Iraq

ABSTRACT

In order to accelerate the learning process and reach the best results and attract the learner to the proposed exercises was used learning method by playing directly on the research sample of (80) players of specialized schools for the year 2019 and in two control and experimental groups (10) players for each group, where researchers introduced a method Learning to play direct in the proposed exercises in order to accelerate the process of learning the skill of passing football and after conducting the pre-test and the application of the proposed exercises and conduct tests after the results proved that there is a positive impact of this method, which lasted (8) weeks (3) units per week and The researcher concluded that the method of learning by playing directly to the sample had a prominent role in learning the skill of passing among the sample members.

Keywords: learning style, playing directly and skill of passing.

Introduction

The method of learning by playing direct, one of the learning methods that take into account the psychology of the learner through which the learner has a positive role characterized by being an active and effective element within the educational unit because of this style of interaction between the trainer and learners during the educational process through educational activities and games are prepared in a practical way Direct play is one of the main entry points of learning that focuses on the learner’s activity and costiveness, the development of a comprehensive development personality in various aspects and the temptation of the learner to interact with educational attitudes, including good motor skills and targeted educational and educational activities.

The skill of passing football is an important skill that requires high concentration, and because this skill is an important factor in determining the outcome of the game, which is the goal of each coach and team, so requires the football player high accuracy in its performance as accuracy is an important variable in the field of motor learning And kinetic behavior because most motor skills require the implementation of motor performance with the least possible errors.

The fact that the learning of these skills is done in formulas or methods and organized and may not be interspersed with direct play, so the researcher considered the introduction of the learning method of direct play to contribute to learning the skill of passing football and then reach the best results. This is what the researcher will seek to achieve through the goal of the research in the recognition of the impact of learning style of direct play in learning the skill of passing football players in specialized schools age (13-14) years.

Research Methodology

The researchers used the experimental method by designing the two experimental and control equal groups as the appropriate method to solve the research problem.

Community and sample research: The researchers selected the players of the specialized schools in the middle Euphrates region for the year 2019. A total of (80) players were then selected. (20) Players were selected to represent the research sample that the researchers will conduct their research. They were divided into two experimental and control groups. The original (25%).
Tools, devices and means of data collection: It means “the means or the way in which the researcher can solve his problem whatever those tools, data, samples, devices… etc.”

- Arab and foreign sources.
- Observation.
- Personal interviews.
- Tests and measurement.
- Playing legal football.
- Goals of different sizes.
- 10 football balls.
- Stopwatch (3).
- Two beeps.
- Tape Measure (1).
- Medical scale for measuring mass (1).
- Two Adhesive Tape.
- Ropes to divide the target.
- Persons of different sizes (20).
- Forms of evaluation of tests.

Search procedures:

Equal groups: To start one line “must be research groups are completely equal in all circumstances and variables except the experimental variable that affects the totals Search” (Vandalin 0.341), the researchers conducted a parity between the two groups of search control and experimental passing football test, as in the table (1).

![Table 1: Shows parity between the control and experimental research groups in the football passing test](image)

Select tests: Researchers have chosen in the test of the accuracy of the skill of passing football on the sources and references and previous studies related to the adoption of objective evaluation in the process of evaluating these tests, and according to their presence in scientific sources and consistent with the objectives of the study, and after reviewing these sources, the researchers developed a set of these tests with a special questionnaire It was presented to a group of experts and specialists in the fields of (testing, measurement and football), and after the collection of forms and unloading data, the test was accepted which received a high agreement rate and as in Table (2).

Specification of Football Passing Accuracy Performance Test:

Test the accuracy of passing performance:

Name of the test: Passing towards a small target at a distance of (10) meters.

Purpose of the test: Measuring the accuracy of the performance of passing football.

Used tools: Football field, football balls (5), Persons (3), small target width (120) cm and height (68) cm, tape measure, colored tape.

Performance description: The player stands at (16) meters from the small target placed the ball at a distance (10) meters from the goal and the first person is placed at (1.5) meters from the ball and the distance between each person and person (1.5) Meters, and the last person away from the starting line (1.5) meters.
Method of registration: Each laboratory is given three attempts as two degrees are given for the successful attempt and one score for the attempt that touches the bar and zero for the failed attempt.

Pretests: The pre tests were conducted to test the accuracy of football passing performance of the research sample (control and experimental) on 17/3/2019 at ten in the morning at Al-Ansar Sports Stadium football in the province of Karbala.

The implementation of the vocabulary of learning style direct play: Vocabulary of direct learning by playing included the following:

1. The duration of the implementation of the vocabulary of learning style by playing direct (8) weeks.
2. The number of educational units per week (3) units.
3. The total number of units (24) educational units.
4. The time of each educational unit (60) minutes.
5. The experimental group followed the method of learning by playing direct in learning the performance of skill passing football.
6. While the control group followed the approach followed by the teacher of the specialized school itself.
7. The method of learning by direct play in the main section of the educational units and by (1-3) exercise in the educational unit.

Posttest tests: The researchers conducted the post-test after the completion of the implementation of the vocabulary of direct learning method within (24) learning units in a period of 8 weeks, under the conditions and conditions of the same pretests on 17/5/2019 at ten in the morning.

Results

To identify the results of the differences between the pre- and post-tests of the skill of passing football in the control group, the researchers used the test (t) of the symmetrical samples, as shown in Table (3).

**Table 3: Shows the values of the mean, the standard deviations and the values (t) calculated between the pre- and post-tests of the control skill of football for the control group**

</tbody>
</table>

Table (5) shows the results of the values of the arithmetic media and the standard deviations and their differences in the dimensional tests of football passing skill between the control and experimental groups. (3.90) with a standard deviation of (1.73), while the mean of the experimental group was (5.40) with a standard deviation of (0.52), and the value of (t) calculated (2.63) at the level (0.017) which is smaller than the significance level (0.05) and below the degree of freedom (18), and this indicates a significance different between the control and experimental groups in favor of the experimental.

Discuss the Results

Through the results presented in tables (4,3) which showed the existence of significant differences between the pre- and post-tests of the skill of passing football for the control and experimental groups and for the benefit of the post-tests. The researchers attribute the reason for these differences for the control group, to the adoption of the members of this group to repeat exercises to implement The kinetic duties required of them during the educational units and their dependence on the teaching method, which included the appropriate repetitions that have been carried out continuously, and this is consistent with what has been stated in the practice and effort to train and continuous repetitions are necessary in The process of learning and acquisition, as well as that training is a key factor in the process of interaction of the learner or player with the skill and control of movements and achieve harmony between the movements and component of the skill in the performance of a sequential sound and appropriate time, which increases the learning and development of skill and mastery.

As for the experimental group that showed the results of table (4) that there is a superiority of the post-tests of the skill of football passing to the adoption of the members of this group to learn the method of direct play in a form that provided them to impose the performance of these skills well because they have acquired mental perception and good perception through repeated practice In the course of direct play and thus access to the correct performance of the skills in harmony and harmony and control without hardening or tension, and that the implementation of exercises this method gave members of the experimental group freedom of movement and move smoothly and good agility and increase their self-confidence through Creating an atmosphere similar to the real situations of play, as the use of the method of learning direct play has created a real competition between them through repetitions of performance in the applied part of the main section of the educational unit, which gave great importance to the ability of cognition to them, and this is consistent with what some relevant sources indicated in The player’s sense of ability to perform skill means a sense of movement.

Through the results presented in Table (5) that show the existence of significant differences in the post-tests of the skill of football passing between the control and experimental research groups and for the benefit of the experimental group, the researchers attribute the reason for these results to the adoption of experimental group learning method of direct play which led to adaptation In the performance of passing and scoring skills with a good level of accuracy and mastery due to the actual practice of them during the direct play and the multiplicity of motor performance positions that earned the learner the ability to perform the two skills in good compatibility, which enhanced the accuracy of their performance in a position commensurate with the special technical performance This is consistent with what has been stated that “compound play exercises play an important role in the achievement of learning motor skills through which it improves compatibility and reduces the appearance of excess movements to a certain extent.

The use of the direct play learning method has provided the members of the experimental group with good mobility performance. Increasing the motivation of learners towards learning and stimulating their interest, as well as the contribution of this method to break the usual method followed, which in turn helped to perform skills and mastery and develop their accuracy more effectively, as one of the most important principles of
good learning is to give students so be responsible for learning and evaluating its performance, which makes it more effective and less dependent on the teacher and increases his motivation which motivates him to learn and absorb and preserve as much as possible from the experience.11

Conclusions

1. The method of learning by playing direct positive impact in learning the skill of passing football.
2. The existence of excellence in the level of learning the skill of passing football players in specialized schools ages (13-14) years and for the benefit of the experimental group.

Prevalence of Cutaneous Leishmaniasis in Babylon Province, Iraq

Alaa Jabbar Tahama AL-Jubbouri, Hayam Khalis Al-Masoudi, Wessam Ali Amin

"Microbiology Department, College of Medicine, University of Babylon, Iraq"

ABSTRACT

Leishmaniasis is a major health problem worldwide, endemic in 98 countries and around 1.3 million new cases are reported every year. A total of 50 patients infected with cutaneous leishmaniasis (36 males and 14 females) during period extended from November 2018 to end of April 2019. Those patients were complained from skin lesion in exposed part of the body mostly in the face, leg, arm and the back, diagnosed clinically by special dermatologist as cutaneous leishmaniasis, monthly rates of cases Cutaneous Lesishmaniasis was have increased especially in December, it was (50 %), which is the highest percent of infection, the percent of infection was high in males compaire with female, especillyb in age ranging from (1-10) years. The percent of infection with Cutaneous leishmaniasis according to site of lesions record (58%, 18% and 14%) in limbs, face and both (face and limbs) respectively while the neck abdomen appear lowest percent it was (2% and 2%) respectively.

Keywords: cutaneous leishmania, prevalence, lesion site.

Introduction

Leishmaniasis are vector-borne diseases caused by obligate protozoan parasites from the genus Leishmania (Trypanosomatida: Trypanosomatidae) (1). They are transmitted to humans through the bite of a female sand fly. The leishmaniases are now considered as neglected tropical diseases (NTD) by the World Health Organization (WHO). The word leishmaniasis is often written as a plural noun because several presentations can clinically be considered as different diseases. In humans (2). Depending on the Leishmania species, the reservoir of this parasite can be exclusively human, categorizing the disease as an anthropoosis, or, involve animal reservoirs (rodents, dogs, etc...).

Leishmaniasis is a major health problem worldwide, endemic in 98 countries and around 1.3 million new cases are reported every year, with an estimated 20,000 to 40,000 deaths every year (3). Cutaneous leishmaniasis (CL) is the most common and least fatal form of the disease, identified by ulcerative skin lesions. (CL) is caused by Leishmania major, L. tropica, L. braziliensis, L. panamensis, L. aethiopica, L. mexicana, L. guyanensis, L. peruviana, and L. amazonensis (4).

More than twenty Leishmania species are pathogenic for humans (1,5). The species classification within the genus Leishmania has always been a controversial matter, and there is not yet a definitively accepted taxonomy. Routine CBC parameters, such as white blood cell count (WBC), neutrophil, lymphocyte and platelet counts, red cell distribution width (RDW), mean platelet volume (MPV), and platelet distribution width (PDW), are used in many settings, including the evaluation of systemic inflammation and the diagnosis and treatment of disease. Recent studies have reported changes in the circulating neutrophil, lymphocyte, and platelet counts, WBC count, MPV, PDW, neutrophil/lymphocyte ratio (NLR) and platelet/lymphocyte ratio (PLR) in cancer, inflammatory disease, and infection. Hematological changes are closely associated with the severity and the prognosis of disease (6,7).

Material and Patients

1. Patients: A total of 50 patients infected with cutaneous leishmaniasis (36 males and 14 females) during period extended from November 2018 to end of April 2019. Those patients were
complained from skin lesion in exposed part of the body mostly in the face, leg, arm and the back, diagnosed clinically by special dermatologist as cutaneous leishmaniasis. Clinically, only 50 cutaneous leishmaniasis patients were observed, among all patients; age range was (1 year-70 years). Diagnosis was based on history (patients coming from endemic areas, persistence of lesions), cutaneous lesions (nodules, plaques, ulcers) and response to specific antileishmanial treatment (pentostam). Duration of lesions varied from 3 weeks to 6 months.

2. **Samples Collection:** Five milliliters of venous blood were collected from patients as well as from controls. The collected blood samples were immediately transferred to two different test tubes, the blood fraction in the first test tube containing ethylenediaminetetraacetic acid (EDTA) was used to determine blood indices. The sample from the cutaneous lesion taken by aspiration with fine needle as the following steps:

1. The lesion and skin around the lesion was disinfected by 70% ethanol.
2. Sterile syringe of (1) ml contain 0.9 ml of sterile normal saline was used to inject the fluid intradermaly through intact skin in to the active red border of the lesion.
3. Aspirate the injected fluid as the needle draw back until the bloody stained fluid aspirate.
4. Small amount of aspirated fluid was taken and placed on clean glass slides, fixed by using absolute methanol and then Giemsa stain applied for 10 minutes to making direct Giemsa smear before the culturing. Amastigote diagnosed as round or spherical shape with kinetoplast (9).

3. **Statistical Analysis:** All Statistical analysis represent in this study were apply by computer pro. grams such as Microsoft Excel 2015 and SPSS Version 22 statistic. Values in the current study were expressed as mean ± standard deviation (SD). The probability (P value) was estimated students t-test to determine the difference that present in patients and controls gorups. The acceptable level of P value was >0.05.

4. **Ethical Approval:** Verbal consent from patients or their followers were obtained. Moreover, all subjects involved in this work are informed and the agreement required for doing the experiments and publication of this work is obtained from each one prior the collection of samples.

**Result and Discussion**

**Demographic Study:**

1. **Distribution on the Cutaneous Leishmaniasis patients according to Months:** The monthly distribution of cutaneous leishmaniasis cases was variable from one month to the other with peak of infection during December and January (Figure:1). Monthly rates of cases Cutaneous Leishmaniasis was have increased especially in December, it was (50 %), which is the highest percent of infection, then in January (24%), followed by November (14%), and then in February it was(12%). This monthly distribution of cutaneous leishmaniasis cases might be due to the transition of parasite by the sand fly occur in September which represent the month with highest intensity of vectors, therefore, the peak of infections appear after about 3-6 months of biting and this is the incubation time for cutaneous leishmaniasis disease (8). The monthly distribution of this study in slightly agree with (9) who also explained that the infections started in December then reach the apex in January and February. In addition (10) showed that February had the highest percent of infections (32%). Study of (11) confirmed the same in that February was the month with highest rate of infection in Euphrates area. The results of the present study in regard the monthly distribution totally, disagree with (12) who cleared up that most cases detected from September to the end of December.
Distribution of the Cutaneous Leishmaniasis in patient according to sex: The results of this study show the percent of infection in males were about (72 %), while female was (28 %). In all months, the percent of infection in males were higher than females as shown in figure (2). The reason in that infection take out in males more than females, possibly, due to the high incidence of working or sleeping males in open areas (surfaces of houses) with less coverage of body as well as more exposure to infected vectors compared with the females (13).

The results of this study nearly agree with previous studies, (11) in AL-haweja city, showed that males infected with CL more than females (57%;43%) respectively, (14) found that male the percentage of infection with cutaneous leismaniasis was 70% in male while it was 30% in female, as well as, (15) confirm that CL is more frequently in males than in females. Also study of (16) confirm that the rate of cutaneous leishmaniasis in male was (51.7%) while in female (48.3%).

![Figure 2: Distribution of the Cutaneous Leishmaniasis in patient according to sex](image)

Distribution of Cutaneous Leishmaniasis patients According to Age group: As shown in table (1). The percent of infection is high in the age group 1-10 years, it was 26%, while the percent of infection in age group 11-20 and 21-30 the same value equal to 22%, while the percent of infection in age group 31-40 years equal 18% in addition the percent decreased in the age group >40 years it was 12% statistical analysis show the reason in that infections less frequency in those people with age more than 20 years (adults) might be because that adults develop resistance and immunity against CL due to their previous exposure to parasite (17). Results of (11) demonstrated results disagree with present study, that incidence rate of CL infections was 57% in patients over 15 years old, and this nearly the same as (14) who found that most patients were in the age group 25-35 years in percent equal to 51%, study of (16) confirm that the highest rate cutaneous leishmaniasis were seen in age group less than 10 years old it was (43.7%) and the least rate were in the age group of 40 to 50 (1.2%). also the results of the present study was agree with (18) who confirm that the range group of 16-20 patients show highest percentage of infection with cutaneous leishmaniasis.

4. Distribution on the Cutaneous Leishmaniasis patients according to blood group: The result in figure (3) show the highest percentage of infection was in blood group (O) it was 42% in compared with other blood group. The lowest percentage of infection was 6% in blood group AB. Statistical analysis show significant different (<0.05) between blood group and infection with cutaneous leishmaniasis. The present study agree with result of (19) they confirm that blood group O was more frequent with cutaneous leishmaniasis than other group. However the results was non-significant. The A, B and O blood group system are determined by the presence or absent of A and B carbohydrate antigen on the surface of erythrocytes (20). this determines nature resistance in human to many infection disease agent that have cell surface antigens similar to the antigens of different blood groups types. Finding of (16) investigated that there is no relation between blood group type and cutaneous leishmaniasis. Blood group was not a risk factor in the occurrence of cutaneous leishmaniasis.

![Figure 3: Distribution on the Cutaneous Leishmaniasis patients according to blood group](image)

5. Distribution of Cutaneous Leishmaniasis patients according to the some Vairable: Table (2) show the highest percentage of infection regarded to duration of infection was in less than months it record (58%) while the lowest percentage of more four months it was (6%). this result was agree with (15) in Wasit. Who recorded that median duration of lesions was under 2 month it was (50 %).

According to number of lesion in patient the present study show that the percentage of infection it was (48%) in patient with more than two lesion, it was higher percent in compare with patients have single lesion (22%), this may indicate that most infection of CL are caused by L. major which is responsible for the multiple lesions, this findings was very close with results of (12) who recorded that single lesion was found in 36% of all cases, also, (15,12) showed that 53.6% of patients presented with multiple lesions. Contrary to the findings of this study (9) found that the majority of patients have only one lesion 80.6%, while (21) found 68.4% of CL patients were had only one lesion, in comparison, with results of (22) showed that half of the patients 50% have one lesion.

The percent of infection with Cutaneous leishmaniasis according to site of lesions record (58%,18% and 14%) in limbs, face and both (face and limbs) respectively while the neck abdomen appear lowest percent it was (2% and 2%) respectively. Hot weather play important factor in distribution of infection because some people prefer to sleep out their rooms, so they become in...
direct contact with insect. In addition, most of the people (especially the children) leave their faces, hands and legs without cover, exposed to the bites of sand flies (17). Regarding, the anatomical sites of lesions, the observations of this study disagree with (23) who showed that in more than 60% of cases, the lesions were on the face. In addition, the result disagree with (15) who showed that the face was the most effected part (64.3%), also (11, 22) showed that lesion site on Hand (62.8%), Leg (10.2%), Face and head (8.8%), Hand and leg (10.2%), other sites (8%), and this observations agree the observation of current study. (11) explained that most lesions were present on exposed area of the body and this match the observations that noticed in present study.

According to residence of in patients the percent study, found that percentage of infection was (52%) in urban it was higher percent in compare with patient rural it was (48%). This results was disagree with (15) Results of this study showed that high (67.4%) were appeared in rural areas. The percent of infection with CL according to taking treatment it was (66%) in patient without treatment it has higher percent in compare with patient with treatment it was (34%).

According to size lesion in percent in patient the percent study found that percentage of infection was (100%) in patient with less than five cm table (2).

Accurate Scoring According to the Brain Sovereignty of Handball Players

Ali Hussein Ali¹, Amer Hussein Ali¹, Mohammed Oudah Zaal²

ABSTRACT

The current research aims to identify the accuracy of scoring according to the brain sovereignty of the players of the Karbala Handball Club, and to achieve this goal has been prepared two tools, one to measure the brain sovereignty and the other to measure the accuracy of scoring after finding their psychometric characteristics of honesty and consistency have been applied to the sample of adult research (18) A player from Karbala Sports Club handball, after analyzing the data using statistical means resulted in the search for the superiority of players of type (D) in the accuracy of scoring.

Keywords: Accurate, scoring and brain sovereignty.

Introduction

The human brain, which weighs three pounds of intertwined neurons and controls our activity in all social, psychological and physical fields, hence the importance of the current research by knowing the patterns of brain sovereignty of outstanding and ordinary players handball as it enables coaches to absorb the thinking of all players regardless of The diversity of brain dominance patterns in players may raise some questions about the optimal pattern of brain dominance, but there is no specific pattern better than the other, but each pattern is associated with sensory, motor and intellectual characteristics that make the owner more compatible in the performance of some The importance of the current research comes from the fact that, as far as researchers know, the first study in Iraq that attempts to know the nature of the relationship of brain sovereignty patterns of outstanding and ordinary handball players, knowing that this will facilitate the work of coaches in the selection of players as well as the identification of play positions according to Of their dominant brain pattern.¹

The success of any team in any individual or team game depends on the accuracy of its performance so it was necessary to identify all the factors and variables that are related to the accuracy of scoring and that relates to the game of handball and hence the current research sheds light on one of the factors represented by brain sovereignty as the brain Is he controlling all behavioral acts of man in general and handball player as the focus of this study in particular? Hence, the researcher may wonder about the level of accuracy of scoring and the pattern of brain sovereignty for each player practicing handball game? I have handball players.²

Research aims:

1. The level of accuracy of scoring for the players of Karbala Handball Club.
2. On the pattern of cerebral sovereignty of the players of Karbala Handball Club.
3. Statistically significant differences in the level of accuracy of scoring according to the pattern of cerebral sovereignty of Karbala handball players.

Research Methodology and Procedures

Research Methodology: The researcher used the descriptive method in the survey method and comparative studies as a better method to solve the research problem due to its relevance and the nature of the current study.
The research sample: The sample included (18) Karbala handball club applicants.

Hermann Cerebral Severity Scale (HBDI): The researcher used the modified Herman scale, expressed by (Haydar Tariq Kazim 2011), which measures the patterns of brain sovereignty (ABCD) according to the classification of Herman see Appendix (1), where the scale prepared is (4) forms containing each form a pattern of expressive patterns of brain sovereignty. It is divided into a number of paragraphs (14) paragraphs for each type of cerebral dominance, and the answer is by choosing one of the two (yes, no) where the score (1, zero) is calculated so the highest score for each pattern is (14) and the lowest score is (Zero) In the middle of the hypothesis of (7) degree and for the purpose of reassurance on the application of the scale has been calculated the reliability and stability as follows: ¹

1. Validity: Validity means that the test measures what it was developed for, that is, the honest test measures the function that he claims to measure and does not measure anything else instead or in addition to (6).

To achieve this, the scale was presented to a number of professors specialized in education and sports psychology to indicate their views of the paragraphs of the scale and its alternatives and instructions and after analyzing their views and found that there is full agreement on the validity of the scale.

2. Stability: A fixed test is a test that has a high degree of accuracy, mastery, consistency and objectivity in what is set to measure it. (7) To achieve this, the scale was applied to a sample of the youth category of (12) players. The correlation coefficient was calculated according to the Pearson correlation coefficient.

Tests used in the research:

Test scoring accuracy: A scoring accuracy test prepared from (Ikoula 2005) was adopted, which includes a board containing (8) squares hanging on the wall as shown in Figure (1). Test scoring accuracy. ⁴

In order to verify the validity of the test and its suitability to the current research sample:

1. Validity: To achieve this, the test was presented to a number of professors in the game of handball to indicate their views on the performance of the test and its alternatives and instructions and after analyzing their views and found that there is full agreement on the validity of the test.

2. Stability: To achieve this, the test was applied to a sample of the youth category of (12) players. Good stability index.

Final Application: After finding the psychometric properties represented by the honesty and stability of the cerebral sovereignty scale and the scoring accuracy test, the two tools were applied to the sample of (18) players. It is (90) minutes for the sample as a whole.

Results

In order to achieve the first goal of the research, which is to identify the level of scoring accuracy among Karbala players handball, the total score obtained by the player was calculated through (8) attempts (corrections) on the prepared plate, which contains (8) two boxes hanging on the wall and away (9) m for the player, it was found that the scores of the members of the research sample ranged between (13-36) with an average of (30.22) and a standard deviation of (4.53). From Table (1) below.

![Figure 1: Represents the goal of handball](image-url)
Table 1: Shows the calculated and tabulated (v) value of the scoring accuracy test

<table>
<thead>
<tr>
<th>Sample</th>
<th>Mean</th>
<th>Mean median</th>
<th>SD</th>
<th>(t) calculated</th>
<th>(t) tabulated</th>
<th>Type of significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>18</td>
<td>30.22</td>
<td>20</td>
<td>4.53</td>
<td>9.64</td>
<td>2.110</td>
<td>0.05</td>
</tr>
</tbody>
</table>

It is clear from the table above that the calculated (t) value of (9.64) is greater than the (T) tabular value of (2.110) at the indication level (0.05) and the degree of freedom (17). This means that Karbala handball players have a good level and high accuracy Scoring. This may be attributed to the low level of psychological tension as the player performs the skill without friction with another player and the absence of an audience which constitutes a stable psychological situation and without any stress or psychological pressure as well as they represent the elite players in the province of Karbala handball have experienced methods Proper throwing on target through daily workouts and experience gained in games x DONC was an official or other and the fact that most of the physical education and sports science faculties, which increases students have the experience and skill in scoring accuracy.

In order to achieve the second objective of the research, which is to identify the pattern of cerebral sovereignty of Karbala players handball, the answers of the respondents were analyzed on the scale of cerebral dominance and found that their scores ranged between ((4-14) in type A), and {5 -13} in Type B), {6-12} in Type C), {6-14} in Type D), and the arithmetic media for each type were {8}, {7.5}, {7.6}, {9.77} with standard deviations of {2.12}, {2.34}, {3.1}, {1.98}) for the patterns (A, B, C, D) respectively, and for the purpose of determining the number of players for each pattern was calculated During the application of the equation of confidence period and at the level of significance (0.05), namely:

\[(X + 1.96 \times p\% \sqrt{U})\]

and for each of the types mentioned and showed according to that equation that the degrees of patterns were respectively \{(8.98), (8.58), (9.03), (10.68)\} for patterns (A,B,C and D), which is a cutoff point where the player is classified according to those patterns when his score is equal to or higher than the score for each pattern, and it turns out that the number of players according to those patterns was \{(2), (4),(3), (9)\} for patterns (A, B, C, D), respectively, as shown in Figure (2), and for the purpose of identifying the statistical significance of the differences in the patterns of cerebral dominance used test (Chi square) The results are shown in the table (2) below.

Table 2: Shows the values (Chi square) of the sample

<table>
<thead>
<tr>
<th>The Sample</th>
<th>(Chi square) calculated</th>
<th>(Chi square) tabulated</th>
<th>Type of significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>18</td>
<td>6.443</td>
<td>7.81</td>
<td>Non sig.</td>
</tr>
</tbody>
</table>

The table above shows the calculated square (6.443), which is less than the value (Chi square) of the table (7.81) at the significance level (0.05) and the degree of freedom (3), which means that there is no preference for a pattern over other patterns in The cerebral dominance of Karbala club players is handball, although the number of players within (Type D) was the highest among the patterns and may be attributed to the homogeneity of the sample members as most of the students of the Faculty of Physical education and sports science have passed the same experiences and received the same training and acquired the same skills Which reflected on their ways of thinking and how they deal with the situations they are going through.

As for the third goal, which is to identify the differences of statistical significance in the level of accuracy of scoring according to brain sovereignty was used analysis of variance and the results are shown in Table (3) in the below.

Table 3: Shows the source of variance in scoring accuracy according to cerebral sovereignty

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>Within groups</td>
<td>310</td>
<td>14</td>
<td>22.14</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The above table (3) shows that the calculated value of F (10) was (3.90), which is higher than the tabular value (f) of (3.74) at the level of (0.05) and degrees of freedom (3.14), which means that the difference is statistically significant, therefore, the differences were calculated in the arithmetic media as shown in Table (4) below.

<table>
<thead>
<tr>
<th>Mean</th>
<th>X A 30</th>
<th>X B 26</th>
<th>X C 28</th>
<th>XD 33.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>X A 30</td>

<td></td>
<td></td>
<td></td>
<td>5.3</td>
</tr>
<tr>
<td>XD 33.3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

From Table (4) above, for the purpose of identifying the statistical significance of the apparent differences in the arithmetic media, Toki test 11 was used and its calculated value was (5.09) at the level of (0.05) and two degrees of freedom (3.14). The spreadsheet with the critical value (Toki test) shows that there is one statistically significant difference between the scoring accuracy averages of the two types (D and B) and (D and C) and in favor of type D) because the mean of that pattern is (33.3) which is higher than Arithmetic mean of type (B) (26) and arithmetic mean of type C) of 28 (possibly due to the characteristic of individuals This style of exploration, as well as their strategic and creative thinking and the overall view, which enables them to access many experiences and this is reflected on their performance in general and their ability to scoring particularly accurately, while these qualities and characteristics are not available to their peers of the pattern (B) and pattern (C).  

Each quarter of the four types of brain is characterized by characteristics that distinguish it from other types, and that each pattern is specific to the way the brain works. Brain (analysis, facts, data, numbers, concentration, feasibility, evaluation, results), the lower left (B) is concerned with (planning, execution, procedures, details, maintenance, arrangement, methods, system, time management, discipline, security And safety), with respect to the lower pattern Yemen (C)(with relationships with others, feelings, emotions, dealing with others, human meanings, care, attention to human, and intuitive sensory), while the upper right (D) deals with (strategic thinking, creative thinking, and a comprehensive view, perceptions, exploration (Hermann’s theory of cerebral sovereignty has resulted from four souls: “the rational self is located in the quadrant (A), the certainty is in the quadrant (B), the emotional self is the quadrant) C) The experimental self-located in the quadrant (D) “is observed Appendix (2) (A,B).**12**

**Conclusions**

1. The students of the Faculty of Physical Education and Sports Science have the ability to accurately aim.
2. Students of the Faculty of Physical Education and Sports Sciences use all types and classes (D)
3. The level of accuracy of corrections in students with type (D) exceeds the other patterns.

Audio Skills and Their Impact on the Development of Response Speed for Handball Goalkeepers

Asaad Ali Safih¹, Raafat Abdulhadi Kadhim¹, Saba Shaker Farhan¹

¹The College of Physical Education and Sports Sciences, University of Al-Qadisiyah, Iraq

ABSTRACT

The research and the importance of the research included: The importance of training in the field of physical education in general and handball in particular. The problem of the research was to identify the development of rapid response to the goalkeepers through the use of audio skills. The goal of the research is to use audio skills in developing responses to handball goalkeepers. The study hypothesized that there were significant differences of statistical significance for the group using the auditory skills. The research included the fields of research was what comes:

1. Human field/goalkeepers in clubs belonging to Qadisiyah Governorate.
3. Field Sphere/Playground College of Physical Education handball.

The research method and its field procedures were also used. The researchers used the experimental method and discussed the sample of the research and they are the goalkeepers in the clubs affiliated with Qadisiyah Governorate. They also discussed the tools used in the research, the testing used and the statistical means.

The results were then presented and discussed as the results were presented in tabular form and then discussed. The research also contains conclusions and recommendations, the most important of which are the following conclusions:

1. There is an evolution of the post tests of both control and experimental groups.
2. There are significant differences of statistical significance for the benefit of the experimental group.

Keywords: Audio skills - Speed response and Goalkeepers handball.

Introduction

Sports activities must keep abreast of the cultural and scientific developments in the world to develop the level of these games and make them an area of practice and follow-up. The effectiveness of handball is one of these sporting events where the level of physical and tactical reached by the players make the game to be faster and therefore requires Of the goal keeper to have a high response speed in dealing with the ball paid towards his goal, especially in areas close to the goal of his team and that the performance is faster and not delay, especially in the cases of fixed and the most important penalty kick as the goalkeeper in the face of one player without any Defender and considered as e This confrontation is one of the most difficult circumstances experienced by the guard during the game so it requires a good response in the right direction in a timely manner.¹

The problem of the research is that researchers will inquire from the coaches of Qadisiyah handball teams found that quite a few handball goalkeepers make mistakes during the game when confronting the attacks of the opposite teams and that these errors are due to the fact that the handball goalkeepers suffer from slow The kinetic response, as well as the lack of interpretation of the audio stimuli well as they are tricked by the players of the opposite team and they do not distinguish the audio stimulator required in the case of receiving more than an

University of Al-Qadisiyah, Iraq
Email: aalkroy@yahoo.com
audio stimulus to deal with, as the traditional exercises given in the training units are formal and monotonous, which makes it give. Therefore, the researchers used auditory stimuli in a new way that develops the speed of the motor response and goes out of the monotony and formal, which makes it a pleasure and pleasure for the exercise. Kinetic response speed through audio stimuli and training goalkeeper’s handball to respond to the appropriate stimulus and identify it from the house of a group of stimuli to be exposed and enrich the sports library the importance of audio stimuli in the training process.

The auditory mechanism is the transmission of the auditory stimuli from the external ear to the middle, then to the inner ear, the auditory nerve, and then to the central nervous system; where the stimuli are explained audio. The ability to recognize sounds from sources and to associate them with some meanings is the primary environment in the process of promoting.

Hence the importance of research in the use of audio skills to develop the speed of response to handball goalkeeper.

**Purpose of study:** The purpose of the study is Use of audio skills in developing response speed for handball goalkeeper.

**Method and Procedures**

**Sample and Research society:** The search community included goalkeepers in the 30 clubs of Al Qadisiyah Governorate and the research community was selected as a sample for research. The sample of the study was 30 goalkeeper and the sample ratio was 100%. The sample was divided into two experimental groups and each one had 15 goalkeeper. The homogeneity and equivalence between the individuals and the sample groups in the variables studying.

**Table 1: Shows the number of the society and the sample of the research**

</tr>
</thead>
<tbody>
<tr>
<td>Goalkeepers handball</td>
<td>30</td>
<td>Experimental group: 15, Control group: 15</td>
<td>100%</td>
</tr>
</tbody>
</table>

**Study design:** The researchers used the experimental approach in the same way as the two groups to suit the nature of the problem studied.

**Tests used in research:** The researchers used the test (color naming)

**Test Name:** Color Label

**Test Objective:** Measure response speed (20 × 25 cm) painted with 10 rows of colored squares in each row (10) boxes of red, green, blue and yellow distributed randomly,

**Test description:** The lab must name the colors following the order of the rows with the largest possible speed and then calculate the time it takes to label the entire painting.

This is followed by 90 degree plate management, repeating this previous work, and another solid board can be managed before returning to the color scheme in which the lab has started testing. The number of alarms becomes 40 alarms.

**Method of calculating the score:** The final result is calculated by dividing the time of the performance of the whole test at 300 we get the reaction time for one alarm.

**Pre Test:** The researchers conducted the pre-test on the research sample on 18/11/2015 for both experimental and control groups at 9:00 am.

**Skills used in research:** After the pretest, a set of skills based on the audio variables of the experimental group of the research sample were used. These skills are given during the training module and within the main section of the training unit for eight weeks. These skills are:

1. The player stands within the goal of the handball and is blindfolded and installs on the scoreboards and the crossbar a set of small-sized speakers. The instructor issued a sound from one of the loudspeakers, the guard refers to the direction of sound directly hand in note that the type and degree of sound changes between one attempt and another.

2. The same exercise, but the instructor selects a specific voice that wants the guard to point towards it and operate two or more amplifiers different sound.

**Post-test:** The researchers conducted the pre-test on the research sample on 19/1/2016 for both experimental and control groups at 9:00 am.
Results

Table 2: Shows the mean, standard deviations and the \( t \) value of the pretests of the control and experimental groups

</tr>
</tbody>
</table>

In table (5), the mean value of the response speed of the control group was (0.51), the standard deviation was (0.057), and the experimental group was (0.446) and the standard deviation (0.051). Differences between the two groups.

![Figure 1: Shows the value of the mean and standard deviation for the posttest of the two groups](image-url)
Analysis and discussion of the results: In Table (2) we find that the value of (t) calculated for the pretest tests of the experimental and control groups is (0.015) and is smaller than the spreadsheet (1.76), so there is no significant differences between the two tests and this indicates that the two groups started from the starting line One is that the respondents are equal in potential for response speed. 

In Table (3) we find that the value of (t) calculated for the tests before and after the control group was (4.096), which is greater than the spreadsheet (1.76), which indicates the development of the control group, which is practicing the usual trainer.

In table (4) we find that the value of (t) calculated for the tests before and after the experimental group was (9.74), which is greater than the spreadsheet (1.76) is that there is a development in the sample of the experimental group, which used auditory skills in the exercises.

Table (5) shows that the value of (t) calculated for the post-tests of the experimental and control groups is (1.867) and is greater than the spreadsheet (1.76). Therefore, this indicates that there are significant differences in favor of the experimental group, the development in the group. Experimental is greater than the phase of the control group and this gives preference to auditory skills in the process of developing the speed of response speed for handball goalkeepers by increasing the intensity of movement through synchronization of sound and movement, which restores the audio image by excessive intensity of the athlete is assisted by electronic their measurements are arranged a It is worth mentioning that there is no separation between mind and body or thinking and motor performance which depends on human ability to work physically and withstand the effort and development and work because of the technological development that made the machines Most of the work and make this natural transition to mental work more comfortable for humans, but in return, these mental work in addition to the rapid and amazing development of audio information, which enter the human mind that the person feels mental efficiency and muscle capabilities, which is one of The most important technological factors in our modern age because despite this a The evolution that happens is ultimately the development of the mental, intellectual and auditory abilities of individuals.

Here we will recognize the need to preserve hearing capacity in training and acquire a knowledge tool for the skills you need, which gives us high abilities and create a system commensurate with our needs and you will get a look at the cognitive and auditory abilities and learn how to improve by practicing mental exercise And audio that enables us to choose any kind of training.

Conclusions

1. There is a variation in the level of motor response of handball goalkeepers.
2. The exercises used to influence the development of motor response to goalkeeper’s handball.
3. The diversity of audio stimuli has an impact on the development of the ability of goalkeeper’s handball and thus raise the level of motor response to them.
4. There is a development of post - tests for both control and experimental groups.
5. The presence of significant differences statistically significant for the benefit of the experimental group.

Academic Personality Assessment Form for Fourth Stage Students Faculty of Physical Education and Sport Sciences Karbala University

Hassan Ali Hussein, Ammar Hasan Abdal Redha, Ali Noaman Trad

Faculty of Physical Education and Sports Sciences, University of Kerbala, Iraq; Directorate of Education Babylon, Ministry of Education, Iraq

ABSTRACT

The problem of research has been demonstrated about the importance of studying the academic personality of the university students as it is one of the most important fields of psychology and the basics of the organizational behavior of the individual in the organization of life and employment of energies and directed to the optimal way and an indicator of psychological and social compatibility, and harmony with the physical and social environment, which is characterized by continuity, change and adjustment, and that the teaching profession is the main source that supplies other occupations and provide all areas of life with trained and qualified human cadres and depends in their practice on mental, physical, psychological and social activity as well as the desire, willingness and familiarity with the type of specialized knowledge of, the study aims to: Building a measure of academic personality among students of the fourth stage College of Physical Education and Sport Sciences and Identify the academic personality traits of the fourth stage students Faculty of Physical Education and Sports Science University of Karbala

The researchers used the descriptive method in the method of surveying and comparative and standard studies to achieve the objectives of their study. The research community also included the students of the fourth stage/physical education and sports sciences Karbala University morning study.

Keywords: Calendar, academic personality and students.

Introduction

Human energies are the foundation of a rising society and one of the main pillars of the formation and organization of life from time to time, and the development and organization of those energies and human resources is a duty in all times of the life of societies using all available means to raise the community in all fields of life.

The Faculty of Physical Education and Sports Science is one of the important means and institutions in the development of the energies and abilities of members of society as it aims to educate individuals in an integrated scientific manner mentally, psychologically, ethically, socially and culturally and its return to the development of various aspects of activities, and there is no doubt that the creation and dissemination of culture in general among the sectors of society One of the important things that underlies the love and practice of various sports activities because culture in its general sense is a lifestyle and a set of values, ideas and behaviors that prevail in society and is often linked to the socio-economic conditions of this community.

Physical and sports sciences Attention to academic personality and culture as a pillar must be available to graduates in all educational sectors, being a set of values that believe in individuals within institutions and organizations that govern their behavior and affect their performance of work noting that the person has a set of positive personality traits and be understood about himself identical to reality or as others perceive him and free from the internal conflict and enjoy a life free of crisis and mental disorders, and the profession of teaching physical education and sports science needs many psychological features Social behavior because the behavior of practitioners of sports activities at different levels stemming from the environment and situations where there are factors that contribute to the direct impact on behavior, especially factors of support, motivation, reward, punishment and learning and this requires a state of mental and psychological readiness and conscience. In the direction of the teaching profession in physical education and sports sciences, and the result of what was addressed to lie the importance of research, in which the researchers clarified the theoretical importance in the research results from the addition of knowledge and theory about the current research variable.²

**Research Aims**

1. Building the scale of academic personality among the students of the fourth phase of the Faculty of Physical Education and Sports Science.

2. Identify the characteristics of the academic personality of the fourth stage students Faculty of Physical Education and Sports Science

3. Disclosure of differences in the personality traits of the academic students of the fourth stage of the Faculty of Physical Education and Sports Science University of Karbala according to gender

4. Determine the standard levels and develop a model for the evaluation of the academic personality traits of the students of the fourth phase of the Faculty of Physical Education and Sports Science University of Karbala according to gender.

**Research Methodology**

The researchers used the descriptive method in the method of surveying and comparative and normative studies, which they see consistent with the specifications of their research and achieve the objectives of their study.

**Community and Sample Research:** The research community included the students of the fourth phase of the Faculty of Physical Education and Sports Science/University of Karbala morning study for the academic year (2018-2019) and the number (128) students distributed by (86) students and (42) students, and the selection of the research sample was random sampling method. The sample was selected as (10) single sample as a survey sample and constituted (7.8%) of the society, (60) item sample was chosen based on academic personality scale and constituted (46.8%) of the society and (105) sample for the basic experiment (sample derivation criteria). It is intertwined with the construction sample and constituted 82.02% of the respondent population.

**Define scale fields:** After reviewing references and sources related to academic personality traits, seven areas of the scale were identified: physical features, mental traits, emotional traits, sports creativity traits, social traits, academic excellence attributes and health traits. A group of specialists in a questionnaire, and the researchers sought to determine the importance of each field and extract the value of relative importance.³

After the questionnaires were collected and the data was unloaded and processed, the attributes that got less than (65) of importance or less than (54.16%) of relative importance were excluded by taking the opinions of (12) experts and specialists.

**Initial Formulation of Academic Self-Measurement:**

When the researchers completed the steps to identify the areas of scale, it became necessary to prepare and compile the paragraphs of their scale, relying on scientific sources and references in the field of specialization.

In order to collect, prepare and formulate an appropriate number of paragraphs concerned with measuring the characteristics of academic personality among the students of the fourth stage College of Physical Education and Sports Science/University of Karbala researchers sought to formulate (60) paragraphs concerned with measuring the characteristics of academic personality (10) paragraph for each attribute, then These paragraphs were presented to a group of experts and specialists for the purpose of evaluating and judging their validity with the necessary observations as well as the opinion on the validity of the alternatives of the adopted answer and after collecting the forms and unloading data and analyzing the opinions of experts.
and specialists, they suggested deleting and changing a section of the paragraphs to be repeated. The brightest Z with other paragraphs or it is not suitable to measure developed for it, modify and move the other part of the field to another area and also suggested that the answer alternatives trilogy (apply to a large extent and do not apply to apply to).

In light of this, the opinions of experts and experts on the adoption of alternatives to the triple answer of the measure of academic personality was taken and one section of the paragraphs were modified and the other section was deleted, and through the use of the test (Chi square 2) if (50) paragraph concerned with measuring the areas of academic personality traits were retained and then presented the scale to the expert to modify the wording of paragraphs.

Survey Scale: In order to know the clarity of the instructions and paragraphs and alternatives to answer by the students as well as determine the time required for the answer surveyed the scale on a sample of (5) students (5) students were randomly selected from the elements of society on (Sunday) corresponding to 14/10/2018.

It was found that the instructions were clear and the time taken to answer the paragraphs of the scale was between (5 - 10) minutes and thus the scale is ready to apply to the members of the research sample.

Application of the scale to the members of the construction sample: After completing the stages of building the academic personality scale consisting of (6) attributes and (56) items with objective response paragraphs, the researchers applied it to the members of the sample of construction (40) students and (20) students in the Faculty of Physical Education and Sports Sciences/University of Karbala On Wednesday, 17/10/2018, the researchers then proceeded to unload the forms, analyze them statistically and reveal the efficiency of each paragraph of the scale.

Scale correction: The measure of academic personality paragraphs formulated in a positive direction and three alternatives were given weights ranged between (3_2_1) according to the sequence of answer for paragraphs.

Basic experience: After completing the procedures that qualify the conduct of the basic experiment, the researchers carried out on the sample of the research sample of the genders and the number of (105) male and female students (70) and (35) female students began to apply the scale on Monday, 12 November 2018 taking into account the same methods. The standardized methods by which the scale is applied, after which the forms were collected and unloaded for statistical processing.

* Tabular value (T) at the degree of freedom (103) and below the significance level (0.05) is equal to (1.96)

In Table (2), it is found that the results related to the analysis of data on the characteristics and measurement of academic personality of the grades of the fourth stage students college of physical education and sports sciences University of Karbala, male and female, and when making comparisons between the arithmetic circles of the characteristics of academic personality between males and females shows that there is a statistically significant difference in the attributes (physical, social, and the total score of the academic personality scale) because the value of (T) calculated at these attributes is greater than the tabular value of (1.96) at the level of significance (0.05) and the degree of freedom (103) and researchers attribute these differences to the value of the average score for the male students in the physical features and the total score of the academic personality scale being greater than the value of the arithmetic mean of female students, which confirms that male students are characterized by a high level of academic features, where young students try to achieve themselves, especially at this age as well as the climate and social environment and the accompanying Of the requirements of life and Iraqi society. The researchers believe that there is a set of social and environmental conditions lead to young people to prepare themselves (efficient and accomplished) and multi-talented and when born with this concept has a high sense of self-esteem as well as socialization methods used by most Iraqi families encourage the creation of youth characterized by a level of personality Personal because school, peer and friends of the neighborhood and the region are social organizations and small size, but that work within them towards common goals develops the status of belonging and loyalty and personality traits in males, and the large value of the arithmetic mean in the social features of students confirmed the moral When they analyzed the data of students in the attributes (mental, emotional, academic excellence, and characteristics of sports creativity) and inference about the difference in morale shows that there is a random difference Between the arithmetic circles among male and female students because the calculated (T) value is less than the tabular value of (1.96) at the degree of freedom (103) and below the level of significance (0.05) and this confirms that there is a discrepancy and difference between the arithmetic circles randomly and due to chance. That’s one of the reasons behind this is the cultural value that has become the decisions of the Faculty of Physical Education and Sports Science University of Karbala for individuals and their contribution to the formation of cultural identity of societies because the knowledge and experience gained are the pillars of cultural construction and the large amount of physical education and sports, because of the multiple fields and diversity among healthy Educational, social, psychological and recreational makes sports culture a tributary of the general culture of the individual and society.
Conclusions

1. Developing a measurement tool concerned with measuring and determining the academic personality of the students of the fourth stage, Faculty of Physical Education and Sports Science

2. The students of the fourth phase of the Faculty of Physical Education and Sport Sciences and both genders have a high level of academic personality traits

3. There are real differences between students (males and females) in the level of physical and social features and the total score of the scale

4. There are no real differences between students (males and females) in the level of mental and emotional features and academic excellence and features of sports creativity.

5. Develop an optimal method (personal model) to evaluate the characteristics of the academic personality according to the standard levels achieved by the research sample by gender in order to (diagnosis, correction, treatment, comparison, guidance, selection, development).

Self-Organized Learning Strategies and their Relationship to the Complex Thinking of Kindergarten Students

Nour Sabbah Lafta¹, Iman Abbas Ali AL-Khafaf⁰
¹Department of Physical Education and Sport Sciences, Faculty of Basic Education, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

The importance and problem of research is summarized through the development of self-organized learning strategies that have a complex response system that enables learners to examine their environments and experiences; to make the right decision for the learning process, to judge, and review their plans, and that self-organized learning strategies help stakeholders in the Ministry of Higher Education to use methods. The second semester dealt with the procedures of the research where the sample consisted of (200) students from all stages of kindergartens department to measure self-organized learning strategies by (58) students. The first, second, third and (26) students from the fourth stage, where the researcher prepared the paragraphs of the scale (test) based on strategies of self-organized learning and testing the validity of the paragraphs of the scale after being presented to experts and specialists and choose what is appropriate for the paragraphs of the scale. Results of identifying self-organized learning strategies among kindergarten students. The main conclusions are:

- Kindergarten students have structured learning strategies.
- There is a significant correlation between the grades of self-organized learning strategies among kindergarten students.

Keywords: Self-organized, strategies and complex thinking.

Introduction

University education is one of the most important stages of education. Human, social and economic development, which provides a qualified workforce to lead the society, which requires educational institutions to prepare and pay attention to the human element so that it can respond to the data of modern life and interact with it. The general development of societies today is greatly influenced by the volume of growth in the circulation of information, its intensity and the way of dealing with it. These societal developments are efficiently commensurate with the quality and magnitude of the problems they face in the age of conflicting changes.¹

The University is part of a society that is undergoing the phenomenon of change. Self-organized learning strategies are an active constructive process through which to develop the complex thinking skills of university students. Self-organized learning is useful in training learners to formulate ideas, feelings well formulated through self-planning, and to strengthen creative effort; to achieve personal standards attention is growing at present to the need for self-organized learning by developing motivation to be self-organized by making them accountable and able to develop themselves. Modern education emphasized learning that leads to behavior modification Learning is a lifelong process, and the university is only one of the institutions through which individuals learn, and the role of a teacher in the educational process is the facilitator of learning, and the best type of learning is based on the needs of learners It follows that the goal of education is no longer the transfer of information and knowledge from generation to generation, but the formation of integrated personality of learners.²

It is thought that some students are incompetent not because of their poor mental abilities, but because their methods of thinking that do not match those of those who do the evaluation process, especially in teaching or is due to their ignorance of the correct means of recall, and to the acquisition of these students many methods of false recall. We need to keep in mind students’ thinking patterns if we want to reach them and communicate with them.3

University education contexts are often more complex than previous subjects, cover more and more quickly, and focus on unfamiliar titles for students.

**Research aims:** First Objective: Self-organized learning strategies for kindergarten students.

**Research Methodology**

The present research aims at describing the self-organized learning strategies of kindergarten students. Relational studies confirm the knowledge of the size and type of relationships between the data, or to what extent the variables of the phenomenon studied are related to each other, whether their partial, total, negative or positive correlation.

**Community and Research Sample:** The community refers to the total group of elements, which the researcher seeks to generalize the results related to the problem. The current research community consists of students from the kindergartens department in the city of Baghdad/College of Basic Education for the academic year (2018/2019) and the student number (311) Student from the Faculty of Basic Education/Department of kindergartens, distributed in (4) stages and table (1) shows that.

A random sample was selected and included (200) students from all stages of kindergartens department to measure self-organized learning strategies. (58) Students from the first, second and third stage and (26) students from the fourth stage.4

**Validity of Self-Organized Learning Strategies Scales:** This procedure requires obtaining the consensus of a group of arbitrators on the validity of the scale.5

1. Validity of each paragraph of the scale
2. Clarity of instructions
3. Make amendments by deletion and addition.

In the light of the opinions of the arbitrators on the scale, Annex (3) was accepted paragraphs that received an agreement rate of 80% and more were (40) paragraphs out of (40) paragraphs and table (3) shows that.

**Preparation scale instructions:** The researchers developed instructions to answer the self-regulated learning strategies scale in the light of the following considerations
Simple language formulation, straightforward.

Emphasis on the accuracy of the respondent to choose the appropriate response alternative to each paragraph of the scale.

Non-disclosure of the true purpose of the scale in order to overcome the problem of social desirability, falsify the answer in a way that makes individuals appear themselves socially acceptable.

It was stressed that these answers are for scientific research purposes only and will not be seen by anyone except the researcher, and that there is no need to mention the respondent to her name.

Scoping Application of the Scale:

The purpose of this application is to identify the following:

- Clarity of scale instructions.
- The clarity of the paragraphs in terms of wording and meaning.
- Calculate the time taken to answer the scale.
- To achieve this goal, the researcher applied the scale to a sample of (20) female students of the phases (the first, second, third and fourth) of the students of kindergarten department, and by (5) students from each stage. Between (8-10) minutes and an average of (9) minutes.

Scale Correction:

Correcting the scale is intended to obtain the total score for each member of the sample, which represents the responses to each paragraph of the scale has been adopted triple gradient and give alternatives grades as follows:

- It applies a lot to three degrees
- Apply to a little two degrees
- Does not apply to one degrees

Statistical analysis of self-organized learning strategies:

(A) Discriminatory force:

The purpose of the analysis of the paragraphs is to obtain data by which the discriminatory power of the paragraphs of the scale is calculated and illustrate the discriminatory power of the paragraphs and their ability to distinguish between individuals distinguished in the quality measured by the measure, and individuals who are weak in that characteristic, and thus works to keep good paragraphs in the scale.

Paragraph analysis requires a sample size that is proportional to the number of paragraphs to be analyzed. Nunley points out that the minimum allowed is five individuals per paragraph.

According to the Self-Organized Learning Strategies Scale among the 40 kindergarten students, a sample of (200) female students was selected. Thus, the ratio of the sample to the paragraphs is (1: 5): 7

- Apply the scale to a sample of (200) students (sample building scale).
- The scores obtained by the sample members were sorted in descending order from the highest to the lowest.
- The 27% of the forms with the highest scores (the highest group) and the 27% of the lowest scores (the lowest group) were assigned.
- According to the research sample, the number of respondents (200) students has reached the rate of (27%) in each group (54) students for the upper and lower groups and therefore we have two groups with the largest possible size and maximum variation.
- Taking such action is one of the most characteristic divisions of the levels of weakness and strength and depends on the division of grades on the top and bottom ends, so that the upper section consists of degrees that are (27%) of the strong and offset by the same percentage of the weak. 1971)

The mean and variance were calculated for each group separately and for each paragraph of the scale. Table (1.96) and Table (4) illustrate this.

Relation of the degree of the paragraph to the degree of total scale:

This method of extracting the internal consistency of a paragraph is based on the correlation between the scores of each paragraph and the overall score of the scale. This gives an indication that each paragraph of the scale is on the same path as the scale in all its paragraphs. The results of the second method analysis were consistent with the results of the analysis in the first way, it indicated that the correlation coefficients for all paragraphs were a measure of self-regulated learning strategies were statistically significant at the level of significance (0.05) and table (4) shows this.
Table 4: The correlation coefficient between the degree of the paragraph and the total score of the self-organized learning strategies scale

View and discuss results: This chapter includes the presentation and interpretation of the results achieved on the basis of the data and the sequence of its objectives as well as recommendations and proposals.

Identify self-organized learning strategies among students of the kindergarten department: The results of the current research for the sample of (100) female students of kindergarten department, showed that the arithmetic mean includes the presentation of the results reached and interpreted based on the data and according to the sequence of objectives as well as recommendations and suggestions.

Presenting and discussing the results of identifying self-organized learning strategies among kindergarten students: The results of the current research for the sample of (100) female students of kindergartens department, showed that the arithmetic average of the scores on the scale of self-organized learning strategies has reached (920.95) degree standard deviation (11.895), while the hypothesis average (When using the t-test for a single sample, it was found that the calculated (t) value (634.80) is greater than the t-value (99.1) at the significance level (0.05) and the degree of freedom (99) where this result indicates that The research sample had structured learning strategies because the sample mean was higher than the hypothetical mean of the sample Among the calculations and the average table and premise (6) shows that.

The mean scores of learning strategies are self-regulated among the students of the kindergarten department in the current research sample higher than the hypothetical mean. This means that they tend to complete the tasks assigned to them in an acceptable manner where policies and practices are developed that help students to educate themselves and update good ideas to develop competitive advantage. This can be
explained by the Robinson model (General Rules for Recalling), in which he asserted that individuals have the ability to control their behavior by observing, judging, and responding to behavior according to the events they face in their daily lives, i.e., individuals can largely regulate their behavior. The result can be attributed to the fact that individuals who feel self-responsibility as a result of their learning and development of their experience and skills as well as possessing internal motivation, which makes them individuals aim to organize their own learning, as the vast majority of students. They are aware of the importance of the information they get from teachers, parents or different means of communication that serve them in organizing themselves for learning to happen and that the results of the current research are consistent.

**Conclusion**

1. Kindergarten students have structured learning strategies, where the results came with an arithmetic average higher than the hypothesis average of the scale.

2. There is a significant correlation between the degrees of self-organized learning strategies among students of kindergarten department.

The Impact of an Accelerated Learning Program on the Development of the Skill Level of Snatch Punch for Boxing Students

Mohammedhussein Hayder Hamuwd¹, Wissam Salah Abdul Hussein¹, Samir Abdul Hady Ahmed¹
¹Faculty of Physical Education and Sports Science, University of Kerbala, Iraq

ABSTRACT

The world is witnessing major developments in many fields, including the sports field, where it witnessed the development of technical performance in all sports and events at all levels, which led to accelerate learning processes and shorten its time, and focuses on rapid learning on the results achieved and not the means used, so you can Through the process of learning to diversify and increase the means and techniques that you use to reach the goal, and because of the boxing game of open skills in which the opponent is unstable, which requires the learner to recognize and care about the speed of movement and accuracy of skill, which made The objectives of the research were to prepare a program in accordance with the accelerated learning in developing the skill level of the snatch punch for boxing students, and to identify the impact of using the program according to rapid learning in the development of the skill level of the snatch punching for boxing students, and to identify its preference for the impact of the program according to the rapid learning and the approach adopted in the development of The skill level of the snatch punch for students boxing, the hypothesis of research there is a positive impact of the program according to rapid learning in the development of the skill level of the snatch punch boxing for students between the tests before and after the program and educational Accelerated Learning preference influence in the development of the skill level of snatch punch boxing students between the post tests.

Keywords: Accelerated learning, skill and snatch punch.

Introduction

The world is witnessing major developments in many fields, including the sports field, where it witnessed the development of technical performance in all sports and events at all levels, which led to accelerate the learning processes and shorten its time.

This is an indication of the great interest of specialists and researchers in the development of the educational process continuously. In order to raise technical performance and achieve sports achievement and study the finer details that lead to convergence of levels to reach the desired goals according to scientific contexts, accelerated learning focuses on the results achieved and not the means used,³ if you want to Do not link yourself to any of the means and techniques, just keep your eye open on the results you must reach, so you can through the learning process to diversify and increase the means and techniques you use to reach the goal, and fast learning is interested in making learning an experience involving the entire body Thinking through feeding human intelligence in its various forms (rational, emotional, physical, social, innate, creative, spiritual and moral) and others at all levels to restore the effectiveness of the educational process, and the boxing game has kept pace with the progress and development in many methods of learning and training In the various aspects and accordingly progress and development focused most attention in the field of boxing specialists on several aspects (physical, skills, mental and emotional), and most prominent of these concerns related to the mental side, which coincides with the special skill level of each.

player or learner in the game, and given the enjoy the
game of boxing of open skills in which the opponent
is not fixed, which requires the learner to be aware
and cares about the speed of movement and accuracy
of skill, which made the researcher need to choose the
best methods for the purpose of reaching the optimal
learning of the various skills, including punch Snatch,2
which is the focus of the current study and which need to
use special devices and tools in order to learn the correct
scientific form.

Research aims:

1. Prepare a program according to the accelerated
learning in developing the skill level of the snatch
punch for boxing students
2. Identify the impact of the use of the program in
accordance with rapid learning in the development
of the skill level of the snatch punch for students
boxing.
3. Identify the preference of the impact of the
educational program in accordance with the
rapid learning and the approach taken in the
development of the skill level of the snatch punch
for boxing students.

Research hypotheses:

1. There is a positive impact of the educational
program in accordance with rapid learning in the
development of the skill level of the abduction
punch and defenses boxing for students between
the pre- and post-tests.
2. To the program according to rapid learning
preference to influence the development of the
skill level of the abduction punch and defenses
boxing for students between post-tests.

Research Methodology: The researcher used the
experimental method by designing the one group with
the pre- and post-test, which is the closest and most
sincere to solving many scientific problems in practice
and theoretically and it fits with the nature of the research
problem.

Community and Research Sample: The selection of
the research community and sample is one of the most
important priorities of the researcher. The research
community was determined by the students of the
second phase in the Faculty of Physical Education and
Sports Sciences at the University of Karbala for the
academic year (8201-1920) as a research community as
the subject of boxing (120) students represented by (4)
people (A-B-C-D) and by lot Division A was selected as
the research sample, and the number of students of this
division (20 students) was randomly divided into two
groups each group (10 students).

Search devices and utilities:

1. Boxing circuit/number (1).
2. Boxing gloves/number (15).
3. Your bags/number (6).
4. Wall cushions/number (6).
5. Hand cushions/number (6).
6. Centimeter tape measure.
7. Chairs and tables (3).
8. Sportswear T-shirt/number (20).
9. Beep number/number (2).
10. Hand calculator type (Casio)/number 2.
11. Video Camera Type (Nikon, d5200)
12. Toshiba laptop calculator Japanese-made, core “i5”
13. Screen display type (Sony) size (32).
15. Sling 5 meters/number (2).
16. CD/number (30).
17. Stopwatch/2 Chinese-made.

Characterization of punching test on numbered bag:3
Test objective: Measure the skill level of the left snatch
punch and the right snatch punch.

Used tools: bag medium size (13) kg, manufacture,
whistle, registration form, boxing gloves, chairs and
tables, stopwatch, camera video type (Sony).

Performance Specifications: When the rectifier signal
to the student to perform the punch and according to
the correct conditions of performance and the learner to
perform five side punches left and then five side punches
right on the numbered pouch from the standby stand
and the best attempt is chosen and the least time to be
characterized by punching the front of the glove and follow
the body weight of the punch and the right coverage The
opposite arm as shown in Figures 1 and 2 below.
Conditions: Return to the standby pause and then perform the second punch and so on for the rest of the punches.

Registration: The researcher designed the evaluation form after presentation to experts and specialists where the skill was divided into three sections and explained each section and give him a score and three residents are sitting next to the learner at a distance of (2 meters) as each rectifier alone assesses each punch of punches and each learner in the evaluation form, which is available to each resident by giving a score of (1-10) agencies: (3 degrees/preparatory section) (5 degrees/main section) (2 degrees/final section).

Figure 1: Shows the performance of the right and left side punch on the numbered punching bag

Pretests: After the implementation of two modules within the program, which included explaining the skill of the abduction punch and live presentation by the teacher and the performance of students, the tests were punched on the numbered bag (skill level) pre sample of research on Thursday (14/3/2019) in the private room. For the boxing game in the Faculty of Physical Education and Sports Science - University of Karbala at nine in the morning and the researcher has proved the conditions related to the test in terms of time and place and the tools used and the method of implementation and the team of auxiliary and in order to provide them in the post-test.

Educational program: Through access to scientific sources and previous studies and ongoing discussions with supervisors and researcher field experience in the field of boxing game, an educational program was prepared according to the tendencies and desires of learners and within the specificity of the method of rapid learning, the program included a set of educational exercises to learn the skill researched, in addition to the organization of these exercises Within the teaching units, repetition and practice were also adopted. Real-time feedback was adopted during the performance of the skill and the stages of rapid learning were used during the application of the program, and the number of teaching units of the program was (8) teaching units. The implementation of the program drowned (10) weeks and by a unit of learning per week, as the researcher used a set of skill exercises that were aimed at learning and mastering skills through diversity in its forms. The program was started on Thursday 21/3/2019 and was completed on Thursday (6/5/2019), note that the educational program was applied to the experimental group with a rapid learning method in which learning through experimentation and action versus learning clearly about the strategy of playing through explanation and clarification and video presentation, while continuing according to the program Teacher for the control group.

Posttest: After completing the application of the educational program of the experimental group and the program followed by the teacher of the control group, which includes (8) teaching units, the researcher
conducted the post-tests of the method of rapid learning on (9/5/2019), and on the members of the basic experiment sample of experimental and control groups and the same conditions and specifications pre-testing, data acquisition and recording in questionnaires to be processed statistically. The skill level of the experimental and control groups was assessed in the same manner as in the pretest tests.

**Results**

**Table 1:** Shows the mean values and standard deviation of the pretest and posttest tests for one group

N = 9 under the significance level (0.05)

**Discussion of the Results**

The researcher attributes the difference between the pre- and post-test of the research group as a result of the positive impact of the prepared educational program that has been applied and works with all learners. Which occurs for every learner when trying to understand himself and the world around him, explaining meanings and making relationships, identifying problems, developing solutions, providing alternatives, evaluating and deciding on them.

**Figure 2:** Shows the mean values and standard deviation of the pretest and posttest tests for one group

Experimental group in the post-test, as the researcher attributes that the use of rapid learning method gives the learner freedom in performance and implementation through the use of this method where the learner is active to issue new ideas and creativity in performance because learning is through linking and integration with the orientation towards facts and concepts in return Abstract thinking and orientation towards the facts and theories and thus the learner is able to overcome the greater difficulties faced and therefore make appropriate decisions.

**Conclusions**

1. The prepared educational program has achieved its objectives in developing the skill level of the left snatch punch and the right punch snatch boxer.
2. The program has a clear and effective impact in learning the skill of punch snatch for students in boxing.
3. The ability of students to find appropriate solutions to educational situations because the method of rapid learning helped to think, induction, conclusion and cognition, which helped to retain more information of meaning

Selective Screening of Inborn Errors of Metabolism in Baghdad Al Karkh/Al-Ielam Sector

Mithal Abdulkareem Abdoun¹, Raghad abd ul Kareem²

¹College of Dentistry, Ibn Sina University of Medical and Pharmaceutical Sciences, Baghdad, Iraq; ²Al Karkh Directorate al Ielam, District al Shabab, Primary Health Center, Ministry of Hrealth, Iraq

ABSTRACT

Inborn error metabolism (IEM) are genetically inherited diseases, though individually rare together they represent a significant percentage of children. In Iraq the neonatal screening program is considered as a systematic public health program for infants screening in the first 3- 5days after delivery up to 2 month of age for congenital hypothyroidism(CH),phenyl ketonuria(PKU) and classical galactosemia(GALT)

Aim: To evaluate the neonatal screening program results in al-ielam district in the period1/8/2017 to 1/8/2018.

Method: This is across sectional -retrospective study that included 6777 client from seven PHCCS in al-ielam district in the period

Result: The screened number in Baghdad/Al-Karkh-al ilam district from 1st of august 2017 –1st of august 2018 was 6777. females were 3732 and 3045 were males. aged 3- 5 days to one month. eight cases were identified and confirmed to have IEM (0.1% From the total number) five of them were female and three of them were males. The metabolic disorders diagnosed were, galactosemia4(0.06%), congenital hypothyroidism were3(0.04%)and phenyl ketone urea l(0.01).

Conclusions: In this study there was a low prevalence rate in in Baghdad/Al-Karkh-al ilam district compared to the international standard. And the most frequent metabolic disorder is galactosemia comparing with the other disorders

Keywords: inborn error metabolism, hypothyroidism (CH), phenyl ketonuria (PKU)

Introduction

Inborn errors of metabolism (IEM) represent a heterogeneous group of disorders caused by genetic mutations and enzyme deficiencies compose a wide spectrum of diseases in mankind which may manifest at any time from early neonatal period to adolescence. Some of the metabolic disorders may even present at adulthood (1,2). The introduction of mass spectroscopy (MS/MS) in the neonatal screening allowed the screening of cases that may have been lost, and therefore believed to be extremely rare(3) prior to irreversible clinical damage(4,5).

Most inborn errors of metabolism (IEM) surveys in Western countries have been largely highlighted, with few studies in developing country contexts. As well Newborn screening has also been integrated in all health policies in developed countries since the 70’s of the last century (6). The service is still relatively retarded in developing countries. Dried blood spot is now widely distributed as sampling device for IEM detection by MS/MS for newborns as well for older children, so that it is easy to ship, relatively rapid and cheap, especially when relevant health facilities do not exist or are limited in the area (7). International efforts are now being made to help developing countries gain the knowledge and skills to improve IEM diagnostic and follow up. Since 2004, Middle East Metabolic Group by Orphan-Europe has been organizing an annual meeting for that issue. In 2006, the National Institute of Child Health and Development launched Strengthening of the Newborn
Screening in the Middle East and North Africa meetings, which is organized every two year (8).

The earliest possible recognition of disorders by using new born screening aims to prevent most serious consequences by timely intervention; it is not a confirmatory diagnosis and requires further investigation.

Guidelines from some developed countries recommend screening of newborn before discharge because of the high prevalence of certain endocrine disease, metabolic errors, hearing loss, And early screening for DDH (9) which, if recognized later, contribute to significant morbidity (10). Although the exact list differs among, and sometimes within countries, testing for phenylketonuria (PKU) and hypothyroidism is universal in the developed world. Amino acids disorders, fatty acids oxidation disorders and G6PDD are also common metabolic disorders which are not included in screening program in Iraq (11).

The need for an established organization for screening and costs are some reasons for the limited number of screened disorders in many countries (12). The benefit of screening programs is to improve health status of early diagnosed patients and to treat them optimally. The dis advantage of screening programs include false positives (causing additional costs, parental stress and anxiety) and false negatives (potentially delaying diagnosis in missed cases) (13).

In Iraq, the Ministry of Health paid particular attention to the newborns as they are the basis for a society free of diseases and their members are in good health, thus it establishes programs needed to achieve this goal (14).

Patients and Method

Setting: Baghdad/Al-karkh Health Directorate/ al Ielam district which includes eight centers, these are:
1. Al-shabab primary health center.
2. Al-saydia primary health center.
3. al -Ielam primary health center.
4. Al-risala primary health center.
5. Al-bayaa primary health center.
6. Ajnadien primary health center.
7. Al-Mowasalat primary health center.
8. Al-Radwanyia primary health center.

All of these health center involved in the study.

Data source: The information about the newborns that are tested in the PHCC are collected in a special statistical form, then these information will be, analyzed, and interpreted.

Sample size: The number should be screened in Baghdad/Al-Karkh al, Ielam district from From 1st August 2017 – 1st August 2018, was 6777. This number was obtained from screening records in each PHCC.

Screening Method: Every infants aged 3to5 days up to 1 month are involved in the screening program. Actually Most of the infants that involved in the screening program were brought to the PHCCs for receiving BCG vaccine and not for performing dried bloodspot card test. The healthcare providers will explain the screening test and its importance to the babies families and encourage them to participate in the program.

In the PHCC: the required information about the identity of the infant is recording, the insurance of the accuracy of the demographic data on the filter paper cards and the collection of blood specimens take place. Then the blood specimens then sent to the Central Public Health Laboratory: if Positive screening tests results detected then the test is repeated in the same filter paper and if it is still positive a phone calling from PHCCs to positive cases families will be done in order to take blood serum samples for the confirmatory tests to confirm CH while in case of PKU and GALT a new filter paper is used for confirmation.

Percent of clients with positive = Number of positive screening test (+ve ST.) x 100/Number screened (NS)

Data Analysis: The data are collected, analyzed, tabulated and figured by using the Microsoft office excel 2007. The data are expressed in form of numbers and percentages.

Result

As shown in Table. 1, The screened number in Baghdad/Al-Karkh-al Ielam district from 1st of August 2017 – 1st of August 2018 was 6777. females were 3732
and 3045 were males. aged 3-5 days to one month. eight cases were identified and confirmed to have IEM (0.118% From the total number) five of them were female and three of them were males. The metabolic disorders diagnosed were, galactosemia 4 (0.059%), congenital hypothyroidism 3 (0.044%), phenyl ketone urea 1 (0.014%). four of them were in al-bayaa PHCC (2 galactosemia, 2 congenital hypothyroidism), 3 of the positive cases were in al-muwasalat PHCC (1 gal, 1 PKU, 1 CHT), Two cases in al-risala (1 gal, 1 CHT).

Discussion

‘newborn screening’ is the term used to describe different types of tests that are performed during the first few days of a newborn’s life, aims to separate those who may suffer from the disorder from those who do not have the disorder. In contrast, diagnostic tests are conducted to establish the presence of a condition (15).

In this study, The screening test was performed on 6777, 8 (0.118%) of those screened showed positive screening test for either CH, PKU or GALT. as shown in Table. 1, is much higher than those obtained by single observational study in Germany (16) reported that from a total of 1,084,195 neonates 0.034% of cases present with confirmed diagnosis of a metabolic disorder screened in one newborn screening laboratory between January 1, 1999, and June 30, 2009, this may be due to short period of our study and fewer disorders involved.

The total no. of screening test of GALT: From the 6777of screening test of IEM Performed there was 4, 0.06% of those screened showed positive screening test for GALT, which is higher than those obtained by Alkhazrajy et al (17), which demonstrate (The total no of screening test of GALT Performed was 80409, 0.011% of those screened showed positive screening test for GALT) while it is lower than those obtained in India (18) [the study which included 10300 newborn showed that 0.388% of those screened reveal positive screening test for GALT]. in our study GALT came first in its incidence among IEM disorders this may be caused by deficiency of any one of the other two enzymes causing galactosemia (GALK and GALE) that are not included in our screening program, so referral, to pediatric metabolic specialist must be done in these cases to measure the level of the other two enzyme (Galactosemia variants).

Our study also demonstrate that, (0.04%,0.01%) of the total number of screening test was positive for CH and PKU respectively this result is consistent with Iraqi study at Baghdad/Al-Karkh Health Directorate done by Alkhazrajy et al (17), which demonstrate that from 80409of screening test of CH Performed, (0.047%) gave positive screening test for CH, and, 0.014% from 80409of screening test of PKU Performed was positive for PKU but much lower than those obtained by study done in Iran, Zohreh Karamizadeh et al (19), [in which 0.20% of 63031 had a positive screening test for CH,] and 0.011% out of 76966 newborns screened had a positive screening test for PKU]. as soon as the diagnosis of hyperphenylalaninemia is established, further studies for biopterin metabolism should be performed to rule out biopterin deficiency as a cause of hyperphenylalaninemia. One of the tests used is BH4 loading test which is not available in our screening program.

This difference in the number of recalled tests, may be due to different sampling methods, different TSH cutoff values, different methods of performing the laboratory tests, and may also reflect the levels of iodine deficiency in different regions.

The total number of the diagnosed cases is low because the program was applied on rare diseases, but it is considered worthy with minimum burden and better outcomes for patients, fewer clinically significant disabilities and fewer deaths achieved from early diagnosis and treatment of IEM diseases which in turn will come back with benefit to the society. Economic cost of early detection of such conditions should also be taken into account, as each Euro spent on the screening program saved more than 25 Euros in health and social costs (15).
Conclusion

The national neonatal screening program in Iraq currently includes screening for three disorders: phenylketonuria, galactosemia congenital hypothyroidism. In this study there was a low prevalence rate in Baghdad/Al-karkh Health Directorate/Al Ielam district compared to the international standard.

In conclusion, incidence and types of prevalent IEM differ in different countries, this explain the necessity to carry out such surveys preparing for disease selection for neonatal screening programs.

The Impact of Adding Silanated Pearl Powder on Some Properties of Heat Cured Acrylic Denture Base Material

Safa G. Dekan¹, Raghdaa K. Jassim²

¹Dept. of Prosthodontics, ²Professor, Head of Prosthodontics Dept., Collage of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: The most widely used material in denture fabrication is heat cured acrylic resin. Although it has many desirable properties but still lacks some of important ones like radiopacity and high strength. Fillers added to improve some properties of this material. Natural types of fillers might be used for this purpose, so the aim of this study was to evaluate the impact of adding silanated pearl powder on radiopacity, impact strength, transverse strength, surface hardness, and surface roughness of heat cured acrylic denture base material.

Materials and Method: As pearl powder used as fillers so methacryloxypropyltrimethoxysilane (MPS) is a chemical saline used for salination of pearl powder. A pilot study was performed to select appropriate concentrations of pearl powder during process of specimens’ making. Accordingly 1.5% and 2% wt. pearl powder were used. A total number of 150 specimens were prepared and divided into three groups (0%, 1.5%, and 2%) of pearl powder by weight, each group further subdivided into five subgroups for the experimental tests which include radiopacity, impact strength, transverse strength, surface hardness, and surface roughness tests. Statistical analysis of data was performed using descriptive and inferential statistics. Data was considered statistically significant at level of $<0.05$.

Results: FTIR analysis revealed that methacryloxypropyltrimethoxysilane was chemically bonded to pearl powder and copolymerized with acrylic resin. And results showed a statistically highly significant increase in radiopacity and a statistically non-significant decrease in surface hardness. Also there was a statistically decrease in mean values of impact strength, transverse strength and surface roughness at 2% silanated pearl powder.

Conclusion: adding 1.5% and 2% wt. silanated pearl powder to heat cured acrylic denture base material improved radiopacity and surface roughness, and this addition causes decrease in mean values of impact and transverse strength but they still within the acceptable requirements of denture base materials with no significant change in surface hardness.

Keywords: acrylic, pearl powder, silane, filler, radiopacity

Introduction

Acrylic resin denture base material is a combination of advantageous properties rather than one perfect property. However it still not ideal in all aspects like poor mechanical properties and lack of radiopacity(1). Several studies were conducted with different types of fillers Such as fibers (2) or powder (3) in order to improve properties of acrylic resin. Silane coupling agent was used to modify fillers for adequate bonding with resin matrix (4).

Natural products play an important role in medical field especially in dentistry. Pearl powder as one of Traditional Chinese Medicine (TCM) had many applications in medical, esthetic, and dental aspects (5). This was related to the main composition CaCO$_3$ (90%) with other trace elements and amino acids.

SPP used as fillers added to heat cured denture base material and studied the impact of their addition on radiopacity and some mechanical properties of heat cured acrylic denture base material.

**Materials and Method**

**Particle size analysis of pearl powder:** Laser particle size analyzer (better size 2000/China) was used to determine the particle size of pearl powder.

**Surface modification of pearl powder:** Pearl powder was modified with methacryloxypropyltrimethoxysilane (MPS) according to the procedure proposed by Jasim and Ismail in 2014 (6).

**FTIR analysis:** This was used to determine whether or not functional groups of MPS were present in pearl powder (7).

**Pilot study:** Radiopacity test was used to select the appropriate percentages of SPP as filler added to heat cured acrylic denture base material. Four percentages were used including 0.5%, 1%, 1.5%, and 2% wt. SPP. And five specimens of each percentage were prepared. The obtained results were statistically analyzed using pooled t-test which showed that percentages of 1.5% and 2% had a statistically significant increase in radiopacity as compared with control group.

**Specimens’ grouping:** In this study 150 specimens were made up from heat cured acrylic and divided into three major categories according to the selected percentages of SPP (0%, 1.5%, and 2%). Each category further subdivided into five subgroups for performing the following tests: radiopacity, impact strength, transverse strength, surface hardness, and surface roughness tests.

**Specimens’ Preparation:** This step started with mold preparation from plastic patterns as following: radiopacity test (30 x 10 x 2.5) mm length, width, and depth respectively (8), impact strength test (80 x 10 x 4) mm length, width, and depth respectively (9), and transverse strength test (65 x 10 x 2.5) mm length, width, and depth respectively (10). For surface hardness and surface roughness tests the instructions of device was followed regarding specimen’s dimensions in which the same dimensions for transverse strength test used.

The procedure for sample preparation including flasking, it was performed using the same procedure used for complete denture construction. SPP in percentages of 1.5% and 2% wt. were added to monomer and well dispersed using prope sonicator apparatus (Soni prep–150/England) then acrylic powder immedietly added to monomer containing SPP according to manufacturer instructions of regular conventional heat cured acrylic denture base material by Vertex (P/L ratio 2.2g/1ml). After that, acrylic dough was loaded into stone mold and a pressure of (100KPs/cm²) applied using hydraulic press for 5 min., then the flask placed in water bath.

A short curing cycle (1.5 hr. at 70 C° and 30 min. at 100C°) (10) was selected for curing of acrylic resin, this was after measuring the tempature of SPP decomposition using melting point apparatus (SPM 30/Stuart). The temperature at which SPP decompose was 330C°.

After that specimens were finished then polished using dental lathe machine (Germany). All specimens were kept in distilled water for 48 hr. before testing (10).

**Testing the specimens**

**A. Radiopacity test:** Aluminum step wedge was constructed from pure aluminum with thickness starting from 1mm reaching to 10mm with 1mm increment at each step. Radiopacity test carried out according to ISO 4049 standards (11). The specimens were placed over a wax plate of 10mm thickness to replicate the media of soft tissue absorption and reflection, and aluminum step wedge was positioned beside the specimens to standardize the density of the radiographic film (12).

The wax plate, aluminum step wedge, and specimens were putted on a cassette contained a photostimulable phosphor plate and irradiated with 50Kv, 200mA, and exposure time (0.1sec.) using computed radiographic system (CR-AGFA), with focus film distance of 1 meter that commonly used in chest x-ray as in figure (1). Digital image was obtained using scanner (CR-30 digitizer/AGFA) and this digital image converted to an x-ray image using x-ray image printer (DRYSTAR 5320/AGFA). The optical density was measured by light transmission densitometer (densonorm 21 i, pehamed/Franch). Three readings were taken for each specimen from standardized sites.
The impact strength test was conducted according to ISO 179, 2000 (9) with an impact testing machine (Amity Vielle/USA) and by using charpy method, each specimen was supported at end and then stuck by swinging pendulum of 2 joules. The impact strength was calculated in kilojoules/square millimeter using the following equation:

\[
\text{Impact strength} = \frac{E}{bd} \times 10^3 \text{ where}^{(13)}
\]

E: The impact energy in Joules
b: The width of the specimen in millimeters
d: The depth of the specimen in millimeters

\[
T = \frac{3PL}{bd} \text{ where}^{(13)}
\]

T = Transverse strength (N/mm²)
P = maximum force exerted on specimens (N)
L = distance between supporting wedges (mm)
b = width of specimens (mm)
d = depth of specimens (mm)

D. Surface hardness test: Shore D hardness tester (Time TH210) was used for testing surface hardness. Hardness value determined by measuring the depth of penetration of shore D hardness indenter (0.8mm), and the readings showed directly on a digital scale. Three readings were obtained from standardized sites.

E. Surface roughness test: The test was performed by using portable surface roughness tester (HSR210/China). This device is capable of detecting surface microgeometry by a stylus that remained in contact with the surface of specimen for 11mm. Three readings were taken from standardized sites.

F. Scanning electron microscope examination: This test was performed for control specimen (0% SPP) and specimen containing 2% SPP using field emission SEM (TESCAN/Czech).

Results

Pearl powder’s size confirmation: The particle size of pearl powder was 18.76µm.

FTIR analysis: FTIR spectrum of pearl powder after silanation revealed that all the absorption peaks of MPS were present in addition to the absorption peak of pearl powder; this indicated that MPS was chemically bonded to pearl powder as shown in figure (2)
Scanning electron microscope examination: Figure (3) showed field emission SEM image for control specimen (A) and specimen containing 2% SPP (B) which revealed the presence of SPP pointed by black arrows and this was viewed in 500 nm scale.

Figure 2: FTIR spectrum of A: Pearl powder B: Silanated pearl powder

Figure 3: Field emission SEM image for A: Control specimen B: Specimen containing 2% SPP
Experimental tests

In table (1) addition of 2% SPP to heat cured acrylic denture base material resulted in a decrease in optical density, impact strength, and transverse strength (1.31 ± 0.02), (10.26 ± 0.94 KJ/m²), and (77.34 ± 3.69 N/mm²) respectively.

Comparison among studied groups using one way ANOVA test revealed that there was a statistically highly significant difference for radiopacity test and transverse strength test only as shown in table (3).

Results of surface hardness and surface roughness tests after adding 2% SPP showed that the lowest mean values were (85.35 ± 0.87) and (0.77 ± 0.77 µm) respectively as in table (2).

Comparison among all experimental groups revealed a non-significant difference for surface hardness test and a highly significant difference for surface roughness test as shown in table (3).

Discussion

For many years, the use of acrylic resin was recommended as a denture base material. Ideally denture base material should possess some key physical attributes including biocompatibility and adequate radiopacity, also good mechanical properties. There are situations where broken pieces of acrylic denture being ingested or swallowed accidentally, so it is very important for acrylic denture base materials to have appropriate radiopacity. As this provide faster observation of these fragments before they threaten patient’s life. In this study adding SPP resulted in a highly significant increase in
radiopacity and this might be due to the influence of atomic number on radiopacity of material in such a way that higher atomic number represents a more radiopaque material (14) i.e. calcium is the main ingredient of SPP which act as an opacifier. In this study, adding 2% SPP to heat cured acrylic denture base material resulted in a statistically highly significant increase in radiopacity with a slight change in color. And this result disagree with Mikael et al in 2018 (8), this might be due to their use of nano sized calcium carbonate pure material while in this study used SPP consists mainly (90%) calcium carbonate micronized (18.76 µm) with other ingredients like trace elements and amino acids.

In impact strength test there was a statistically significant decrease in mean values as the concentration increase which might be explained by location of SPP particles inside or between acrylic resin chains which may result in weakness and breakdown of intramolecular forces along the side of individual chain. However the intermolecular attraction forces between acrylic polymer chains may also weaken and subsequently affect the capability of acrylic resin matrix to transfer the adsorbed load between its chains using shear movement. This means that fillers might restrict mobility of chain and their ability to deform when subject to force during testing procedure (15). 0-addition of fillers to the hwesting procedure may be restricted by the addition of fillers to the hwest cured acrylic resins dMeanwhileMM Meanwhile the interfacial adhesion between inorganic fillers and organic matrix was obtained by Van der walls forces, these weak bonds at high impact loading tend to break down making the material more brittle(16).

Results of transverse strength test indicated that the addition of SPP decreased the transverse strength mean values and this can be explained by the fact that cross sectional load bearing area of acrylic polymer matrix may be reduced by the presence of increased amounts of SPP fillers (17) which may act as impurities that can decrease the rate of polymerization, thus increasing the amount of residual monomer (18). Residual monomer might act as plasticizer in acrylic resin matrix and resulted in decreased transverse strength (19).

Regarding surface hardness, there was a slight decrease in mean values as compared with control group with a statistically non-significant difference and this may be related to low concentration of SPP used (2%) that can result in low network density, or due to agglomeration of SPP within the matrix of acrylic resin (20). Another explanation may be related to the micron size of added fillers (21).

Finally, the results of surface roughness mean values revealed a highly significant decrease that may be related to surface modification of pearl powder using MPS which can increase bonding between inorganic fillers and organic resin matrix so that chipping of particles away from surface of modified polymer during deflasking and grinding procedures is difficult leading to decrease surface roughness. In addition to the small particle size of SPP fillers that can be accumulated at surface of acrylic resin and fill the micro spaces at the surface (22).

The Skill of Personal Effectiveness and Management of the Profession as a Function to Predict the Adequacy of the Management of the Game for Volleyball Coaches

Oras Neamah Hasan¹, Kadhim Habeeb Abbas², Saeed Hussein Hasan²

¹Faculty of Physical Education and Sports Science, Al-Muthana University, Iraq; ²Faculty of Physical Education and Sports Science, University of Basrah, Iraq

ABSTRACT

The study aimed to identify the level of skill of personal effectiveness and management of the profession of Iraqi Premier League coaches and first class in the management of volleyball matches for the sports season 2017-2018, and the level of adequacy of the management of games for volleyball coaches of the Iraqi Premier League and first class, as well as to know the relationship between the skill of personal effectiveness, The management of the profession and the adequacy of the management of games for volleyball coaches and the prediction of the adequacy of the management of the volleyball coaches of the Iraqi premier league and the first degree in terms of the skill of the ability to scientific analysis.

The researchers identified the research community and they are coaches of the Iraqi league Premier and first division volleyball for the sports season 2017-2018, and the number (147) coaches (20) coaches in the Premier League and (127) in the first division, the search procedures included the construction of two metrics, measure the skill of personal effectiveness and career management and the adequacy of the management of matches Volleyball coaches consist of (6) areas (the field of planning in sports training, the field of technical and training competence, the field of adequacy of leadership and decision-making, the area of adequacy of organization and guidance, the area of communication adequacy, the field of evaluation of the training process).

Keywords: Management, predict and adequacy.

Introduction

The skill of personal effectiveness and management of the profession of a group of individuals have a common goal possess different skills complement each other to achieve the common goal of team members, personal effectiveness and management of the profession is necessary between the existing and increase the degree of cohesion of the group and rooting team values and unify the vision among team members, which increases the effectiveness of teams Reducing friction and conflict between teams within the group through unity of vision.

Self-efficacy refers to the convictions of an individual’s ability to conduct a particular behavior that leads to specific outcomes, and Schwurzer defines them as predictions of the end result of perceiving the potential consequences on an individual’s activity and indicating control of the activity. An individual’s personal power or strength as a personal judgment of an individual about his or her abilities to perform a particular task successfully.¹

Adequacy of management is the ability to do something with a certain level of performance effectively and efficiently, and the adequacy in the form of a general goal and behaviorally formulated reflect the skill or tasks that the supervisor or educational leader should be able to perform, and the ability to competence is absorbed and understood after knowledge, and the use of efficiency is In the Patricia report on the competency-based education movement, she pointed out that competencies are precisely defined goals that describe all knowledge, skills and attitudes.²
The first dimension is the content that must be included in the competencies, and includes knowledge or skills or trends or a combination of all of them and the second dimension: is the degree of determining the functions, tasks and skills involved in the competencies, and technical competencies include specialized knowledge of methods, processes, procedures and techniques required to do The implementation of a specific activity, and the training process is an organized and planned effort to provide manpower in the administrative apparatus with a certain knowledge, and improve and develop their skills and abilities, and change their behavior and attitudes positively, has long discussed the departments of sports clubs and Teams of qualified coaches who lead their players technically and administratively to win in various sports tournaments and competitions, and the competent coach at the discretion of these departments must have a positive impact on his players can increase their motivation in training and their determination to develop themselves and do their best in the competition to get their approval before Appreciation of others.³

**Methodology**

**Society and Sample Research:** The researchers identified his research community, namely the coaches of the Iraqi Premier League and the first division volleyball for the sports season 2017-2018, through a statistical obtained by the Iraqi Central Union in Baghdad, the number (147) coaches (20) coaches representing the Premier League and (127 - Coach representing the first division, where the sample of construction (100) trainers by (68.201) from the community of origin, and the application sample (120) coach by (81.702) of the community of origin.

**Variables considered:** For the purpose of obtaining the results of the research and achieving the objectives put forward, there must be a measurement tool. Where the researcher built a skill scale of personal effectiveness and management of the profession, and built a measure of the adequacy of match management for volleyball coaches and includes (6) areas (planning in sports training, training and technical competence, leadership and decision-making efficiency, organization and guidance, adequacy For communication and coordination, the adequacy of the training process evaluated.⁴

**Tests used in the research:** Steps to build the standards of skill personal effectiveness and management of the profession and the adequacy of the management of games for volleyball coaches. The researcher has the following steps and in sequence:

1. The purpose of building the standards of personal effectiveness skill and profession management and the adequacy of the management of games for volleyball coaches.
2. Determine the phenomenon to be measured: The phenomenon that the research aims to measure is to build the skill standards of personal effectiveness and management of the profession and the adequacy of the management of games for volleyball coaches.
3. Identify the areas of personal effectiveness skill management, profession management and adequacy of match management for volleyball coaches:

   For the purpose of identifying the areas of skill scales personal effectiveness and management of the profession and the adequacy of the management of games for volleyball coaches, the researcher reviewed many of the previous literature and references related to the subject (scientific research and management of games for volleyball coaches), as well as access to sources in the psychological sciences and science of sports training.

4. Determine the relative importance of the areas of the skill of the personal effectiveness skill and management of the profession and the adequacy of the management of games for volleyball coaches: Determining the relative importance of the axes of the study is very useful to know whether one of these areas is more important than the other in measuring the areas of personal effectiveness skill and profession management and the adequacy of management Matches for volleyball coaches, as well as to determine the number of paragraphs appropriate for each area of study in light of their relative importance.

5. Preparation of paragraphs of the measures of the skill of personal effectiveness skill and management of the profession and the adequacy of the management of games for volleyball coaches:

To develop a preliminary version of the standards of personal effectiveness skill and management
of the profession and the adequacy of match management for volleyball coaches followed the following volleyball methods, (see related resources, see related metrics, open questionnaire)

6. The validity of the paragraphs of the measures of the skill of personal effectiveness and management of the profession and the adequacy of the management of games for volleyball coaches.

This procedure requires the consensus of a group of experts on the validity of the paragraphs of this measure. The researcher has prepared a questionnaire for the skill of personal effectiveness, management of the profession and the adequacy of the management of games for volleyball coaches and was presented in a questionnaire form to the experts and specialists and the number (20) adopted by the researcher for the purpose of determining the validity of phrases. Personal effectiveness, career management and adequacy of match management for volleyball coaches.5

7. Preparation of Personal Effectiveness Skill, Profession Management and Adequacy of Match Management for Volleyball Coaches in the Initial Image: After the unacceptable paragraphs were excluded by the experts and specialists, the paragraphs were redistributed on the scale form randomly in a new form (the initial form of the scale).

8. Preparation of the instructions of the skill standard of personal effectiveness and management of the profession and the adequacy of the management of games for volleyball coaches: These instructions are written in a separate page of the test pages, and included instructions on the clarity of the answer as well as explain the importance of focus in the answer and honesty and not leave any paragraph without answered and characterized by instructions The conditions of the implementation of the test as easy, clear and objective.

9. The keys to correct the personal effectiveness skill, career management and the adequacy of the management of games for volleyball coaches: after the approval of the experts gentlemen on the alternatives of the answer formulated for the measure of personal effectiveness skill and management of the profession and the areas of the adequacy of the management of the match for volleyball coaches were (0%, 10%, 20%, 30%, 40%, 50, 60%, 70%, 80%, 90%, 100%), and the score is (0. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10)

10. Main Application of Personal Effectiveness Skill, Profession Management and Adequacy of Match Management for Volleyball Coaches: After the measures of personal effectiveness skill, profession management and adequacy of match management for volleyball coaches with their instructions and paragraphs are ready to be applied (final metrics), the researcher started with the assistant team to apply the standards. On the research sample (construction sample) of (100) trainers and their percentage (76.87) of the research community, on 30/4/2018 corresponding to Monday.

11. Statistical analysis of paragraphs measure disability learner collective: The most important analysis followed in psychological research are: (indicators of discrimination, scientific indicators of the scale).

**Results**

Table 1: Statistical Characterization by the value of the Kolmogorov Smirnov test for the sample building model in the variables studied

The results of Table (1) indicate the good prevalence of the model building sample scores (volleyball coaches in the Iraqi Premier League and the first degree) at each of the variables of skill of personal effectiveness and management of the profession, the adequacy of the management of the games, and when calculating the
value (KS) of the variables researched results (0.068) The values of the associated significance level were (0.195, 0.200) and respectively and were greater than (0.05). All variables achieved the moderation curve and confirm

their selection and validity in the representation of the studied community trained in the Iraqi Premier League and the first class. The following figures illustrate this.6

**Table 2: The matrix shows the correlation between personal effectiveness skill, career management and adequacy of match management for volleyball coaches**

When reviewing the results of tables (2 and 3), we find that the values of the correlation coefficient between the variable (the adequacy of the management of games for volleyball coaches) and the skill of personal effectiveness and management of the profession, reached (0.858) and the value of the associated significance level came by (0.000) which is smaller than (0.025) This indicates that the correlation is significant and the relationship is real, did not come by accident.

**Table 4: Quality indicators of the linear regression equation model**

</table>

Table (6) indicates the significance of the intersection coefficient (a) as well as the regression coefficient - slope - (B1) where the significance level values associated with the calculated (t) values were smaller than (0.05) which indicates the significance of the parameters (A, B) for simple regression model.

The fixed amount refers to the relationship between the degree of adequacy of the management of volleyball coaches and the skill variable of personal effectiveness and management of the profession, and return to the same table we find that the value of (t) calculated for the fixed amount (b) came by (34.516), and the level of significance associated with it came by (0.000) is less than (0.025) and this means that the value of (B) is significantly different from zero, and that the variable skill ability of scientific analysis, contributes effectively in estimating the result values (the adequacy of the management of games for volleyball coaches).7
From the above we summarize that the test (t) has indicated that the values of (fixed amount) were different from zero when compared with the values (fixed amount) of similar samples, when the values of the standard error is small, any small deviation from zero can reflect a difference. Important because the constant amount represents the majority of the different samples, although the values of the constant amount and their significance level are important statistics to be studied, but the interpretation of the standard versions of the constant values is easier (not independent of the units of measurement of the variables). The standard tells us how many units of standard deviation will change (B) this is the result, because predictive variables change by one standard deviation.8

After the researcher has realized that the model is able to predict the adequacy of the management of games for volleyball coaches well, it will apply the model to do some expectations, where the model will take the following form:

Non-standard equation:

\[ Y = A + B \times X \]

The results shown in the current study show the ability of personal skill and professional management of coaches to predict the adequacy of the management of volleyball games, as games can be managed adequately by the trainer through the skill of personal effectiveness and management of the profession, where the coaches’ methods are reflected in the performance of the players and translated their guidance to reality. If the failure occurs before there is a sense of effectiveness, and success experiences are important in sports practice, which is not simple, as the sports competition includes the characteristics of winning and loss experiences and it depends on the way athletes in the interpretation of success experiences as long as they are an essential part of the characteristics of sports, especially competitive sports. When an athlete experiences many experiences during a successful sporting competition, it reinforces a sense of sufficiency and strengthens the need for more excellence, and it convinces the individual of his or her own ability to conduct a particular behavior that leads to specific outcomes.9

Conclusions

In the light of the results obtained by the researchers, the following conclusions were reached:

1. There is a significant correlation between the skill of personal effectiveness and management of the profession and the adequacy of match management for volleyball coaches.

2. Predictability in the adequacy of the management of games for volleyball coaches of the Iraqi Premier League and first class in terms of skill personal effectiveness and management of the profession.

ABSTRACT

Objective: Humans are exposed to intricate combinations of chemicals in their food. Antioxidants are examples of these chemicals and used as food preservatives. Such chemicals are presented in the food to advance aroma, taste, and/or appearance and preserve decent qualities of food (antioxidants, preservatives) like sodium benzoate (NaB) which is commonly used as a food preservative.

Aim of study: This experiment intended to realize the sodium benzoate effects on certain hormonal and histological parameters on male rat reproductive system.

Material and Method: As a mammalian, model thirty mature albino male rats. Distributed these rats into three assemblies once tagging them in a 10 rat/group. The experimental groups (TG1 and TG2) were orally managed with sodium benzoate 400 and 800 mg/kg body weight throughout the 70 days of the experiment, control group (CG) was managed orally with purified water only. Post-anesthetic blood sampling from left ventricle was used for hormonal measurements.

Result: The statistical analysis illustrates a vital reduction in both seminal vesicles and testes masses (P < 0.05) in comparison with CG. Sperm parameters reveal a vital reduction in the means of both sperm motility and concentration in treated groups (TGs) (P < 0.05) in comparison with CG. Additionally, seminiferous tubules diameters, secondary and primary spermatocytes, and spermatids had an extremely substantial decrease, while increasing interstitial space when treated with sodium benzoate in comparison with the CG. While comparing the levels mean of the hormone in the CG, testosterone serum levels show vital (P < 0.05) reduction in TG1 and TG2. The verdicts proposes that sodium benzoate administration with (400 and 800 mg/kg body weight) for 70 days prompted destruction in the reproductive organs and cause harmless of the sperm parameters functions causing both hormonal and histological changes.

Keywords: Sodium benzoate, rats, reproductive organs, testis.

Introduction

Preservative is a substance or a chemical that is added to products such as food, pharmaceutical drugs, paints, biological samples, cosmetics, wood, and many other products to prevent decomposition by microbial growth or by undesirable chemical changes. In general, preservation is implemented in two modes, chemical and physical. Chemical preservation entails adding chemical compounds to the product (1). Traditional preservatives, such as sodium benzoate (NaB) which is commonly employed as food preservative have raised health concerns in the past. Benzoate was shown in a study to cause hypersensitivity in some asthma sufferers. This has caused reexamination of natural preservatives, which occur in vegetables.(2,3)

NaB is a salt form of benzoic acid that is employed as an agent for preservation in cosmetics, drugs, mixtures and shampoos (4), it is used as part of the treatment of hyperammonaemia that occurs as an inborn error of urea cycle. In addition, a new study shows that sodium benzoate may be beneficial as add-on therapy (1 gm/day) in schizophrenia (5). However, its concentration as a preservative has been limited by Food and Drug Administration (FDA) to 0.1% by weight (6, 7) and is “permitted as an animal food preservative up to 0.1%” as issued by the World Health Organization (WHO) (8). It is
proven as non-toxic in its organic form but its synthetic form at a chronic dose is toxic to living organisms (9). NaB is also connected to cancer in soft drinks, by stirring it with vitamin C; leading to the formation of benzene (10). Irritations in the eyes, skin, and bronchi caused by short-term exposure to benzoates can, but large skin sensitization needs a prolonged and continuous contact (11, 12).

This experiment study elucidated histological changes in the albino rats testes on oral management of NaB.

Materials and Method

In this article, 30 albino male rats weighing 150 to 200 gm were divided into three equal groups. Group 1 (G1) with a dosage of 400 mg./Kg. NaB orally in distilled water; Group2 (G2) with a dosage of 800 mg./Kg. NaB in distilled water and Group3 (G3) was administrated orally with purified water only throughout the 70 days of the trial. A nozzle fitted into a measuring syringe was used to feed the rats.

Post-anesthetic blood sampling from left ventricle was used for hormonal measurements. Animals were sacrificed and testes dissected out instantly taking the weight of each one and conserved in 10% formalin solution. This solution was castoff after one day, an alternative fresh solution was assembled, and the tissue was conserved for secondary fix. The tissue then experienced standard procedure of dehydration, clearing and wax impregnation once appropriate injection was realized. Hereafter, segments of thickness 4-5 μm were ceased and marked with hematoxylin and eosin stain. With no prior knowledge of the drug and the dose of the samples, which were then independently analysed by two pathologists who read and revised the samples.

Biochemical Measurements: the biochemical measurement was realized after separation on the serum using extraordinary enzymatic kits as follow:

Testosterone ELISA Kit: Total testosterone concentration in plasma or serum quantitative measurement was attempted using a microplate enzyme immunoassay (13).

Sperm concentration measurement: The epididymis was removed and chipped in 5 ml of normal saline, stored in a rocker for 10 minutes and permitted to incubate for 2 minutes at normal conditions. The supernatant was diluted once incubation at 1:100 with a solution having sodium bicarbonate and 1 ml formalin (35%). The newly renovated Neuber’s counting chamber (hemocytometer) was adopted to count spermatozoa overall number. Roughly, ten μl of the thinned sperm suspension was conveyed to every counting chamber of the hemocytometer and inspected using an ordinary light microscope.

Results

In this article, results were classified to three main components comprising the histological verdicts of the testes and the parameters of testes weight, testosterone hormone, and are as foAllows

1. Organs Weight Changes: The statistical analysis showed an important reduction in weights of testes (P < 0.05) in both groups in association with the CG as depicted in Figure 1.A. Comparable findings has been perceived in the seminal vesicles weight in association to the CG as depicted in Figure 1.B.

2. Sperms parameters: Oral treatment outcomes of sodium benzoate on sperm parameters for 30 days are presented in the table (1) and revealed:
   i. Concentration of sperm: The statistical investigation revealed an important reduction (P < 0.05) in sperm concentration in TGs in association with the CG as depicted in Figure 2.
   ii. Motility of sperm: There was an extremely significant reduction (p ≤ 0.01) in TGs, as the results of progressive sperm motility percentage suggested. Furthermore, treatment of sodium benzoate revealed an important reduction (p ≤ 0.05) in non-progressive motility and a rise in immotile sperm (p ≤ 0.05) comparing with CG.
   iii. Morphology of sperm: An outstanding decline (p ≤ 0.05) in normal sperm morphology in both TGs has been noted in the results when resembled with the CG.

3. Histological Observations: In NaB TGs, segments indicated a rebate in the the germ cell (GC) layer thickness, stretching the lumen of the central seminiferous tubules, and prominent necrosis of the population of GCs. Multiple vacuoles were observed in the tubules. Sertoli cells were abnormal in number and shape as per the control. Furthermore,
A peritubular fibrotic switch was noticed in the testicular sections as depicted in Figure 3. There was an extremely significant reduction in seminiferous tubules diameters, as depicted in Figure 4, primary spermatocytes, spermatids and rise in interstitial space as soon as administration with sodium benzoate associated with the CG.

CG testicular sections manifested seminiferous tubules with normal GC population layer thickness with regular smooth organized pattern up to mature spermatid. Neither the malignant nor the abnormal cell was observed inside the germinal epithelium. The vacuoles in the tubules were undetectable. There were sufficient populations of Sertoli cells; the result confirms the disengagement of spermatogonial cells and necrotic debris in seminiferous tubules and germ layer necrosis, exfoliation of GCs into the lumen of seminiferous tubules and Sertoli cell hyperplasia as depicted in Figure 3.b.

4. Serum hormones level: An important reduction (P < 0.05) was noticed in the levels of testosterone hormone in the TGs when associated to the CG as depicted in Figure 5.

Figure 5: Testosterone levels influence (ng/ml) of sodium benzoate NaB (400 and 800 mg/kg) in male rat serum
Discussion

The present study revealed that administration of NaB causes a vital decline in the weight of the rats’ testes. Histopathological segments of the testes exhibited drastic degradation and seminiferous tubules necrosis and denudation of germ epithelium layers in TG. The result shows disengagement of spermatogonial cells and necrotic debris in seminiferous tubules and germ layer necrosis, exfoliation of GCs into seminiferous tubules and hyperplasia of Sertoli cells. The findings presented are in agreement with Kanth et al. and Bhelonde (14, 15), who described germ membrane necrosis, GC exfoliation in the seminiferous tubules lumen.

Sperm counting is a very sensitive sperm test because it gives the cumulative results of all sperm production stages and is deeply linked to fertility. Our results confirm that NaB is cytotoxic to the sperm because it reduced the sperm count notably during the experiment period (16). The duration of the spermatogenic cycle in rats is 52 to 60 days and our findings denote that the affected GCs were almost the spermatids, spermatocytes, and spermatogonia. The count was degraded even at the end of the 30 days. This in all probability implies its effect on the stem cells. The deterioration in sperm count was maximum at the CG. It is also likely that the Sertoli cells could have been affected and the other likelihood could be due to its effect on the epididymal function (17).

The effect of NaB on epididymal sperm characteristics and testosterone hormone, after 30 days of treatment exhibited a vital reduction in all groups in comparison with the CG; this may be due to that administration of NaB could alter the histological architecture of testis, which appeared disruption of the spermatogenic process and seminiferous tubules (18, 19). Kehinde et al. (19) reported that the histological section of testes of TGs appeared alter in sperm quality and function and it showed distorted spermatogenic cells and seminiferous tubules, delusorius basement membrane with lumen vacuolation with hyperplasia of Sertoli cells. Vulnerability to preservatives, like paraffin, benzoic acid, negatively influences the male reproductive system function and changes the adipose hormone flow (16).

Testosterone plays a vital role in the final maturation of spermatozoon and while FSH is needed for the maintenances of the gametogenic function of the testis (20). The results of this study showed a vital reduction in testosterone in rats that were exposed to NaB, which is consistent with previous observations (14). The possibility of the low levels of plasma testo concentration following NaB exposure in this study may be due to increased oxidative stress. Oxidative stress may suppress the sensitivity of the gonadotrophic cells to gonadotropin-releasing hormone and, therefore, may prevent gonadotropin secretion (19). In this regard, Sohrabi et al. reported many alterations attributed to the direct cytotoxic effects of NaB leading to reduce testosterone synthesis (20).

Investigation the Role of *Lactobacillus* ssp. on *Entamoeba histolytica* Pathogenesis

Zainab Sameer Sabti¹, Shatha Khudaier Abbas¹, Nibras Nazar Mahmood¹

¹Department of Biology, College of Science, Mustansiriyah University, Baghdad, Iraq

ABSTRACT

*Entamoeba histolytica* is a type of parasite with global distribution. Infection with parasite causes amoebiasis which is responsible for more than 100,000 deaths each year, that marking it the 3rd leading cause of death. Presence of parasite leads to kill host cells because of the cytotoxic activity of the parasite. 157 stool samples were collected from AL-Kindi teaching hospital and Fatima Zahara hospital in Iraq. The cysts of *Entamoeba histolytica* were isolated from the feces and inoculated the mice with cysts. After 3 days the mice infected with parasite. The infected mice showed the presence of trophozoites in the larger intestine and found in the larger intestine many histological abnormalities, while in serum of the infected mice the level of IL-10 and IFN-γ were high compared with uninfected mice, mice treated with *Lactobacillus acidophilus* and mice treated with metronidazole.

Keywords: *Entamoeba histolytica*, *Lactobacillus* ssp, *Lactobacillus acidophilus*, IL-10, IFN-γ, Histological study

Introduction

*Entamoeba histolytica* is a type of parasite with a global distribution, the infection by *Entamoeba histolytica* parasite was estimated reach to 50 million people in developing countries and responsible for more than 100,000 deaths each year, 1% of the infected people may improve pathologies such as acute amoebic colitis or amoebic liver abscess. Most infections have no symptoms but gastrointestinal diseases may happen with many weeks of abdominal pain, bloody or watery diarrhea, loss of weight and cramping¹. *E. histolytica* is characterized by two stage the first is the trophozoite and the second is the cyst, The virulent stage is the cyst, cyst is non-motile form of the *Entamoeba histolyticae* the cyst found in the feces and has the ability to stay alive for some days in the environment, Mature cysts bear four nuclei and a dimension ranging 8 to 20 µm in diameter, while the trophozoite is the motile form the a dimension ranging is from 10 to 60 µm, trophozoite resides in the intestinal tract, and has the ability to destruction the tissue of intestinal tract and cause diarrhea with bleeding³. The gastrointestinal tract that infected with *Entamoeba histolytica* is common in the developing countries and the parasitic protozoa infected the human bowel⁴. Amoebic infection occurs by ingestion of mature cysts in fecally-contaminated food or water or from the hands. Excystation of the mature cysts occurs in the small intestine and trophozoites are released; the trophozoites then move to the large intestine. The trophozoites increase by binary fission and produce cysts. Both stages pass in the feces. The cysts can survive days to weeks in the external environment because of the protection provided by the cyst wall. The cyst is responsible for further transmission of the parasite⁵. Interferon gamma IFN-γ activated neutrophils in response to amoebic invasions which carry out amoebicidial activity. Macrophages are amoebicidal after stimulation with IFN-γ or TNF-α⁶.

Interleukin-10 is an important regular of the intestinal immunity that block an immoderate pro-inflammatory immune response by inhibiting the production of the TNF–α. Interleukin-10 gene that disrupts in mice leads to colitis that which used as a model to study the disease of inflammatory bowel⁷.

*Lactobacillus* is a type of friendly bacteria, There are lots of different species of *lactobacillus*, which normally

live in our digestive, urinary, and genital systems without causing disease. It is also in some fermented foods like yogurt and in dietary supplements. In this study two species of lactobacillus it would taken to experiment there effect on treatment and prevention of diarrhea which caused Lactobacillus acidophilus is a big species of lactic acid bacteria that available in some products such as yogurt, milk and daily supplements. Growth of Lactobacillus acidophilus in the milk is slow which mean that the fermentation in the milk products achieves by starter culture of yogurt and then Lactobacillus acidophilus is added for additional probiotic value.

Material and Method

Feces Samples Collection: The study including 157 stool specimens were collected from patients infected with amoebiasis in AL-Kindi Teaching hospital and Fatima Zahra hospital, from November 2018 to April 2019. Stool samples were collected in clean plastic cup and transferred to animal research laboratory in collage of science, at Mustansiriya University.

Purification of E. histolytica: According to Robert and Thomson method was utilized to isolate the parasite then cyst was suspended in phosphate buffer saline (PBS-7.2) and the final concentration was attended by rate 1 x 10⁶ cells/ml.

Preparation of free cells and supernatant: Both free cells and supernatant obtained from MRS broth culture after incubated for 18hr at 37°C in an anaerobic jar, then the culture was centrifuged at 10,000 rpm for 10min. Supernatant was removed and filtered through 0.22 µm pores size filters and concentrated, while bacterial cells were taken, then washed and suspended in to contain (1×10⁸ cell/0.1 ml), after that stored in refrigerator to use later.

Animals: Using 60 white albino mice male and female were obtained from Iraqi Center For Cancer Research. Their ages were between (6-13) weeks old (16-22gm). All mice setted in clean plastic cages that proved with sterile water and the special food of mice. The feces of mice were examined by wet mount to make sure there isn’t any parasitic infection and all groups were immunosuppressed by dexamethasone (0.03 ml/mouse) daily as by intramuscular for five days.

Experimental design: This study included 60 albino mice divided in to six group each group include 10 mice, 50 mice was given (1×10⁸ cell/0.1ml) to make infection and ensure the mice was infected by examined their feces. A Group from 10 mice without infection as control negative. The mice were inoculated orally by single dose every day through the experimental.

1. Group one (uninfected): inoculated with (0.1ml/day) of normal saline consider it as control negative.
2. Group two (infected): inoculated orally with (0.1ml/day) of normal saline consider it as control positive.
3. Group three (infected): inoculated orally with (0.1 ml/day) of Lactobacillus acidophilus.
4. Group four (infected): inoculated orally with (0.1 ml/day) of free cells which contains (1×10⁸ cell/ml/day).
5. Group five (infected): inoculated orally with (0.1 ml/day) of supernatant.
6. Group six (infected): inoculated orally with (0.1 ml/day) of metronidazole.

During the experiment, stools of mice were collected and checked by light microscope and numerate the number of parasite. After the end of experiment all mice were killed and the blood collected from ocular vein of mice, then large intestine removed from each mouse and fixed in 10% formalin for studying histopathological changes.

Result

IL-10 and IFN-γ result: The present study showed the effect of Lactobacillus acidophilus in gradually reducing the number of Entamoeba histolytica parasite in the infected mice. The level of as in all treated groups after 12 days of treatment after infected the mice by E. histolytica the results were showed in table 1 and table 2.

4. Cross section of the large intestine of mice treated with bacterial supernatant showing look-like normal histological structure appearance with few goblet cells. (40X) (H&E stain)

Histology Result
5. Cross section of the large intestine of mice treated with L. acidophilus bacteria showing near to the normal appearance but with increase prominent goblet cells in numbers and its secretion. (40X) (H&E stain)

6. Cross section of the large intestine of mice was treated with Metronidazole showing near to the normal appearance with hyperplasia of epithelial cells and glands but few goblet cells. (40X) (H&E)

Discussion

In this study a species of Lactobacillus has been selected to determine its effect on Entamoeba histolytica in vivo and in vitro. Selection of this bacteria was based on their use it in some fermented foods such as yogurt and in dietary supplements. Lactobacilli are normal flora of mouth, intestine, and female genital tract with important role in the control of undesirable microorganisms that can be considered as natural bio-preservatives. Lactobacillus was successful as the metronidazole in reducing Entamoeba histolytica cyst excretion over than the control group, Lactobacilli are main component of commensal human bacteria in the gastrointestinal tract that have been shown to be protective against pathogen infection, Lactobacillus species have been successfully used in clinical trials to treat various forms of diarrhea. As well as one of important reason for use of the Lactobacillus acidophilus in treatment E. histolytica was the pH value, L. acidophilus live in low pH below 5.0, while parasite prefers to live in pH neutral and thus leads to death of parasite because of changing the environment in which parasite lives. Dietary supplementation with L. acidophilus could alleviate the inflammation and intestinal impairment, which improve intestinal morphology and barrier integrity, and modulate the intestinal microflora. Consequently, L. acidophilus addition benefited the intestinal health. Lactobacillus acidophilus supplementation can influence villus height, thus inducing small intestinal goblet cell hyperplasia. Lactobacillus used for treatment and prevention of acute diarrhea and antibiotic-associated diarrhea in children and in adults. In present study Lactobacillus acidophilus was able to influence the regulation of TH1 and TH2 cytokines through increased production of IL-10 and IFN-γ. Lactobacillus acidophilus that orally administered to the mice stimulated specific systemic immune functions, such as macrophages, increases in lymphocyte proliferative responses and enhanced stimulation of IL-10 and INF-γ cytokines. Mice that inoculated with L. acidophilus had significantly enhanced IL-10 and IFN-γ levels in the serum compared to the control mice. In metronidazole group, the results showed decreased IFN-γ and IL-10 due to the important role of metronidazole as antimicrobial agent that shown to be effective against other protozoal infections and causes damage to DNA and proteins in the cell.

Estimation the Level of Survivin in the Serum of Iraqi Patient with Gallbladder and Liver Disorders

Mohammed Kadhim AL-Kafajee¹, Zainab Thamer Showait AL- Asady²

¹College of Education for Pure Science Ibn AL-Haitham, University of Baghdad, Iraq; ²ALKarkh University of Science, Iraq

ABSTRACT

Aim: The present study was carried out to estimate the level of anti-apoptic protein Survivin in serum of Iraqi patients with Gallbladder and Liver disorders

Materials and Method: Serum of 63 patients with Gallbladder and Liver disorders was tasted, in addition 24 person with normal Gallbladder and Liver was tested as a control group, to estimate the level of the Survivin according to ELIZA technique.

Result: Survivin level was high expressed in serum of patient with Gallbladder cancer, Liver cancer and Bile stone (P≤0.05). While there was no significant association in patient with Liver inflammation, Gallbladder inflammation and Liver fibrosis compared with the control group

Conclusion: Result of this study indicated that the highest level of Survivin observed in the serum of patients with Liver cancer and Gallbladder cancer compared with other groups of Liver and Gallbladder disorders

Keywords: Survivin, Liver disorders, Gallbladder disorders

Introduction

There are many pathogens which can make injury of Gastrointestinal organs such as the Liver and Gallbladder and cause changes in the tissue as well as the function (1). These changes include hepatitis, biliary inflammation as well as cancerous infections (2,3). These changes occur in the liver as a result of viral infections, alcohol consumption, drugs, or genetic defects (1) and leads to an acute inflammatory response due to the stimulation of the immune cells within the liver tissue that secrete pre-inflammatory cytokines and inflammatory cytokines as well as anti-inflammatory cytokines (3). Also, any defect in the composition process of bile juice caused by hepatocyte or in the process of transferring it to the Gallbladder causes cholestasis. Liver infection by cancer tumors (Hepatocyte carcinoma) it is the most common disease and it has two type Primary Liver cancer occur due to transformation of the Hepatocytes into cancerous cells and Secondary Liver cancer, in this case it is not a direct infection but the cancer is transmitted to the liver tissue from other tissues (2). Gallbladder diseases occur as a result of many factors such as Gallstone, a cute and a chronic Cholecystitis as well as cancerous tumors (4). Apoptosis is physiological cell death or programed cell death take part in expansion and preservation of healthy cells and tissue (5,6), and it is one of the important of the defense mechanisms in Immune system to eliminate the infected body cells without inflammatory response (7). Apoptosis regulated by family of 8 proteins named Inhibitor of apoptosis (IAPs) and these protein have been identified in almost all vertebrates (8). IAPs protein have important role in preventing the cell from entering the stage of programed death by direct binding to caspases (9) in addition regulating the Immune response of T lymphocyte against tumor cells (10). Important member of IAPs is Survivin, Survivin is the smallest member of IAPs family which regulated apoptosis, and cell proliferation and cell cycle for this reason its unique protein because it have opposite effects (8).

Survivin expressed in tumor cells and embryonic cells as well as in embryonic and adult stem cells but not diagnosed in normal cells and tissues (11), also expressed in chromosomal Kinetochores of Metaphase in tumor cells (12) and inside mitochondria (13). Survivin is important component in chromosomal passenger complex (CPC) so it have important role in cell division (14), and it can inhibit apoptosis by binding directly or indirectly to caspase 3 and caspase 9 (15), as well as can inhibit apoptosis mitochondrial pathway by binding to Secondary derived activator of caspase (SMAC) to inhibit caspase 9 (16). High expression of Survivin in Endothelial cells lining Bladder infected with tumors compared with normal Urothelium that indicate the Survivin is attractive target for both anti-cancer therapy and as tumor marker (17). Therefore, the aim of this research is to estimate the level of Survivin in Iraqi patients with Liver and Gallbladder disorders

**Materials and Method**

The blood serum collected from 63 patient with Gallbladder and Liver disorders (25 male and 38 female). In addition 24 normal person (9 male and 15 female) as a control group, with an age ranged from 20 – 68 years. Patient samples collected from AL-Emamen AL-Kadhimin Teaching Medical city, AL-Kindi Teaching Hospital, Oncology Teaching Hospital in Medical city and Gastro-Enterology and Liver disease Hospital in Medical city in Baghdad during the period from 20/10/2018 to 15/2/2019. A questionnaire was prepared to collect information from patients including name of the patient, age, gender, chronic diseases, drugs used, previous surgical processes as well as alcohol, smoking, and time spent smoking and drinking

The serum was kept at Temperature 20 - °C, the samples were tested to detect concentration of Survivin by using Enzyme Linked Immune - Sorbent Assay (ELISA) analysis in the laboratory of the College of Health and Medical Technology in Baghdad. Survivin level was calculated by using the standard curve.

Statistical analysis was performed with the statistical package for social sciences (SPSS). Numerical data were described as mean ± standard error also, comparison between groups done using independent sample t-test. Categorical data were described as frequency and percentage. P-value of ≤ 0.05 was used as the level of significance.

**Results**

The results of the present study showed a significant increase in the level of Survivin in patients with liver cancer, Gallbladder cancer and Gallbladder stones compared to the control group (Table 1).

(**) highest significant increase

The result of present study showed that there are significant increase in Survivin level in patients with Gallbladder cancer among age group (20-35) compared to age group (52-67) the Survivin concentration was (39.178 ± 1.32150, 26.2110 ± 3.6760) Pg./ml respectively (Table 2), as well as the result showed there are significant increase in Survivin level in patients with Liver fibrosis among age group (20-35) compared to age groups (36-51) and (52-67) the Survivin concentration was (34.168 ± 1.5915, 10.4786 ± 1.7133, 14.6187 ± 2.7233) Pg./ml respectively. The result showed there are no significant differences in Survivin level in patients with Liver inflammation, Liver cancer, Gallbladder inflammation and Gallbladder stones between age groups.

**Discussion**

Survivin is the smallest member of anti-apoptotic proteins family (IAPs) which has a dual role by controlling the process of cell division in addition to inhibit programmed cell death mechanism by blocking caspase activation. Survivin level significantly increase in different type of human cancer such as Breast and Pancreas cancer and its role can be observed in tumor cell division, development and angiogenesis (18, 19)

The results of the present study showed a significant increase in the level of survivin in patients with liver cancer (HCC), Gallbladder cancer (GBC) and bile stone compared with its level of healthy people, as well as its level was not significant increase in the other groups (hepatitis, cirrhosis, Gallbladder inflammation) compared to its level in the healthy group.

Previous research indicates that Survivin is expressed in 64.7% of hepatocellular carcinoma (HCC), which is at an early stage of cancer infection (20). The high expression of Survivin mRNA was found to be 41% in HCC (21). In most type of cancer including Colon, Pancreas, Lung, Liver, Brain, Lymph nodes and Prostate (22,23). Previous research has indicated that a high level of survival in cancer cells can be useful as a diagnostic factor for patients with HCC in early stage (20). The study of (24) found that the survival rate in cancer cells within the tissue biopsies of the GBC sac was 76.27%, this is in line with the result of current study, because Survivin level was elevated in the serum of patient with Liver and Gallbladder cancer. It is therefore possible to rely on the rate of expression or high level as a diagnostic feature of these two types of cancer.

GBC arises in the BIH sac and BIH duct, but it is difficult to detect early due to rapid cell division, metastasis and Invasion, and the absence of a specific diagnostic relationship (25). Thus the result of the current study is consistent with the results of the previous, as the high level of Survivin can be relied upon as a diagnostic tool for Gallbladder cancer (24). Some studies have shown that the function of Survivin belongs to its location within the cell, it has been found that the high level in the nucleus is a good diagnostic marker for cancer suggested its predominant role in promotion of cell proliferation compared with its location in cytoplasm (19,26).

There are many factors that influence the expression of Survivin within the cell, including the gene PHLPP, which is an anti-tumor gene and prevents
the Transformation and proliferation of cancer cells, migration and metastasis (27) it also inhibits the activity of AKT, Survivin phosphorylation and its transfer to the nucleus, thus contribute to stimulate the mechanism of programmed cell death in cancer cells (24).

Previous studies have shown that the expression of Survivin gene can occur during the initial stages of cancerous transformation and follows the imbalance in cell proliferation and death, as expressed in different polyps, including polyps of colon, breast adenomas and Bowen’s disease (28), it was also found in the cases of viral infection as well as in liver cells that surrounding cancer cells (20). In this study, there was a significant increase in the level of serum in patients with bile stones and a non-significant increase in other diseases such as hepatitis, Gallbladder inflammation and cirrhosis. In these conditions, the activation of transcriptional expression factors can be activated by Cytokines such as NF -KB and STAT3, which will affect the factors responsible for cell vitality such as anti-apoptotic proteins, including Survivin (29).

The study of (30) noted that Survivin expression was not associated with the age and sex of patients in addition to the size of the tumor mass and the degree of differentiation of hepatocytes affected by cancer and this is consistent with the results of the present study, where there was no significant difference in the level of Survivin between males and females within Study sample for different pathological conditions In terms of age groups, there was no significant difference in the survivin level among the age groups (20-35), (36-51), (52-67) for people with liver cancer, bile stone, hepatitis and Gallbladder inflammation, which makes this result consistent With the previous study (30), while its level was increased in age group (20-35) in patients with cirrhosis and GBC. This result was not consistent with the result of (31) indicating that high level of survivin was noted in the cells of older persons.

The Effect of Socioeconomic Level on Dental Caries among Preschool Children in Baghdad City

Mariam F. Abo Nayla¹, Athraa M. Alwaheb²

¹Dentist, in Baghdad, Ministry of Health and Environment, Iraq; ²Professor in Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Dental caries and periodontal disease are the most common oral problems. It may start early in life and if not treated may end with tooth loss. Oral health is influenced by the socioeconomic status in which the socialization of the child takes place.

Aim of the Study: The survey was made to investigate the effect of socioeconomic status on dental caries of preschool children.

Subjects and Method: The total sample composed of 893 children aged (4-5) year selected randomly from different kindergartens in Baghdad governorate. WHO 2013 index was used for assessment of the dental caries experience and questionnaire was send to parents to assess their knowledge and behavior.

Results: Results showed that the prevalence of dental caries was 98% for the total sample, highly significant differences were seen between SES and dental caries experience dmfs of primary teeth, highly significant relation between SES and parents knowledge in all questions except questions concerning tooth decay and crowding of the permanent dentition was no significant while in behavior questions a highly significant relation was seen in all questions except questions concerning the type of bristle of the brush and preferable time for eating sweets was no significant.

Conclusion: Preschool children in Baghdad were found to have a high prevalence of dental caries SES effect on the dental condition. Hence this survey highlighted the need for children to dental health education programs and public and school preventive measures among those children.

Keywords: socioeconomic status, Dental caries, Preschool children

Introduction

Dental caries most commonly affect children, the impact of the oral conditions on children life include: difficulty with chewing, oral pain, missed school days due to their cumulative dental caries experience and changes in emotional e.g being upset and worrying about being different as well as anxiety or distress about their mouth(1). The association between social and economic condition and dental caries prevalence has been observed, Inequalities in the distribution of dental caries were observed and socioeconomic factors were found to be strong predictors of the prevalence of oral disease in preschool children, family income, occupational prestige, and educational attainment are measures of SES that have been found to influence an individuals life opportunities(2).

Iraq is one of the developing countries that exhibited an increase of dental caries prevalence and severity. Many of studies found that dental caries prevalence showed low while the other studies was high prevalence (3,4), many studies conducted to revel the relationship of socioeconomic status with dental caries all these studies depended on one or combination parameters of

Email: mariamfaze89@gmail.com
socioeconomic level, In the economically developing countries the prevalence and severity of dental caries has increased with industrialization and exposure of these populations to western diets. The families with higher level of education, higher income, better occupation have higher caries experience which is attributed to the reason of consuming more refined sugar and cariogenic foods (5).

This study was conducted on group of preschool children 4-5 year old living in Baghdad governorate to find out the effect of socioeconomic level on dental condition.

**Subjects and Method**

A sample of 893 preschool children 4-5 year old were selected randomly from different kindergartens in Baghdad governorate (471 boys and 422 girls) from urban areas in Baghdad city, from different kindergartens distributed in the city. The study received approval from the Research Ethics Committee of the College of Dentistry, University of Baghdad, Iraq.

Knowledge and behavior questions was recorded by 20 questionnaire (6), which consist of: Question knowledge of parents about the mouth and teeth (Q1. and 2 concerning the number of deciduous and permanent teeth, tooth composition. Q3, 4 and 6 concerning tooth decay. Q5, 8 and 10 concerning crowding of the permanent dentition, and early loss of the primary teeth and thumb sucking habits. Q7 concerning the benefit of fluoride Q9. concerning visit to dentist), Question about the behavior of the parents (Q11., 12, 13, 16 and 19 concerning the frequency of the tooth brushing, brushing technique, use of dental floss and tooth picks, the way that child used to brush his teeth and the type of bristle of the brush respectively. Q.14 concerning the preferable time for eating sweets. Q.15 concerning the number of visits to the dentist Q17 and 18 concerning with toothache of child and dental decay respectively. Q20. concerning the use of tooth in bad habits).

Intra oral examination of dental caries status was recorded according to WHO 2013 (9) using CPI probe. Dental caries was measured by dmft/s for deciduous teeth.

The statistical data analysis was approached by using statistical package (SPSS) ver.(23.0) in order to analyze and assess the results of this study through application of descriptive data analysis, by frequencies and percentages. Inferential data analysis, these types of analysis were used to test hypotheses by accept or reject it, which include the following; Spearman Rank Correlation test, analysis of variance and significant at p≥ 0.05.

**Results**

Results showed that the prevalence of dental caries was 98% for the total sample. The mean dmfs (13.180).

The highly significant of relation dmfs with the level of SES found p value equal to 0.0000.

Highly Significant differences were seen between knowledge questionnaires and dental caries experience dmfs of primary teeth, some knowledge questions were no significant, the question about concerning crowding of the permanent dentition, and early loss of the primary teeth the dmfs p value=0.172 and the question about tooth decay the dmfs p value=0.985 also the question about thumb sucking habits the dmfs p value=0.150 and the question about visit to dentist the dmfs p value=0.086.

No significant differences were seen between behavior questionnaires and dental caries experience dmfs of primary teeth except the question about use of tooth in bad habits highly significant p value=0.000, and question about way that child used to brush his teeth p value=0.001.

Discussion

In this study, the prevalence of dental caries was found to be high for primary school (4-5) year children. This percentage was more than study done in Indian (7) and more than some Iraqi studies (3,8,9). The high caries prevalence recorded by this study may partly be attributed to lower fluoride level in drinking water in Iraq that was ranging between 0.12-0.22 (11), and may also related to other factors related to the socioeconomic condition and living style of the families(12). For the diagnosis and recording of caries-experience; dmfs indices was used in present study. This indices allows measurement of the past caries-experience indicated by missing and filled fraction, and the present caries by the decayed fraction. In addition, dmfs index allow the measurement of dental caries by severity. The mean dmfs value was (13.180) compare with other Iraqi studies (14,15).

This study showed that the mean of ds fraction (12.205) was higher than ms and fs components of dmfs index, which is an indication of a poor dental treatment. which is mean that even if treatment is present, it is directed toward extraction rather than restoration. This result is in agreement with other studies (8,13,9).

In this study, the knowledge questionnaire has highly significant difference with SES, may be attributed that low knowledge group compared to children from high SES families. This discrepancy differences in the home learning environment, and in parent beliefs(16), except the question about dental caries and crowding in permanent teeth had no significant difference. Also the study showed that there was highly significant difference in the relation behavior questionnaires to SES, may be attributed, The relationship between family life events and rates of maternal reports of child behavior and child rearing problems preschool-aged children. Mothers experiencing a large number of life events reported higher rates of child rearing problems(17), except the question about type of bristle and preferable time of eating sweet had no significant difference.

Conclusion

This survey highlighted the need of children to preventive measures and dental health education and improvement of dental knowledge and attitude towards good oral hygiene.

Acknowledgment

I thank all the participants in the study and Dr. M.Galib for helping in the data analysis and statistical work.

The Effect of Mouth Wash Containing Alcohol on Force Degradation of Colored Elastomeric Chains

Reem Atta Rafeeq Al-Ani
Assistant Professor, Department of Orthodontic, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Objective: To test the effect of alcohol and non-alcohol containing mouthwashes on the force decay of clear and colored elastomeric chains.

Method: An in-vitro prospective study to test the effect of exposure to alcohol on orthodontic elastomeric chains clear and colored. A sample of 72 specimens divided into three test groups, each group exposed to a single type mouth wash (deionized water (control); Listerine-zero; Listerine-original (26.9% alcohol)) for 60 seconds twice a day. Force measurements by a digital force tester were taken at days 0, 1, 7, 21.

Finding: Increase in force decay over time was observed in all test groups, and is observed more with colored elastics. The test group exposed to Listerine original mouth wash had the highest mean force decays in all types of elastomeric chains, being more with colored chains. All of those findings were statistically significant.

Conclusions: Mouth wash containing alcohol increase force decay of colored elastomeric chains with time, with color related differences in force decay of elastomeric chains.

Keywords: Force decay; colored Elastomeric chain; Alcohol; Mouth wash.

Introduction

Elastomeric chains are force generating units that aim to consolidate space and facilitate movement of teeth, are composed of polyurethane materials and manufactured as a spool of linked elastic chains, used in orthodontic practice since 1960s due to their minimal adverse effects during effective tooth movement.1,2,3

Elastomers have many advantages of being inexpensive, convenient, patient cooperation not required, and relatively hygienic despite of the inherited disadvantages that they undergo permanent staining and deformation in the oral environment 4 that is besides the unavoidable loss of force due to stress relaxation.

Various factors affecting the degree of force decay were observed with elastomeric chains. Immersion in water bath leads to quick force decay; acidic fluoride and initial load applied to the elastomers have appositive correlation with the percentage of force degradation of elastomeric chains 5, yet the effect of temperature and pH remains controversial.6,7

Some researchers 8,9,10,11 have reported that a force decay of 50 to 75 percentage was noticed after 24 hours of stretching and followed by 10 percentage more by 21 days and only 30 to 40 percentage of the initial force after 28 days is retained.

Orthodontists recommended the patients to use mouth washes in order to maintain a good oral hygiene during treatment. Many mouth washes contain alcohol in different concentrations ranging from 0%–26.9%.12

Although increase in force decay of elastomeric chains with time is known to be caused by alcohol. Yet dependence of force decay of elastomeric chains on alcohol concentration was not observed.13
Distinct configurations of clear elastomeric chains tested in vitro showed rapid force degradation in Listerine original mouthwash containing alcohol and showed more force decay compared to those tested in alcohol free mouthwash (Listerine zero).14

Many manufacturers have added colored elastomeric chains to their inventories by adding Filler particles to provide color to elastic chains due to the increasing esthetic demands and to solve the staining problem of elastomeric materials from certain types of food.

Despite the widespread use of colored elastomeric chains in clinical practice there are relatively few studies describing the effect of addition of pigments on the mechanical property of elastomeric chains, some researchers 15 found that force delivery behavior of colored elastomeric chains were significantly affected by the filler material used in tinting the chains. Other researchers 16 found various manufacturer effect on force delivery properties of elastomeric chains due to color specification, but the differences in force levels did not appear to be clinically relevant 17.

The present study was designed to examine the effect of alcohol and non-alcohol containing mouthwashes on the force degradation of clear and colored orthodontic elastomeric chains in vitro.

Materials and Method

This is a prospective cohort in vitro experimental study over 21 days. A total of 72 specimens were collected and tested within two weeks of reception from the manufacturer, they were divided into three groups, each containing 24 specimens having 8 elastomeric chains from each type of specimens. A specimen is described as a closed looped configuration elastomeric chain (Morelli; Brazil) that is either: 1. Clear ; or 2. Crystal yellow ; or 3. Pearl lilac, these colored specifications constitutes the specimen types. Each group is mounted on an acrylic board of 30x4x1 cm dimensions, and each acrylic board includes a total of 48 circular pins arranged in 2 parallel lines, with 1 cm distance between each two pins on the same line, to hold the stretched elastomeric chains at a constant length of 29 mm across.

Each group of specimens was kept in a separate glass container water bath, containing Deionized water, in an incubator at 37°C and monitored daily with a thermometer, and then was submerged in a single type of mouth rinse for 60 seconds according to manufacturer recommendations, twice a day, for a whole 21-day test period which was calculated by a digital clock, with 9 hours separating each of the two daily exposures; after the 60 seconds of submerging in the mouth rinse the specimens were immediately washed in a new DI water bath (separate from the above mentioned 3 water baths) for 10 seconds to mimic salivary rinsing of the alcohol from the oral cavity after each exposure, and then returned back into the same 37°C, DI water bath from which they were pulled out. The control group constituted of 24 specimens mounted on a single acrylic board that were only exposed to DI water washes and underwent the same protocol.

Two types of mouth rinses were used:
1. Listerine original mouth wash (alcohol content 26.9% by volume) (Johnson & Johnson, UK);
2. Listerine zero (0% alcohol: mild Mint Johnson & Johnson, UK).

On each group four test measurements of load values in (gm) were taken at days 0,1,7, 21, and the percentages of force decay were calculated as: \(\frac{\text{load value at day 0}}{\text{load value at day n}} \times 100\%\). Measurements of force were taken with a digital force tester (Weiheng, sensitive to 3 digits, Japan) which was reset back to zero before making each new measurement.

Measurements were done by securing one end of the elastomeric chain on the pin and fixing the other end to the force tester; measurements of the tensile force were recorded with the elastomeric chain stretched to the same 2.9 cm length the board pins had previously secured. All chains were measured in the same manner to guarantee accurate measurements.

Statistical workup: Data were analyzed using the statistical package of social science “SPSS” software version 21. Those included:

1. Descriptive statistics: including means and standard deviations.
2. Inferential statistics: including:
   a. One-way ANOVA test: to compare the percentage of force decay among the different mouth washes, durations and elastomeric colors.
b. Tukey’s honestly significant difference test: to check for any statistically significant difference in the percentage of force decay between each two mouth washes, durations, and elastomeric colors.

Significance level: P<0.05

Finding

Tables 1, 2 illustrate the means of initial loads and force decay: lilac elastics showed highest percentage of force decay followed by yellow then the clear elastics.

**Discussion**

No known studies have been published regarding the effect of mouth washes containing alcohol on the colored orthodontic elastic chains that are widely used for force transmission to obtain different types of tooth movement.

The colored elastomeric chains generated less force at all 3 time intervals compared to clear ones. Force decay was higher during the first 24 hours, followed by a gradual decrease in force levels in the remaining time periods (Table 2,3), the difference in the force decay manner between colored and clear elastomeric chains over all time intervals may be due to the presence of pigment and variation in the manufacturing process. The results of the present study is in agreement with the findings of previous studies on the force decay of colored elastomeric chains.²,¹²,¹⁶,¹⁹

Clear differences in force decay were noticed for colored rather than for the clear elastomeric chains, in spite of the matter that all of the studied elastomeric chains were stretched to the same length, still there was significant variation in the force delivery property among the pigmented elastomeric chains, force decay was more in pearl-lilac color than crystal-yellow ones (Table 5), these differences in the force delivery regarding the color could be attributed to the filler material used in tinting the chains, these findings was consistent with findings of many researchers (Williams and von Fraunhofer)¹⁵ who believed that the filler material used in tinting the chains had significant effect on colored elastomeric chains.

This study showed that all types of elastomeric chains exposed to mouth rinse containing alcohol demonstrated an increment in force decay compared to those exposed only to distilled water or mouth washes without alcohol, with p<0.05. (Table 4,5, Figure 1). That was similar to that noticed in many other studies¹³,¹⁴, where it was demonstrated for clear elastomeric chains and not tested for colored elastomeric chains.¹³,¹⁴ Besides that, this study illustrates that alcohol had significantly
more effect on the force decay of colored elastomeric chains than on the clear ones that by the end of 3 weeks the clear elastics had 54.97% force decay compared to 57.53% and 57.85% force decay of yellow and lilac elastics respectively (Table 2). This finding is first tested in this study.

The force applied by elastomeric chains can be classified either to those managed by the orthodontist or to those related to the components of the elastomeric material which are altered by the manufacturing process; as a result of that, there would be a difference of force applied by different orthodontists. 20

In our study colored elastomeric chains showed a significant but not total force decay when exposed to mouthwashes containing alcohol in vitro. Further research is ought to be conducted in-vivo to investigate the degree of force decay associated with these mouthwashes. Otherwise, the current practice of replacement of elastomeric chains every 21 days seems acceptable from the aspect of work of dental materials.

Conclusions

Alcohol containing mouth washes increase force degradation rate of colored orthodontic elastomeric chains with time, with color related differences in force decay.

Serum Levels of Adrenomedullin in Women with PCOS before and after Rosuvastatin Treatment

Mohammed T. Dawood¹, Salam S. Ahmed², Hassan K. Rajab²
¹Kirkuk General Hospital, Ministry of Health, Iraq; ²Clinical & Medical Biochemistry, Pediatrician, College of Medicine, University of Tikrit, Iraq

ABSTRACT

Background: Polycystic ovary syndrome is represent one of the prevalent endocrine disorders in women of reproductive age. A part from the important squeal of polycystic ovarian syndrome such as menstrual disturbance, infertility, and excessive hair growth, women with polycystic ovarian syndrome also presented with wide range of secondary consequences including abnormal lipid profile, hypertension, insulin resistance, hyperandrogenaemia and eventually amplified risk of cardiovascular injury.(1-3) Adrenomedullin is a vasodilator peptide with 52 amino acids.(4)

Materials and Method: This is follow-up study concerning women with polycystic ovarian syndrome, which constitutes a total of 45 women affected with polycystic ovarian syndrome, this study was conducted in Kirkuk City. The serum levels of adrenomedullin was compared before treatment with rosuvastatin with its levels after 3 months treatment with rosuvastatin a dose of 10 mg/day. The body mass index was calculated for each women included in this study as well as 4 milliliters of venous blood samples were obtained by using a disposable syringe and the samples were kept in plain tubes before and after treatment with rosuvastatin therapy, serum was separated. Serum adrenomedullin was tested by an enzyme linked immunosorbenent assay method.

Results: This study showed that the majority of women with polycystic syndrome enrolled in this study were within the age group of 21 to 35 years, this study also reveals that the mean of body mass index was 26.01 ± 1.49 Kg/m² for women with polycystic ovariansyndrome before treatment and decreased significantly (22.42 ± 1.153 Kg/m²) at a P<0.01 after treatment with rosuvastatin. The current study found that the serum level of adrenomedullin was elevated significantly (P<0.01) in women with polycystic ovarian syndrome after treatment (397.6 ± 65.1 ng/dl) compared with that before treatment (122.0 ± 12.3 ng/ml). There was a positive correlation between BMI before and after treatment (r = 0.68), also there was a positive correlation between the serum levels adrenomedullin in women with polycystic ovarian syndrome before and after treatment with rosuvastatin (r = 0.36).

Conclusions: It is concluded from this study that the serum levels of adrenomedullin was significantly increased after 3 months of treatment with rosuvastatin a dose of 10 mg/day in women with polycystic ovarian syndrome.

Keywords: Polycystic ovarian syndrome, adrenomedullin, and rosuvastatin.

Introduction

The name “polycystic” suggests, many cysts typically develop in the ovaries of a woman with this condition. These cysts or follicles (fluid filled sacs) remain and build up in the ovaries, preventing ovulation, in addition, the ovaries tend to produce excess levels of androgens (male hormones) in women with PCOS, which can also negatively impact ovulation and fertility.(5) Stein and
Leventhal in 1935 presented a group of 7 women with common features: menstruation disturbances, hirsutism and enlarged ovaries with the presence of many small follicles. They were also the first to describe the lack of menstruation in women with increased volume of ovaries and to suggest using ovarian wedge resection. The syndrome has been re-evaluated during the years and is no longer regarded as a uniform condition, but a syndrome with a spectrum of different manifestations with different complexity and a considerable phenotypic variability.

Diagnostic criteria based on oligomenorrhea, amenorrhea and clinical or biochemical hyperandrogenism were broadened in the 2003 Rotterdam criteria to include PCO findings at ultrasound. recently the Androgen Excess Society (AES) suggested that the diagnostic criteria should be modified to exclude those with PCO on ultrasound and oligomenorrhea/amenorrhea but no hyperandrogenism.

It is now recognized that women with regular cycles and hyperandrogenism and/or polycystic ovaries (PCO) may have the syndrome.

Figure 1: In a normal ovary, eggs mature and are released every cycle. In women with PCOS, the ovary does not produce enough hormones for egg maturation. Immature follicles may remain in the ovary and ovarian walls may thicken.

Adrenomedullin (ADM) is a vasodilator peptide hormone composed of 52 amino acids, it was first discovered in 1993 in human pheochromocytoma tissue of adrenal medulla tumor. Adrenomedullin has local paracrine or autocrine effects on the tissue and it can trigger many physiologic events by remaining in the plasma like the circulating hormone. Rosuvastatin is a lipid lowering drug, rosuvastatin reduced total plasma cholesterol. This study aims to evaluate the effect of rosuvastatin therapy on the serum level of adrenomedullin in women with polycystic ovarian syndrome.

Materials and Method

This study was designed as a follow-up of a total of 45 women with polycystic ovarian syndrome; their ages range from 18 to 45 years of age. This study was conducted from the 1st of February 2019 till the end July 2019 in Kirkuk City. The serum levels of adrenomedullin was compared before treatment with rosuvastatin with its levels after 3 months treatment with rosuvastatin in a dose of 10 mg/day. The body mass index was calculated for each women included in this study as well as ten milliliters of venous blood samples were obtained by using a disposable syringe and the samples were kept in plain tubes before and after treatment with rosuvastatin therapy, the blood samples were left at room temperature to be clotted, then the samples were transferred to a centrifuge for the separation of serum and the serum samples were kept in plain tubes and stored at -20 °C until the time of analysis of adrenomedullin by an enzyme linked immunosorbent assay method.

Results

This study showed that 71.05% of PCOS women enrolled in this study were within the age group 21-35 year with mean age 29.41 year, table 1.

Discussion

PCOS is the most common form of chronic anovulation associated with androgen excess, occurring in 5 to 10% of reproductive age women. Beyond its reproductive consequences, PCOS is characterized by a metabolic disorder in which hyperinsulinemia are central features.

It is evident from this study that the majority of women with PCOS were from the age 20 to 30 years, this finding initiate the idea that younger age group are more prone to PCOS, this finding may be related to that the ovaries are more physiologically active in women at the child-bearing age, therefor the ovaries are more liable to undergo cystic changes. This finding was in agreement with the finding of Banu Ucar et al., who found that the mean age group for women with PCOS was 23.53 ± 5.51 years. While Ali I. Al-Gareeb et al demonstrated that BMI of the women with PCOS were within the normal limit, this discrepancy with the present study could be attributed to sample collection.

This study demonstrate that women with PCOS included in this study were an overweight, while after treatment the body weight retrain back to normal. This finding reveals the benefit of rosuvastatin in reducing the body fat deposition which affect the mean body weight. The finding of this study was in agreement with the finding of Maitham Ali Abdul-Nabi. While Ali I. Al-Gareeb et al demonstrate that BMI of the women with PCOS were within the normal limit, this discrepancy with the present study could be attributed to sample collection.

Adrenomedullin, a unique regulatory peptide with different action, has been intensively studied due to its...
remarkable range of effects (vasodilatation, regulation of vascular cell growth, angiogenic properties in endothelial progenitor cell, and natriuresis) \(^{(3,9)}\) and promising therapeutic potential. \(^{(12)}\) It is shown to be related to various conditions including congesting heart failure, \(^{(17)}\) sepsis, \(^{(18)}\) hypertension \(^{(19)}\) and renal failure. \(^{(20)}\) The previous research on animal models revealed that hyperglycemia increases vascular ADM expression; \(^{(21)}\) in addition circulating ADM levels are increased with severity and poor metabolic control in Type 2 diabetic patients. \(^{(22)}\)

The study showed that there is a significant difference between women with PCOS before and after treatment with rosuvastatin concerning ADM level and the level of ADM was higher after treatment as evident in table 4. and figure 4. This increase may be related to an improvement in ovarian function after treatment compared to that before treatment. This finding was in agreement with the finding of Ali I. Al-Gareeb \(^{(15)}\) who found that rosuvastatin as adjuvant therapy in patients with polycystic ovarian syndrome has many beneficial effects. Banu Ucar et al. \(^{(14)}\) reveals that there was a non-significantly lower serum level of ADM in patients with PCOS compared to control. The plasma levels are mainly a result of production in the vascular endothelial and smooth muscle cells, \(^{(23)}\) why ADM is regarded as a marker of endothelial function, ADM is elevated in CVD and obesity. \(^{(24)}\) Similar results were described in Chang et al. \(^{(25)}\) study, the authors found that plasma ADM is significantly decrease in subjects diagnosed with overweight and or obesity.

Training According to The Required Calories as a Function of Muscular Work and its Impact on the Development of Some Physical Abilities and the Achievement of Long Distances Running 5000 Meters

Nabeel Muttlak Nasser1, Suhail Jassem Almsalmawi1, Maher Abdulhamza Hardan Al_Alwani1
1The College of Physical Education & Sports Sciences, University of Babylon, Iraq

ABSTRACT

The idea of the research is to prepare daily exercises in accordance with the calories required to complete the work muscle appropriate to run 5000 m for students of the Higher Institute for Security and Administrative Development in Baghdad, and the total volume of training (jogging periods and positive rest periods as completed distances) is measured in advance before application and the corresponding calories required for the body. Using a special electronic program, there is no demolition in the cells at the expense of their construction according to the standard that says that each calorie corresponds to 4.186 kilocalories as a work. In order to be prepared and applied these exercises according to the scientific bases based on the type of food appropriate for daily exercises to enhance the physical and physiological situation and reach them to the ideal and appropriate state to achieve the best achievements.

The researcher believes that the current exercises are applied according to the special physical abilities and general endurance without paying attention to the needs of these exercises of a special diet suited to the effort exerted on the application of these exercises. The researchers concluded that the daily exercises did not fit the daily energy expenditure spent by the research sample, which causes a decrease in the level of achievement. They recommended the need to pay attention to the type of food appropriate to the level of daily training.

Keywords: Work, calories, joule and sponsorship.

Introduction

The term energy was first associated with mechanical movement or the ability of the body to accomplish a mechanical job, which helps in achieving the goal of performance and related to the physical, functional and mechanical aspects. The importance of the research is that it is studying the assessment of mechanical and vital energy for students of the Higher Institute for Security and Administrative Development, and compare what changes occur in accordance with the diet and physical training (endurance when ran 5000 m) and the associated assessment of the health of the associate and the level of development and calorie depletion reflects the harmony of exertion of effort and the output of biological energy and mechanical during this effort according to calories. Thermal and physical labor, which can be specialists in the field of training in the detection of some scientific facts to put them into the eye when training staff for this competition and in accordance with the requirements of the physical, functional and mechanical game.

The “joule” refers to the body’s possession of energy can be measured by the indications of the calories spent during the effort, which leads to his movement and do all the required kinetic acts, and the law of energy survival stipulates the stability of the amount of energy in a particular system (for example, the human body)
energy level available to athletes of different distances, including running 5000 meters and consumed during the daily training per 1 kg of lean body to monitor the health of athletes and their progress according to the type of effort used and the suitability of the type of energy available to these athletes. Carbohydrates are one of the main sources of thermal energy generation in the body, as one gram of these substances gives 4.1 its price, and athletes may need from (500) grams to (700) grams of carbohydrates per day depending on the difference. The quality of sports activity, and experiments have shown Ziad The actual capacity in the case of giving food rich in carbohydrates. It was found that when the available energy level falls below the average daily intake of 30 calories/kg (per 1 kg) fat-free mass this leads to an energy level falls below the average daily intake of

The researchers used the information related to the subject of research and derived from the international information network and research and related studies, stopwatch (range of 100 sequential timing) number 3, tests and measurements, a special balance to measure the length and weight of the virtual body. Body mass index, body mass index and calories needed to sustain the vitality of the body were measured according to a special program ((Calculator. Net) which calculates the above variables after the introduction of age, weight, height, gender and type of private practitioner activity (see Figure 1).
To measure BMR (calories spent at training), the researchers used the following program shown in Figure (2).

**Pretest tests:** The researchers conducted the pretest tests on 22/2/2019 and included tests of anaerobic and pneumatic abilities for the 5000 meters as follows:

- Test ran 180 meters (anaerobic) to measure muscle tolerance for a special speed.
- An attempt is given to each member of the sample and the player starts from standing. It is measured by a certified timer for the nearest ten seconds.
- Test ran 600 meters carrying your muscular performance, given each member of the sample one attempt and measured for the nearest 1 second.
- Achievement test for a distance of 5000 meters is timed by three temporary for each member of the sample according to international law.

The researchers applied the high intensity interval training method and adopted the maximum time of the
tests used in determining the intensity of training and calculating training volumes, and the adoption of the working period to rest in the calculation of recovery periods between the repetition of exercises (Appendix 1), the researchers were calculating the amount of effort during the daily training in terms of Joule as follows:5

1. Running training (5 × 200 m) is equivalent to the size of 1000 meters, which is equal to the joule (695.800) according to each 1 kg of the weight of the adult player (for example 71 kg), which is equivalent to joules (695800 kilojoules) which is equivalent to 16566.5 kilocalories, and so calculates the joule performed by training and the corresponding calories.

Post-test: Post-test was conducted with the same procedures as the pre-test on 8/4/2019.

</table>

As for the special muscle endurance variable (600 meter running test), the differences were also significant. This means that the biological efficiency of the research sample has evolved in the post-test as a result of exercises based on work values performed and that oxidation is done economically in the muscles
working in the cells of the group members. Experimental and the resulting heat from the metabolic rates required for this effort and according to the energy possessed by the sample members before the effort.\textsuperscript{6}

As well as the result above indicates that energy systems and adaptation become more efficient and allow more exercise time and at the highest intensity. These axioms are associated with the quantity and type of appropriate food, which can give a positive impact in the development of functional efficiency and capabilities of the type of effectiveness, which reflects the biological and physical efficiency and the desired work output, as we can identify the required and appropriate calories as a cost per 1 kg of body mass, through Work output exerted and measured in kilojoules in terms of body mass and ground acceleration. This reflected on the development of the completion of the 5000 m range of the experimental group.\textsuperscript{7}

It is noted from Table (3) that there are significant differences between each calorie variable available between the members of the experimental group between the pre and post as the value of (t) calculated (3.23) in front of an error level greater than 0.05, and this indicates that the group members have calories Good in the post-tests due to their regular diet similar and according to what the researcher provided to members of the experimental group during the training period, as well as the measurement of these calories equivalent in kilojoules was statistically significant differences, indicates that the available calories in the post-test according to the verification of physical occupation (Kinetic energy) was better than the pretest as it was The energy storage rate of the members of the research sample in the post-test is better than the pretest according to the statistically significant differences of this variable. There were no significant differences in the results of the control group for the same modulator.\textsuperscript{8}

As for the residual energy variable in the body after performing the effort, whether in calories or kilojoules, the differences were a function of the experimental group. This means that the quantities of energy remained the same in both the pre- and post-test. Larger than the post-test and be similarly in the cells of the body of the sample individuals and the resulting quantities of heat resulting from the metabolic rates needed for this effort and according to the energy possessed by the sample before the effort.\textsuperscript{9}

The energy cost index per 1 kg of body showed that the differences were significant between the experimental group between what the body consumes during physical activity and the remaining calories in the body for both tests and that there is a balance between calories and output in kilojoules taken by the sample of food, and calories The index indicates that the output was less than 30 calories/1 kg (equivalent to 126 kJ/kg) of energy available per 1 kg of body mass and this indicates that the calories consumed by the experimental group Fulfills the purpose required for physical progress despite the This system should be subjected to medical supervision in order to improve the physical effort appropriate to the type of calories, it was found that when the level of energy available below the average daily consumption by 30 kilocalories (1265 kilojoules) per 1 kg fat-free mass leads to Having a significant impairment in the function of metabolism and hormonal, this deficiency can affect performance, growth and health.\textsuperscript{10}

### Conclusions

1. Better physical activity (kinetic energy) is achieved in the post-test of the research sample due to the calories they have from their normal diet.
2. The special variable speed has evolved considerably as a result of the rationing of food and the application of the exercises consistent with it.
3. Evolution of variable speed tolerance as a result of the calories taken from the food which is proportional to the effort of the experimental group.
4. The evolution of special muscular endurance also showed that oxidation was similar in the cells of the body in the sample and the resulting heat from the metabolic rates required for this effort and according to the energy possessed by the sample before the effort.
5. The results indicated that there is a balance between calories and output in kilojoules taken by the sample of food, and the calories they burn to exert physical effort as the indicator indicates that the output was greater than 30 calories/1 kg (equivalent to 126 kilojoules/Kg of energy available per 1 kg of fat-free body mass.
6. The cost output per 1 kg of the body indicates that construction is more than demolitions and that the daily diet available is proportional to the daily experience of the sample.

Indications of Intra-Vitreal Anti-VEGF

Zeena Adnan Abd

1Surgery Department, Ophthalmology Unit, College of Medicine, Al-Nahrain University, Baghdad, Iraq

ABSTRACT

Background: Anti-vascular endothelial growth factors are being widely used in the field of ophthalmology, with a variety of indications which are expanding over time.

Aim: To assess the frequency of different types of diseases treated with anti-VEGF agents.

Method: A cross-sectional study involving 100 patients, data included: age, gender, indication for anti-VEGF & presence or absence of diabetes.

Results: The mean age was 57.7 years males represent 61% while females 39%, and the most common indication for intravitreal anti-VEGF was diabetic maculopathy with clinically significant macular edema (CSM0) which represent 80% of cases, the second and third indications were vitreous hemorrhage 6% and wet type age related macular degeneration (AMD) 5%. Diabetes was present in 94% of all cases.

Conclusion: Diabetes is the major risk factor causing varieties of retinal diseases that need intravitreal anti-VEGF agents, among which clinically significant macular edema is the most common pathology.

Keywords: Anti-VEGF, Clinically significant macular edema, diabetes

Introduction

Anti-vascular endothelial growth factor (anti-VEGF) drugs, for the last decade, became a very important and commonly used class of medications in the field of ophthalmology, as VEGF plays a basic role in endothelial cell proliferation and vascular permeability involved in a variety of retinal diseases such as: diabetic retinopathy and maculopathy, retinal venous occlusion, age related macular degeneration and others. The currently available anti-VEGF agents include: bevacizumab (avastin), ranibizumab (lucentis), and aflibercept (eyelea) (1).

Diabetic retinopathy: In general is a microangiopathy where high glucose levels particularly damages small blood vessels, and here vascular endothelial growth factors (VEGF) appears to play an important role in the pathophysiology, however, hyperglycaemia may also have a direct effect on retinal cells. Diabetic maculopathy: is the leading cause of visual impairment in diabetic patients, especially type 2, mainly in the form of edema, exudation & or ischaemia. Extensive capillary leakage leads to diffuse edema, where fluid spreads from the space between the outer plexiform and inner nuclear layer, where it initially collects, to sometimes involves the entire retinal thickness. Edema is caused by focal leakage from microaneurysms and dilated capillaries (2).

1. Clinically significant macular edema (CSM0): defined by the Early Treatment Diabetic Retinopathy Study (ETDRS) classification; protocol14, as: retinal thickening at the center of the macula or within 500 micron from it, hard exudates at the center of the macula or within 500 μm from it when associated with thickening of adjacent retina, and/or retinal thickening of one disc diameter in size, any part of which is within 1 disc diameter of the macular center (3).

2. Age-related macular degeneration (AMD), at the age of 50 years and above is a leading cause of irreversible blindness in the developed world (4).
The neovascular form of the disease (wet AMD) in which there is abnormal new blood vessels growing under or within the macula, causes severe visual loss, as it destroys the central portion of the retina which is responsible for high-resolution vision (6).

Pharmacologic therapies that was available for neovascular disease included: verteporfin photodynamic therapy(7,8) and pegaptanib sodium(9).

The pathophysiology for neovascularization still incompletely understood, but (VEGF-A) vascular endothelial growth factor A, which is a diffusible cytokine, promotes angiogenesis and vascular permeability, so has been implicated as an important factor promoting neovascularization (10,11).

3. Vitreous Hemorrhage: Proliferative diabetic retinopathy causes 31–54 % of vitreous hemorrhages. Neovascularization from central or branch retinal vein occlusion causes 4–16 %, AMD causes 0.6 –4 % (12).

4. Retinal vein occlusion (RVO): Retinal vein thrombosis (whether central or branch) typically causes edema, hemorrhages & or cotton wool spots in the area drained by the occluded vein. Formerly laser was the standard treatment for macular edema, but intravitreal injections of anti-VEGF are being widely used & probably raises aquity more than laser (2).

5. Central serous chorioretinopathy (CSC): An idiopathic disease that causes serous detachment of the neurosensory retina & or retinal pigment epithelial (RPE). Angiography shows leakage of the dye at the level of the RPE (13,14).

CSCR has been given a variety of names, reflecting the long-standing debate about its pathophysiology. Von Graefe regarded it as a recurrent central retinitis (15,16). Other names included central serous retinopathy, pigment epitheliopathy, (17). However it typically affects men in their working age, who are otherwise healthy (18).

Visual acuity show mild to moderate reduction with hyperopic shift (19). The diagnosis of CSCR is often made clinically, and beside other diagnostic technique, OCT (optical coherence tomography) is a very good tool for diagnosis and treatment planning (20). For many cases, the disease is self-limited; although some experience recurrent attacks and signs of chronicity. The standard treatment for the persistent or recurrent cases was thermal laser and photodynamic therapy, however definitive randomized trials are lacking (21-24).

Guyen and his colleagues, hypothesized that in the pathogenesis of CSCR could be choroidal vascular hyper-permeability, with or without associated active pigment epithelial leaks and detachment (25).

Prolonged detachment may cause photoreceptor and RPE degeneration and permanent reduction in vision. Cystoid macular edema and choroidal neovascularization may develop in some case (2).

6. Neovascular glaucoma: It is a secondary glaucoma previously called (hemorrhagic glaucoma) or Rubecotic glaucoma. At 1906 the histologic finding of new vessels in the irides of eyes of patients suffering from central retinal vein occlusion was first described by Coats1. In 1928, Salus 2 found similar new vessels at irides of diabetic patients (26). Usually iris neovascularization is seen in eyes with longstanding retinal ischemia or those with failed pars plana-vitrectomy who suffer persistent retinal detachment (2).

Patient & Method

A Cross sectional study was conducted, data collected from patients who were admitted to the ophthalmology surgical theater at AL-Emamain Al-kadhimain medical city for intravireal injection of anti VEGF, from first of September till the end of November 2018.

Data from 100 patients were taken included; age, gender, indication of intravitreal anti VEGF & presence or absence of diabetes).

Results

Mean age was 57.7 years ± 9.55. The youngest patient who received injection was 26 year old male with proliferative diabetic retinopathy and vitreous haemorrhage, and the oldest patient was a 74 year old man with wet AMD.

According to sex, there was male preponderance with a percentage of 61%, in comparison with females 39%, as shown in figure (1).
According to age, the most common age group affected by different types of pathologies that necessitate intravitreal anti-VEGF was those above 60 years which involved 44 patients out of 100 (44%). The second age group affected were those between 51 & 60 years which included 36 patients out of 100 (36%), the least age group affected were those below 30 years which involved 2 patients only (2%), as shown in table (1).

According to indications of anti-VEGF, the most common indication was clinically significant macular oedema (CSMO) in diabetic patients which represented 80 patients out of 100 (80%), and the least indication was central serous chorioretinopathy CSR involving only 2 patients out of 100 (2%).

Among all age groups, and among different indications of anti-VEGF, diabetes was present in 94% of cases.

### Discussion

The mean age in current study was 57.71 years, it is almost similar to a study done in University of Port Harcourt, Nigeria (27) where their mean age was 59.56 year.

The most common age group affected in this study and their study was those patients above 60 years old, however males were more in the current study (61%), while females were more in their study (52%).

Regarding indications the current study found that diabetic macular oedema was the most frequent indication for intravitreal anti-VEGF representing 80% of cases, while Bassey and his colleagues (27) found that retinal vein occlusion was the most common indication for anti-VEGF representing 32.11% of all cases.

On the contrary, to some extent, and like what we found in our stud, Shuaib and Hassan (1) found that diabetic macular oedema was the most frequent indication representing 42.5% of patients, while retinal vein occlusion representing the second most frequent indication 25.9%.

However, in our study, diabetic macular oedema in the form of clinically significant macular oedema was much more (80%) of cases, and the second and third indications were vitreous haemorrhage (6%) and retinal vein occlusion (5%), probably this reflects the very high prevalence of diabetes as a major risk factor for retinal diseases in our community.

Another study done in Ibadan, Sub-Saharan Africa (28) also found that the most frequent age group who needed intravitreal anti-VEGF were those patients above 60 years old, but the most frequent indication was retinal vein occlusion associated macular oedema 19.4%, the second most common indication was wet AMD 17.1%, whereas diabetic macular oedema represented only 7.5% and proliferative diabetic retinopathy with vitreous haemorrhage 9.7%.they attributed their results to the
fact that systemic hypertension, the strongest risk factor for retinal vein occlusion, is the most common medical disease in Nigerians\(^{(29)}\), several studies showed that the prevalence of hypertension in Nigeria ranges between 11.2\(\%\) \(^{(30)}\) to 25\(\%\) \(^{(31-33)}\).

Back to our study, the major risk factor for retinal diseases that required intravitreal anti-VEGF agents was Diabetes Mellitus, which was present in 94\(\%\) of cases and this might be due to the fact that Iraq is facing an epidemic of diabetes mellitus just like that in the middle east, this was mentioned in a study done by Abbas Mansour & Fadhil Al Douri \(^{(34)}\), who stated that the prevalence of DM in Iraq increased from 5\(\%\) in 1978 to 19.7\(\%\) in 2012, in addition the prevalence of dysglycemia was 48.8\(\%\) in their study.

**Conclusion**

Our study showed that Diabetes Mellitus is a major risk factor causing retinal damage that requires intravitreal antivascular endothelial growth factor agents and the most common age group affected are those above 60 years, this causes a great social and economic burden on Iraqi people and it has several implications:

- The necessity of providing anti-VEGF agents with affordable prices, hoping to be supported routinely by health insurance.
- Increasing awareness of people about the effect of diabetes on the retina, providing programs for screening.
- Further studies are needed including higher number of patients to establish all possible indications of anti-VEGF which are increasing with time.

Sera Troponin-I Levels in Rheumatoid Arthritis Patients

Mayada Noori Iqbal

1PhD Immunology, Department of Medical Laboratory Technology, College of Health and Medical Technology, Middle Technical University, Baghdad, Iraq

ABSTRACT

Background: Rheumatoid arthritis (RA) is defined as a chronic inflammatory disease with autoimmune pathogenesis which affects nearly 1.5% of the community. Cardiac troponin-I (cTnI) is falsely elevated in patients with seropositive rheumatoid arthritis.

Objective: Determine if rheumatoid arthritis patients with seropositive and seronegative have unusually raised concentrations of cardiac troponin-I (cTnI), in order to find out if this cardiac marker is elevated or not and its association with other inflammatory diagnostic markers.

Method: Serum samples were drawn from early diagnosis patients with RA groups 110 (60 without treatment group; 50 treated group) and (30) subjects as healthy control group. cTnI levels measured by using Immunoassay System.

Results: Forty-nine of the 73 patients with seropositive RA had cTnI levels upper than 0.8 ng per ml that had no significant difference P=0.062, while 11 of the patients with seronegative RA levels above this value and P-value in this group non- significant P= 0.350. With RF+/− the sensitivity of troponine-1 was 100%, but the specificity with rheumatoid factor (RF)+ve 20% while with RF−ve 100%. The correlation of troponine-1 with other studied marker had high significant value P<0.05.

Conclusion: cTnI quantification was create more in patients with seropositive RF than patients with seronegative RF with no significant difference among studied groups, this recommends that inflammation might not be the primary driver of troponin raise in RA.

Keywords: Cardiac troponin-I, Rheumatoid Arthritis, rheumatoid factor.

Introduction

A troponin complex consist of three subunits. Each subunit is a protein, and together they regulate the calcium-dependent connections concerning actin and myosin, which cause striated muscle contraction and relaxation. While the identical troponin-C is expressed by together cardiac and skeletal muscles (1) Cardiovascular (CV) disease is now recognized as a major cause of morbidity and mortality in patients with rheumatoid arthritis (RA). (1,2) Certain biomarkers appeared as strong analysts of cardiac diseases, even in a very early course of the disease such as troponins. Cardiac troponins (cTn) are indicators of injury and myocyte necrosis. Assessment cTn with highly sensitive assays demonstrated to hold respected prognostic value in several conditions, comprising patients with chest pain, heart failure, doubted acute myocardial infarction. (4) According to existence of cTnI certain reports suggest the antibodies presence may cause cTnI to be falsely elevated; (5) while others propose that rheumatoid factor (RF) is not effected on troponin levels. (6)

So study aimed to detect serum cTnI concentrations in RA patients and their correlation with other markers among seropositive and seronegative patients. according to hypothesis that (cTn-I) may raise in RA patients, and RF seropositive have cTnI oddly raised.
Method

We examined serum samples from 110 eligible patients with early rheumatoid arthritis encountered the American College of Rheumatology classification for RA (7) and 30 control subjects without RA were studied. RA patients with early diagnosis of less than 1 year duration, and classify into two groups 60 patients without treatment and 50 patients with treatment. All recruited patients were seen in rheumatic disease of Baghdad infirmary in Iraq. None of patients had infection or flares of their diseases at the time of blood samples collected. Questionnaire form formulated involved age, sex, clinical history, disease duration, family history. The patients were excepted from the study for the ensuing reasons: age<18years, chronic renal failure, pregnancy, congestive heart failure. The 30 healthy controls were recruited from subjected to the above exclusion criteria. Blood was collected for determination of C-reactive protein (CRP) by (AGAPPE, 52009002 cat. number, Switzerland) kit, Westergren erythrocyte sedimentation rate (ESR), cTnI tested by using the Immunoassay System (VEDALAB Inc, 28091 cat. number, France), The IgG-RF concentrations measured by Immunoassay System (Chorus Inc, 86038 cat. number, Italy) and Anti-antibody against citrullinated peptides/proteins (ACPA) determine by (Chorus Anti-CCP device, 86094 cat. number, Italy). Statistical analysis performed by the SPSS 10 statistical package. T-test and ANOVA methods were used to compare the difference in mean of continuous numeric variables. Receiver-operating characteristic (ROC) curve was used to assess the diagnostic usefulness of marker as valued by the area under the curve (AUC). and Pearson’s correlation for normally distributed variables, a p-value of less than 0.05 was reflected to be significant. (8)

Results

Table (1) shows demographical characteristics variables, the patients mean age (42.22±11.23 years) while (36.40±11.15 years) of healthy controls, gender of patients comprised female 80 (72.7%) and male 30 (27.3%), disease duration (49(44.5%), 61(55.5%) for first and second periods respectively. The study showed positively results of ESR,RF,CRP and Anti-CCP of patients [87(79.09%),70(63.6%),93 (84.5%), and99 (90.0%) respectively].Mean results of cTn-I showed in patients (48.08±6.61ng/ml) vs (6.19±2.73 ng/ml) in control.

</table>

(*) ESR: Normal value for female: 0 - 20 mm/h; Normal value for male : 0 - 9 mm/l = 0 - 20 mm/h.
CRP: Positive value (up to 6 mg/l) in Serum; Negative value) less than 6mg/l).
Anti CCP: Positive value >18 AU/ml, and Negative value ≤ 18 AU/ml.
Troponin-1: Positive value>0.8; Negative value<0.8 ng/ml.
Table (2) represents a summary statistics for (ESR, CRP, Anti CCP, and Troponin-I). Regarding to ESR, CRP and Anti- CCP results shows that vast majority of 5% trimmed mean were accounted in RF+ve of non-treated group, then followed in RF+ve treated group, and similarly results in RF–ve groups. Results illustrated that ESR,CRP and Anti CCP marker could be reliable indicators for RF patients and especially for non-treated groups. Troponin-I marker shows similarly concentration in sera RF+ve, either for treated or non-treated groups, as well as somewhat low in RF-ve, concerning non-treated group. Kruskal Wallis test’s statistic for testing the distribution of ESR,CRP, Anti-CCP, and Troponin-I marker’s among studied groups, appeared that a highly significant differences are considered at P<0.01 at least between two studied groups, and that needs to be continuing the test statistics in order to be sure in which pair are forming that significant differences, As well as not should doing that comparison with Troponin-I marker.

Table(3) shows the distribution of studied troponin-I marker in RA patients and control, to make definite that different independent groups are thrown from the same population in light of that variable. The troponin-I showed non-significant differences among studied groups at (p=0.175,CC=0.421).Results shows more part of RF+ve of diseased patients concerning troponin-I marker has a positive diagnosed, and they are accounted 49(67.1%), which non-significant different at P>0.05.In addition to that for RF-ve group result showed that 11(29.7%) of studied sample has a positive diagnosed concerning troponin-I, but no significant differences.

**Discussion**

The present study revealed RA prevalence more in female patients similar to result in 2014 showed(75.25% female vs 24.75% male). (9) Few studies appeared opposite result more frequent in male.(10) Sex hormones affect the immune system and assist as modulators of autoimmune disease, women experience significantly more natural and artificial sex hormone inconstancy through their lifespans, for example through the puberty onset the
Menstruation, contraceptive use, and pregnancy, this led researchers to carefully observe the sex hormones effectiveness on the RA progression. The female hormones, estrogen and prolactin as pro-inflammatory hormones and androgens as anti-inflammatory hormones influence RA predisposition. The general increased exposure to pro-inflammatory hormones along the women’s lifetime could clarify the greater female to male ratio in RA, supportive the indication that androgens are defensive.\(^{(11)}\)

In present study the percentage of patients had 7-12 months of disease duration more than the 1-6 months, 53% with disease interval of \(\leq 3\) months, matched with 94% of patients who offered with disease period of >12 weeks, therefore the potent predictor of persistent disease was a disease period of >3 months.\(^{(12)}\)

Although family history of RA is an old concept, \(^{(13)}\) present data appeared patients had family history less than non historical family this whether the small sample that taken in this study or due to it differs by age, sex or serology. A high rate RA in female offspring with a maternal history of RA.\(^{(14)}\)

Non-specific ESR and CRP showed high positivity results, could significant assisting indicators for the diagnosis of RA. Concurrent revealing of RF, ESR Anti-CCP, and CRP stays cooperative the complete diagnosis of RA.\(^{(15)}\)

Patients that had positive RF and Anti-CCP more than with negative test results, A data suggested that Anti-CCP have the power to expect the development of RA in patients with early arthritis.\(^{(16)}\)

Chief results of present study appeared that concentrations of cTn-I, were higher in patients with RA compared to controls, cTn-I concentrations were 67.1% higher in seropositive RA than seronegative 29.7% but non-significant. similar to result that reported in 2012, cTn-I levels were 49% higher in patients with RA than controls, the difference remained significant after modulation for demographic features.\(^{(17)}\)

Other results reported that RA patients with seropositive RF do not possess sera falsely elevation of cTnI levels. Results appeared no significant opposite link between cTn-I and inflammatory markers unlike to paper reports that high significant correlation of cTn-I with other inflammatory markers.\(^{(18)}\)

The behavior of cTn-I concentrations for each RF-ve and RF+ve of treated and untreated patients is similar. However, the concentrations of cTn-I remained significantly higher in patients with RA than controls, this proposes could be extra mechanisms fundamental raised cTn-I in RA, The greatest probable clarification the elevation of cTnI in RA patients may be return to subclinical myocardial damage, or small vessel disease or age, or hypertension, and other cardiovascular peril factors. Enlarged cTn-I concentrations might be misleading subsequently rheumatoid factor and other heterophilic antibodies possibly intervene with antibody-based immunoassays by non-specific compulsory with exposure agents.\(^{(17)}\)

Rheumatoid factor, present in 66.4% of studied groups however, was not associated with higher circulating cTnI the most correlations were opposite, inadequacy of the study because it did not consideration in myocardial functions, also elevation and diminishing levels of some inflammatory mediators through RA exacerbations may influence on cTn-I levels, it is probable that high stages of inflammation, as happens in unwell controlled disease, can impact on concentrations of cTn-I. Outcome inflammation could not be cause troponin-I raise in RA. Stress, anxiety and tension of lifestyle which due to illness and its treatment could causing rise myocardial stretch which may play a turn in the elevation of troponin concentrations in RA. Further studies are necessary to determine the value of cTn-I to expect Cardiovascular disease in RA.

ABSTRACT

Background: It is evident from the literature that an increased body mass index (BMI) and low socioeconomic status are potential risk factors for periodontal diseases. Most related studies are international and have investigated such associations in adults, and there have been few Iraqi studies targeting school-aged children.

Objective: To investigate the impact of paediatric obesity and mothers’ educational levels on the periodontal health status of children.

Method: The study sample was composed of 300 children (152 males, 148 females) aged 6-12 years. The subjects’ weight and height were measured, and the body mass index was calculated for each child to obtain a percentile ranking; the percentiles were used to allocate the total sample population into four subgroups (underweight, normal weight, overweight and obese). The children’s periodontal health was assessed using the Plaque Index (PLI) and Gingival Index (GI), and the mothers’ educational level was assessed by direct parental interview.

Results: Compared with the other categories of children, obese male (84.35) and overweight female (82.92) children had greater values for the PLI, while overweight children of both sexes (89.47 male, 92.11 female) had greater values of the GI. Male and female children with mothers who had the lowest level of education were found to have the highest values of PLI & GI. Non-significant differences were recorded between the male –female matched study groups with regard to the body mass index and mothers’ educational levels.

Conclusions: Childhood obesity and socioeconomic disadvantages have negative impacts on children’s gingival health in this representative sample.

Keywords: Obesity, Mothers’ Education, Plaque Index, Gingival Index, Body Mass Index, Iraq.

Introduction

Periodontal diseases are a multifactorial entity in which host, microbial, environmental and socioeconomic factors control disease development and progression. Current approaches in dealing with chronic illness, such as periodontal diseases, are directed towards the identification and management of risk factors and disease modifiers, such as obesity and socioeconomic status, to establish a state of health in the young population¹².

In the Middle East, Iraq and other Arabic countries have high prevalence rates of childhood obesity³-⁷. Obesity refers to excess body fat that alters the balance of the affected individual. The most scientifically accurate method of determining the amount of fat mass in a subject is the Body Mass Index (BMI). The link between obesity and periodontal health has been explored extensively through several epidemiological and case-control studies⁸,⁹, and it was found that obesity is a risk factor for periodontitis¹⁰.

Previous studies revealed a link between socioeconomic status, as represented by mothers’
educational levels, and children’s oral health status \(^{11-13}\) because the child’s oral hygiene patterns are influenced by socioeconomic factors. Low familial socioeconomic status is associated with deficient oral hygiene and greater susceptibility to frequent oral diseases; the postulated explanations for that connection are the effects of limited knowledge concerning health and oral hygiene habits and economical restraints, which mean that those families cannot afford dental appointments or oral hygiene products \(^{14}\).

To the best of our knowledge, only a limited number of Iraqi studies have linked BMI and mothers’ educational levels to periodontal health status in Iraqi children. The present study aimed to investigate the association between obesity, mothers’ educational level and periodontal health status in a sample of children aged 6-12 years.

**Materials and Method**

The present observational cross-sectional study was conducted with children attending the Paediatrics and Prevention Dentistry Clinics of the Dentistry Department at Al Rafidain University College, Baghdad-Iraq.

The sample population was composed of 300 children (152 males, 148 females) with an age range of (6-12) years and a median age of 9 years. All the children and their parents who were willing to participate in the present study were enrolled after signing an informed consent form.

Through a questionnaire, the following were assessed: child’s name, age, address, hospitalization history, medication history, and mothers’ educational level. All the enrolled children were healthy and had a non-contributory medical history.

The children’s weight and height were measured when they were dressed in light clothing and barefooted. Body weight was measured to the nearest 0.5 kg with a mechanical scale, and height was measured with a portable measuring unit to the nearest 0.5 cm.

The BMI was calculated according to the following formula: body weight/(height\(^2\)) = BMI kg/m\(^2\) \(^{15}\). According to the obtained BMI value, the following categories were defined: underweight (BMI < 18.5 kg/m\(^2\)), normal weight (BMI from 18.5 to 24.9 kg/m\(^2\)), overweight (BMI from 25 to 29.9 kg/m\(^2\)) and obese (BMI > 30 kg/ m\(^2\)). The BMI number was plotted on the BMI-for-age CDC Growth Charts for either girls or boys to obtain the percentile ranking \(^{16}\). For each gender, the children were stratified into four subgroups based on their percentile ranking: the underweight group was defined as below the 5\(^{th}\) percentile, the normal weight group as between the 5th and 85\(^{th}\) percentiles, the overweight group as between the 85th and 95th percentiles and the obese group as greater than or equal to the 95th percentile. Due to the lack of Iraqi reference values, the values of nutritional indicators were compared with international reference values using the CDC growth charts \(^{17}\).

The mothers’ educational levels (MEs) were categorized into five levels based on a modified Kuppuswamy’s scale: 1 for illiterate (neither read nor writes), 2 for completed primary school, 3 for completed secondary school, 4 for who completed higher education, and 5 for education beyond college (Diploma, M.Sc., and Ph.D.) \(^{18}\).

Periodontal health status was assessed using the plaque index (PI) developed by Sillness and Löe in 1964 \(^{19}\) and the gingival index (GI) developed by Löe and Sillness in 1963 \(^{20}\). Ramfjord’s index teeth \(^{21}\) were examined as representatives of the whole dentition; only fully erupted teeth were scored, and in cases of partially erupted or missing index teeth, that segment was excluded. The periodontal examination was conducted in the dental clinic in a dental chair under artificial light by the researchers using plane dental mirrors and colour-coded WHO probes. The data were tested for normality of distribution with the Shapiro-Wilk test. For the descriptive statistics, the following tests were applied: mean, median, number, percentage and P-value; a value of p < 0.05 was considered statistically significant. For the inferential statistics, the following tests were applied: the Mann-Whitney U, Dunn-Bonferroni, and Chi-square tests. All statistical analyses were performed with SPSS version 21.0.

**Results**

As illustrated in Table (1), greater values for the PLI were recorded for male children in the obese group (84.35) than in the normal weight (82.92), overweight (74.26) and underweight (64.98) groups, with no significant differences among the groups. Among female children, the highest PLI was recorded in the overweight group (82.92) compared with the underweight (68.31) and normal weight (74.97) groups, with no significant differences among the groups.

The descriptive statistics for the periodontal health parameters according to the ME are illustrated in Table (3). Among the groups stratified by ME level, male children with mothers with MEs of 1 were found to have the highest values of PLI and GI values, with a significant difference among the groups. Similarly, among the groups stratified by ME level, female children with mothers with the lowest ME (1) were found to have the highest PLI and GI values, with a highly significant difference among the study groups.

Discussion

The microbial biofilm undoubtedly plays a role in the pathogenesis of periodontal diseases. Researchers emphasizing the importance of the microbial biofilm among a long list of other secondary aetiologic factors or risk factors that co-determine the initiation, progression and clinical picture of periodontal diseases. These risk factors negatively affect both the tissue and the immune response of the host, increasing his/her susceptibility to the disease process (23). Since childhood is the critical period during which an individual acquires the knowledge and habits that are later reflected in his/her behaviour patterns as an adult (2), two of the aforementioned critical determinants of childhood periodontal health, namely, obesity and ME level, were assessed in a total of 300 school-aged children Iraqi.

The results of this study confirm that among children stratified by BMI, both obese and overweight children have the highest values for the PLI and GI, revealing the presence of an association between poor periodontal health status and increased BMI; these results agree with those of accordance with the results of multiple studies 6,22,23.

The negative impact of paediatric obesity on gingival health can be explained first by the metabolic profile related to the biological consequences of an unhealthy diet, including impaired glucose tolerance due to excess sugar and an abnormally high lipid profile, which in turn affects the inflammatory profile, resulting in a deficient immune response, such as hyperactive macrophages, altered microcirculation and the secretion of pro-inflammatory substances, such as TNF-a, IL-6 and C-reactive protein by the adipose tissue, which act as an endocrine organ (21). Second, a lifestyle with the reduced exercise greatly affects periodontal health (24). Third, periodontal health can be affected by the attitude towards general and oral health, including nutritional awareness, the practice of oral hygiene procedures at home, and understanding the need for periodic dental and medical check-up.

The second variable explored in this study was the ME level as a representative of the sample population’s socioeconomic status. Our study revealed that ME level had a major impact on the child’s oral health, as the highest values for the PLI and GI were recorded in children of mothers with the lowest ME level, reflecting the pivotal role of the mother as the main caregiver in the family. Mothers are generally responsible for the implementation of oral health behaviours in their children. A mother with a low level of education may not be well informed regarding good oral hygiene practices; hence, it is expected for her offspring to exhibit deficient oral health attitudes due to the limited availability of information.

Conclusion

Childhood obesity and socioeconomic disadvantages had negative impacts on children’s gingival health in the representative sample. Both obesity and periodontal diseases can be prevented; prevention first starts in the home and family, so it is of prime importance to carefully supervise and check the oral health, healthcare attitudes and dietary profiles of all children, with special attention paid to overweight/obese children to prevent future systemic and oral health problems.

Comparison of Anti Mullerian Hormone in Working Women with Different Social Class in Babylon City, Iraq

Hanan Abdul Jabbar Al-Taee
College of Medicine, University of Babylon, Iraq

ABSTRACT

Many factors have been claimed to impact fertility in women, fertility in Iraq starts deteriorating in the past years, the effect of wars on fertility of Iraqi women have been demonstrated in our previous study. Aim of this study: To look for the association of socio-economic class with Anti Mullerian Hormone in reproductive age women in Babylon city in Iraq.

Total of 166 married educated, working women, with age between 17-35 years, belonging to different socio-economic class. These women were assessed for ovarian reserve using Antimullerian hormone. The study was a cross-sectional study including women who attended fertility management clinic in Babylon City. They were interviewed using a structured questionnaire.

AntiMullerian Hormone shows a significant positive association with socio-economic class (P = 0.0009).

Higher socio-economic state of the women, are associated with better ovarian reserve as assessed by Anti Mullerian Hormone.

Keywords: Antimullerian hormone, socioeconomic status, Fertility, mid-reproductive age women.

Introduction

Socio-economic status (SES) is considered a vital factor that affects reproductive potential of women in many ways; it is widely studied variable in public health and social science research. Besides women level of education has been found to effect couples fertility (1-3).

Socio-economic parameters, such as type of work, religion and geographic location were also found to have impact on fertility status. Fertility rates have started declining in Iraq during the past three decade, as documented by Al-Jebouri and Altaee (4, 5).

Fertility potential of women can be estimated by ovarian reserve parameters, which may include hormones (Follical stimulating hormone and Anti Mullerian hormone) and ultrasonic markers (Antral follicle count). These markers also may help in choosing the appropriate programme and adjusting the dose of gonadotropin in infertility treatment (6-9).

Anti-Müllerian hormone (AMH) is a dimeric glycoprotein, belongs to the transforming growth factor-beta superfamily (10, 11). In women AMH is a product of granulosa cells of pre-antral and antral follicles (12), its main physiological role seems to be limited to the early inhibition of follicular development (13,14). AMH testing can be done at any day of the women cycle, and it is not influenced by oral contraceptive pills, and has very little intra- and inter-cycle changes.

Limited numbers of studies focused on the relationship between social class and AMH (15-20). The purpose of this study is: was to find out if any inference of social class on AMH in mid reproductive women selected for this study.

Materials and Method

A total of 166 married, educated women, age between 17-35 years, belonging to different socio-economic class were assessed for the clinical ovarian reserve parameter Anti Mullerian hormone. The study was
a cross-sectional study including women who attended fertility management clinic in Babylon City. They were interviewed using a special questionnaire. Informed written consent was signed by all participants. The work have been confirmed by the research ethical committee of College of Medicine/University of Babylon

**Inclusion Criteria:**
1. Healthy, mid reproductive age women with cycle length of (25-35) days.
2. Women whose AMH measurements were performed with the same kit.
3. Women living in urban places
4. Women with body mass index (BMI) less than 30kg/m²
5. Women working as clerks, or work at money transfer company, water and piping company, car sailing company, tourism company or teachers in high or primary school.

**Exclusion Criteria:**
1. Women on oral contraceptives.
2. Smokers,
3. Pregnant women
5. Women with any endocrine disorders.

In reviewing the literatures, there were many suggestions for how to calculate socioeconomic class (SEC), the life chances of individuals and families are largely determined by their occupation which is is taken to be the central indicator system (21, 22), and there is a high level of agreement over occupational rankings in the population (23). We didn’t find such studies in Iraq, but on asking about that issue the socioeconomics, we noticed this verbal classification, those who attain below 500.000 Iraqi dinner (ID)\ month were classified as low income class, those how gain between500,000-1,000 000 ID as medium and above one million ID as high income.

**Hormonal Analysis:** Ten milliliters of venous blood was withdrawn from the women for estimation of AMH. Patient name was written on the plain plastic tube. The samples were left to stand at least 15 min at room temperature. Centrifugation at 3000rpm for 10min to separate the serum was done, they were kept at (-20°C) temperature deep freeze until the time of analysis. The Serum samples for AMH were examined by sensitive Enzyme Linked Immune Sorbent Assay (ELISA) method, and the kit used for hormonal analysis is Anash labs which (Germany).

Statistical examination was done using (SPSS version 16 IBM). Pearson correlation was used and curve were measured for correlation. P < 0.05 was considered to be statistically significant (24).

**Results**

Demographic characters of the study group:

**Age:** The total number of the patients was 166, their mean age ± (SD) (28.6 ± 5.6), ranging (17- 35) years.

**Residence:** All women were living in urban areas

**Educational level:** All females attain college level of education or institute graduate

**BMI:** (mean ± SD) (28.8 ± 6.84) Kg/m²,

**AMH:** (Mean ± SD) (5.08 ± 4.93) ng/ml

**Job:** The women were working as clerks, or work at money transfer company, water and piping company, car sailing company, tourism company or teachers in high or primary school.)

![Figure 1: Correlation of anti mullerian hormone (ng/ml) with women income, there were significant positive correlation r= 0.203; p = 0.009.](image)

**Discussion**

This study demonstrates that there is a significant Positive Correlation between Socioeconomic class and AMH in our selected population. This finding confirms that of Tadisetti and his team in India (24) and Barut and his coworkers in Turkey (25). The strength of the study is the homogeneity of the investigated group, the selected population was chosen so that AMH is affected only by the income factor, that’s to say that all women were belonging to nearly same reproductive age (Figure 1), all attain same level of education, nearly the same
working circumstances and finally they live in urban area, although migration factor is well seen in Iraq in the last 10 years, but recent study done in Poland concluded that no effect of inhabiting rural areas, large cities on ovarian reserve (26,27).

A low socioeconomic class associated by stress such as under nutrition and financial suffering may have effect on ovarian reserve. In addition Iraqi women have many other stressor factors which add to the above mentioned factor, Iraqi population suffered from severe environmental stress like war impact, different types of pollution and psychological stress since 1980 (4). The circumstances of wars and sanction might led to unbearable stress on women and their families. The result of this study may be confirmed by larger sample size to determine the impact of SEC on ovarian reserve.

Conclusion

Positive correlation exists between socio-economic state of the women and Anti Mullerian Hormone.

Acknowledgment

Role of Interleukin-12 Cytokine in the Cellular Response to Mycobacterial Disease

Raafat M. AL-Enzi¹, Jawad Kadhim Tarrad¹, Moshtak A. Wtwt¹
¹College of Medicine, University of Babylon, Hillah, Iraq

ABSTRACT

Interleukin-12 (IL-12) is a multifunctional cytokine acting as a key regulator of cell-mediated immune responses through the differentiation of naive CD4+ T cells into type 1 helper T cells (Th1) producing interferon-gamma. IL-12 act as a chemoattractant for macrophages, promotes the migration of stimulated dendritic cells and associated with several pathogenic inflammatory responses such as a mycobacterial infection.

This study, have suggested that IL-12 could play a vital role in treating mycobacterial diseases.

This case-controlled study used The enzyme-linked immunosorbent assay (ELISA) to detect the role of IL-12 in 42 patients with pTB who were referred to consultant clinic for respiratory diseases in Hillah – Babylon province/Iraq during the period from December 2017 to July 2018, and 42 healthy persons’ control. Blood samples were collected from both groups according to the standard methods.

Data analysis revealed that median serum level of IL-12 in patients was 38.91 pg/mL (range 15.68-540.29 pg/mL) which was significantly higher than controls (34.06 pg/mL, range 10.97-672.44 pg/mL) (P= 0.042). IL-12 Cytokine showed significant protective role against Mycobacterium tuberculosis through activated Th1 cellular immunity.

Keywords: Interleukin 12, Mycobacterial infection, Tuberculosis.

Introduction

Tuberculosis (TB) is an acute or chronic bacterial infection caused by Mycobacterium tuberculosis (M. tuberculosis). It primarily affects the lungs, but may spread to other organs (extra-pulmonary TB) (1). Nearly one-third of the world’s population (two billion people) are infected with M. tuberculosis and is at risk of developing tuberculosis (TB). Every year, about nine million people get infected with active TB and approximately 1.5 million people die of this disease, more than 90% of the infections and deaths arising from TB occur in developing countries (2). Interleukin 12 (IL-12) is an important immunoregulatory cytokine that is produced mainly by antigen-presenting cells. The expression of IL-12 during infection regulates innate responses and determines the type of adaptive immune responses. IL-12 induces interferon- gamma (IFN-γ) production and CD4+ triggers T cells to differentiate into type 1 T helper (Th1) cells. Studies have suggested that IL-12 could play a vital role in treating many diseases, such as M. tuberculosis infection (3).

Materials and Method

Study Groups: This study designed into two groups. The first group involved 42 TB patients. Those patients were referred to consultant clinic for respiratory diseases in Hilla – Iraq during the period from December 2017 to July 2018. All patients were subjected to full clinical and radiological examinations prior to laboratory examination. The subjects with TB were selected from those who had a confirmed diagnosis by a healthcare professional and who presented clinical symptoms, radiological evidence and positive sputum acid-fast bacillus (AFB) smears. The second group involved 42 apparently healthy individuals were considered as control.
Collection of Blood Samples: The blood was collected by venous procedure. The site of venipuncture is sterilized by 2% iodine. Five milliliters of venous blood were collected in gel tube from each participant and this 5ml was centrifuged to obtain serum, preserved at -20°C until be used. A total of 84 blood samples were collected (42 subjects with pTB patients and 42 healthy controls). ELISA assay was used to measure levels of IL-12 in serum of TB patients and controls. ELISA assay was accomplished using (Elabsience/China) kit according to the manufacturer’s instructions.

Statistical Analysis: The Statistical Package for the Social sciences (SPSS, version 20) was used for statistical analysis. Mann Whitney test was used to compare median (range) of IL-12 between patients and controls. Chi-square was used for testing the deviation to compare between categorical variables such as age and gender. A P-value ≤ 0.05 was considered statistically significant.

Results

The demographic characteristics of study population for pTB patients and controls groups were involved the following factors as in (Table 1).

Data analysis revealed that median serum level of IL-12 in patients was 38.91 pg/mL (range 15.68-540.29 pg/mL) which was significantly higher than controls (34.06 pg/mL, range 10.97-672.44 pg/mL) (P= 0.042) as shown in (figure -1). Immunity to *M. tuberculosis* infection is associated with the emergence of protective CD4 T cells that secrete cytokines, resulting in activation of macrophages and the recruitment of monocytes to initiate granuloma formation. The cytokine-mediating macrophage activation is IFN-γ, which is largely dependent on IL-12 for its induction (4).

Discussion

In active pTB, the main immune response is cell mediated immunity (CMI) in which the *M. tuberculosis* is engulfed by macrophage which activate the Th1 through MHC II through produce IL-12 (5).

The early phase of acquired cellular immunity to *M. tuberculosis* infection is mediated by the emergence of protective CD+4 T lymphocytes that secrete cytokines including IFN- γ, IL-2 and TGF-β a molecule which is pivotal in the expression of resistance to tuberculosis. Recent evidence demonstrates that infection with *M. tuberculosis* induces peripheral blood mononuclear cells to release the cytokine IL-12, a molecule that promotes the emergence of T-helper type-1 (Th1). Demonstrate that
IL-12 mRNA expression was induced by *M. tuberculosis* infection both in vivo and in vitro and that exogenous administration of IL-12 to mice transiently resulted in increased resistance to the infection (6).

When the *M. tuberculosis* engulfed by phagocytes cells (dendritic and Macrophages cells) leading to produced IL-12 and IFN-γ. These cells present *M. tuberculosis* antigen to CD+4 Th1 cells which are activated and start to release IL-12 and IFN-γ aims to destroy *M. tuberculosis* (7).

Impact of Breast Feeding Duration on the Presence of *Candida* in Relation to Nonnutritive Sucking Habit among Group of Iraqi Children

Ohud Faik Taha¹, Aseel Haidar M. J. Al Haidar¹

¹Department of Pedodontics and Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

The objective of this study was to evaluate the effect of breast feeding duration on the presence of *Candida* in relation to nonnutritive sucking habits.

This study was conducted by multistage sampling method. In the first stage calculation of the sample size was done, while in the second stage questionnaires were distributed to obtain the children personal information including: the date of birthday, gender, type of feeding, breast feeding duration, presence the nonnutritive sucking habits (dummy sucking, thumb sucking) with the duration of the habit. In the third stage, a sample of 100 children attending private and public kindergarten in Baquba city/ Iraq were identified (50 children with nonnutritive sucking habits and the other 50 were without any sucking habits). Samples had been obtained from the oral cavity of the selected children and cultured on sabauraud dextrose agar media, identification of *Candida albicans* was done by germ tube under the light microscope.

A highly significant relation was found between the duration of breast-feeding and the presence of *Candida*, by which the mean rank of the presence of *Candida* was higher among children with breast feeding duration less than 6 months than children who got breast-feeding for more than 6 months. Although the mean rank of the candida among the study group was higher than that among the control group, the difference was statistically not significant. The mean rank of *Candida* was higher among children with mixed feeding than the children with breast-feeding and the difference was statistically highly significant.

Type of feeding has an impact on the presence of *Candida* among children. Concerning the presence of *Candida*, children who fed with their mother’s milk for 6 months or more had the lowered median.

**Keywords:** Breast-feeding duration, *Candida* infection, Nonnutritive-sucking habits (NNSH).

**Introduction**

The ideal nutrient for newborn babies is the mother’s milk, which is considered as a necessary element that is required for their proper growth and development. It provides them with the essential and the bioactive nutrients (as a digestible and complete food)¹,². Breast-feeding has an immunization effects, which is important for the protection of the infants against various infectious diseases while the development of the infant’s immune system is complete. It acts as a link between the mother and her infant that transfers the immune components, which have a vital factor in the immunity system development later in life. Many immune modulatory compounds are found in the breast milk; including “antibodies, immunoglobulins, cytokines, chemokines, soluble receptors (CD4, TLRs), oligosaccharides and intact immune system cells”³.

Human milk oligosaccharides are important, because they modulate the immune system and act as a prebiotic; eliminate bacteria that stimulate the host defense ⁴. Breast-feeding had long-term health outcomes as it was reported by many researches including decrease the occurrence of diabetes type 2, reduction of obesity, reduction of the complications of necrotizing enterocolitis, hospitalization and respiratory diseases ⁵.

The duration of breast-feeding varies as the opinions and the cultural environments varies between the countries. Harmful effects on the child’s health may arise if the duration of the breast-feeding was less than two months, which in turn may lead to lack in the protective factors that are found in the breast milk. Therefore, nowadays the studies showed that newborns must be fed from their mothers’ breast until six months of age.  

Sucking habit is the first coordinate muscular activity of the infant that is considered as a natural reflex. There are two types of sucking; the nutritive type which feed the child with the essential nutrients, while the nonnutritive type of sucking NNSH (on a thumb or pacifier) insures a feeling of warmth and sense of security. This form of sucking had a vital role in the child’s physiological growth and psychological control of emotions. Babies use non-nutritive sucking, to comfort themselves when they are upset to satisfy their urge and need for contact. It is considered as a method for exploring the world and in some instances, sucking practicing by babies to spend the time. On the other hand, if the NNSH (especially pacifier sucking) last for 3 years, and after this age, deleterious effects may arise. Some of these unfavorable effects may include interference with the proper breastfeeding or even early weaning. It may increase the risk of recurrent otitis media, dental caries, in addition to the development of malocclusion.

*Candida albicans* is commensals that may found in several areas of the human body like the gastrointestinal tract, genitourinary system and skin but when the immune system had been weakened, these opportunistic commensals invade the host tissue causing serious consequences. *Candida* infection and oral thrush had been reported to be associated with prolonged use of pacifier sucking habit.

In Iraq, there is no available data concerning the impact of breastfeeding duration on the presence of *Candida* in relation to nonnutritive sucking habit. Therefore, this study was done to assess the impact of breastfeeding duration on the presence of *Candida* infection in relation to nonnutritive sucking habit among group of Iraqi children aged 3 to 5 years old in Baquba city.

**Materials and Method**

The scientific and the ethical committee at College of Dentistry/University of Baghdad approved this study (Ref No: 2019-58318).

Sample selection was done using a “multi-stage cluster random sampling”. Firstly, children aging (3-5) years old were chosen by random sampling clustering technique from 18 kindergartens in Baquba city (the capital of Iraq’s Diyala Governorate, which is located some 60 km to the northeast of Baghdad). Secondly, information through questioners concerning the personal information for each child included in this study was collected. The questionnaires included the date of the child birth day, gender, type of feeding, breast-feeding duration, presence of NNSH (pacifier sucking or thumb sucking) and duration of the sucking habit. After that, a study group composed of 100 children who attending the public and private kindergartens in Baquba city/ Iraq and who were aging from 3-5 years old of both genders was chosen. They were divided into two groups: study group (those children who had sucking habit) and the control group (those children who had no sucking habit and they were matching the age and gender of the study group). Microbiological samples were obtained from four areas of the oral cavity of the selected children (floor of the mouth, dorsal surface of the tongue, oral mucosa of the check and hard palate) using un contaminated cotton swap. Each sterile swab had been streaked on “Sabaura dextrose agar” then the plates were aerobically incubated for 48 hours at 37°C. The morphological features of *Candida* was identified according to Emnous and Binford (1974) and Fingold and Baron (1986). Slides was prepared, stained by lactophenol cotton blue technique and examined under light microscope for identification of *Candida albicans*. *Candida* is oval in shape with budding cells also germ tube was used for identification.

Statistical analysis was done depending on SPSS program version 23. Level of significance was set at 5%, by which if the p>0.05, it was considered not significant. If the p value was ≤0.05, it was considered as statistically significant while if the p value was <0.001, it was considered as highly significant. Data was not normally distributed, so Mann Whitney U test was used for the statistical analysis.

**Results**

The sample consisted of 100 children who were divided into two groups (fifty for each); study group consists of children with NNSH and control group composed of children without any sucking habits. The highest percentage of children with NNSH was found within the age group of 4 years, as shown in Table (1).

Table (2) illustrates a highly significant association between breast-feeding duration and the *Candida* infection. The mean rank was higher among children with breast feeding duration (less than 6 months) while the mean rank was less among children with breast-feeding duration (more than six months). The median of the *Candida* presence was 40 among children with breast feeding duration (less than 6months) while it was 0 among children with breast feeding duration that last for 6months or more.

The type of feeding in relation to the presence of *Candida* was elucidated in Table (4). The mean rank of *Candida* was higher among children with mixed feeding than the children with breast-feeding and the difference was statistically highly significant. The median of the presence of the *Candida* was (0) among children who were fed by breast-feeding while the median was (10) among children who were fed by mixed feeding.

Discussion

The short-date mother’s milk benefits (as well as the long-date) on both, the health and growth of the new born baby, in addition to the effects on his/her mother health, had been well recognized. In infants, less than six months aged, prevalence of exclusive breastfeeding had been increased globally from about 24.9% to 35.7%. It is well known that the use of pacifier has an adverse influence on breastfeeding duration by increasing the tendency of early weaning. This study revealed that (NNSH) was higher among the four years old children (27 children 54%), Table (1). This result came in accordance with the findings of other study. Nonnutritive-sucking habit at 36 months of age considered as a natural condition and if it persists after this age, it means a presence of a psychological disturbances.
The current study tried to analyse the impact of the duration of breast feeding on the presence *Candida*. There was an inverse relationship between breast feeding duration and the occurrence of *Candida albicans* by which children who were breastfed for more than six months had significantly less *Candida* presence. However, *Candida albicans* had been presented among children with breastfeeding duration of less than six months, Table (2), and this was in agreement with other studies 3,6.

According to the results of the present study, that had been showed in Table (3), the median of the presence of the *Candida* was higher among the children with NNSH. This finding was coincide with the results of many other studies 16,17,25,27,28. After certain duration, the pacifier itself (thumb), like any other oral removable appliance, may be colonized with microorganisms that in turn can alter and modify the oral flora 29,30. In addition, sucking of a pacifier/thumb can be considered as a risk factor for the cross infection as it has a role in the horizontal transmission of the microorganisms which can facilitate the *Candida* presence and proliferation. Meanwhile, stagnation of saliva, which is related to the sucking habit, and subsequent drop of its pH will favor and facilitate the growth of *Candida* and other aciduric microorganisms 18.

Breastfeeding is important to increase the infant immunity against infection 2-4. As shown in Table (4), a highly significant association had been found between the feeding type and the presence of *Candida*, supporting the role, stated by many studies 10,11, of the type of feeding on the presence of the *Candida*.

**Conclusion**

In conclusion, NNSH was associated with the higher presence of *Candida* among children. Type of feeding has an effect on the presence of *Candida* among children. Duration of breastfeeding has a potential impact on the presence of *Candida* in relation to NNSH among the Iraqi children. Therefore, all the efforts should be made to increase the duration of breastfeeding more than six months to decrease the likelihood of *Candida* infection and not engaging in NNSH.

The Occurrence of Certain HDV Genotype in Patients with Chronic Hepatitis and Hepatocellular Carcinoma

Nawfal Saeed Amen¹, Dawood S. Dawood², Safaa Abd Alrazaq³
¹Medical City, Baghdad Hospital, Ministry of Health, Iraq; ²Ministry of Higher Education and Scientific Research, Middle Technical University, Iraq; ³Medical City, Gastroenterology and Hepatology Hospital, Ministry of Health, Iraq

ABSTRACT

Objective: Analysis of hepatitis delta virus (HDV) isolates from around the world has indicated that there are at least three phylogenetically distinct genotypes with different geographic distributions. The aim of this study was to determine the occurrence of HDV genotypes by direct sequencing in patients with chronic delta hepatitis in Iraq.

A cross-sectional analytical study was done on 364 chronic hepatitis B patients from both Gastroenterology and Hepatology Hospital and Baghdad teaching hospital from August 2017 till August 2018. Serological tests for HDV Ag was measured by ELISA in these patients and confirmed by Nested PCR. All patients with chronic hepatitis B had positive hepatitis B surface antigen for at least 6 months before the study entrance, it confirmed by ELISA for HBs Ag.

Design and methods: Serum samples from 364 chronic hepatitis patients (males to females ratio was 2: 1 with mean age 37 years, range 18—63 years). Samples with positive HDV Ag were undergoing RNA extraction. After reverse transcription, cDNA of partial delta antigen was amplified by nested PCR. The products of the HDV PCR were direction sequenced of 327 bp for HDV gene and it was performed by the National Instrumentation Center for Environmental Management (NICEM), at biotechnology lab. Nucleotide sequences of HDV were compared with previously reported sequences and aligned by using BioEdit.

Keywords: Genotype, Hepatitis delta virus, Sequencing

Introduction

Hepatitis is a disorder in which viruses or other mechanisms produce inflammation in the liver cells, resulting in their injury or destruction

Hepatitis may be temporary (acute) or long term (chronic) depending on whether it lasts for less than or more than six months. Viral hepatitis is the most common type of hepatitis worldwide. Viral hepatitis is caused by five different viruses (hepatitis A, B, C, D, and E).

HDV is a defective satellite RNA virus which requires the helper function of HBV for its replication and assembly of new visions. The smallest virus to infect humans, is increasingly again becoming a cause of fulminant hepatitis or a more rapid progression of liver disease in the setting of chronic hepatitis B virus infection.

A single stranded RNA that can have a linear or circular conformation is 35–37 nm viruses like particles consisting of Coat of HBs Ag and a unique internal antigen (D Ag). The delta encapsulated with delta antigen is the genome. The RNA does not hybridize with HBV DNA. Synthesis of HDV results in suppression of synthesis of HBV component temporarily. Hepatitis delta (D) virus (HDV) is a small, replicatively incomplete RNA virus belonging to the Deltavirus family that requires the presence of Hepatitis B virus (HBV) for virion packaging and transmission.
Infection with HDV can occur concurrently with HBV infection or as a super-infection in those already HBV positive. HDV infection is associated with poorer outcomes compared to those with HBV mono-infection, with increased rates of fulminant hepatitis and faster progression to cirrhosis and end-stage liver disease, resulting in high rates of liver-related morbidity and mortality. Studies regarding the risk of HDV infection and hepatocellular carcinoma (HCC) formation are inconsistent. Some showed no increase in incidence, whereas one found that HDV co-infection increased the risk of HCC threefold and mortality twofold compared to HBV mono-infection. HDV appears to suppress HBV replication, with HBV DNA levels tending to be lower in co-infection.

HDV is highly pathogenic. Whereas coinfection evolves to chronicity in only 2% of the cases, superinfection results in chronic infection in over 90% of the cases. Hepatocellular carcinoma (HCC) is the second most common cause of cancer-related death in men worldwide. Persistent HDV replication and hepatic inflammation end up with cirrhosis and HCC formation. Active replication of both HBV and HDV may be associated with a more progressive disease pattern leading to early cirrhosis and HCC.

To date, there are eight genotypes of HDV which have been reported with unexplained variations in their pathogenicity. Furthermore, HDV genotypes have a distinct geographical distribution, apart from HDV genotype 1 which has been observed universally.

In this study HDV type I seems to be the unique genotype found in the Iraqi population. The aim of this Study is Determination the occurrence of HDV in chronic hepatitis and hepatocellular carcinoma, Assessment of HDV genotype in these patients.

**Materials and Method**

Three hundred and sixty four patients aged from 18 to 63 years, CHB patients had positive hepatitis B surface antigen for at least 6 months before the study entrance from both Gastroenterology and Hepatology Hospital and Baghdad teaching hospital from August 2017 till August 2018.

Questionnaire sheet was completed for each patients including personal data (age,sex)only.

Five ml of blood was collected from each patient by vein puncture using disposable syringes. The blood was placed in plastic disposable tube then the serum was separated by centrifugation at 3000 rpm for 10 minutes then stored of samples at - 45°C until the time of test HBsAg (Acon- USA), HDVAg (Cusabio-China) by enzyme-linked immunosorbent assay (ELISA), PCR (intron biotechnology/Korea) for HDVAg (positive samples).

HDV-RNA was extracted from 150 μL of serum samples by extraction Patho Gene-spinTM DNA/RNA Extraction Kit (intron biotechnology/Korea) and 50-μL eluate was prepared. The RNA pellet was reverse transcribed to complementary DNA (cDNA), 1.5 microliters of the resultant cDNA preparation were added to 25 μL of a PCR solution containing 20 pmol of external sense primer (nucleotides (nt) 858–881) 5’ GCC CAG GTC GGA CCG CGA GGA GGT 3’ and external antisense primer (nt 1289–1312) 5’ ACA AGG AGA GGC AGG ATC ACC GAC G 3’, and 5U Taq polymerase. The mixture was amplified by 50 cycles of PCR (95 °C for 1 min, 62°C for 1 min, 72 °C for 1 min) followed by a 7-min extension at 72 °C. 1.5 microliters of the product were used for the second round PCR using 20pmol internal sense primer (nt 883–906) 5’ GAG ATG CCA TGC CGA CCC GAA GAG 3’ and internal antisense primer (nt 1265–1288) 5’ GAA GGA AGG CCC TCG AGA ACA AGA 3’ set with the same conditions as the first PCR. PCR working precautions were strictly followed and negative controls were added between samples. Products were analyzed by electrophoresis on 1% agarose gel and the expected 327 base pair length was confirmed.

The products of the HDV PCR were direction sequenced of 327 bp for HDV gene and it was performed by the National Instrumentation Center for Environmental Management (NICEM), at biotechnology lab. Nucleotide sequences of HDV were compared with previously reported sequences and aligned by using BioEdit(The BioEdit Sequence Alignment Editor software) for sequencing analysis.

The HDV sequences used in this study were deposited in GenBank under accession number MK185100.1

Nucleotide sequence accession numbers of the reference HDV sequences

The accession numbers of the reference sequences used were as follows: (MF175319.1, MF175258.1, LT604938.1, AM779582.1, AF352570.1, MF175337.1, KT722840.1, AM779591.1, KJ744234.1, KF660602.1, AB201270.1).
Results

In this study we can demonstrate in table (1), the distribution of group study by age and gender. This table show age range (<20 years) 14 (3.8%) and (20-29 years) 101 (27.7%) while age range (30-39 years) 117(32.1%) Whilst age range (40-49 years) 72 (19.8%), (50-59 years) 50 (13.7%) and also age range (>=60 years) 10 (2.7%). From 364 cases with chronic hepatitis, 199(54.7%) males and 165(45.3%) females; there was no significant difference between male and female among patients (p>0.05).

This means infection can occur at any age group. The mean age for hepatitis B virus was 36 years, these results agreed with (18) who found that mean ages of 37 years. Moreover, other studies agreed with this study were done by (19) who reported a mean age of 35.6 years, and (20) who indicated a mean age of 41.9 years. The difference in the source of infection or the environmental and geographical distribution could be led to lower mean age which was 27 years and this result agreed with (21).

The gender difference in HBV patients could be explained by the fact that males may have a greater chance to come in contact with the risk factors for HBV more than females and this agreed with (22) who showed a male to female ratio of 3:1 Other researchers showed similar results as well (20,23). The higher rate of chronic HBV infection among males may be due either to a prolonged replicative phase of the virus in male or to differences in sexual behavior (24).

Table 4 has shown the correlations between HDV Ag and PCR for HDV when analyzed by Pearson correlation. The result showed a high significantly positive relationship (p<0.0001).

These Results Agreed With (25) who showed difference Percentage when Comparison Between HDV Serology and PCR Positive Samples. The sensitivity of HDV RNA detection can be influenced by the variability of the HDV genome and the primers selection. Today, there is no available international or control to calibrate a quantitative assay for HDV.

One and half µl of PCR Product (PCR 1) external were used for each PCR reaction. A conventional PCR protocol was used to analyze simultaneously the presence of HDV viral was identified by 327bp as shown in Fig. 1.

The results of sequences of this study were compared with the reference sequence of in national center biotechnology information (NCBI) Gene Bank and showed that the degree of similarity was high between sequences which give greater confidence (16).

From the Gene Bank, found that having 99% compatibility with standard in Gene Bank. This sequence was submitted to gene bank NCBI, DNA data bank of Korea/Macrogen (26). In another study on geographic distribution and genetic variability of hepatitis delta virus genotype I, sequence divergence among genotype I isolates from different countries ranged from 3.1% to 13.4% (27).

Conclusion

HDV genotyping was successfully performed by direct sequencing of the amplicons obtained from routine HDV-RNA screening PCR tests. The HDV isolates from the chronic delta hepatitis patients included in this study were found to be genotype I. HDV type I seems to be the unique genotype found in the Iraqi population, which is an expected finding in agreement with similar epidemiological studies from the Mediterranean region and confirms previously published data.

The occurrence of hepatitis Delta virus was significantly in patients with chronic hepatitis and hepatocellular carcinoma. The distribution of hepatitis Delta virus in patients with Chronic hepatitis and hepatocellular carcinoma revealed non significan association regarding age and gender.

Organizational Loyalty and its Correlation to the Creativity of Members of the Federations in Tennis Games in Iraq

Munaf Abdulazeez Mohammed1, Anees Hussein Ali2, Ali Mohammed Jawad Al-Sayegh3, Hayder Naji Habash Alshawi1

1Department of Physical Education and Sports Sciences, Faculty of Education for Girls, University of Kufa, Iraq; 2The College of Physical Education and Sport Sciences, University of Babylon, Iraq; 3Fine Arts Institute for Boys, Al-Najaf Education Directorate, Ministry of Education, Iraq

ABSTRACT

The research problem centered on studying one of the important aspects of the organizational loyalty of the members of the Union as well as their ability to administrative creativity in the work of the Union to promote it and whether there is a correlation between them, and certainly the level of sports leaders represented by the President of the sub-union have a positive and negative impact on the work of the Union. The problem of research is the need to know the extent of the organizational loyalty of the president of the sub-union of the tennis games and the characteristics that should be characterized by the president in order to be a successful leader because his work in the field is an important and decisive factor in improving the performance of the federation and its reflection on the ability of creativity of the members of the federation and thus in achieving the desired results for the members of the federations in racket games.

The objectives of the research was to identify the level of organizational loyalty and administrative creativity of the members of the federations Iraq, and identify the relationship between organizational loyalty and creativity ability of members of the federations in tennis games in Iraq, and predict the level of organizational loyalty in terms of the ability to creativity among members of the federations in tennis games in Iraq, Descriptive of the members of the federations in tennis games (tennis, table tennis, badminton and squash) in Iraq for the season (2017-2018) and the number (84) members distributed in (18) provinces, the researchers concluded the validity of organizational loyalty and creativity measures used in measuring the degree of organizational loyalty and ability. There is a positive correlation between the organizational loyalty and the ability of the members of the federations to play tennis in Iraq.

Keywords: Organizational loyalty, creativity and federations.

Introduction

Organizational loyalty promises to be the employee’s reaction to the characteristics of the organization to which he belongs. It also means the employee's sense of his association with the goals and values of the organization and the role he plays to achieve these goals and commitment to functional values for the organization, and creativity is new and useful ideas related to solving specific problems or grouping Restructuring known patterns of knowledge into unique forms. Creativity is not limited to the technical side, as it involves not only the development of goods and related processes, the preparation of the market, but also the machinery and equipment, manufacturing methods, improvements in the organization itself, and the results of training and satisfaction. Creativity requires the ability to sense a problem that requires treatment, and then the ability to think differently and creatively and then find the right solution.1

One of the important aspects of the organizational loyalty of the members of the Union as well as their ability to administrative creativity in the work of the Union to promote it and whether there is a relationship...
between them, and certainly the level of sports leaders represented by the President of the sub-union have a positive and negative impact on the work of the Union, so a good choice the problem of research is the need to know the extent of the organizational loyalty of the president of the sub-federation for tennis games and the characteristics that must be characterized by the president in order to be a successful leader because his work in the field constitutes An important and decisive factor in improving the performance of the federation and its reflection on the ability of creativity of the members of the federation and thus in achieving the desired results of the members of the federations in racket games.²

The objectives of the research was to identify the level of organizational loyalty and administrative creativity of the members of the federations of the games. Researchers have assumed a significant relationship between the level of organizational loyalty and ability the creativity of the members of the federations in the tennis games in Iraq, and the predictability of the level of organizational loyalty in terms of the ability to creativity among the members of the federations in the tennis games in Iraq.

**Research Methodology**

The researcher used the descriptive method of survey methods, correlations and standard studies to suit the requirements of the research on the members of the federations in tennis games (tennis, table tennis, badminton and squash) in Iraq for the season (2017-2018) and the number (84) members distributed in (18) governorates.

**Description of organizational loyalty scale:** The measure consists of (35 paragraphs) distributed over its three domains (11) paragraphs for the emotional field, (14) paragraphs for the moral field, and (10) paragraphs for the continuous field, it is corrected by the correction key which consists of five alternatives namely (always, Often, sometimes, rarely, at all) weights were given (5-4-3-2-1), respectively, the highest score obtained by the subject (175) and the lowest score (35). The hypothetical mean of the scale (105), and whenever the degree obtained by the examiner is equal to or higher than the hypothetical mean that indicates the prevalence of organizational loyalty when the member was added paragraphs lie detector outside the total number.

**Describe the ability to creativity:** After examining the researcher on a number of tests related to creativity. It was found that the scale is the most suitable for research, which consists of (70) items aimed at measuring the creativity of the members of the federations in racket games and answered by five alternatives (always, often, sometimes, rarely, Absolutely) Since the total degree of the scale of (70-350) degree, the scale was adjusted to suit the nature of the sample of the research sample, then it was presented to the gentlemen experts to ensure the validity of its use as they confirmed the safety of the procedures followed and the validity of its use on the members of the research sample, and thus The scale is made up of (60) items and is ready for application.³

This section includes the presentation, analysis and discussion of the results reached in the light of the objectives set as a result of its application of research tools, and verified by the first research objectives, which was to identify the reality of organizational loyalty and creativity among members of the federations in tennis games as follows:

1. **The reality of organizational loyalty and creativity among the members of the federations in racket games:** To achieve the first objective in identifying the reality of organizational loyalty and creativity among the members of the unions, after analyzing the data, the mean of the organizational loyalty scale was (134.72) and a standard deviation of (6.24). 248.99 with a standard deviation of (23.62) and table (1) shows this.

</tbody>
</table>
From Table (1), there are many benefits such as commitment, motivation, and increasing morale. In contrast, there are benefits that the member of the Union can get from his job in the Union as a source of livelihood. At the same time, these benefits increase the belonging and loyalty that may be due to physical and social values of respect and appreciation in society, which increases the emotional attachment to the organization, and therefore increased the average emotional sphere, and whether physical or social reasons, it is a direct factor to achieve self-fulfillment that leads to job satisfaction, the latter enables the Union member to accept On performance His duties are enthusiastic and harness his full potential and energies, and bear the responsibilities assigned to it, and thus increase the level of integration and membership in the Union, which reflects positively on the continuity of work in the Union, and this result is consistent with the study. conducted on a sample of faculty members in Jordanian universities, The study conducted at the University of Sana’a in Yemen, which concluded that the level of organizational loyalty was high, and can be attributed to the low level of continuous loyalty among members of the Union compared to other dimensions of organizational loyalty, due to the lack of material advantages of rewards, incentives and promotion opportunities, This gives them a sense of job satisfaction and makes them more associated with the union, as well as a sense of instability and job stability and that they work in temporary jobs, as a result of the unions adopted a four-year election policy in their appointment. The results of this study are consistent with the results of the study, whose results indicated that employees have a moderate degree of organizational loyalty in its three dimensions (emotional, continuous and normative) and a study that found that faculty members in private universities have an average level of organizational loyalty to their universities.

Also, Table (1) shows that the mean average of the sample on the creativity scale was (248.99) and the standard deviation (23.62) degree, that the average achieved is greater than the hypothetical mean of the scale of (4.91). It is found that the value of (sig) is smaller than (0.05), and this result explains that the members of the unions have a high level of creativity.

The reason for this is that creativity means the distinctive activities that people do and cannot be done by the machine, so a good creativity system focuses on retaining highly skilled and highly trained staff, providing them with additional knowledge, encouraging them and making them able to think and work creatively. It also requires the diagnosis and provision of suitable conditions for creative activity and help in achieving the target creative output. The focus was on the components of the system of creativity or pillars on which to determine the level of creativity and development and included a range of factors, including organizational culture It means the creativity values that encourage employees to think distinctly and calculate risk and challenge the existing situation, as well as responsibility, which is to determine who is responsible for creativity and that means all employees in the organization and everyone should work to make proposals and implement improvements to the workflow, as well as the human resources system that contributes In developing individuals and encouraging them to be creative, this requires following up the requirements of training, evaluation, monitoring and rewards in order to encourage social behavior, and in the same context the system of measuring the performance of individuals, by developing accurate and objective systems to measure the performance of individuals, E level of creativity and its effects in improving the performance of individuals working in the organization, as well as the acquisition of knowledge the exercise of administrative processes that provide the organization with new ideas, information, concepts and knowledge through the use of specialized centers in the acquisition and development of knowledge, and the management of knowledge and creativity.

Table 2: Shows correlation between organizational loyalty and creativity among members of federations in racket games

</tbody>
</table>

The above table shows that there is a correlation between organizational loyalty and creativity. This result can be explained by the fact that it is the members of the federations who have organizational loyalty as belonging
to the organization in which they work and because it is the art of influencing others with the desired criteria of loyalty and creativity. Thus, their performance in sporting events and activities necessitating their administrative work in the management of their federations and their practices. Artistic and as influential must be followed by organizational loyalty and educational help to the cohesion and commitment of members of society and the values that affect them positively, and also that some members are working to raise organizational and sports at the level of loyalty of their colleagues.9

This finding is consistent with the findings of the Moller et al. 2001 study (1). The results show that organizational loyalty helps to guide colleagues, achieve a higher level of education and develop positive relationships between management and teachers, which means collaboration through joint leadership. Without organizational loyalty, there is no effectiveness for the organization. Organizational loyalty is reflected in all its employees through its actions, where employees learn modern behaviors and how the principles of organizational loyalty are entrenched by their subordinates and thus reflect on their ability to innovate at work and affect them in the future.

And encourage some to follow the desired modern methods in order to create a kind of effective interaction as well as their responsibility, which results in building strong relationships between the group and move their performance and social organization in order to obtain distinctive results. As well as their sense of importance and value between their colleagues and the community they work with, and also that the members of the unions attach importance to social relations because of the exercise of sports activities within and outside the union.

The researchers attribute this to the fact that organizational loyalty has a significant impact on the creativity of members as a result of the fact that organizational loyalty is a cornerstone of leadership and is also the way of successful management, so there is a close relationship between each of them, the more the member has a high organizational loyalty, the positive impact Organizational loyalty instills in individuals a set of values that help them identify acceptable and unacceptable behavior, and what is beautiful, true, disliked and wrong, and increases the adherence of individuals to the organization and increases the character of altruism and self-denial and present the interest of the institution on the private interest.10

Table 4: Shows the results of the predictive equation of the variables contributing to transformational leadership

This shows the possibility of predicting organizational loyalty in terms of the ability to creativity, including the behavior of members of the federations in tennis games in Iraq, and through the results and predictive equations reached to note the possibility of detecting any member of the federations in the case of characterized or possessed organizational loyalty to reveal its potential in the ability to This early detection is a positive step for them in correcting their performance because the prediction process is a speculative and discretionary process based on sound scientific bases that gain full confidence and that this process is not
necessarily to be 100% identical with reality but has a percentage A beer to know the attitudes of the members of the Union and the manner of its actions, actions or performance in the administration of the Union.\textsuperscript{11}

**Conclusions**

1. The validity of the organizational loyalty and creativity measures used in measuring the degree of organizational loyalty and creativity among the members of the federations in the racket games in Iraq.

2. The members of the federations enjoy a good amount of games (organizational loyalty, creativity).

3. There is a positive correlation between organizational loyalty and creativity among the members of the federations with tennis games in Iraq.

4. The possibility of predicting organizational loyalty in terms of the ability to creativity among members of the federations in tennis games in Iraq.

Leeches Review: Biology, Ecology and Medical Important

Nebrass Faleh¹, Zaid Naji Hassan¹, Maan Abdul Azeez Shafeeq¹
¹Department of Biology, College of Science, Mustansiriyah University, Iraq

ABSTRACT

Hirudotherapy (HT) is the submission of healing leeches (Hirudo medicinalis) for beneficial use. It is one of the firstborn medications, being active by several healing experts. HT contains the accessory of cultivated leeches against the pretentious zones. Leech treatment includes an original chew, which is frequently an easy mouthful, trailed by the slurping of 5 and 15 ml of blood. Its main healing assistances are not only owing to blood drunk during the piercing, but also from the many bioactive matters, such as Hirudin, Calin, Hyaluronidase, and Histamine-like ingredients, to name a scarce.

HT has been active in numerous illness circumstances and clinical difficulties. It has been effectively used in soft and reconstructive operations, cardiovascular difficulties, varicose veins, hemorrhoids and various joint ailments. Nowadays, it is also being utilized in intestinal complaints, dermatology and antenatal irregularities.

More newly, HT has created new claims in tumor healing, sensitivity situations, like asthma, male/female sterility and diabetes. Attractive into deliberation all the truths, HT labors should be made in improving the achievement of remedial leech therapy in scientific and isolated practice.

Keywords: Hirudotherapy, leech, annelid, saliva, bioactive, reconstructive surgery

Introduction

Leeches are of worldwide distribution they are ectoparasites animals wild and domesticated animals, they return to phylum Annelida and to subclass Hirudinea¹, distinguished from other annelids by having two suckers in the interior end and the posterior end have well developed sucker, the body contain from 34 body segments no setae or parapodia like other species returns to phylum Annelida² and³ (Figure 1).

Figure 1: Anatomy of leeches⁴

Corresponding Author:
Zaid Naji Hassan
Department of Biology, College of Science, Mustansiriyah University, Iraq
Email: gmoon4444@uomustansiriyah.edu.iq

They life in freshwater, marine and on the surface of trees, grass and under stones in damp places. Some are parasites and other are involved lifecycle of parasites, they consider vectors of Protozoans like Trypanosoma, Cryptodira, Haemogregarina on fish, Amphibians,
Reptiles, Cattles, Man and other domestic animals cause anemia for them, they can serve as hosts, both intermediate and final, they demonstrate both pathogenic and beneficial effect on humans and animals \(^{(5}\text{ and } 6)}.

**Biology of Leeches:** They have slender, leaf shape body that distinguished them from other species return to phylum Annelida, no have any appendages on their bodies, they have tow suckers the first one large adhesive the posterior while the anterior sucker was small and located surrounds its pointed apical mouth finally they have soft body that lacks a skeleton for protection \(^{(7)}\), their eyes commonly vary from one to five pairs depended on species. They small animals their long range from 10 to 35 cm but ectoparasites leech their long range from 5 mm to 45 cm and they have brightly color but their dorsal surface is olive green \(^{(8)}\), clitellum region extends from 10 – 12 segments, contain male and female genital openings, secrete the eggs cocoon which is only visible in summer and they excretion by Nephridia found in special segmental in the body, they respiration through the body wall, their blood is red because has hemoglobin dissolved in blood, that help to transport oxygen via capillary network to all parts of the body \(^{(9)}\). They are hermaphrodites animals that meaning each has both ovaries and testes, sperm transfers from leech to another by spermaphoroses they occur during copulation, clitellum hold their eggs and secrete cocoon during reproduction time, the type of fertilization called X- fertilization and each leech shoots spermaphore into pores in clitellum of his partner the cocoon damped into the soil \(^{(10)}\).

Young leeches hatch from cocoon after they feed for a few days on yolk every cocoon contains different number of fertilizer eggs depended on species, adult leech lives 18-27 years \(^{(11)}\).

**Digestive system and feeding in Leeches:** They are have jaws and three blades set at the angle to each other, they slice the skin of their hosts and contain Y-shape behind the blades there is mouth located at ventrally in the anterior end of the body then there is pharynx, esophagus, crop, gizzard finally intestine, which end at the posterior sucker, the function of crop is storage while in blood sucking species of leeches when crop storage blood mail it produced an anti-coagulant that prevent clotting (Figure 2) . In the predatory leeches instead jaws there are proboscis and some of leeches feed small invertebrates or detritus so they have proboscis nor jaws but simply engulf their food with the mouth. \(^{(12)}\)Most predatory leeches are feed on worms, snail and insect larvae, they swallowed the soft parts of preys bodies in the digestive tract of leeches there are many types of bacteria they live like colonized \(^{(13)}\), they synthesizing essential nutrient digesting food and killing harmful animals, they are obligatory symbiotic relationship with leeches like Aeromonas veronii, Rikenella species, Erpobdella punctate, Pseudomonas aeromonas, P. hirudinicyla, Klebsiella spp and Bacterium hirudinicolum, all these bacteria produced many vitamins for example (B complex) to participate in food digestion, bacteria are passed to offspring in the cocoon as it is formed \(^{(14}\text{ and } 15)}\). These organisms have many touch receptors upper lip region to find a good site to feeding blood that site specialized with good taste – glucose and feels pulsating movements that indicate to artery before feeding leeches starts to pump air into and out of cavity after that positions its jaws on its victim, after that leech secrete saliva into the wound while teeth deeper into hosts skin like efficient micro pipettes that inject substances into wound, through feed period they appear to fall asleep after 20 – 60 minutes they release victim by open its jaws, continue involved to host for 30 minutes 6 hours for nourishing, they can taste about 5 – 15 ml of body fluid \(^{(16)}\).

![Figure 2: Digestive system of Leech](image)

**Nervous system:** Nervous system of leeches contain large nerve cells, so researcher use their nervous system as an example in the study of the nervous system of Invertebrate \(^{(18)}\), the main nerve center consist of cerebral ganglion, ventral ganglion, posterior ganglion and
various sensory receptors and there is lower pharyngeal ganglion consist of four fused ganglia and there is caudal ganglion consist of seven fused ganglia, they have large neurons that models for neural performance in higher animals. They have 2 – 10 pigment spot ocelli and they have sensory papillae each one contain sensory cells. They can detect touch movement of nearby objects, vibration and chemicals that secret by their hosts with movement head and waving body.

**Environmental Factors:** Many environmental factors will lead to great important on diversity of leeches in aquatic habitat destruction and fragmentation, perhaps cause disappear some of leech’s species in the next century. Urban areas are increasing rapidly day by day so that during construction the roads all wastes with precipitate may kill leeches and destroy the cocoon breeding field in wetlands.

When people used leeches in medical purposes that lead to decline in their habitats and many of factors effect on leeches like Endocrine disrupting compounds (EDC5) are pollutants have the ability to alter the growth, reproduction and general embryonic and morphological development of aquatic animals, these EDC5 come from a variety of sources like pharmaceutical, plastics, pesticides, ordinary household chemicals and industrial chemicals.

All these can anomaly leech offspring deformities in leech embryos and disruption of leech reproduction, they poikilotherms and they live in 0 C° - 30 C° temperature but when temperature changes rapidly these animals’ death.

Finally, leeches are one of the most important components of freshwater lakes, streams, rivers and in many marine and terrestrial habitats, and leeches constitute the most important element of fish diet in their habitat.

**History of Leeches therapy:** AL-Hijamah (Bloodletting=Phlebotomy) was part of Islamic medicine and was mentioned by Prophet Mohammed (peace be upon him) many elaboration on different type of bloodletting was done in Islamic time, after that Ibn –al-Quff put many guidelines on beneficial and toxic types of Leeches, Linnaeus in 1758 he is first described two worms they return to Annelida the first one was *Lumbricus terrestris* while the other was *Hirudo medicinalus*. The Indian God of Ayurveda hold Leeches in one of his hand some presumed the snake of Asquliiboos (Eusculpian) staff in actually leech, while remember in 1955 that Markwardt was first one who isolate hirudin from pharyngeal glands of Leeches and Fourcher himself described used Leeches in medical treatments.

The world Leech resultant since an ancient English world for medical doctor lace. In Egypt as 155 BC, where used leeches to treat nose blood and gout, in Greece, Chine, India and Pre-Columbian America they used leeches for therapeutic purpose, in 19th America were frequently a homebase remedy for secretion complaints hemorrhoids and great discolorations. In 1884 Haycraft remember esophagus and entrance of leeches confined a material prohibited the body fluid from clotting while Jacoby in 1904 explained that material was named hirudin.

**Discussion**

To date, many scientific studies published and some part of effect mechanisms were enlightened. a leech bite, it has to open a “sucking” pathway (extracellular matrix destruction), inhibit adhesion, aggregation and coagulation (inhibition of platelet functions, anticoagulant effect), increase the blood flow, protect itself (antimicrobial activity) and try not to be noticed (analgesic and anti-inflammatory effects). leeches immediately release hyaluronidase and collagenase enzymes to easily penetrate the tissue and spread its bioactive molecules. These enzymes also have supportive effect on antimicrobial activity. some studies indicate that some kinds of kininases and “antistasin” molecule may inhibit the kinin kallikrein mechanism which is a major pain-composer route. Destabilase has beta glycosidase activity which directly disrupts beta 1-4 binds that are key of the peptidoglycan layer in cell walls of bacteria. It is clear that this act is similar with Lysozyme (muramidase) that is commonly found in human saliva and lachrymal fluid. Furthermore, additional studies stated that antimicrobial activity does not only depend on enzymatic glycosidase activity, but it has also non-enzymatic ways to show this action. Of note, it is shown that dose dependently, even the denaturated form shows bacteriostatic effect on Staphylococcus aureus, Pseudomonas aeruginosa and Escherichia coli. Chloromycetyn is a potent antibiotic...
found in leech secretions, but unfortunately the data is limited about this issue. Additionally, theromacin, theromyzin and peptide B were isolated as antimicrobial peptides. In vitro studies were published indicating anti-cancer effects of leech saliva extracts. Since coagulation is related to metastasis and tumor progression, blocking the cascade can be an anti-tumor act. Hirudin has been studied upon this topic and very promising results about metastasis, especially with mesothelioma were reported. In addition, another anticoagulant derivates were claimed to have similar effect, but also reducing cell growth and tumor angiogenesis. The extracts were found to be provoking apoptosis and cell differentiation and causing cell cycle arrest. The main action mechanisms seem to be depending on suppressing ongogenic gene expression and upregulating apoptotic chains. On the other hand, effects against cell degeneration were also reported. Eglin C, bdellastasin, destabilase, bdellins and hirudin were found to be very protective and/or stimulative actions positively, especially on neurons, but these studies are on just preliminary phase.

Conclusion

Leeches have slender, leaf shape body that distinguished them from other species return to phylum Annelida, they have clitellum region contain male and female genital openings secrete the eggs cocoon, they excretion by Nephridia, they respiration through the body wall, their blood is red because has hemoglobin dissolved in blood. They are hermaphrodites’ animals, the type of fertilization called X- fertilization. They are having jaws and three blades set at the angle to each other, there is mouth located at ventrally in the anterior end of the body then there is pharynx, esophagus, crop, gizzard finally intestine, while in blood sucking species of leeches when crop storage blood mail it produced an anticoagulant that prevent clotting. In the predatory leeches instead jaws there are proboscis and some of leeches feed small invertebrates, they synthesizing essential nutrient digesting food, they are obligatory symbiotic relationship with bacteria produced many vitamins.

The Personality of the Obsessive and Their Relation to the Motivation of Achievement of Volleyball Players

Hameed Shamkhi Ghazi

Directorate of Student Activities, Al-Furat Al-Awsat Technical University, Iraq

ABSTRACT

The objective of the research is to find the relationship between the personalities of the obsessive and identify the relationship between them and the motivation of achievement of the teams of the University of the Middle Euphrates Volleyball, the researcher assumed that there are no significant differences between the personality and aerodynamic achievement volleyball. The study sample consisted of (96) athletes representing the Middle Euphrates Technical University for the 2016-2017 sports season, 12 of whom were excluded for participating in the exploratory experiment. The researcher used statistical means (percentage, arithmetic mean, standard deviation, and global analysis).

Through the results obtained by the researcher, they derived the following:

1. The relationship that has emerged is a negative relationship between the personality Obsessive and motivation to achieve volleyball.
2. The plane players enjoy varying degrees of personality and under the conditions of sports competition and low grades during the training modules.

Keywords: Obsessive, motivation and achievement.

Introduction

The relationship between psychology and sports and physical games is an interrelated and dialectical relationship that is characterized by the interaction of the living and cannot be separated from this link as psychology generally addresses the problems experienced by individuals in their lives, which appear in the form of emotions and acute and sometimes abnormal and in the form of deviations, disorders and diseases and psychological contract. Psychological problems are always the result of the poor compatibility of the individual with himself on the one hand and poor compatibility of the individual with his environment and the environment on the other. This causes failure to achieve the individual’s goals and satisfy his psychological needs. And social and social.¹

“Sport psychology plays an important role in the lives of individuals, as it directly affects their behavior, and therefore we see its effects in many of their actions. Sports psychology can be seen as a kind of motivation, desires, mental and physical abilities, attitudes, personality, Attention, control, stability and other situations are acquired, fungus and development of experience in the first case and since birth in the second case can be developed.¹ The individual must strive for success and that “feeling inferior is normal for people and can lead to a state of creativity and the goals are In order to overcome problems by the creative force inherent in the human that helps to achieve the natural talents of self-realization.”² Hence the importance of research in finding the relationship between the personality and aerodynamic achievement of volleyball players as it tries to shed light on the nature of the relationship between Two variables are important, the first relates to the psychological aspect of the personality of the obsessive of the players the other variable is the motivation of achievement as well as that the study comes in the field of volleyball game and the motivation of achievement to urge the player to be advanced and

distinguished among his peers in the team, Achievement and excellence work on stimulating and raising the potential energy of the friendly and working to double and directing its efforts and energies towards achieving the goal of higher achievement. As a result of the above, the importance of research lies in the identification of the level of personal intuition of the players as well as the level of motivation achievement and thus know the type of relationship and influence between the personality and motivation and motivation to achieve.

Research Aims:

1. Identifying the personality of the virtuoso and the motivation of achievement among the players of the Euphrates Middle Technical University.
2. To identify the type of relationship between personality and motivation and motivation of achievement of players.

Hypothesis: There is a significant relationship between the identity of the obsessive and the motivation of achievement in the players of Al-Furat Al-Awsat Technical University volleyball.

Research Methodology: The nature of the study necessitated the use of the descriptive method of surveying, which aims to “collect data to try to select hypotheses or answer questions related to the current or current situation of the members of the research sample”.

Community and Sample Search: The research community included the players of the Middle Euphrates Technical University and participated in the Middle Euphrates Technical University for the academic year (2017-2018). Therefore, the sample consisted of (96) players representing the players of the Middle Euphrates Technical University of institutes and colleges Technical Institute of Kufa, Diwaniyah, Technical Institute of Samawah (participation in this tournament as shown in table (1).

Search tools and devices: The search included the following tools and devices:

- Arab Sources
- Observation
- Questionnaire

Either used equipment:

1. Hand calculator.
2. A computer type (dell).

Field research procedures:

Procedures for setting up the research criteria: It was based on the scientific sources and the personal scale of (Essam Mohammed Abd Al-Redha), which consists of (24) items to be answered by the examinee. The scale was presented to a group of experts and specialists (Appendix 3) and they expressed their opinion on the adequacy of the scale with some minor modifications and appeared in His final image.

As for the measure of achievement motivation, it was based on the measure of achievement motivation which has been applied in the Iraqi environment, where the scale consists of (31) paragraph answered by the examinee and also presented to the experts and specialists and showed his suitability to work.

Pilot study: The researcher carried out the pilot study on 12/12/2017 on 12 players from Al-Furat Middle Technical University from the Technical Institute in Kufa, where he was able to identify the extent of the players’ understanding of the standards and the clarity of the instructions and overcome the difficulties that may occur in order to prepare for the main application of the measurements.

Correction method for the meter: The measurement of the personality of the obsessive (24) paragraph and answer them according to three alternatives (often, rarely, rarely) and weights are given to grades (1,2,3) respectively for the positive paragraphs and vice versa.
negative paragraphs As for the measure of achievement motivation consists of (31) The player answers them according to four alternatives (which apply to me to a large extent, apply to me to a medium degree, apply to me to a small degree, do not apply to me) and score (1,2,3,4) respectively, and this answer to the positive paragraphs and vice versa negative paragraphs.

Total score calculation: Since the measure of personality is composed of (24) paragraphs, the highest score of the player is (72) and the lowest score is (24) and the mean of the rate (57.34) and the standard deviation reached (4.97) As for the measure of achievement motivation consists of (31), So the highest score for the player is (124) and the lowest score is (31) and the mean (39.76) and the standard deviation reached (3.85).

Main experience: This was done during the Euphrates Middle East Technical tournament for the period 6-11/12/2017 and in the collective style and at the Technical Institute in Kufa where the questionnaire forms were distributed on the sample of (96) players and after the measurement by the players the forms were collected for the results of the research.

It is evident from Table (2) that the value of the arithmetic mean is greater than the mean value of the research sample, which indicates that they have an unbalanced, obsessive personality. Therefore, the calculated value is less than the tabular value at the level of freedom (11) (0.05) indicating significant differences between calculated and tabular scores. As for achievement motivation, Table (3) shows how to identify the motivation of achievement in the research sample and the relationship between the arithmetic mean and the mean medium.

Table (3) shows that the value of the arithmetic mean is less than the mean value of the mean, indicating that the sample of the research in the achievement motivation is low. Therefore, the value of (t) between the arithmetic mean and the mean is not significant at the significance level (0.05) (t) is smaller than the tabular value (t), indicating that the differences between them are not significant between the calculated and the tabular of all the participating teams.

Identify the relationship between the personality and the motivation of achievement in the research sample:
To find out the relationship between the personality and the motivation of achievement in the sample of the research, it is necessary to find correlation coefficient (Pearson) as in Table (4).

</table>

As shown in table (4), the relationship between intuition and motivation is negative, and the reasons are many. The researcher attributes it to the concerned personality in the study sample, which affects the level of performance of the players because “there is a statistically significant inverse relationship in the level of personality and skill performance at the level of the player. For the player to achieve the psychological stability and personal stability of the player to achieve stability in the level of the player and the success of the player in the achievement of motivation to achieve an effective motivation to achieve otherwise the opposite happened and balance and control and stability depends on the experience of the player because “sports experience has an important role and effective in the to control unwanted psychological situations before racing and competition, as providing emotional excitability at a good level helps to achieve motivation for a good achievement.”

The motivation, motivation, pleasure, joy and pleasure of the trainer in the training modules have a positive effect to increase the motivation of achievement of the player so.”

The successful coach is skilled in organizing the physical and psychological energies of the players and how to control and control the ideas and feelings of players during the competition, making the performance develops correctly “. The construction of an influential and balanced personality that depends on stability distanced the tension and anxiety and dispersion of the ideas that accompany the performance in strong games because”.

The optimum excitation rate leads to behavior and effective performance. “It has been achieved by imposing the search for a relationship Between the personality of the obsession and motivation of achievement, but this obsessive must be at a level that can be used and is not effective in the player’s motivation is done through the preparation of good psychological by the coach during the training period and to familiarize the player on how to cope with the difficult conditions with control and without nervous in order to benefit from this personality Positivistically to increase motivation and achieve good team performance “.

Conclusions

1. Owning a sample of the search on a personality and a large and high and low motivation and achievement.

2. There is an inverse relationship between the achievement motivation and the obsessive personality of the research sample.

3. The adoption of one of the means of mental training works to reduce the degree of personal obsessive and the player’s level of good after the end of warm-up and the beginning of competition.

Building the Predictive Scale for the Psychological Efficiency of the Athletes Students at Al-Furat Al-Awsat Technical University

Hameed Shamkhi Ghazi
Directorate of Student Activities, Al-Furat Al-Awsat Technical University, Iraq

ABSTRACT

The objectives of the research focused on the preparation of a questionnaire to build a predictive measure of psychological efficiency for the students of the athletes of the University of the Middle Euphrates technical, as well as “the recognition of predictions of psychological efficiency, and applied research on a group of athletes at the University of the Euphrates Middle Tech for the period of 22/11/2017 and The researcher used the descriptive method in the survey method. The most important steps of the research are to limit the number of athletes in Al-Furat Al-Awsat Technical University from the students. The main questionnaire was composed of (48) Building a collective and individual scale, as required (325) questionnaires were returned (301), (24) of which were excluded due to lack of complete answer.

The number of valid questionnaires reached (265) questionnaires In the final statistical analysis, using the appropriate statistical methods, and then presenting them, analyzing them and discussing them in a scientific manner based on the relevant sources and references, and then concluding the conclusions, the most important of which was the establishment of a suitable questionnaire to build a predictive measure for the psychological efficiency of the students. In the light of these conclusions, the researcher recommended a number of recommendations, including the possibility of using the current measure by the supervisors of athletes at the University of the Euphrates Middle Tech, as well as the need to pay attention to the psychological side, especially with regard to students in the same physical, skill and educational aspects.

Keywords: Building, predictive scale and psychological efficiency.

Introduction

The relationship between psychology and sports and physical games is an interrelated and dialectical relationship that is characterized by the interaction of the living and cannot be separated from this link as psychology generally addresses the problems experienced by individuals in their lives, which appear in the form of emotions and acute and sometimes abnormal and in the form of deviations, disorders and diseases and psychological contract. Psychological problems are always the result of the poor compatibility of the individual with himself on the one hand and poor compatibility of the individual with his environment and the environment on the other. This causes failure to achieve the individual’s goals and satisfy his psychological needs. And social and social. “Mathematical psychology plays an important role in the lives of individuals, as it directly affects their behavior, and therefore we can see its effects in many of their actions. Sports psychology can be seen as a kind of motivation, desires, mental and physical abilities, attitudes, skepticism, fear, And control and stability and other cases are acquired and fungus and develop experiences in the first case and since birth in the second case can be developed. 1

The individual must strive for success and that “feeling inferior is normal for people and can lead to a state of creativity and that the goals are In order to overcome the problems by the creative force inherent in the human that helps to achieve the natural talents
to achieve the psychological.” Hence the importance of research in the creation of the measure and test the relationship between testosterone and the accuracy of the performance of some of the basic skills of volleyball players being trying to shed the first is the accuracy of the performance of the skilled as well as the study comes in the field of volleyball.²

The choice of the problem has major criteria that must be taken into consideration, including the originality of the problem, its novelty, its theoretical importance, its scientific value, the availability of adequate literature relevant to the problem and its compatibility with the researcher’s interest, experience and qualifications. In the process of research, which prompted the researcher to choose his problem when he felt the existence of a confusing and mysterious situation needs to know and answer or solve through the guidance of expert opinions and sources of information, which provides knowledge about the problem. And through the follow-up of the researcher for most of the matches of the Iraqi league and the Iraqi universities and for many years, noted the weakness of the result of lack of interest in the trainers most of the vocabulary of the current training modules do not rely on appropriate psychological situations commensurate with the effort and emotions that appear on the players, Iraqi teams during interviews, Thus, through the work of the researcher in the field of training of the university sports teams and coach of the team of the University of the Euphrates Middle Tech and the Kufa Sports Volleyball Club for many years, observed in different games, especially for Iraqi universities, the player is different in the elements of predictions of psychological efficiency during matches and at the same time noticeable changes in the level Predictions of psychological competence and for that the researcher has always overcome negative situations and find the appropriate level of balanced personality of players and access to the level of good championship.³

Research Methodology

The researcher used the descriptive approach in the method of correlative relations to suit the study, which is the method used by the researchers to be able to obtain accurate and accurate information to portray the social reality that affects all activities.

Research community: Is “all individuals, objects or persons who constitute the subject of the research problem, which is all elements related to the problem of the study to which the researcher seeks to generalize the results of his study”. Thus, the research society included the athletes of the University of the Middle Euphrates technical (325) athletes as shown in Table (1).

Sample: The sample was selected from the original community consisting of (325) players from the teams of institutes and colleges (312) athletes, who constitute 96% of the society of origin. They are distributed among eight institutes and colleges. The 13 respondents who were randomly selected from the community of origin were excluded (4.16%).

Scientific steps of the psychological efficiency prediction scale: The initial preparation of the scale formula for prediction of psychological efficiency requires many procedures, including the process of drafting the standard paragraphs that are appropriate to the study society, as well as setting instructions on how to answer them and methods of correction.

1. See the sources and references.

2. To see the previous studies, standards and questionnaires in physical education and self-employment that relate to personality and predictions of psychological competence.

Determining the method of drafting and responding to paragraphs: The process of setting up the scale paragraphs is one of the most important steps in the
construction of the scales. The measuring instrument stops measuring what is being measured to a large extent on the accuracy of its performance and its representation of the attribute to be measured. “Therefore, the researcher must be attentive and fully aware of the instructions the preparation of the paragraphs and their specifications because the standard characteristics (paragraphs) of the paragraphs, has been adopted (3) In the selection of alternatives to the scale, and the alternatives of the scale were chosen on the proportion of the agreement (75%) by choosing one of two alternatives (yes) or (no).”

Formulate paragraphs as follows:
- Include the paragraph on one phrase.
- Phrases formulated in the form of the speaker.
- Do not use the words that bear the answer or to bear the answer of everyone so as not to lack the opportunity for the researcher.

Formatting the paragraphs of the scale: Of the “Building Conditions of Psychological Standards” that the instructions to answer them are clear to those who prepare the scale, as well as to conceal the true purpose of the scale (not to write the scale name) to obtain true data “(1). (3) of the Psychological Prediction Scale, and was presented to the experts and specialists to demonstrate their validity to measure the purpose that was developed and excluded (75%). Thus, the agreed paragraphs are (12) paragraphs and the proportion of agreement (80%). “Bloom points out that (0) the rate of reliance on expert approval is 75% and more in such a kind of truth.”

Pilot study: To demonstrate the validity of the scale, the pilot study was conducted on a sample of (13) athletes representing the Technical Institute Kufa volleyball on 22/12/2017. The purpose of conducting the exploratory experiment is as follows:
1. Understand the comprehension and comprehension of the subjects of the scale.
2. Identify the constraints and factors that appear when the scale is implemented and exceeded in the exploratory experiment.

Statistical Analysis of Psychometric Prediction Scale: “The criterion of testing and the good measure is to conduct statistical analysis of its poverty to distinguish between individuals who have obtained high grades and who have obtained low degrees of the scale, that is, the extraction of the power of the parity of the paragraphs”.

The characteristics of the scale depends to a large extent on the characteristics of cykometrics of the paragraphs, In their degrees, the more their distinct power gives an indication of the accuracy of the performance of the scale and its ability to measure what was put to measure. The statistical analysis was conducted in two ways:

1. Internal consistency factor: In order to reach the power of excellence, we must use and extract the internal consistency of the paragraphs. “This method gives us a homogeneous scale in its paragraphs. Each paragraph measures the same behavioral dimension measured by the scale as a whole. With an internal check that is the scale of the scale as a whole. “(2) Table 2 is also constructed.

2. The two radical groups: One of the objectives of the analysis of the paragraphs is to “ensure that they are sufficient to achieve the principle of individual differences on which the scale is measured. Therefore, the power of distinction is calculated for the purpose of retaining the distinguishing paragraphs and deleting the undefined paragraphs.” The scores obtained by the players were arranged in descending order (27%) of the upper and lower grades of the two extremes were selected. Stanley and Hopkins assert that “this ratio makes the two groups ideal for reservation and differentiation”.

Stability of the scale: “The stability tests are necessary indicators and the researcher used the half-way method because it requires a one-time test.” The data obtained by the researcher regarding the scores of answers (13) were adopted. This method depends on the split of the test into two parts, the first part contains the individual numbers, and the second part contains the even numbers. The simple correlation coefficient (Pearson) was calculated between the scores indicated between the scores which reached (0.841). This method represents the stability coefficient of half the test.
Table 2: Correlation coefficients between the score of each paragraph in the total number of the construction sample of the psycho-psychological efficiency prediction scale

Correction of scale: After the completion of the scientific transactions by the researcher for the paragraphs of the scale of predictions of psychological efficiency, based on the previous procedures, the standard in its final form consists of (13) paragraphs see Annex (1). The answer will be answered by choosing one of two alternatives, namely (yes) or (no), with two degrees of response (yes) and one score for the answer (no) and the total score of the scale ranged between (48 - 96).

Results

Table 4: Shows the mean, standard deviation, standard error, and torsion coefficient to predict the psychological efficiency of the sample members

Discussion of results: The study showed that the majority of the study sample was centered in the intermediate level and (159) out of (312) athletes from Al-Furat Al-Awsat Technical University of the Psychometric Prediction Scale. And the provision of support and incentives to them and provide the requirements that help them to provide a better level, especially on the psychological side, which led to the prediction (average), because most of the activities of the University of the Middle Euphrates technical focus on the physical, technical and technical rather than on the psychological side, especially Efficiency prediction Psychological competence is one of the basic dimensions of the mathematical personality and the athlete’s appreciation of it has a good impact on facing the problems, obstacles or obstacles facing him during his sports career and achieving the desired goals and aspirations towards the predictions as well as their affiliation to Al-Furat Al-Awsat Technical University to enhance their tendencies and achieve and develop the social aspects of During the various activities which are part of the curriculum and various activities that include the formation of values, habits, skills and methods of thinking in the construction of personality.11

Conclusions

1. Achieving the construction of an appropriate measure of self-efficacy predictions for athletes at Al-Furat Al-Awsat Technical University.
2. The vast majority of the research sample was at the intermediate level in the current scale.
3. The poor level was (10%) and the good level was (48%).
4. Athletes at Al-Furat Al-Awsat Technical University have enjoyed general efficiency.

Lymphocytosis and Increases in Complement Protein C3 Level in Women with Polycystic Ovarian Syndrome

Sahlah Kh. Abbas¹, Aseel Sh.Abdullah²
¹Department of Biology, ²Environmental Research Unit, Collage of Science, University of Kirkuk, Iraq

ABSTRACT

Background: Polycystic ovarian syndrome is a common endocrine disorder affects women in reproductive age. The inflammatory markers play an important role in this disease. Therefore, this study was aimed to evaluate the hematological, some biochemical and serum levels of C3 in women with polycystic ovary syndrome compared with healthy women.

Method: Hematological parameters, lipid profile and complement protein C3 serum levels, were evaluated in 60 women (30 obese and 30 lean) women with Polycystic ovarian syndrome whose age ranged between (17-43 years), in addition to 30 healthy women as controls. The patients attended Azady Teaching Hospital in Kirkuk city, Iraq for diagnosis and treatment during the period from September 2017 to March 2018.

Results: Analyzing the collected data, we observed significant increase in total white blood cells, monocytes, lymphocytes count, and serum level of complement protein C3 in women with Polycystic ovarian syndrome compared to control subjects (P<0.001).

Conclusion: This study suggested that changes in inflammatory markers in women with Polycystic ovarian syndrome predispose them to increased risk of type 2 diabetes mellitus and cardiovascular events. Raised thyroid stimulating hormone suggested a possible role of thyroid dysfunction in the pathogenesis of Polycystic ovarian syndrome.

Keywords: Polycystic ovarian syndrome, Hematological parameters, Lipid profile, Complement protein C3, TSH.

Introduction

Polycystic ovarian syndrome (PCOS) is one of the most common hormonal disorders affecting approximately 6-20% of women in reproductive age [1] and it’s characterized by the presence of small saes filled with ovarian fluid causes infertility resulting from non-ovulation, this is identified by irregular menstruation [2].

PCOS is characterizing by many clinical symptoms such as diabetes, coronary artery disease, hyperandrogenism, obesity [3], the appearance of acne and hirsutism. The causes are not known accurately and multiple opinions in the interpretation of the occurrence, including disorders of the hormones stimulating Menopausal Gonadotropins or a defect in the pituitary gland resulting in an increase in the hormone Lutin to the hormone stimulating the follicle, or the result of disorders in the adrenal gland [4]. The other opinion has pointed to the role of insulin in increasing the secretion of male hormones, especially testosterone resulting from the presence of resistance to insulin. The syndrome leads to a disorder in the distribution of fat, cardiovascular disease and endometrial cancer, and affects the external appearance of women due to obesity, acne and hirsutism [5]. It is widely known that total and deferential count of white blood cells (WBC) [6] and serum level of complement protein C3 were elevated in women with PCOS [7]. Complement protein C3 is highly related with dyslipidemia, insulin resistance and hypertension. It is considered a high risk factor in the causation of diabetes mellitus type II [8]. Accordingly, this study was aimed to evaluate the role of total and differential count of white blood cells, dyslipidemia and change in the serum

DOI Number: 10.5958/0976-5506.2019.03257.1
level of complement protein C3 in patients suffered from polycystic ovaries syndrome compared to healthy women in Kirkuk governorate, Iraq.

Materials and Method

This study conducted in the laboratories of Azady Teaching Hospital in Kirkuk governorate for the period from September 2017 to March 2018. Sixty women with polycystic ovarian syndrome and an age range of 17 to 42 years enrolled in this study. Special questionnaires were prepared and the diagnosis confirmed clinically and by using ultra sound scanning by the medical staff at the hospital. In addition to the patients group, the study included 20 women as control group after ensuring their safety of hormonal disorders or other chronic diseases.

A 5-ml sample of fresh venous blood was collected from each woman under study and 2ml placed in a tube containing the anticoagulant (EDTA) for the examination of hematological parameters using self-work Autoanalysis hematology, and 3ml transferred in a test tube and centrifuged at 1500rpm for 15min to obtain serum for serological tests.

Levels of cholesterol and high-density lipoprotein in the serum were determined using kit from the British company Randox according to the instructions provided by the company. To determine serum level of triglycerides used kit processed by CTM (UK) according to the instructions of the supplier company. Complement protein C3 determined using single radial immunodiffusion plate provided by Busserio company/Italy. CRP agglutinin test measured using Biocon/German kit.

Statistical Analysis: Data were analyzed using statistical package for the social science (SPSS) version 13, and presented as mean±SD. A t-test used to measure the differences between the two groups. P-value less than 0.05 considered statistically significant.

Result and Discussion

As shown in Table (1), out of the 60 patients with PCOS, 45 were married (75%) and 15 were single (25%). Irregular menstrual cycle presented in 80% of patients, it is a feature of polycystic ovarian syndrome. Hirsutism found in 81.6% of patients. In addition, 31.1% had primary infertility (that affects women since the beginning of life) and 68.8% had secondary infertility (affecting women after one or two children reproduction or after abortion). In addition, 18% had higher level of TSH. Moreover, all women (100%) had positive agglutination for C-reactive protein (CRP) test, it is a non-specific marker of inflammation and the most predictor of risk of cardiovascular conditions in women with polycystic ovarian syndrome with or without of cardiovascular events [9].

In Table (2) the mean±SD of age was (25.89±6.90) years in patients, and (23.89±4.56) years in controls (P=0.329). Body mass index in cases and controls was 27.14±4.7 and 23.22±2.17 kg/m², respectively, (P ≤0.05). The waist circumference in patients and controls recorded as 85.36±4.04cm and 73.3±5.1cm, respectively, the mean of waist hip ratio were 0.87±0.03cm and 0.80±0.05cm, respectively. The systolic and diastolic blood pressures was (122±16.43mmHg) and (82±8.36mmHg) in patients.

Our study indicated significantly increased count of the total white blood cells, monocytes and lymphocytes in patients compared with healthy women. These results were in agreement with other studies which revealed elevated count of total WBC and lymphocyte in PCOS patients [6,10]. Increased total and differential counts may give an indication of chronic inflammation in infected women [11]. These cells have immune functions that may be complementary to each other and contribute positively to enhancing the immune response. Increased WBC is involved in the process of atherosclerosis and recognized as a marker of cardiovascular disease [12]. Also, the increase in these cells may be due to increased production of IL-1 and IL-6, which stimulate production of white blood cells and proliferation of all their kinds from bone marrow, causing an increase in the number of peripheral blood cells [11,12]. Increased monocytes count may lead to development of cardiovascular disease by stimulating the formation of thrombosis in the affected endothelial cells of blood vessel [13]. Increased lymphocytes count (Lymphocytosis) may reflect the chronic status of disease, lymphocytes play a role in identification of non-self-antigens and then respond against them with help of other immune cells modulated through inflammatory cytokine [14]. Metabolic abnormality, especially, dyslipidemia is a common metabolic disturbance in women with PCOS [15]. Our study confirmed the increased level of total cholesterol, which is considered as a risk factor for cardiovascular disease when combined with a low level of high-density lipoproteins in adult women [16].

In addition, the mean serum level of complement protein C3 increased significantly in patients compared with control group. This finding was consistent with previous studies [7,8], but not in agreement with [17] who did not find such relation between level of complement component C3 and poly cystic ovarian syndrome. Complement protein C3 is an acute phase protein produced by the hepatocyte, macrophage and by the adipose tissue. Increased level of this protein maybe associated with obesity, dyslipidemia, and hypertension as well as insulin resistance [7].

C3 fragments enhance proliferation of T lymphocyte when fixed to the APCs and form a bridge between the APCs and T lymphocyte, which enhances cell-to-cell contacting intracellular signaling.

This study revealed that 11 women out of 60, who did not respond to the treatment, had higher levels of thyroid stimulating hormone (TSH; 6.32±3.22nmol/L) and all of them considered to have hypothyroidism. This observation was in agreement with others who revealed a close association between polycystic ovarian syndrome and abnormal thyroid function [4,18]. Furthermore, [19] stated that long time hypothyroidism enhances cyst formation and bigger ovarian size.

When we analyzed the results between obese and lean women with polycystic ovarian syndrome, obese patients had higher levels of total cholesterol and LDL ($P<0.05$) than did lean patients (Table 3).

*: P<0.05 considered significant difference between groups.

Many studies had reported that LDL-C is increased in obese or over-weight women with PCOS $^{[20,21]}$. Increased LDL-C levels may be related to genetic factor and hyperandrogenism in women with polycystic ovarian syndrome, and such alterations may be associated with increased cardiovascular risk $^{[16,22]}$. Previous studies revealed that C3 level associated with abdominal adipose tissue $^{[23]}$, and it had important role in the pathogenesis of low-grade inflammation $^{[24]}$. Obesity increases the risk of metabolic dysfunction and insulin resistance. Moreover, increased C3 concentration reflected metabolic syndrome in obese subjects especially when related with other factors such as CRP and ESR, and these were strongly related to insulin resistance $^{[23]}$.

**Conclusion**

From this study, we concluded that women with PCOS had higher levels of some inflammatory markers such as TWBC, monocytes, lymphocytes count, increased serum level of complement C3 and CRP. All that might reflect a chronic low-grade inflammatory status, which is considered as a risk factor for cardiovascular complications. On the other hand, increased TSH level may suggest a possible causational relationship between thyroid dysfunction and polycystic ovarian syndrome.

The Prevalence of PCOS in Infertile Women According to Clinical Features and its Associated Hormonal Changes in Al-Hilla City, Iraq

Ban Amer Mousa
Department of Gynecology and Obstetrics, College of Medicine, University of Babylon, Iraq

ABSTRACT

Background: Polycystic ovary syndrome is a significant hormonal condition that occurs due to ovulatory reason of infertility in reproductive age females. Polycystic Ovary Syndrome is a group of clinical features. These with Polycystic Ovary Syndrome commonly have two of the following criteria: (menstrual) ovulation disorders, abnormal levels of androgens (biochemical or clinical) and polycystic variations in the ovary (thick stroma looks-like “string of pearls” on the surface of an ovary by U/S). Polycystic Ovary Syndrome was a women problem which cumulating in our women society without significant reasons. The aim of current study was to estimate and diagnosis infertile women with Polycystic Ovary Syndrome and its degree confer to procedures of diagnosis concerning markings outcomes of its investigations as well as appraisal of its spread in AL- Hilla City, Iraq.

Method: A case-control study carried out for patients from infertility unit in private clinic and Babylon Teaching Hospital during the period from January 2017 to the end of December 2017. In this study, 100 infertile women were enrolled randomly. Their histories regarding symptoms like (excessive hair growth, acne and amenorrhea) were recorded, their age, number of infertility years. In addition, Prolactin, FSH/LH ratio, BMI, AMH hormones were done in lab. Then antral follicular count was estimated for them through vaginal U/S. Verbal and written consents were taken from participants for their admission.

Results: Data from current study showed that the percentage of PCO in infertile women, who were diagnosed by signs and symptoms, was 33.0%. In addition, the Mean ± SD of LH/FSH ratio, LH, FSH, AMH and prolactin of infertile women with PCOS, who were diagnosed through signs and symptoms, was 1.8, 2.07 ± 0.77, 12.19 ± 4.55, 5.97 ± 6.62 ± 2.17 and 33.97 ± 10.36, respectively. Also, data showed that the Mean ± SD AFC and ovarian size of infertile women with PCOs, who were diagnosed by signs and symptoms, was 13.58 ± 5.1 and 16.45 ± 4.48, respectively.

Conclusions: Data from present study and other same studies revealed that the incidence of infertility is about 12% and found fright increase of infertility in couples. In addition, with progress of age the incidence of PCO in general females is about 35%.

Keyword: infertility, Anti-mullerian hormone, polycystic ovary syndrome, antral follicular count, FSH.

Introduction

Ladies present with irregular cycles, period of prolonged aminohrria, excessive hair growth on her face and body, scalp hair loss, acne, dark skin pattern on body folds such as thighs and neck and history of gaining weight (1). Incidence of infertility in the world is about 12%. Infertility is an increasing challenge between couples wanted babies and had multiples causes with 1/3 male causes, 1/3 female causes and 1/3 unexplained causes, but especially in Iraq, it has more incidence than that written.

in books for a lot of reasons which need a lot of studies to document the real problem and try to find possible solutions. Numerous principles for diagnosis of Ovarian Syndrome commonly (PCOS) have been proposed. The Rotterdam criteria are highest broadly used diagnostic method for PCOS detection which is established with existence of two from the following features (2):

1. Oligomenorrhea and amenorrhea.
2. Presence of overexcited androgenism.
3. Polycystic ovaries texture on vaginal U/S.

It has been confirmed that ladies with PCOS have an amplified danger for infertility, hypertension, cardiovascular disease, metabolic disorders, Type 2 diabetes mellitus, obesity (carbohydrate intolerances), sleep apnea and endometrial hyperplasia and endometrial carcinoma. A probable connection between all these disorders in addition to cardiovascular disease was insulin resistance, which was existent irrespective of BMI, but exploited by obesity (7). It was newly recognized a compromised cardiopulmonary functional capacity strictly related to insulin resistance in women with these diseases (8). Hence, it should be diagnosed as quickly as possible to avoid and treat related disorders earlier if possible. Diagnosis of PCOS depends on clinical features and method of diagnosis being used. Also, the incidence of PCOS differs from region to region (3). Causes of PCOS at this time are unknown, even though scientists consider that hereditary and ecological features had major causes for its occurrence. Main threatening factor for it is having a family history of PCOS.

There is no cure for this syndrome but there are methods to improve symptoms. The latter include lifestyle modifications like decreasing weight, diet, taking adequate exercise and leaving smoking if present. The prevalence of PCOS varies with diagnostic principles. PCO on U/S was distinguished in up to 25%-30% from reproductive aged females (4,6). Anti-mullerian hormone (AMH) was one of prospective blood tests for evaluation for female fertility done at any time of the cycle, especially to detect ovarian reserve and there are other important test currently used in the last decades for evaluation of the remaining ova in ovaries supply which is the antral follicles count (9). Fertility professionals frequently use a mixture of fertility investigations to best evaluate female’s ovarian reserve, comprising transvaginal U/S to count the number of antral follicles and AMH levels. It is important to remember that AMH levels decrease and FSH levels rise as females age progresses. Age-related Standard FSH and AMH Levels (10) are shown in Table (1).

The aim of current study was to estimate and diagnosis infertile women with Polycystic Ovary Syndrome and its degree confer to procedures of diagnosis concerning markings outcomes of its investigations as well as appraisal of its spread in AL- Hilla City, Iraq.

| Table 1: Age-related Standard FSH and AMH Levels |
|-----------------|--------|--------|
| Age/yr          | FSH (mIU/mL) | AMH (ng/mL) |
| <33             | <7.0    | = 2.1  |
| 33-37           | <7.9    | = 1.7  |
| 38-40           | <8.4    | = 1.1  |
| ≥41             | <8.5    | = 0.5  |

Materials and Method

Current study was cross-sectional study that involved 100 infertile females. Their histories about important related symptoms such as (acne, amenorrhea and excessive hair growth) were recorded; their age was between (21-44) years, period of infertility (3-20) years, their BMI ranged from 24 to 37Kg/m². Then, their hormonal analysis (FSH, LH, Prolactin, and AMH) was done. Also, their ovarian size and antral follicular count were measured by endovaginal U/S at day 2-4 of the cycle.

Data were presented as numbers, range, mean and standard deviation. Comparisons were made using unpaired t-test. Level of significance was considered at P≤0.05.

Results

Figure (1) showed that the percentage of PCO in infertile women, who were diagnosed by signs and symptoms, was 33.0%.

Figure 1: Proportions of the patients with polycystic ovary diagnosed via signs and symptoms
Table 2 showed that the Mean ± SD of LH/FSH ratio, LH, FSH, AMH and prolactin of infertile women with PCOS, who were diagnosed through signs and symptoms, was $1.8, 2.07 \pm 0.77, 12.19 \pm 4.55, 5.97 \pm 6.62 \pm 2.17$ and $33.97 \pm 10.36$, respectively.

Discussion

Antral Follicle count (AFC) has been found to be a credible sign for ovarian reserve (9). Women with PCOS are exceedingly sensitive to gonadotropin stimulation, information of age-related AFC is clinically important. Age-related normogram for AFC in women with PCOS by using transvaginal ultrasound were published by (9) who found that the decline in number of AFC as the age progresses was linear and slower in PCOS when compared to infertile women without PCOS.

AFC correlates negatively with age. A percentile normogram will be useful to inform a woman about her ovarian reserve relative to her age group. The ovarian reserve decline rate relative to age group is important because of declining fertility with increasing age (7).

The prevalence of PCOS is conventionally estimated at 4% to 8% of all reproductive age females based on studies performed in Spain, Greece and the USA (10-13). The prevalence of PCOS has increased with the use of different diagnostic criteria and has recently been shown to be 18% (17.8 ± 2.8%) in the first community-based prevalence study based on current Rotterdam diagnostic criteria (14).

Significantly, 70% of women in this recent study were undiagnosed (15). PCOS has also been noted to affect 28% of unselected obese and 5% of lean women (15-18). Hopefully, lifestyle interventions including dietary, exercise and behavioral therapy improve fertility and reduces costs per birth significantly (19).

AFC is considered one of the authoritative signs for evaluation of ovarian reserve (19-21). The total ovarian volume and the number of antral follicles measured through transvaginal US predict declining fertility related to reproductive age. AFC has the closest connotation lower in infertile women than in matched controls with increased chronological age. In Indian women the baseline and cut-off values are lower than that mentioned in the Western literature (21). Because of low cost and high predictive value, AFC is commonly used and is careful best clinical predictor for ovarian response in assisted reproductive technology (21).

Conclusion

Data from present study and other same studies revealed that the incidence of infertility is about 12% and found fright increase of infertility in couples. In
addition, with progress of age the incidence of PCO in general females is about 35%.

ABSTRACT

Background: The post-operative management of a patient’s fluid balance is one of the most critical aspects of hospital care. Nowadays, many opinions exist as to the best volume of intravenous fluid after elective surgery, as recent studies suggested that a reduction in fluid need after operation to lowest need to reduce complication and postoperative hospital stay. The aim of current study was to evaluate fluid requirement and maintenance in patients after elective laparoscopic cholecystectomy in comparison with elective open cholecystectomy.

Method: A prospective study involving cholecystectomized patients at Al- Diwaniyah Teaching Hospital for the period from February 2018 to February 2019. Age, sex, body mass index, bowel sound parameters used and selection with aid of American society of anesthesiologists classification also used. Post-operative fluid regime of formula with 10ml/kg of glucose saline was used for the first 8 post-operative hours, with follow up chart. Onset of oral intake and discharge from hospital were discussed and evaluated.

Results: Our study included 140 patients who underwent cholecystectomy ; 90 patients with laparoscopic cholecystectomy and 50 patients with open cholecystectomy. The patient’s median age was 40 years. There were ninety two females (66%) and forty eight male (34%) patients. In patients with laparoscopic cholecystectomy; 78 patients (87%) needed no further fluid support, resumed oral intake and discharged home within 10-14 hours after operation, whereas 34 patients (68%) of open cholecystectomy were continued on intravenous fluid support. Discharge of all patients with open cholecystectomy was after 24 hours. Statistically, there was highly significant timing change in starting oral feeding in laparoscopic cholecystectomy and timing to start oral intake in comparison with open cholecystectomy, and showed highly significant relation between age of patient and timing needed to start oral intake postoperatively. On the other hand, there was no significant relation between age and time needed to start oral intake postoperatively in open cholecystectomy.

Conclusions: Restrict post-operative intravenous fluid for maintenance therapy in elective and uncomplicated laparoscopic cholecystectomy in fit patients in the aim of early discharge of patients from hospital as a day case surgery.

Keywords: laparoscopy, cholecystectomy, intravenous fluid, oral intake, postoperative.

Introduction

The post-operative management of a patient’s fluid balance is one of the most critical aspects of hospital care. Nowadays, many opinions exist as to the best volume of intravenous fluid after elective surgery, as recent studies suggested that a reduction in fluid need after operation to lowest need to reduce complication and postoperative hospital stay. Normally, the optimum physiological change secondary to stimulant factor like operation leads to increase intake of water and sodium, and loss of potassium. Open cholecystectomy increases the levels of antidiuretic hormone (ADH), cortisol, aldosterone and catecholamines where they play many physiological changes to maintain osmotic stability.
Minimally-invasive techniques that require general anesthesia have a greater physiologic effect because of the anesthesia pneumoperitoneum which may lead to lowering renal blood flow and urine output (4). This decrease in renal blood flow leads to increasing sodium retention. Pneumoperitoneum also leads to increase ADH (5). Also, insensible fluid loss in open cholecystectomy is absent during laparoscopic operation.

Regulation of total body water: If water loss exceeds gain, a reduction in total body water content and the osmolality of body fluid increase. This has two effects; Thirst, with consequent ingestion of water and Release of ADH so that water is retained by the kidneys. Other mechanisms are available for stimulation of thirst and ADH release, these include:

1. Reduced arterial blood pressure (signals via carotid and aortic baroreceptors),
2. Reduced central venous pressure (signals via atrial low pressure receptors) and
3. Increase angiotensin II in the brain. These mechanisms reflected by change in pulse rate and blood pressure, both can be used for patient’s monitoring (7).

The aim of current study was to evaluate fluid requirement and maintenance in patients after elective laparoscopic cholecystectomy in comparison with elective open cholecystectomy.

The objectives of current study were

1. to sharpen the effect of restriction of post-operative intravenous fluid in laparoscopic cholecystectomy on discharge of patients from hospital as a day case surgery,
2. To study the influence of application of this regimen to different age groups and sex, and
3. To make the results of the study available to the health authority in order to improve the services required to deal with this condition.

Patients and Method

It’s prospective, comparative study performed at Al–Diwaniyah Teaching Hospital for the period between February 2018 and February 2019. The study included 140 patients presented with symptomatic chronic cholelithiasis, proved by clinical examination and ultra-sonic evaluation, were prepared for elective cholecystectomy. The decision for the type of operation (open or laparoscopic cholecystectomy) was determined according to surgeon’s recommendation, anesthetic opinion and patient’s preference. Patients who had ASA grade 3 or more and those with laparoscopic operation converted to open cholecystectomy were excluded from the study. Patients were entered to the hospital one day before surgery and an informed consent was taken. All patients were fasting for eight hours for solid food and 4 hours for fluid before surgery. Patients received a single prophylactic dose of ceftriaxone 1gm intravenously at the induction of anesthesia. No intravenous fluids were received before operation. The operation was done under general anesthesia. Post-operatively, all patients received 10mL/kg of intravenous glucose saline (5% dextrose with 0.45 NaCl) infused over 8 hours through a peripheral intravenous line. Patients were also given paracetamol vial (1000mg/100ml) every eight hours. A follow up chart that included pulse rate, blood pressure and bowel sounds to be assessed every two hours together with absence or presence of vomiting.

These parameters were collected and registered in a special formula together with patient’s body parameters (body weight, height and body mass index). Comparison was made between the two groups (open vs. laparoscopic) regarding the aforementioned parameters after 8 hours and the ability to resume oral intake was assessed depending on the return of bowel sounds and the absence of vomiting as well as hemodynamic stability. All patients were advised to mobilize 6 hours post operation.

Data were presented as numbers and percentages. Comparisons were made using Chi-squared test and level of significance was considered at P value ≤0.05.

Results

Our study included 140 patients who underwent cholecystectomy at AL-Diwaniyah Teaching Hospital, 90 patients with laparoscopic cholecystectomy and 50 patients with open cholecystectomy. Patients’ age varied from 20 to 60 years with an average of 40 years. In addition, ninety two were females (66%) and forty eight were males (34%).

Assessment of patients who underwent laparoscopic cholecystectomy revealed that 78 patients (87%) were hemodynamically stable, had audible bowel sounds and got no vomiting at the end of the first 8 hour
postoperatively. Therefore, those patients required no further fluid support and they resumed oral intake. They were discharged home within 10–14 hours after operation and given an appointment for further surgical follow-up.

On the other hand, 12 patients (13%) did not resume bowel activity, had vomiting or showed unstable hemodynamic state, they were not allowed to resume oral intake, kept on intravenous fluid and their discharge from hospital was delayed until stabilization and resumption of oral intake.

Sixteen of patients (32%) with open cholecystectomy could start oral intake after the first 8 hours, whereas 34 patients (68%) were continued on intravenous fluid support as they had vomiting, absent bowel sounds, or hemodynamic instability. Discharge of all patients with open cholecystectomy was after 24 hours. Those who started oral intake were discharged next morning; others were kept in hospital till resumption of oral intake and discharged within 24–28 after operation.

Statistical studies showed highly significant relation between laparoscopic cholecystectomy and time needed for starting oral intake ($X^2 = 13.8; P$-value <0.001 at 99.9 confidence interval) in comparison with open cholecystectomy as shown in Table (1).

The relation between age of patients and resuming oral fluid intake was shown in Table (2). For those with laparoscopic cholecystectomy it showed highly significant relation between age of patient and time needed to start oral intake postoperatively in laparoscopic cholecystectomy ($X^2= 12.7; P$-value <0.001 at 99% confidence interval). On the other hand, Table (3) showed the relation of age of patients and resuming oral fluid intake for those with open cholecystectomy. Statistical analyses showed no significant relation between age and time needed to start oral intake postoperatively in open cholecystectomy ($X^2= 1.7; P$-value > 0.005 at 95% confidence interval).

Discussion

The aim of postoperative fluid is maintaining normal functional volume indicated by optimum recovery (10). As known that both fluid overload and underload should be avoided, the suitable volumes needed to achieve euovolemic status have not been decided yet (10). A previous study (13) found that excessive post-operative fluid administration is a recognized most important cause of postoperative morbidity, prolonged hospital stay, organ failure and mortality. The level of surgical stress is related directly to the degree of surgical trauma (14). This means that, in euovolemic post-operative patient, the target is to allow wise net excretion of excess salt and water until the patient has returned their sodium and fluid balance. So, the fluid volume should be for daily maintenance and replacement of any ongoing additional losses, and postoperative fluid regime should be considered in relation to current balance due to previous fluid treatment (pre- and intra-operatively) which really affects post-operative state of the patient (15). Previous studies reported an early return back to daily activity when fluid intake is restricted post-operatively (16-18).

In our study we used the simplest formula of post-operative fluid supply in uncomplicated elective cholecystectomy patients, and we found that laparoscopic cholecystectomy patients can resume oral fluid early post operatively with minimum intravenous fluid and discharged on the same day of surgery without ill effects, those within younger age group were more rapidly regained their homeostasis and were ready to start oral fluid early, which reflected that less trauma was induced by laparoscopic cholecystectomy. These data were in agreement with other studies (16,19). The sex of patients showed no effect on amount of post-operative fluid needed in both types of operations. Regarding open cholecystectomy, patients did not respond well to restrictive intravenous fluid and most of them needed further follow up till they could start their bowel activity, which indicated more trauma induced by open cholecystectomy and more fluid loss in this type of operation.

Our regimen was to use glucose saline in the post-operative period for uncomplicated cholecystectomy as it is devoid from potassium, contains less amount of sodium and can maintain fluid requirements.

The surgical stress causes an impairment in gastrointestinal motility (26,27), which may theoretically be increased both by decrease of fluid in the body and fluid overload (as decreased motility secondary to fluid accumulation in the bowel wall and surrounding tissue) (28), which may lead to post-operative nausea and vomiting as well as the effect of anesthetic drugs and type of cholecystectomy procedure (29). Other studies concluded that post-operative pain, vomiting and nausea have been found to influence post-operative fluid administration (10) and to potentially predict hospital stay after surgery (31).

It is proved that post-operative pain is less severe after laparoscopic cholecystectomy, so needs less post-operative pain killers than open cholecystectomy (32), this was reflected in our patients by early return of bowel activity, cardiovascular stability and early discharge from hospital.

Absence of complications, stable homeostasis, positive bowel movement, mobility and toleration of a general diet are considered criteria for early discharge by most (including us) of surgical opinions (33).

We recommend further studies about the effect of intra-operative fluid regimen on the amount of post-operative fluid in elective cholecystectomy.

Conclusions

Restrict post-operative intravenous fluid for maintenance therapy in elective and uncomplicated laparoscopic cholecystectomy in fit patients in the aim of early discharge of patients from hospital as a day case surgery.

Estimation of the Efficacy and Safety of Totally Real-Time Ultrasonography-Guided Percutaneous Nephrolithotomy: A Single Center Study

Ahmed Abdul Ameer Alwan1, Ahmed Hamza Abd2, Hussain T.Ajee2
1Urosurgeon Department of Surgery, College of Medicine, University of Al-Qadisiyah, Iraq; 2Urosurgeon, Department of Urology, AL-Diwaniyah Teaching Hospital, Iraq

ABSTRACT

Background: Percutaneous removal of urinary calculi is superior to open surgical removal in terms of morbidity, recovery and expenses. Even for large complex renal stones PCNL now considered the first choice of treatment at most institutes. The aim of current study was to determine the efficacy and safety of percutaneous nephrolithotomy under total ultrasound-guidance.

Methodology: From January 2015 to March 2018, a total of 300 patients, (200 males and 100 females) their age ranged from 20 to 65 years with a Mean ± SD age of 40.75 ± 11.8 years who visited the outpatient urology clinic and presented with stones size ranged (20–50mm) with a mean size of 33.5mm, were included in this study. All calculi were situated in the renal pelvis with different degrees of hydronephrosis ranging from mild to severe hydronephrosis as appreciated by radiological investigations. The patients were positioned in the standard lithotomy position, a double J stent was placed cystoscopically, and urethral catheter was also inserted. Then the position of patient was changed to prone position. The PCS was punctured by using an 18-gauge nephrostomy needle through the lower pole calyx, and all steps of the operation were performed under ultrasonography guidance. Lithotripsy was done by using pneumatic probes.

Results: Data showed that 276 (92%) patients had complete stone clearance in patients with single stone (180 patients). The stone-free rate was 100% and in patients with multiple or staghorn stone (120 patients), the stone-free rate was 80% (120 patients). In addition, 20% (16 patients) had residual stones ;10 patients of them had insignificant residual fragments that passed spontaneously four weeks postoperatively and 6 patients needed SWL for clearance of stone fragments. The complication rate was 30%, the most common complications being mild fever (35%), clinically insignificant hemorrhage (8%), urinary tract infections in 5%, 5% had flank pain and there were no injuries to adjacent organs. The Mean ± SD time of the operation was 70 ± 35.68 minutes (range was 35–160 minutes). The Mean ± SD time of hospitalization was 2.8 ± 1.15 days (2–5 days).

Conclusion: Totally ultrasonography-guided PCNL has excellent results in comparison to the ordinary method of PCNL with no major complications and with the benefit of precluding radiation exposures and injury to the neighboring organs.

Keywords: PCNL, ultrasound, renal stone, nephrostomy, hydronephrosis.

Introduction

The introduction of percutaneous nephrolithotomy (PCNL) as a new method for treatment of large renal stone was in 1976 [1]. By 1995, large number of studies about PCNL had been made for estimation of the efficacy and safety of this minimally invasive technique and its complications [2].
Percutaneous removal of urinary calculi is superior to open surgical removal in terms of morbidity, recovery and expenses \cite{1}. Even for large complex renal stones PCNL now considered the first choice of treatment at most institutes \cite{2}.

Now, this operation is done under guidance of fluoroscopy, and this will lead to exposure of the surgical team and patient to radiation \cite{3}. Using ultrasonography as a guidance, PCNL can abolish the side effects of radiation exposure during fluoroscopy-guided PCNL, and eliminate the hazard of radiation \cite{1}. The aim of current study was to determine the efficacy and safety of percutaneous nephrolithotomy under total ultrasound-guidance.

**Patients and Method**

From January 2015 to March 2018, 300 patients (200 males and 100 females) with renal calculi sized (20–50mm) and mean size of 35.5mm situated in the pelvis and with different degrees of hydronephrosis ranging from mild to severe hydronephrosis with a Mean ± SD age of 40.75 ± 11.8 years, were involved in this study at the urology unit in Al-Diwaniyah Teaching Hospital (Table 1).

Complete preoperative assessment was done for all patients. Criteria of stones regarding size, site, number, opacity and the degree of obstruction that caused by the stone were done by radiological investigations. Before the operation, an informed consent was taken.

All of our patients operated under general anesthesia and all patients received single dose (1000mg) of ceftriaxone at the induction of anesthesia. After completion of anesthesia the patient was placed in standard lithotomy position and cystoscopy was done and insertion of the double J stent was done and urethral catheter was inserted, then patient’s position was changed to the prone position, and under ultrasound guidance, the PCS and the calculus were localized.

The PCS was punctured by an 18-gauge nephrostomy needle through the lower pole calix. After achieving puncture to the PCS and with the urine flowing out, a floppy guidewire was passed through the needle into the PCS. After that the dilatation of the tract was done using an Alken (metal) dilator up to 28Fr. After that 30 Fr. an Amplatz sheath, was passed to the PCS. All steps of the operation were done under ultrasound guidance.

A nephroscopy was placed in the PCS. Calculi fragmentation was done by using a pneumatic Swiss lithoclast. Grasping forceps were used for removal of calculus fragments. At the end of the operation a nephrostomy tube was inserted in all patients and this tube was removed 48 hours postoperatively.

Patients received parenteral antibiotics for 3 days postoperatively and discharged with oral antibiotics as well as analgesia for 7 days. The follow-up of our patients was done at outpatient clinic with radiography of the (KUB) and/or ultrasound at 14, and 28 days postoperatively as needed for evaluation of the stone-free rate and removal of DJ stent under local anesthesia by flexible cystoscopy.

**Results**

The characteristics of our patients were shown in Table (1). The Mean ± SD operative time (from the induction of anesthesia to the insertion of the nephrostomy tube) was 70 ± 35.68 minutes (range was 35–160 minutes).

Successful access to the PCS was achieved in all patients. The Mean ± SD time of hospitalization was 2.8 ± 1.15 days (range was 2–5 days).

Results of current study revealed that 85% of patients had complete stone clearance and this was confirmed by ultrasonography 48 hours after surgery. In 180 patients those with single renal stone the stone free rate was 100% while the (120 patients) with staghorn or multiple calculi the stone-free rate was 80%. Sixteen patients had residual fragments; 10 of them had insignificant residual stone fragments that passed spontaneously after a period of 4 weeks and in six patients had residual stone greater than 10mm at the end of the operation. For those patients, extracorporeal shockwave lithotripsy was used to eliminate the residual stone fragments after the primary procedure.

The complication rate was 30%, these complications included mild fever (35%), clinically insignificant hemorrhage (8%), urinary tract infections 5% and flank pain (5%) without injuries to the adjacent organs.

**Discussion**

Nowadays, open surgical approach for removal of large renal stone is less applicable because of the availability of other less invasive alternative methods of treatment of renal stone such as SWL, flexible ureteroscopy and PCNL [7].

The most important thing in achieving excellent results of PCNL with minimal or no complication is good selection of the patient and good follow up [8].

By using ultrasound guidance, there was no need for contrast, and there was more accurate access to the collecting system without injury to the neighboring organs [9]. The main advantages of ultrasound over fluoroscopy in PNL are avoidance of radiation, visualization of radiolucent stone and avoidance of injuries to the adjacent organs [10-12].

In our study all steps of the operation were done under ultrasound guidance without need for fluoroscopy while Osman and colleagues [13] used sonography just for the primary access to the pelvicalicyal system, while the dilatation of the tract has been done under the guidance of fluoroscopy [14].

The primary stone-free rate was 45.7% as reported by Osman and colleagues [12] that performed PCNL with ultrasound-guided renal access and the total stone-free rate was 96.5%, which is comparable to the result that achieved by our study.

Osman and colleagues [15] reported that 33% of patients needed an auxiliary measure (a second PCNL, SWL, or a URS) for achievement of complete stone clearance while in our study only 5% of patients needed subsequent SWL for getting a stone-free state.

The overall complication rate in our study was 30% which was comparable to that seen in other studies [16].

**Conclusion**

PCNL under ultrasound guidance is considered as a realistic, consistent, safe, and effective substitute to fluoroscopy in experienced urologist and eliminate radiation hazard to both the urologist and the patient.

The Effect of the Use of Parachutes and Gloves in Some Kinetic Variables and the Completion of a Swimming Pool (50M) Free for the Armenian Club

Tabarek Mohammed Salman¹, Nada Mohammed Ameen¹, Mawahib Hamid Al-Jubouri¹
¹College of Physical Education and Sports Science for Girls, University of Baghdad, Iraq

ABSTRACT

Background: Scientific research in sports biomechanics is not limited to diagnosis or treatment of the strengths and weaknesses of the training process for young swimmers. The study was aimed to prepare special exercises using the parachute and the gloves as a means of resistance in the training process in accordance with the abilities of the sample and to identify its effects on the kinetic parameters of length of the cloud, velocity of the cloud and rate of speed.

Method: A 50-meter swimming pool was completed for young swimmers. The researcher adopted the experimental method of group design with the design of the three experimental groups with tight control in the pre- and post-tests. The first experimental group was trained using the umbrella resistance, the second experimental group was trained using paw resistance and the third experimental group was trained by combining the two types of resistance (parachute + gloves) on a sample of young swimmers in the club of the Armenian. Nine swimmers were chosen by a vertical (100%) of their community origin. The training curriculum lasted for eight weeks with two training units per week. The number of training units per group was 16 training units in the study experience.

Results and Conclusions: Data of pre- and post-tests were statistically determined by the SPSS system. The researchers concluded that training by combining two types of resistors (parachutes + gloves) improved the rate of speed, length and frequency of the strike and the completion of a 50-meter swimming pool in the young swimmers who trained them. The researchers argue that it is necessary to have resistance training based on the principle of experimentation and not to exaggerate with young swimmers to be appropriate for their age, training level, gender and privacy of swimming distance specified for them.

Keywords: parachutes, kinetic variables, young swimmers, resistance, frequency of strike.

Introduction

Scientific research in sports biomechanics is not limited to diagnosis or treatment of the strengths and weaknesses of the training process for young swimmers. In many fields it extends the training methods used in formation of resistance on swimmer’s body, which has gained considerable space in the training operations of global swimmers to break the routine of the training process. Resistors with and reverse swimmer, which develops some physical characteristics and some biomechanical variables in swimming extending that role to motor performance and helps correct it to reach the optimal motor performance that serves the effectiveness “Biochemistry did not really evolve from mechanics alone, but it is a modern science that has evolved from a range of other sciences: anatomy, organ function, and curriculum”. In this way, Samir Abdullah presented his opinion that “work (training/competition) against very strong resistance, whether slow or rapid, requires muscles to strengthen the three types of fibers. It has be mentioned that “The training, which is derived from the sports biomechanics, what is the main muscle group to be trained, which method of training to use, and what is the energy production system to focus on during work), then the trainer should determine the following”[1].

So the steps can be followed: Determine the position of the joint and its movement in the specific exercise, determine the muscles responsible for the movement required and determination of nature. By adoption of these determinants, it is possible to employ
the mechanical principles in the direction of training process to go into the effects of resistors to provide an explanation of their roles in these. The process is subject to limitations imposed by laws of force that invest as a resistance to the mass that constitutes disability different from normal conditions, thus increasing the ability of the swimmer to improve it to achieve. So that, the productivity of the study is directed towards raising achievement through the adoption of what is built on the language of numbers and avoids personal speculation of some trainers to exaggerate the loads of training in order to raise the achievement. Also, the speed of link with the nervous system as well as type of muscle fiber are genetically determined so the nervous system must be prepared to accept the additional burdens and accept the physical burdens (50 meters) and the training umbrella to induce change in the target muscles for development[2].

Studies that are scientifically proven indicated that there is no increase in the number of neurons because they do not contain the central particle, but it is possible that the work is improved by shortening the period of latency in muscle contraction which showed clear in the speed of performance. In the training of resistors in swimming, muscles are trained to achieve the development of work of muscle fibers when faced with different circumstances. In other words, to develop motor velocity, attention must be paid to a large extent by strengthening the muscle groups on which the motor function is based [7]. Moreover, through the work of the researcher as a trained assistant, I noticed that the need to achieve consistency in the length of the cloud and frequency to serve the achievement in a distance of (50) meters for young swimmers in the Armenian club. Therefore, the study attempted to answer the following question: Is it possible to use the parachute and cabbage as resistors to have an impact in some biomechanical variables and the completion of swim (50) meters in young swimmers?

To achieve the goals of the study, the researchers assumed that:

1. There are statistically significant differences between the results of the pre and post tests of the kinematical variables of the three research groups represented by (velocity of the cloud, length of the cloud and speed of the speed) and completion of the swimming pool (50) meters.

2. There are statistically significant differences between the three research groups in the results of the tests in the kinematical variables represented by (frequency of drawing, length of the cloud, speed rate) and completion of the swimming (50) meters in the young swimmers.

**Method**

The experimental group followed the empirical research approach by designing the three experimental groups with tight control in the pre and post tests. The first experimental group was trained by using parachute resistance; the second experimental group was trained using paw resistance and the third experimental group was trained by combining the two types of resistance.

**Study sample:** The sample included (9) swimmers, the sample of the study was chosen by (110%) and according to the determinants of experimental design of the study; the sample was divided into three groups of equal numbers.

**Measuring tools, tests and study procedures:** The resistors were in the umbrella (6 and 6), while the instruments in the search experience were (whistle, stopwatch, legal swimmer, Sony high speed camera (100 sec); (15) meters from each distance, (25) meters of the distance and (50) meters after excluding the starting distance and rotation and the distance of the end. After analyzing this imaging, the data of the values (speed, strike length and strike frequency) as well as recording the completion time of 50 meters, were extracted. The training curriculum lasted for eight weeks with two training units per week. The number of training units for each group was 16 units during the field study, after which the post-tests were carried out on 24/9/2018, and results were processed with SPSS (Version 25).

Discussion

The researchers attributed the emergence of these results to the role of resistors interpreted by kinematic laws for the practice of training these exercises, as the gloves used in swimming as training aids helped increase the surface area for hand comfort and then increase the amount of water pump to the gloves. The gloves constituted a driving force forward helped improve the values of dependent variables in the trained swimmers. On the other hand, the umbrella is a resistance to reverse the movement of the swimmer and pull back, so the use of gloves makes the player swims quickly above the maximum due to the amount of payment generated\(^3\). It is a resistance to reverse the movement of the swimmer and then strengthens the muscular capacity of the swimming pool and develop the force, but the use of these means with some puts the swimmer under the influence of two forces opposite in the direction; one forward (gloves) and the other force backward (umbrella), positive along the swimmer’s pull because he will try to overcome the resistance to the back of the hand to extend the most possible point to avoid fatigue and this could improve the length of the draw and the continuity of training and continue it\(^4\).

The addition of the burden means increasing the torque of the inertia of parts of the body or the whole body when swimming, and this requires the swimmer to exert greater strength to overcome the increase in the determination of inertia due to the impact of resistors. The amount of this force is increased by type and how much resistance and it needs to make a greater force to match the increase in the resolve of body inertia and increasing the resistance requires increased strength to maintain the proportion of this force as required by performance, as speed and mass are inversely proportional\(^5\). Increased resistance will reduce the amount of speed and this, as the training of resistors, increases the strength due to increased resistance. In the process of physiological response and access to the physiological adjustment phase and the lifting of these resistances, the speed will increase by increasing the force that has been developed by the resistance. Salma Toukan provides evidence that “The weight of the body, the age, the sex and the difference in sports. There is an important principle that “the less weight, the less energy is needed to do the same work\(^6\).”

This means that mechanical work will be increased (labor = energy) and that this increase will be offset by a dynamic energy exchange commensurate with the work high effort mechanical resistors\(^7\). After the process of adjustment in the increase of mechanical energy (kinetic ones), these resistors are lifted and maintain the output of mechanical energy with the least resistance (only the inertia of the pool and resistance to water friction and others without resistance). The bio energy will be reduced to fit the resistance in the swimmer’s environment, but the work itself, based on the principle mentioned (because the resistance was said and the work itself). It is possible to obtain a high-level work in bioenergy\(^8\).
According to [8], biomechanics is an associated science, as the content of this science directly benefits from the theories and laws of several different basic sciences [9]. These sciences contributed to the science of biomechanics by determining the motor characteristics associated with the exercise of sports activity, which led to the development of high skill technique and increased the kinetic experiences. Biomechanics contribute to the development and improvement of sports movement and to achieve skill and motor performance to the closest ideal performance, a goal that each coach seeks to eloquence. It is the duty of science related to sport to find the latest methods that can be used to analyze and study sports movements [10].

Conclusions

1. Training by combining two methods of resistance (parachute + gloves) improves the rate of speed, length and frequency of strike and the completion of swimming pool (50) meters free among young swimmers who trained and outperform the swimmers who train one.

2. The parachute training improves the rate of speed, length and frequency of strike and the completion of swimming pool (50) meters free with young swimmers who train them, and excel on swimmers who train with cabbage.

3. It is necessary to train resisters based on the principle of experimentation and not exaggeration with young swimmers, to be appropriate for their age and training level and gender and the specific distance of swimming identified for them.

The Impact of Problem Solving Strategy in Developing the Technical Performance and Accuracy of the Skill of the Serve Facing from the Top (Tennis) Volleyball for Students

Nuha Yousef Hashem Abbas, Rawa Allawi Kazim, Mahmoud Nasser Radi

1College of Physical Education and Sport Sciences, University of Babylon, Iraq; 2College of Physical Education and Sport Sciences, University of Kufa, Iraq

ABSTRACT

Background: The field of education in physical education and sports has undergone significant changes that have shown the interest of specialists and researchers in developing the educational process continuously in order to raise the level of education and learners. The aim of current study was to identify the effect of problem solving strategy in developing the skill of Serve from the top (tennis) to the students’ volleyball.

Method: The research community included 3rd-stage students at Faculty of Physical Education and Science. The total number of students was (71). However, the number of students who were rejected and deferred was (7) students. Therefore, total number of participants was 64 students. The sample was randomly selected by 32 students and divided equally into two groups. After conducting the tests, the experimental group began applying the units prepared by researcher and continued for eight weeks each week in one developmental unit. After the completion of the unit items, the researchers carried out the remote tests. The researchers collected data and were processed statistically to reach the most important conclusions.

Results: The exercises, which were developed in accordance with the strategic steps of problem solving, have greatly helped to develop the pilot skill of the upper plane (tennis) volleyball students’ experimental group.

Conclusions: There was a positive development, of experimental and control groups, of the technical performance and accuracy of the skill and the Serve of the upper (tennis) volleyball for students.

Keywords: volleyball, technical performance, Serve, upper tennis, problem-solving.

Introduction

The field of education in physical education and sports has undergone significant changes that have shown the interest of specialists and researchers in developing the educational process continuously in order to raise the level of education and learners. The task of the teacher is no longer limited to explaining and dumping and following the traditional methods of education. For the strategy of the lesson and developing it according to scientific standards which are compatible with the potential of students’ physical skills, achievement, mental and individual differences and others to achieve the goals of the lesson set in advance [1].

Scientific development includes the emergence of ideas and strategies that tend to make the learner takes the largest role in the learning process, while teacher’s role is in guidance and giving student the opportunity and time to use a variety of strategies to solve the problems facing them and identify them and find appropriate solutions to them according to his own thinking and opinions. So, the attention of specialists is in teaching various skills in various sports such as volleyball to use unconventional strategies in the unit for educational purposes.

Moreover, volleyball of athletics, which took a distinguished position in terms of practice and spread in
the countries of the world, and the advantage of the game in containing basic skills of many offensive and defensive, is one of the strong pillars on which the game is based and that learner’s access to success depends on mastering his skills. The serve of the offensive skills of the volleyball team is the key to obtain points for the team in case of proficiency after learning and familiarity with types and methods of performance theoretically and practically as well as problems that accompany this performance. This usually takes longer time in the lesson plan or requires a lot of effort and thinking from the learner [2].

The aims of current study were to identify the impact of problem solving strategy in the development of the skill of serve from the top (tennis) volleyball as well as the link between practical and theoretical aspects of their impact in helping learners to understand the skills and improve their performance.

Research Hypotheses:

1. There is a positive impact of the strategy of problem solving in the development of the skill of the transfer from the top (tennis) volleyball for students.

2. There is a preference in influencing the problem solving strategy and the method used in the development of the skill of serve from the upper face (tennis) volleyball for students, and the effectiveness of the influence of the strategy of problem solving in the tests of post.

Method

The researchers followed the experimental approach to fit the nature of the research problem. They also chose to design the style of the two study groups (experimental and control) with both the pre and Pre-tests.

Study Sample: The study sample represented 3rd-stage students at Faculty of Physical Education and Sports Sciences/University of Kufa, their number was 71 students. Seven students were excluded because they retarded and deferred, therefore, total number of participants was 64 students. The latter were divided equally into two groups; experimental and control groups.

Sampling Homogeneity: The researchers used the torsion coefficient before applying the main experiment to the two study groups (control and experimental) as shown in Table (1).

- Office tools (papers and pens).
Field Research Procedures

Specify search variables: The search variables were determined according to the search problem, which is the technical performance and accuracy of the skill of the Serve facing the top (tennis) volleyball.

Identification of Variable Tests: After reviewing several sources, scientific references and similar studies, in addition to the interviews of some experts and specialists in the field of motor learning and volleyball, the tests were determined to measure the research variables which can be measured in terms of motor and skill abilities.

Testing the technical performance of the skill of the Serve facing from the top (tennis): The objective of the test was to evaluate the technical performance of the skill of Serve through its virtual form and its three divisions (preparatory, president and conclusion). The tools used included legal volleyball court, legal plane balls number (3) and performance evaluation form.

Performance specification: The student will perform the skill of sending the tennis from the Serve area specified by (9) meters to the corresponding field on the ball passes the net (without touching) trying to drop in the opposite half of the stadium.

Conditions of performance: The laboratory gets zero points in the case of the performance of the Serve in a manner not agreed.

The registration: Three evaluators evaluated the three attempts of each student laboratory and gave three degrees for each rectifier (the final calendar grade for each attempt is 10 degrees distributed on the three sections of the skill which is (3) grades for the preparatory section, (6) and (1) grades for the final section. Then, they chose the best score for each rectifier and through the extraction of the mean of the best three grades, the final grade for each student laboratory was calculated.

Testing accuracy of skill of the Serve from the top (tennis): Objective of the test was measuring the accuracy of the Serve skill. The tools used included Legal volleyball court, legal plane balls (5) and colored bar to divide the corresponding playground areas.

Performance specifications: The student stood in the middle of final line of the stadium (9) meters from the network, so that the student labored to hold the ball to perform the Serve to cross the ball network to half the planned stadium.

Conditions of performance: In the case of touching the ball to the network and transit to half the planned stadium or out of the boundaries of the stadium, it was counted as an attempt for the student laboratory (of five attempts) and did not calculate their grades.

Registration: The student took the degree of the area where the ball is located for each correct sending and since each student has a laboratory (5) attempts and because grades are distributed on the regions of (1-4) degrees, the maximum score for this test was (20). The fall of ball on the line separates the two regions; it was counted for the student’s upper region score.

Main experiment procedures

Pre-Tests: The researchers conducted the pre-tests on the research community of the two groups (control and experimental) of the study variables; technical performance and accuracy of skill of the Serve facing the top (tennis) on Sunday, 16/12/2018, at ten o’clock in the morning in the indoor closed hall at the Faculty of Physical Education and Science. The researchers used two cameras (Canon) to portray the technical performance of the skill of the Serve from the top (tennis) volleyball and recorded videoconference by (CD) to be presented to the gentlemen for analysis and recording the results of their evaluation of the technical performance through the evaluation form prepared for humiliation as preset.

Application of problem solving strategy: The researcher applied the experiment according to the following steps: After reviewing vocabulary of the curriculum for 3rd-stage students at Faculty of Physical Education and Sports Sciences/University of Kufa, the development of curriculum was carried out in the form of developmental units and began applying the experiment to students of the research group in (23/12/2018) in the closed gymnasium of the Faculty of Physical Education
and Sports Sciences/University of Kufa, at the rate of development unit each week duration (90 days) and continued until the end of the experiment in (17/1/2019). The total number was (8) development units. **Pre-tests:** After the completion of the problem-solving strategy, the Pre-tests were carried out on the control and experimental groups. This was on Sunday, 27/1/2019, in the same sequence of pre-tests.

### Discussion

Results of current study showed that there were significant differences in the pre and Pretests of the two groups and the Pretests among the experimental and control group members [5]. For members of control group, findings might be attributed to researchers, to the variables and/or effects of several overlapping factors in the process of development that led to emergence of moral differences between the tests pre and Pre including feedback as it has an effective role. Feedback was given in the manner of the teacher directly to the student during...
the performance, at the end of the lesson, which was confirmed that “After the end of the application period and preparing for the end of the lesson, the teacher corrects the mistakes of students” (Schmidt, 2000). “The feedback increases the capacity and motivation of individuals, corrects performance and avoids erroneous performance”[6].

The differences shown in the above tables of the experimental group members were attributed to use the strategy of problem solving in terms of planning and implementation of developmental units [7], as the exercises developed by researchers using the problem-solving strategy had transferred learners of the usual pattern that makes them receive information from the teacher to a new style based on question and choice of the appropriate solutions. This motivated learners to respond to this strategy, trying to succeed and to demonstrate their abilities and assert themselves and prove their potentials, which is often seen in palaces and indifference. The latter facilitated the process of understanding and assimilation of skills studied in the three sections (preparatory, president and final). In addition, the reason for these differences may be the new educational attitudes of learners [8] that clarified the target and what was required from learners to achieve and was not recognized in the educational units that led to a clear improvement in their performance. Moreover, [9] said that “The clarity of the goals and their identification in light of certain behaviors or performance levels are meaningful and effective”. Also, [10] said that “The interaction between group members and the discussions around the educational task that they had, affected their understanding of the educational material”.

The presentation of educational material whether written text or static and moving images or videos that enable the student to use more than a sense in the process of learning [11] had contributed significantly to the diversity of sources of knowledge and increased opportunities for good learning, and this improvement in technical performance and accuracy of skills is the result to stay away from the familiar in teaching through the use of problem solving strategy. The latter has a role in making learner’s focus on educational process and its performance organized and arranged according to the steps of the strategy in addition to the use of different positions and the continuous guidance from the supervisors supervising the performance of those exercises. These prepare to minimize the mistakes that the learner may have in performing the exercises during the unit [12].

Conclusions

1. There was a positive development, of experimental and control groups, of the technical performance and accuracy of the skill and the Serve of the upper (tennis) volleyball for students.

2. The exercises that were prepared according to the strategic steps to solve problems, significantly helped develop the skill of Serve from the top (tennis) volleyball students in the experimental group.

3. The problem solving strategy increased enthusiasm of learners, which was reflected positively in the development of motor abilities, which led to learning the skill of transfer from the top (tennis) significantly and effectively.

Effect of Battle Ropes Training in Some Components of Health Fitness and Vision of the Body Image of Women Aged (30-35) Years

Raghda Hassan Ibraheem¹, Sahira Razzaq Kadhem², Suhad Qassim Saeid²
¹PhD Student, ²Professor; College of Physical Education and Sport Science, Baghdad University, Iraq

ABSTRACT
The training of Battle ropes is one of the forms of modern exercises, which proved to be effective in the West by affecting the components of fitness and weight reduction and burning calories, and based on the interest of women in their bodies as well as its important role in society being more sensitive than men to see her body, Beauty is an objective phenomenon that all women seek to highlight, which requires more attention and use exercise appropriate sports methods. And highlights the importance of research in providing the woman with a healthy body and the vision that aspires to see her body, through the performance of exercises using heavy ropes, The aim of the research is to prepare exercises using heavy ropes and to identify the effect of these exercises on some components of health fitness (muscular endurance, flexibility, weight, BMI) and body vision for women aged 30-35 years, The research community consisted of women trainees at the Black Gym Fitness Center. The sample was deliberately selected from women aged 30-35 years. The researchers used the one-group experimental approach to suit the study. The tests and questionnaire were tools for collecting information, The researchers conducted a number of exercises that were applied to the sample for two months, (3) training units per week. After conducting pre- tests and post-tests (before and after exercise), the data were obtained and then statistically treated using the appropriate statistical methods. The results showed that there were significant differences between The tests, According to the results, the researchers made a number of recommendations.

Keywords: Battle Ropes training, Health Fitness, Vision of the body Image.

Introduction
Health fitness is essential for every woman, whether it is sports or not. It is part of the general fitness and one of the components of the overall fitness that qualifies the individual to live in a balanced manner in society. The concept of health fitness is not limited to the free the individual from diseases or functional deficiencies, but represents the state of safety and physical, psychological, mental and social Satisfaction. As a result of the increasing awareness that coincides with the great development and scientific progress we are witnessing today and the growing interest in beauty and shape of the body, especially for women, the importance of fitness through its association with daily life and the possibility of women to doing the requirements of life activity which may be professional or sports.

The concept of improving the level of health fitness requires the development of its basic components through the adoption of the best methods of training is the main means to affect the individual functionally to make the adjustments required, so training experts have been constantly searching for the latest forms of physical exercise taking into account the impact of economic and effective. The training of Battle ropes is one of the forms of these modern exercises, which proved to be effective in the West by affecting the components of fitness and weight reduction and burning a lot of calories as it has a number of features as easy to transfer and it
is not considered expensive and that work on the whole body at the same time without the need to train every part of the body in addition to it gives an atmosphere of enthusiasm and pleasure during the performance, which increases the motivation of the practitioner to continue the exercise.

Vision of the body image: It is the impression of the individual feelings and sensations of the sense of the body has attractive features that reflect the female or male character and what others see it from his point of view 1.

The study highlights the importance of the woman in giving the healthy and the vision she aspires to see her body by undergoing two-month Battle-duty exercises for women aged 30-35 years and responding in the following question: Does heavy rope exercises affect some in components of fitness and body vision for women aged 30-35 years? And finding out the results.

**Method & Participants:** The researchers used the experimental approach with a single experimental group design that suit the nature of the problem in order to find the results of the research.

The research sample was chosen in a deliberate manner. The research community consisted of (30) female trainees aged 30-35 years in the fitness court of Black Gym. The sample of the experiment was 9 female trainees, represented (30%) from Community of origin.

**Materials:**

- Medical Balance *
- * Laptop (hp)
- * Ropes with diameter (1.5) inches and length (25) feet.

**Procedures:** After reviewing the scientific sources and references, researcher depended on the American Health, Physical Education Recreation and Dance Association (AAHPERD) classification of health fitness components was classified as:

{Muscular endurance, muscle strength, flexibility, efficiency of the circulatory system, physical composition}\(^2\).

### Table 1: Criterion measures

**Vision of the body image Scale:** After studying the sources and references related to the subject of the researchers based on the scale of vision body image 1. The scale consists of three axes:

1. The individual’s vision of his body: the feelings and emotional tendencies of the individual by his personal assessment of the attractions and contradictions in the parts of his body.

2. The vision of others for his body: feelings and emotional tendencies that the individual has for himself because of others’ view of him or his thoughts as a personal analysis to see others of the attractions and contradictions in parts of his body.

3. Emotional response: It means the ideas and psychological trends that the individual as a final outcome of the behavioral and emotional aspects of attraction and dissonance of parts of his body.

The scale consists of (24) paragraphs divided into three axes, respectively: (7) paragraphs of the individual’s vision of his body, (8) paragraphs of the vision of others to his body, and (9) paragraphs of the emotional perspective and the answer according to the alternatives (yes, sometimes, no) In accordance with the triple grading criterion (3.2.1) and that all paragraphs of the scale are negative except for paragraphs (1.6, 7). The highest degree of the scale (72) and the lowest degree (24) and the Hypothetical mean is (48).

**Exercise protocol:** Exercises were carried out using heavy ropes (with arms) which were a training method used to influence and improve some of the components of health fitness (muscular endurance, flexibility) and reduction of weight and BMI and know the effect of this improvement in the change or survival of the vision of the image of women to her body.

The number of training units (24) units and the (3) training units per week, distributed on days (Sunday,
Tuesday, Thursday) for a period of (45) minutes and the duration of exercise for two months period from 17/8/2018 until 15/10/2018.

The researchers designed a number of exercises based on the scientific sources and personal experience of the researchers and videos of exercises on the site (You Tube), taking into account the level and age of the sample research.

The main factor behind these exercises is the length and thickness of the rope. The researchers used 25-foot and 1.5-inch (about 4 kg) polyester ropes, which are a good start for novices, and are the best choice for gyms where individuals of different sizes and physical levels, in addition to the ropes ensure full freedom of movement of all directions, as included exercise uses the entire body and not just the arms to increase the energy and efficiency of the legs which play a crucial role in generating and transferring energy to the arm and then to the rope. Through the combination of exercises of the upper and lower part, the researcher was able to prepare exercises for the body as a whole. The training unit also included some exercises that are performed with the partner with the musical accompaniment to facilitate performance and create an atmosphere of enthusiasm for performance and break the boredom.

The researchers adopted the interval training method in the organization of the load training, taking into account that the trainees beginner did not exercise before and they are not similar in their abilities and characteristics of health and biological, so when the formation of the training load should be taken into account the differences and factors associated with the age of time and health status and the rate of hospitalization as well as keen Seeking to adopt the principle of gradualism in giving intensity.

Statistical analysis: To extract the statistical differences between the pre-tests and the post-tests of the research sample, the researcher used the statistical program (spss) version 22.

Results

After the completion of the application of the exercises and the tests of pre and post data were obtained and after processing statistically by the appropriate statistical means were reached the final results and as shown in Table (2), which shows the computational and standard deviations and the value of (t) calculated between the pre-test and post-experimental group and then Analyzed and discussed.

</table>

The value (t) calculated for the variables shown in the above table is greater than the value of the significance level between (0.000) and (0.001) indicating a significant difference between the tests and for the post test.

Discussion

The results revealed that there is improvement and decrease in weight and body mass index, which is a way to infer the proportion of fat accumulated in the body, and is used as a General for the classification of individuals on the basis of weighting and weight gain and monitoring changes in the proportion of fat and thus determine the dangers resulting from obesity.

The researchers attributed the decrease to the fact that the exercises were designed to target the accumulated fat as sources of energy, leading to a decrease in the lipid
component, where “physical activity ensures weight loss of accumulated fat and not muscle decay” 4 «.

“Regular physical activity helps to reduce body weight and increase energy exchange” 5. and “If the daily calorie requirement (food intake) is balanced with the daily caloric intake rate, The thermal energy balance will be moderate in the sense that the amount of energy consumed equals the energy consumed and thus lose weight and maintain it “ 6. Therefore, the regularity of the sample in the exercise led to fat burning resulting in a decrease in weight. In addition, the exercises designed to include various physical movements and different parts of the body with oxygen to complete the metabolism and production of energy for the continuation of muscle work, where “this decrease in weight occurs as a result of targeting aerobic exercise of storage places that do not degrade oxygen only with oxygen” 7.

As a result of the specificity of the exercises, which are designed by using more parts of the body and involving more muscles (such as double-wave exercise instead of single-arm use) and lower body participation, which leads to greater metabolic rate and thus more fat burning 8. and through high-intensity interval training, which is more effective according to the American College of Sports Medicine, whenever the intensity is high with a few rest periods, the impact of cardiovascular and metabolism is a greater 9. According to the site (greatest.com) Using heavy ropes burns (10) calories per minute. As a result of weight loss, health fitness components improved.

The researchers attribute the significance differences that shown between the pre-test and post-tests in the flexibility variable to the use of stretching exercises in the training program, which helps to increase the flexibility of the joints “ The stretching exercises in the training program, which aims to stretch the muscle, ligament, The extent of movement in the joint as these exercises are the most important means of development of flexibility “ 10. As well as” systematic and continuous training can improve the rubber muscles, and then the expansion of the range of motor joints, which improves the flexibility of the body 11 «.

The results showed significant differences between the tests of pre and post and for the benefit of post-test in the variable muscular endurance of the arms in the members of the research sample, and attributed the researcher the reason for this positive impact of exercise, citing the site (Onnit.com) that the benefits of training with heavy ropes increase strength.

A studies conducted in 2013 published in the European Journal of Sports Sciences and in 2017 published in Indian journal of research, that heavy rope training has proved effective in the development of strength and endurance higher than traditional resistance exercises 12,13.

From the definition of (Bool Shelder) to vision of the body image as “the vision of our body that we form in our mind or the way in which the individual (fat, thin, long, short) appears on which the individual is his idea of himself and his behavior, emotions and responses are affected” 14. We can say that this vision may change depending on the change of body shape, and when this change is generated we have a view that may be positive or negative Although there is no scientific link between any type of exercises and change this view, but there is a psychological link that generates a sense of satisfaction And discomfort about body shape especially for women who are more likely Because of the weight and shape of her body and of course if we work to modify the reason, which is the body shape we have modified this view and in a positive way too, so exercises have an impact on the psychological state of women, which is represented in this study as the vision of the body image, And the post-test in the above scale.

Conclusions

In general, the findings of this study showed that Battle rope training can improve some components health fitness, as well as development in the scale of vision of the body of women.

The Cytotoxic Effect of Zinc Oxide on Colon Cancer Cell Lines in Vitro

Shihab Ahmed Jasim¹, Nihad A. Saleh²

¹Department of Physics, College of Science, Kufa University, Iraq; ²Department of Physics, College of Science, University of Babylon, Iraq

ABSTRACT

Background: The small size and surface properties of Zinc Oxide Nanoparticles enabled them to diffuse easily through, and localize inside, tumor cells. The aim of current study was to evaluate the anticancer effects of Zinc Oxide Nanoparticles on a colonic cancer cell line in vitro with the use of Methyl Thiazolyl Tetrazolium assay.

Method: The cytotoxic effects of of Zinc Oxide Nanoparticles against colon cancer were planned with a serial doubling dilution concentrations (µg/mL). The microscopic features of apoptotic cell were shown and viability was measured by using Methyl Thiazolyl Tetrazolium assay, a reliable and common colorimetric test for evaluation of cell viability.

Results: According to cell viability assays, 15µg/mL and 8µg/mL of Zinc Oxide Nanoparticles were found to be highly toxic with the most potent antitumor activity on colonic cancer cell line. In addition, the obtained results showed a major reduction in cell viability and increased apoptosis comparison with normal cell line by same doubled increase concentrations.

Conclusion: ZnONPs can be used as anti-cancer agents in treatment modalities. They were able to decrease tumor growth in cancer cell lines.

Keywords: MTT Assay, HCT116 colon cancer cell line, Zinc Oxide Nanoparticles, Cytotoxicity, Anticancer.

Introduction

Cancer is unique of the most common illnesses all over the world in which an abnormal growth of cells invades and destroys normal cells. Free radicals, one of the main cause for the transition of normal to cancerous cells, are created as a consequence of a number of endogenous metabolic procedures involving redox enzymes and bioenergetics electron transfer and exposure to an excess of exogenous chemicals or high irradiation dose.

Nanoparticles are microscopic particles which have dimensions less than 100nm; they are widely used in the field of medicine and health sciences although minimal harmful effects on animal cells had been noticed.

The properties of Zinc Oxide Nanoparticles (ZnO NPs) like availability, high stability, high solubility and biocompatibility make their usefulness in biomedical applications [1]. They have a wide range of biomedical applications like drug delivery, anti-cancer, anti-diabetic, anti-bacterial, anti-fungal and agricultural properties [2-4].

Despite the common application of ZnO NPs in biomedicine, their use is still controversial. Nanoparticles were stated to have therapeutic aids. However, they were reported to have toxicological hazards as well, ZnO NPs were shown to induce toxic effects in different body organs and systems. The toxic effects of ZnO NPs depend on their concentration, dose, route of their administration, and time of exposure to those particles. Thus, it is crucial to assess their efficacy and safety to determine their toxicological risks and therapeutic benefits [5].

DOI Number: 10.5958/0976-5506.2019.03264.9
ZnO NPs are used in topical applications such as sunscreens and cosmetics. This nano-size was assumed that they would be non-toxic in comparison to the bulk size, but studies have found that this is not necessarily true. ZnO NP, in particular, have been found to demonstrate strikingly different toxicological profiles in vitro than bulk ZnO [6–7].

ZnO NPs showed positive charges in the physiological conditions such as in tissue fluid or in blood, while cancerous cells have negatively charged phospholipids on their outer membranes, therefore, an electrostatic attraction occurs between ZnO NPs and the cancerous cells. Also, their small size and the surface properties enabled them to diffuse easily through tumor cells and localize inside them with 30 times selective cytotoxicity towards cancer cells compared to healthy cells and that could kill cancer cells selectively in vitro. Several studies suggested an increased in vitro cytotoxicity with nano-phase ZnO compared to micronized ZnO for several types of cancers [8–9].

The advantages for considering ZnO nanoparticles to be used in treatment of cancer are the inherent preferential cytotoxicity against cancer cells in vitro. It is suggested that their selectivity towards cancer cells may be even further improved by changing their shape in order to decrease their harmful effects on normal body cells, which has been observed to occur at very high concentrations of ZnONPs, particularly those in the size range of 4 – 20nm [10].

We noticed that ZnO NPs have ability to kill both cancerous and normal cells. Although the cytotoxicity of ZnO NPs affects multiple types of cancer cells, it was more obvious on non-adherent cells of hematopoietic lineage, the elecility of reactive oxygen species towards cancerous cells more than normal cells. The endocytosis of nanoparticles (presence of nanoparticles inside the cell) is required for cytotoxic effect rather than presence of nanoparticles extracellularly. The charge of NP is an important factor in toxicity. Cationic nanoparticles have greater toxicity and selectivity toward cancerous cells than neutral or anionic charged particles. This suggests utilization of ZnONPs as anticancerous agents [11].

The Methyl Thiazolyl Tetrazolium (MTT) assays were used to investigate cell viability after ZnO application of doubled increase concentrations. Solution was used according to MTT was added to cell cultures for 3h and, after incubation, formant crystals were dissolved in Dimethyl Sulfoxide (DMSO) and the plates were analyzed using a plate reader at 630nm wavelength.

The aim of current study was to evaluate the anticancer effects of ZnONPs on a colonic cancer cell line in vitro with the use of MTT assay.

**Materials and Method**

**Zinc Oxide Nanoparticles (ZnONPs):** The reference powder of ZnONPs was obtained from SKY Spring Nanomaterial, Inc., (SSNANO) (USA) (10-30)nm, treated with silane coupling agents, and suspended in deionized distilled water (DDW) and sterilization was done by 0.4 Micro align filter subsequently.

**Preparation of culture media and cell culture:** Liquid medium was prepared from culture media powder, with helps buffer, L-glutamine and phenol red 16.650g was dissolved in approximately 900ml of DDW in volumetric flask and pH of the media was adjusted to 7.4 by using NaOH. Sterilization was done by 0.4 Micro align filter subsequently and the media was incubated in sterile flask for 4 days then stored at 4°C.

Tissue culture flask with a monolayer cells was incubated until cell layer detached, then centrifuged and resuspended with freezing media and transferred to sterile freezing vial which was stored in liquid nitrogen tank. Harvesting is a technique that uses proteolytic enzyme trypsin, to detach and disaggregate the adherent monolayer cells. When cell growth reached a monolayer, the medium was aspirated and discarded. Then the cells were gently pipetted up and down to disrupt cell clumps into single cells. Then the cells were cultured on culture plate.

**Survival cell assay:** The growth inhibitory effect of ZnONPs can be determined in vitro on cell lines by using MTT colorimetric assay with a concentration of 5×10^3 cells/well were seeded in 96-well flat bottom plates containing 300μl of medium. After 48 hour, serial doubling dilutions of ZnONPs were used to treat cell lines. Afterwards, the medium was aspirated and discarded and cells received 10μl of MTT. All plates were incubated at 37°C for 4h and Formozan blue was dissolved in 200μl of dimethyl Sulfoxide (DMSO).

**Statistical Analysis:** Our data were expressed as means ± SD. Analysis of variance and significant differences
were obtained by SPSS version 22 software and one-way ANOVA analysis. Values of $P<0.05$ were considered significant.

**Results**

To measure the growth inhibitory effect of ZnONPs, all cell lines HCT116 and normal cells were treated with a serial doubling dilution concentrations ($\mu$g/mL) of ZnONPs. (i.e. 30, 15, 8 and 4) with no treatment (control) for 48h and the MTT assay was used to determine the viability and propagation of cells and finally presented as statistical analysis (SPSS) and proliferation rate. The results of MTT assays revealed that ZnONPs had cytotoxic effects on all cell lines in a dose-dependent manner (Figure 1) in comparison with normal cell lines treated with a serial doubling dilution concentrations ($\mu$g/mL) of ZnO NPs (i.e. 60, 30, 15, 8, 4 and 0; Figure 3).

![Figure 1: Effects of double-increased concentrations of ZnONPs on cancer cells line compares with controls (0μg/ml).](image1)

![Figure 2: HCT116 cells morphological changes after treatment with ZnO NPs with doubled increase concentrations compares with non-treatment cancer cells (0 μg/ml).](image2)
As presented in Figure (1), proliferation rates of HCT116 cells were reduced in a dose-dependent style. The lowest propagation rates of cells were achieved at 30μg/ml concentration of ZnONPs, however, similar effects on normal cells were attained using 15, 30 and 60μg/ml concentrations (Figure 3).

Discussion

In our study, we evaluated the anticancer effects of ZnONPs on a colonic cancer cell line in vitro with the use of MTT assay. The results revealed that presence of ZnONPs significantly inhibited the growth of tumors as data from current showed that ZnONPs exhibited growth inhibition and morphological changes on tumor cells in a concentration-dependent manner.

Conclusion

As a result of the obvious induction of toxicity and apoptosis on tumor cells in our and other studies, ZnONPs can be used as anti-cancer agents in treatment modalities. They were able to decrease tumor growth in cancer cell lines.

ABSTRACT

Background: Acute myeloid Leukemia is one of the rapidly progressing leukemia and it is diagnosed in all age groups (pediatrics, teens, adults, and geriatric group). In addition, most of physicians depend on complete blood count to evaluate whether the patients need bone marrow aspiration to be diagnosed for CD markers to determine type of leukemia. The aim of current study was to compare white blood cells, red blood cells and hemoglobin levels among Iraqi patients with acute myeloid leukemia.

Method: So a pool of 60 newly diagnosed patients segmented within 4 growth levels (0-15 years, 16-40 years, 4-65 years and 66-above) with 15 subjects in each segment. Complete blood counts done for them then another 60 samples were collected from the same patients a month after 3- and 7-treatment receiving. The comparison was done between growth levels from one side and treatment effect from another.

Results: The outcomes showed significant difference in white blood cells count within the same growth level between pre and post treatment patients (44.65 ± 8.51, 15.62 ± 2.83) for the 1st age group pre and post treatment, respectively (P<0.05). Also, there were differences between age groups for the pre-treatment patients (44.65 ± 8.51, 29.03 ± 9.16, 8.35 ± 5.96 and 32.02 ± 6.06) for the four age groups, respectively, and the post treatment patients (1.95 ± 0.21, 3.16 ± 0.20, 5.77 ± 0.84, and 2.34 ± 0.23) for the four age groups, respectively. Red blood cells evaluation showed significant differences between pre and post treatment within the same age group (1.95 ± 0.21, 4.10 ± 0.17 for 1st age group) pre and post treatment, respectively, and within the same age group for pre and post treatment alone. Hemoglobin evaluation showed statistical differences between pre and post treatment samples within the same age group, but not between age groups.

Conclusion: White blood cells, red blood cells and hemoglobin evaluation give a primary reflection for AML patient’s status whether they improve or get worse.

Keywords: AML, CBC, growth level, Platelet, MPV.

Introduction

Acute myeloid leukemia: Blood malignancy influences white blood cells (WBCs), platelets (PLTs) and red blood cells (RBCs). An individual with Acute Myeloid Leukemia (AML) creates anomalous quantities of these cells in all respects rapidly, giving the malady the name “intense”. The WBCs tally is either upper or under than ordinary tally, which are all in blast stage. Since WBCs are a significant piece of battling contaminations, patients regularly have different incurable diseases. A few patients develop low RBCs tally and/or PLTs tally, yet that isn’t generally [1].

Diagnoses Methods: Biopsy from Bone Marrow (BM) to determine the classification of AML, these may include
cytogenetic testing (karyotype and/or FISH testing), immunophenotyping, molecular testing and human leukocyte antigen (HLA) typing for potential future bone marrow transplant. Classification helps guide treatment. There are two classification systems for AML\(^2\).

World Health Organization order of AML\(^3\) utilizes hereditary variations from the norm to group classes of it. That framework modifies the idea and vision toward AML diagnosis to more than twenty percent of immature cells in BM and gatherings different subtypes of AML dependent on hereditary variations from the norm and forecast.

**Acute myeloid leukemia (AML) and related neoplasms:** The second classification system for AML is FAB grouping (M0 – M7). The FAB (French American British) (2016) order (Table 1). The FAB framework depend on percentage of more than thirty percent immature cells in BM to allocate an analysis Patients characterized into prognosis hazard groupings (ideal, moderate and poor) in view of the hereditary variations that may help decide the best proper treatment.

**Complete Blood Count indicators for AML**

A. **Count of white blood cells:** Elevated WBCs check more than one hundred thousand connected to a more regrettable viewpoint \(^4\).

B. **Other blood components count:** By characterizing the platelet check 50×10\(^9\)/L and 120×10\(^9\)/L as two cut-off focuses, we ordered the patients into three gatherings: low (<50×10\(^9\)/L), medium (50–120×10\(^9\)/L) and high (>120×10\(^9\)/L). On univariate examination, patients with medium platelets check had longer OS and DFS than those with low or high platelets tally. In any case, the multivariate examination demonstrated that solitary longer DFS seen in patients with medium platelets check than those with low or high platelets count. So their discoveries showed that pretreatment platelets tally has a prescient incentive for the anticipation of patients with non-M3 AML\(^5\).

In a separated evaluation included 107 instances of once more AML, patients from ten to sixty years from each gender chosen arbitrarily. Symptoms included elevation in body temperature, shortcoming, weight loss, spewing, draining gingiva, hepatomegaly and splenomegaly. The findings included drop in Hemoglobin (HGB) levels below 8g/dl in 46% near the drop of RBCs and PLTs count. Also, the study showed more common incidence of AML in adults than in children (86% and 4%, respectively) \(^6\).

The aim of current study was to compare white blood cells, red blood cells and hemoglobin levels among Iraqi patients with acute myeloid leukemia.

**Method**

**Samples collection:** One hundred and twenty peripheral blood samples were collected between 1\(^{st}\), May 20\(^{th}\), September from Baghdad special nursing center (which is the drainage of all Iraq to diagnose the tumor type) and AL-Yarmouk Hematology Center using EDTA tubes. In addition, 60 non-AML samples of healthy patients with similar age groups of patients were collected in EDTA to compare the results with the pre and post treatment groups. he Sysmex\(^\text{®}\) (2019) \(^7\) method accurately counts and sizes cells by detecting and measuring changes in electrical resistance when a particle (such as a cell) in a conductive liquid passes through a small aperture. Each cell suspended in a conductive liquid (diluent) acts as an insulator. As each cell goes through the aperture, it shortly increases the resistance of the electrical path between the submerged electrodes on either side of the aperture. This causes a measurable electronic pulse. For counting, the vacuum used to pull the diluted suspension of cells through the aperture must be at a regulated volume. The number of pulses correlates to the number of particles. The height of the electrical pulse is proportional to the cell volume. Differential Analysis as the sample, prepared for differential analysis, streams through the flow cell these three measurements occurs simultaneously on each individual white cell to classify it: Low-frequency current measures volume, High-frequency current senses cellular internal content through measuring changes in conductivity. Light from the laser bouncing off the individual WBCs characterizes cellular surface, shape and reflectivity. On the other hand, the Sysmex HMX Hematology Analyzer is a quantitative, automated hematology analyzers and leukocyte differential cell counters for In Vitro diagnostic use in clinical laboratories. The purpose of the HMX Hematology Analyzer is to separate the normal participant, with all normal system-generated parameters, from the participant who needs additional studies. These studies include further measurements of cell size and cell distribution, biochemical investigation,
or any other test that helps diagnose the abnormality. The HMX measures the following parameters in whole blood; WBCs, RBCs, HGB, HCT, MCV, MCH, MCHC, Platelets, MPV, Neutrophils, Lymphocytes, Basophils, Eosinophils and Monocytes.

The methods used to derive CBC parameters is based on the Sysmex® method of counting and sizing, in combination with an automatic diluting and mixing device for sample processing, and a single beam photometer for hemoglobinometry. WBCs differential uses VCS technology. Analysis and classification of WBCs used three simultaneous measurements of individual cell volume (V), high frequency conductivity (C), and laser light scatter (S). The scatter gram plots cells based upon measurements of these three parameters.

**Results and Discussion**

The statistical difference between pretreatment age groups ed different immunological response to the pathological status among ages which reflected the maturity status of the immune system. WBCs tally test demonstrated noteworthy contrast among pre and post treatment bunches in a similar age gathering and we found high WBCs means within first, second and fourth age bunches with a mean higher than 29.03^10^9/L, while the control gathering stayed in the principle run between 7.88-8.66^10^9/L which offered an emergence to the huge distinction. On the other hand, 3rd age group showed no significant difference when compared with other treatment groups and its mean remained in the normal range of WBCs count (Table 1).

RBCs, the O₂/CO₂ carriers, also included in the overall blood cells disorder as shown in Figure (3.8). Both RBC count and HGB concentrations dropped below control values for most of groups. However, some elevation appeared in post treatment groups that reflected the impact of treatment on these two parameters which gave us an image of case prognosis whether it responds to treatment or not (Tables 2 and 3).

* (P<0.05).
Numerous signs and side effects of AML are the consequences of a lack of ordinary WBCs which happens when leukemia cells group out the typical blood-production cells in bone marrow. Therefore, individuals don’t have enough ordinary red blood cells, white blood cells and blood platelets. These deficiencies appear on blood tests and they cause additional manifestations[8].

ACA (2018) 9 referenced that contaminations can happen in light of a deficiency of typical WBCs (leukopenia), explicitly a lack of disease battling WBCs called neutrophils (a condition called neutropenia). Individuals with AML can get contaminations that don’t appear to leave or may get one disease after another. Fever frequently obliges the contamination.

Despite the fact that individuals with AML can have high white blood tallies because of abundant quantities of leukemia cells, these cells don’t secure against disease, the manner in which ordinary WBCs do.

Renin expression in an updated research of [10] in 45 AML patients and five controls by using quantitative real-time reverse-transcriptase PCR since renin is the direct responsible for hematopoiesis. Result in renin expression detected in 93.3% of AML patients at diagnosis and 100% at relapse. Relapsed AML patients showed higher renin gene expression levels compared to those detected at complete remission and at diagnosis (P = 0.000 and 0.001), respectively. None of our control subjects was positive for renin gene expression. At diagnosis, HGB below 10 grams per dl showed higher renin levels compared to those with HGB of at least 10g/dl. We used median renin gene expression levels to divide AML patients into high and low groups at diagnosis. At diagnosis, the group with higher renin expression showed higher total leukocyte count (TLC) than did the group with lower renin expression. At relapse, the higher renin expression group showed a higher peripheral blood (PB) blast percentage than did the lower renin expression group. So Renin expression can predict outcomes in AML patients and could be used as a therapeutic target.

Hyperleukocytosis is characterized as a WBCs count more prominent than 100,000/μL in patients influenced by intense or constant leukemias. Hyperleukocytosis is more typical in intense leukemias than in interminable leukemias. Hazard elements incorporate more youthful age, intense myeloid leukemia, the microgranular variation of intense promyelocytic leukemia, intense lymphoblastic leukemia and some cytogenetic irregularities. Despite the fact that it can influence any organ framework, side effects as a rule emerged from association of the cerebral, pneumonic and renal microvasculature. The expression “leukostasis” alludes to ‘symptomatic Hyperleukocytosis ‘ which is a medicinal crisis that requires brief acknowledgment and inception of treatment to anticipate renal and respiratory disappointment or intracranial discharge. The basic instruments of hyperleukocytosis and leukostasis are inadequately comprehended [11].

With WBCs at determination of under 30×109/L (57.1%) and overall again intense myeloid leukemia (62.2%), survival bends demonstrated that better anticipation was identified with age underneath 60 years (middle: 12.4 months; p-esteem = 0.2227; Odds Ratio = 0, 6676), great prognostic cytogenetic markers (middle: 97.7 months; p-esteem = 0.0037; Odds Ratio = 0.4239) and platelets tally at conclusion of under 30×109/L (middle survival: 23.6 months; P value= 0.0001; Odds Ratio = 0.3651). As to French-American-British subgroups, the middle by and large survival was 23.5 months for M0, M1 and M2; 97.7 months for M3 and 7.4 months for M4, M5, M6, and M7 (p-esteem = 0.0288) [12].

A randomized (2:1) investigation about directed by [13] of prohibitive (LOW) HGB trigger (7g/dL) contrasted with higher (HIGH) HGB trigger (8g/dL). The essential result was plausibility of directing a bigger preliminary. The four necessities for progress necessitated that beyond what half of the qualified patients could be agreed, over 75% of the patients randomized to the LOW arm endured the transfusion trigger, less than 15% of patients traversed from the LOW arm to the HIGH arm, and no sign for the need to stop the investigation for wellbeing concerns. Auxiliary results included weariness, dying and RBCs as well as platelets transfused. The examination brought about ninety patients were agreed and haphazardly doled out from LOW to HIGH. The four criteria for the essential goal of plausibility were met. At the point when the quantity of units transfused was looked at, modifying for gauge HGB, the LOW arm was transfused all things considered 8.0 (95% certainty interim [CI], 6.9–9.1) units/tolerant, while the HIGH arm got 11.7 (95% CI, 10.1–13.2) units (P= 0.0003). There was no noteworthy distinction in draining episodes or neutropenic fevers between study arms.
Conclusion

White blood cells, red blood cells and hemoglobin evaluation give a primary reflection for AML patient’s status whether they improve or get worse.

The Relationship between Peak Systolic Velocity of Thyroid Gland Arteries and Thyroid Stimulating Hormone Level in Diffuse Goiter Patients

Laith F. Farman Al-Hialy1, Mohammed A. Mahmood1

1College of Medicine, University of Baghdad, Iraq

ABSTRACT

Background: Thyroid disease is the second most common type of endocrine pathology after diabetes mellitus, diffuse goiter accounts for more than 80% of all thyroid abnormalities. Sonography and Doppler study permit direct visualization of thyroid gland including its abnormalities with minimum cost and reduced time of diagnosis. In addition, pulse wave Doppler study can confirm increasing and decreasing blood flow within thyroid gland including measuring the peak systolic velocity of thyroid arteries. Patients with diffuse goiter have variable thyroid-stimulating hormone levels in their blood which reflects their clinical status as eu-, hypo- or hyper-thyroidism. The aim of this study was to find the relationship between peak systolic velocity and thyroid-stimulating hormone level in diffuse goiter patients.

Method: One hundred and twenty one patients with diffuse goiter were involved in this research measuring their thyroid-stimulating hormone levels – resembling normal value (0.4-2.5 μu/l) and examined with ultrasound and calculating their thyroid arteries peak systolic velocity – resembling normal value (10-28cm/sec) by Pulse wave Doppler study. No such study was done including these variable data in diffuse goiter patients.

Result: Sixty seven patients with normal thyroid-stimulating hormone level had normal peak systolic velocity, 29 patients with low thyroid-stimulating hormone level had high peak systolic velocity, and 25 patients with high thyroid-stimulating hormone level had low peak systolic velocity.

Conclusion: There was a significantly high negative correlation between peak systolic velocity value and thyroid-stimulating hormone level in diffuse goiter patients (if thyroid-stimulating hormone decreases, then the peak systolic velocity increases) giving indirect information about patients’ clinical status variation from euthyroidism, hypo- and hyperthyroidism.

Keywords: Diffuse goiter, Peak systolic velocity, Thyroid-stimulating hormone, Doppler study, Sonography.

Introduction

Thyroid gland is a butterfly-shaped gland located at midline of neck above the clavicles, it consists of right and left lobes and the isthmus and it surrounds the larynx and trachea covered by perthyroid muscle, subcutaneous fat and skin. According to WHO the normal thyroid gland adult size as (AP diameter of RT & LT lobes is 16-18mm, width 13-18mm, isthmus 2-6mm) in liner based measurements [1]. Thyroid gland is supplied with blood from two paired superior thyroid arteries (UTA) from external carotid artery and inferior thyroid arteries (ITA) from subclavian artery and inter mediate artery to the isthmus [2]. The normal average of peak systolic velocity (PSV) of UTA is 10-28cm/sec [2]. Diffuse enlargement of thyroid gland or called goiter is observed in 1-5% of the population and accounts for 80-85% of all thyroid abnormalities, including the following pathologies (diffuse hyperplasia, iodine or auto immune –induced goiter, idiopathic goiter, thyroiditis and Graves ‘ disease) [3].

Ultrasound and Doppler study have 92.9 % accuracy in diagnoses of Graves ‘ disease with 96.3% specificity and 80.3% sensitivity [4].
Thyroid gland produces thyroxin which regulates body weight, temperature, muscle strength and even mood. This hormone release is controlled by the TSH hormone or called thyrotropin which is produced from the pituitary gland \[^{[5,6]}\]. High level thyroid hormone indicates low level TSH and results in a case of hyperthyroidism which gives these symptoms (anxiety, weight loss, tremors, increase heart rate, puffiness, bulging eye and difficulty sleeping). On the other hand, low level thyroid hormone indicates high level TSH and results in a case of hypothyroidism which gives these symptoms (weight gain, tiredness, hair loss, low tolerance for cold temperatures, irregular menstrual cycle and constipation). However, normal TSH level averages (0.4—2.5µU/L) \[^{[7,8,9]}\]. The aim of current study was to find the relationship between peak systolic velocity and thyroid-stimulating hormone level in diffuse goiter patients.

Patients and Method

Current study involved 121 patients with diffuse goiter, measuring their TSH levels – resembling normal value (0.4-2.5µU/l) and examined with ultrasound and calculating there thyroid arteries PSV- resembling normal value (10-28cm/sec) by PW Doppler study.

These patients were referred from medical and endocrinology clinics with their pervious diagnoses and their lab tests results. The study extended from 2017 to 2019 when all patients with diffuse goiter were examined by senior radiologists, in Sonography department at AI Furat General Hospital, Baghdad and Sonography clinics, collecting their findings, particularly their PSV of thyroid arteries and TSH test results for each of them.

Ultrasound & Doppler examination procedure: Patients were positioned supine with head thrown back and examination was performed in 3 plans; longitudinal, transverse and oblique lateral views. Examination was performed with (7.5 – 12MHZ) liner ultrasound probe, but convex (2.5-5MHZ) may be used for larger goiter.

Statistical Analyses: Statistical analyses were performed using statistical package for Social Sciences (SPSS version 20.0 for windows, SPSS, Chicago, IL, USA). Data were presented as Mean ± SD, while numbers and percentages for gender, PSV and TSH ordinal groups. Correlation test was used to study the relation between PSV and TSH. Chi-squared test was used to test the relation between PSV and TSH groups. P value of <0.05 was considered statistically significant.

Results and Discussion

Data from current study showed that Mean ± SD age of participants was 43.19 ± 10.75 years and the range was 22-69 years (in males the age was 46.48 ± 13.03 years with a range of 27-66 years, while in females it was 42.50 ± 10.16 with a range of 22-69 years). There were 21 males (17.4%) and 100 females (82.6%). Male to female ratio was 1:5. In all cases, the Mean ± SD PSV was 21.04 ± 11.77cm/sec (range was 5-58 cm/sec); 26 were below normal range of (10-28 cm/sec) with Mean ± SD PSV of 7.05 ± 1.25cm/sec (range was 5-9cm/sec), 68 cases were with normal PSV level had Mean ± SD PSV 19.37 ± 4.09cm/sec (range was 10-28cm/sec). On the other hand, 27 cases were with above normal range of PSV had Mean ± SD of 38.74 ± 8.12cm/sec (range was 30-58 cm/sec) (Table 1 and Figure 1).

Moreover, data showed that the Mean ± SD level of TSH was 1.52 ± 1.08µU/l (range was 0.05-4.2µU/l). Also, 29 cases were below normal TSH range (0.4-2.5µU/l) with a Mean ± SD level of 0.21 ± 0.09µU/l (0.05-0.30µU/l), 67 cases were with normal range of TSH had a Mean ± SD level of 1.46 ± 0.48µU/l (0.5-2.4µU/l) and 25 cases were with above normal range had a Mean ± SD level of 3.2 ± 0.41µU/l (range was 2.7-4.2µU/l) (Table 1, Figure 1).
Furthermore, there was significant high negative correlation between PSV and TSH (Pearson correlation (r)= -0.813, P<0.0005) which indicated that when TSH decreases, PSV increases (Table 2 and Figure 2).

On grouping the cases into below, within and above normal ranges for PSV and TSH and studying the relation between them, we found that the majority of cases 66(54.5%) had normal PSV and TSH, while low TSH (<0.4µU/l) was associated with high PSV (>28cm/sec) in 26(21.5%) cases. On the other hand, high TSH (>2.5µU/l) was associated with low PSV (<10cm/sec) in 25(20.7%) cases. There was highly significant relation (P<0.0005; Table 2 and Figure 2).

The Role of microRNA 122, MCP-1 and TGF-β1 as Diagnostic Biomarkers for Endometriosis

Ekklas Saddam Falih1, Suhad Hassan Aubaid1, Wala’a Taha Yousif1
1Collage of Health &Medical Technology, Baghdad, Iraq

ABSTRACT

Background: Endometriosis represents a major medical concern in women of reproductive age. A Reliable single biomarker or panel of biomarkers may help diagnose endometriosis earlier and reduce unnecessary operation. Simple blood tests for prediction and diagnosis of endometriosis have a major impact on women’s health. MicroRNAs are small Non-coding RNAs that have been intensively evaluated as biomarkers for several diseases and may hold promise for endometriosis diagnosis. The present study was aimed to explore the possible role of using serum miRNA122 in endometriosis patients to supply a more accurate assessment of the disease and improve the role of other serum biomarkers in endometriosis.

Method: Twenty-five endometriosis patients diagnosed by laparotomy were admitted to the Gynecology Department of Al-Emamain Al-Kademian Medical City, Baghdad, Iraq. A total of twenty-five apparently healthy women were chosen as controls. The miR122 was detected by reverse transcription-quantitative polymerase chain reaction (RT qPCR), while the MCP-1 and TGF-β1 were detected by the ELISA technique.

Results: This study showed that the mean log fold change value of miR122 in plasma of endometriosis patients, which was (19.65), was higher in comparison to controls (3.42) ($P=0.001$). The mean concentrations of MCP-1 and TGF-β1 were significantly higher in patients with endometriosis than in controls ($P<0.05$).

Conclusion: Measurements of serum, miRNA122 may be useful in the evaluation of endometriosis patients in combination with other serum markers.

Keywords: Endometriosis, MicroRNA122, MCP-1, TGF-β1, PCR.

Introduction

Endometriosis refers to the presence of ectopic endometrial glands and stroma outside the uterine cavity with development primarily in the pelvic cavity. Endometriosis affects 5% to 10% of women of reproductive age and is characterized primarily by pelvic pain and infertility (1). The identification of specific biomarkers for the disease which may let earlier detection and may demand less invasive diagnostic measurement would minimize not only the time to diagnosis but also minimize the cost associated with implementing laparoscopy and consequent diagnosis of the disease(2).

A need for simple blood test for endometriosis-specific biomarkers would offer a timelier and precise diagnosis for the disease conferring earlier therapeutic intervention (3). MicroRNAs (miRNAs) have stand out as potential diagnostic markers for endometriosis based upon the premise of identification of endometriosis-specific miRNAs after been suitable for the field of cancer diagnostic biomarkers (4). Cytokines are the main mediators and communicators of the immune system; their dysregulation is acknowledged as an important aspect of the pathogenesis of numerous conditions, including endometriosis (5). Monocyte chemo–attractant phagocytosis (MCP-1) was a chemo-attractant for mononuclear phagocytes. It was one of the products of the mevalonate pathway and secreted by white blood cells, macrophages, endometrial ectopic tissues and endometriotic tissues (6). It promotes monocytes migration from the peripheral blood to the peritoneal cavity where they transform into macrophages and contribute to the

local peritoneal inflammation commonly observed in endometriosis (7). According to these reasons, MCP-1 may play an important role in the pathogenesis of endometriosis (8). While there have been considerable attempts to identify such biomarkers, a simple blood test for endometriosis-specific biomarkers would exhibit a timelier and accurate diagnosis for the disease allowing earlier therapeutic intervention. The present study was aimed to explore the possible role of using serum miRNA122 in endometriosis patients to supply a more accurate assessment of the disease and improve the role of other serum biomarkers in endometriosis.

Materials and Method

Subjects: Twenty-five endometriosis patients diagnosed by laparotomy and admitted to the Gynecology Department of Al-Emamain Al-Kademian Medical City, Baghdad during the period extended from November 2017 to November 2018. Inclusion criteria were women at reproductive age. Exclusion criteria were women with a malignant tumor, smokers and those with current infection (genital or systemic). Blood and peritoneal fluid were collected from each patient. Twenty-five apparently healthy women were chosen as control group they were age-matched to the study group. The controls were fertile, not pregnant and non-smoker with no current infection (genital or systemic).

Molecular detection of miRNA-122: Molecular detection of miRNA-122 was carried out according to (Taq Man™ MicroRNA Assay, inventoried, SM, Applied Biosystems, USA) which occurred in three steps:

1. RNA extraction.
2. Reverse transcription step.
3. Real-time PCR for the detection of mature miRNA-122.

Measurement of MCP-1 and TGF-β1 by ELISA: The concentrations of the serum MCP-1 and TGF-β1 in an individual patient and healthy controls were managed according to ELISA kit (Ray Bio) for MCP-1, (My Biosource) for TGF- β1.

Statistical Analysis: Analysis of data was carried out using the available Statistical Packages for Social Sciences (SPSS, version 25). Data are presented as mean ± SD, median and standard error. Qualitative relations were evaluated using Chi-squared test. P-value ≤0.05 was considered statistically significant.

Results

Demographical picture and clinical presentation: The results of this study were based on the investigation of 25 patients with endometriosis, compared with 25 apparently healthy women considered as controls. The mean ± SD age of patients was (32.76±7.82) years with a range of (18-45) years, while the mean ± SD age of the control group was (31.98±7.28) years with a range of (20-45) years. Statistically there was no significant variance in the mean age between both groups, (P>0.05; Table 1).

Discussion

Endometriosis describes a major medical interest in women of reproductive age. No single serum biomarker has been found with enough sensitivity and specificity to diagnose endometriosis, but recently researchers focused on studying a panel of serum biomarkers for diagnosing this disease \(^9\). miRNAs serve as potential biomarkers for early detection of the disease \(^10\). Consequently, studies on the expression of miRNAs in patients with endometriosis will provide unprecedented penetrations for the development of specific miRNAs as diagnostic markers and therapeutic destinations for endometriosis in the future \(^11\). In the current work, there was an increased expression of microRNA-122 in patients as compared with healthy controls. This finding agreed with \(^12\) who was the first to estimate serum microRNA levels in women with endometriosis and healthy women. They obtained increased levels of miR-122 and miR-199a and decreased levels of miR-145, miR-141, miR-542-3p and miR-9 in women with endometriosis and stated that these compounds could be used as possible biomarkers for the disease. Their findings also reported that evaluation of the expression of miR-122 and miR-199a might be of use in evaluating severity of the disease. In agreement with our results, \(^13\) determined that the relative expression levels of miR-199a and miR-122 were raised in endometriosis patients samples than those in controls \(^14\). Interestingly, \(^15\) stated that up-regulation of miR-199a and miR-122 in the serum of endometriosis patients suggested that they might be involved in disease pathogenesis via the organization of SOX4 expression. This hypothesis warrants further investigation. Hence, miR-122 may be helpful for diagnosing EMs although this will need to be proved by other studies and validation in a large cohort of samples \(^16\). Several cytokines such as transforming growth factor-β1 (TGF-β1) and monocyte chemo-attractant protein-1 (MCP-1) have been described to associate with pathogenesis of endometriosis and provoke infiltration of blood monocytes or macrophages into the peritoneal cavity \(^17\). In the current study, there were statistically significant higher levels of MCP-1 and TGF-β1 in serum and peritoneal fluid of patients as compared to healthy controls. Monocytes are delivered to the endometriotic lesion by the chemotactic chemokine MCP-1, and they are then transformed into mature macrophages. Really, some investigators had reported higher concentrations of MCP-1 in the peritoneal fluid in women with endometriosis than in those without endometriosis \(^18,19\). These results agreed with our findings. Prior studies showed an increased quantity and activation of macrophages in the peritoneal fluid of patients with pelvic endometriosis as well as raised levels of macrophage-related cytokines and growth factors \(^20,21\). Moreover, the level of TGF-β1 was significantly higher than in healthy controls. Numerous studies had reported significantly higher levels of TGF-β1
in serum, peritoneal fluid, peritoneum and ectopic endometrial tissue of women with endometriosis when correlated to women without endometriosis, implying that changed TGF-β expression and/or signaling may contribute to the pathophysiology of endometriosis. Numerous studies in mice and women had reported that increasing levels of TGF-β ligands are associated with decreased immune cell activity within the peritoneum, concomitantly with an increase in ectopic endometrial cells survival, attachment, invasion and proliferation, meanwhile endometriosis lesion development.

**Conclusion**

Significantly increased levels of miR-122, MCP-1, and TGF-β1 in endometriosis indicated that these biomarkers serve as the diagnostic marker of endometriosis. Increased concentrations of inflammatory cytokines within the peritoneal fluid and serum were thought to contribute to peritoneal lesion formation.

Assessment of Health Related Quality of Life in Children with Nephrotic Syndrome in Iraq—A Comparative Study

Uday Khalid Abdul Jabbar Al Qaisy¹, Shatha Hussain Ali¹, Iyad Hussein Ali²

¹Department of Pediatrics, College of Medicine, Al-Nahrain University, Iraq; ²Imamain Kadhimain Medical City, Baghdad, Iraq

ABSTRACT

Nephrotic syndrome is a relapsing and remitting disease. Comprehensive care of affected children may benefit from assessments of the impact of disease on physical and psychosocial aspects of health-related quality of life.

The aim is to assess the quality of life (QOL) in a sample of Iraqi children with NS in relation to children with other chronic disease. And To evaluate the relation of functioning at the physical, emotional, social and educational domains of quality of life with phenotype of NS and medication

This case control study was conducted in pediatric consultation clinics at two hospitals in Baghdad. Fifty children with nephrotic syndrome aged 2–12 years, and 50 patients as controls with chronic diseases were evaluated by using a structured questionnaire of Pediatrics Quality Of Life™ 4.0 Generic Core Scale

Scores in all domains of quality of live were significantly higher in nephrotic syndrome patients compared to those with chronic disease. Frequent relapsing and new diagnosis types showed significantly higher score in physical and emotional domains. Patients treated by prednisolone alone showed significantly higher score in physical and social domains

Quality of live in children with nephrotic syndrome is better than children with other chronic illnesses. Infrequent relapse type, newly diagnosed and steroid treated groups showed better quality of life in certain domains

Keywords: Nephrotic syndrome, Children , Life quality

Introduction

Nephrotic syndrome (NS) is defined as persistent heavy proteinuria mainly albuminuria, hypoalbuminaemia, generalized edema and hyperlipidemia. Males appear to be more affected than females at a ratio of 2:1 in children, but this predominance fails to persist in adolescence.¹

The main pathogenic abnormality in nephrotic syndrome is an increase in glomerular capillary wall permeability, resulting in pronounced proteinuria, with most common sign being edema which is excess fluid in the body due to the serum hypoalbuminemia.²,³

Quality of life in children with nephrotic syndrome is better than children with other chronic illnesses. Infrequent relapse type, newly diagnosed and steroid treated groups showed better quality of life in certain domains

Treatments include steroid therapy, diuretics antihypertensive medications, lipid lowering agents, chemotherapy together with diet and activity.⁴,⁵,⁶

Nephrotic syndrome may be associated with a series of complications which can affect an individual’s health and quality of life.⁷,⁸

Behavioral abnormalities are another established complication of steroid therapy. Internalizing and externalizing behavioral disorders, including anxiety, depression and aggression, have been reported.⁹-¹⁰,¹¹

Frequently, the disease process spans a significant portion of the formative years of a child’s life and can extend into adulthood. As a result, the comprehensive care of children with NS may benefit by the formal assessments of the impact of disease on the physical and psychosocial aspects of health-related quality of life (HRQOL).¹²,¹³
There is broad agreement that HRQOL is the functional effect of a medical condition and/or its consequent therapy upon a patient. HRQOL is thus subjective and multidimensional, encompassing physical and occupational function, psychological state, social interaction and somatic sensation. The World Health Organization (WHO) defines quality of life (QOL) as the individuals’ perception of their position in life in the context of culture and value systems in which they live, and in relation to their goals, expectations, standards and concerns.

This study was conducted to:

1. Assess the quality of life (QOL) in a sample of Iraqi children with NS in relation to children with other chronic disease.
2. Evaluate the relation of functioning at the physical, emotional, social and educational domains of quality of life with phenotype of NS and medication.

**Materials and Method**

This comparative case control study was conducted at pediatric consultation clinics at Imamein Kadhimain Medical City and Central Child Teaching Hospital in Baghdad, Iraq between 1st of May to 31st of August 2018.

A convenient sample size of 100 patients was selected. Patients consist of 50 patients with NS. The controls included 50 pediatric patients with the following chronic diseases: asthma, thalassemia, epilepsy, leukemia and diabetic mellitus. Ten patients of each of these chronic conditions were randomly selected.

Data were obtained from the parents with direct interview, after explaining the purpose of the study to them and having their informed consent to participate in the study. Data collected from NS parents included: age, gender, and residence, duration of illness and types of NS., medication used, complications and number of admission to the hospital.

Data collected from controls included: age, gender, residence, duration of illness and disease category.

The data concerning quality of life were collected by a structured questionnaire using PedsQL™ 4.0Generic Core Scale. PedsQL™ 4.0 Generic Core Scale is a well-used instrument that assesses the physical, emotional, social functioning, and school performance, depending on age of child age; (2-4), (5-7) and 8-12 years old. It evaluates the QOL in five domains: Physical, emotional, social and School functioning. A 5-point response scale is used from 0 (never a problem) to 4 (almost always a problem). The scores of each item are then reversed and linearly transformed into a 0–100 scale (0 = 100, 1 = 75, 2 = 50, 3 = 25, and 4 = 0) i.e. the interquartile range (IQR), with higher PedsQL scores indicating a better QOL.

The parent report form of the tool with formats of ages (2-4),(5-7) and (8-12) years were translated to Arabic language and piloted on ten parents before initiation of the study. It took approximately 15-20 min to gather the required information from the parents. Children with congenital NS and secondary NS were excluded. SPSS version 23 (Statistical Package for the Social Science) software was used data analysis. P <0.05 was considered statistically significant

**Results**

One hundred patients aged 2–12 years were included in the study distributed as 50 patients with NS and 50 patients as control cases. The two groups were homogenous regarding demographic characteristics with no statistically significant difference between them. (Table 1)

The majority of NS patients (60%) have more than (24) months as duration of illness. Majority of patients (38%) were of steroid dependent and frequent relapsing phenotypes. Fifty patients (100%) were treated by prednisolone either alone (62%) or combination with other drug (38%). As complications, peritonitis was present in (36%) and hypertension in (30%) of NS cases. (36%) reported no hospital admission, while frequent admission five and more was detected in (8%) (Table 2).

The median IQR was found to be higher in NS patients compared to controls. There were significantly better scores in physical (P = 0.001), emotional (P = 0.001), and social (P =0.001) functioning, and school performance (P = 0.001). School domain was studied in (28) children with NS out of the (50) patients because (6) of them were below 4 years old and other (16) patients above 4 years but left school. In the control group (13) children did not attend school, (7) of them were below (4) years of age and other (6) of them did not attend school. (table 3)
Patients with Infrequent relapsing NS and newly diagnosis NS showed better and statistically significant score in the physical (P = 0.046) and emotional (P = 0.021) domains in comparison to other phenotypes, while both social functioning (P =0.249) and school performance (P = 0.337) showed nearly similar scores and were not statistically significant different from other phenotypes.(table 4)

NS children treated by prednisolone alone showed better score in both physical (P = 0.022) and social functioning (P =0.043) domains and the difference was significant compared to those children on combined drug treatment. (table 5).

P value significant <0.05

**Discussion**

This study found significantly higher score for physical, emotional, Social domains and school performance indicating better quality of life in NS patients than patients of chronic diseases. Two studies by Sonia Agrawal et al in India, and El-Gamasy M.A. et al in Egypt, both assessed the quality of life (QOL) of 50 children with NS and 50 children with other chronic disease as control both aged between 2-18 years and found that children with NS had significantly higher scores in physical, emotional, and social functioning as compared to controls while found no difference regarding school performance\(^{(19,20)}\).

Furthermore Rüth et al in Netherlands evaluated QOL in 45 European pediatric patients with steroid-sensitive NS. Only the QOL subscale “social function” was impaired while other domains were not affected.\(^{(12)}\). NS patients are free of symptoms and acquire a normal life style in between relapses especially Infrequent relapse type which constituted 30% of total patients with NS in the current study, in addition most of relapses are mild and without complication and does not necessitate admission to hospital as found in the current study. Thus these children with NS move physically and actively better than children with other illnesses.

For emotional functioning, the nature of disease added to absence of the aggressive treatment used during relapses make the patients with NS better emotionally, while in social aspect the long time of remission and normal life style during it, help the patients to contact socially and play easily with other children. This
conclusion is supported by findings of Mbafeno et al in Nigeria who detected close association between low quality of life and complications in their 50 children sample with NS(21).

The results concerning school performance of the current study needs to be taken in caution as not all children were evaluated for this domain as many of them were less than 4 years old and considerable number did not attend school at all.

On the other hand Nguyen et al in Vietnam found lower quality of life in all domains when compared a sample of 71 NS children with healthy controls indicating that although NS patients do better than other chronic diseases yet they have lower quality of life in comparison to healthy controls.(22)

This is supported by findings of Rahman et al in Bangladesh who found low quality of life in their sample of NS patients although their sample included more infrequent relapsing type and longer duration of illness and they did not compare their sample with control group(23)

In the current study, patients with infrequent relapse NS and newly diagnosis NS, reported better quality of life in physical, and emotional domains, that may be explained by the longtime of remission and less complications in patients with infrequent relapsing.

On the other hand Sonia A and Al Gampsy whose samples included more difficult phenotypes did not find differences in QOL according phenotypes supporting the notion that samples with more difficult cases show comparable levels of QOL while samples with considerable representation of less complicated cases may show better levels(19,20).

Children treated by prednisolone alone showed better score in both physical and social functioning. Additional medication rather than prednisolone will add new burden to the patients as cyclosporine, cyclophosphamide and others need strict follow up and regular investigation in addition to suspected side effect and this may adversely affect physical and social domains.

Still further studies with larger sample size and adequate representation of different phenotypes and treatment modalities are needed confirm these findings and explanations presented.

Conclusion

Quality of live in children with nephrotic syndrome is better than children with other chronic illnesses. Infrequent relapse type, newly diagnosed and steroid treated groups showed better quality of life in certain domains

The Use of Erubium Yag (Er:YAG) Laser to Treat Burns and Study Laser Effect on the Environment

Jamal Suheel abd1, Hana Hasan k1, Ahmed Jumaah Mhawes2, Hayder Hasan Ali1, Enass Mohammed Abdulzahraa3

1College of Basic Education, University of Sumer, Iraq; 2College of Medicine, University of Kufa, Iraq; 3Ministry of Health, Iraq

ABSTRACT

Er: YAG laser wavelength (2940nm) was used in burns treatment. The result of treatment acne scar by Er:YAG is better than by using IPL. This process is occurs by absorption laser beam by skin layers. especially superficial treatment. There are different properties related to skin layer such as thermal and thermal relaxation time (TRT) and the target [TRT = Time required for the heated tissue to lose about half of its heat]. When using laser beams incorrectly affect human health and the environment, which leads to the spread of radiation and this leads to the incidence of various cancers.

Keywords: Er:YAG, Laser, Burns, Environment.

Introduction

The laser mean [light amplification by stimulated emission of radiation]. However laser light is different normal light because laser light have (intensity, energy, tip, frequency) is high compare of normal light. The different type of laser such as (CO₂ (10600nm), Nd:YAG (1064nm), Er:YAG (2940nm). The effect laser ray in biological tissue is dependent on (wave length, tip, energy, frequency). The low the absorption coefficient is burns types is simple use Er:YAG fraction in the treatment and the high absorption coefficient is burns type is deep of the skin use Er:YAG fractional and thermal in the treatment (1,2). The use laser in treatment burns or acne scar and vascular make temperature on the tissue we need to cool system treatment region. The cooling system express cold air used temperature low on the tissue (3,4).

Laser Er:YAG: The Er:YAG laser main crystal of the yatrium aluminium garnet [YSAG]. The laser Er:YAG emission wavelength (2940nm). The laser gives radiation wavelength (2940nm), which is the absorption by tissue. The laser Er:YAG is two type (fractional and fractional thermal) is used data in treatment burns. The burns type simple use fractional and deep burns is used fractional thermal. The Er:YAG near infrared laser, pumping optical, solid state. The properties laser is monochromatic, coherent, directional but is normal light is not have laser properties. The laser properties used in the treatment burns but is not normal light in the burns and acne scar.

Selectiver photo- thermolysis: Selective photo-thermolysis term was introduced by Anderson and Parrish (5). That clearly indicates to the objective of the selective destruction of a tissue structure by an increase in temperature induced by a light source. There are three significant parameters to be taken into account in achieving selective photothermolysis.

Wavelength is determines depth of penetration through the epidermis and dermis figure (2).

![Figure 2: Wavelength and absorption coefficient](image)

Pulse duration (3.5mm, 9mm): Determined by the thermal relaxation time (TRT).

**Spot size:** Spot size to have less scattering of the laser beam and deep dermal penetration in figure (3).

![Figure 3: relation between penetration level and size spot](image)

**Cooling system:** The cooling includes air-cooling or cool gels applied to the surface.

**Laser tissue interaction:** Light is an electromagnetic radiation that covers a broad spectrum of wavelength (from x-ray to radio waves). When we irradiate tissue – in this case the skin – with a light source, several significant physical phenomena occur (fig.4). Because of the difference in refraction coefficients between air and the corneal epithelium, some of the radiation is reflected.
Another part of the radiation transmitted or penetrating the tissue become dispersed. Finally, the radiation that reaches the target tissue be absorbed by the structure. Any target tissue or structure must contain a substance or molecule with the appropriate physical and chemical characteristic to absorb this radiation. A molecule that absorbs a given wavelength is known as a chromophore. All of the medical applications of light sources are built upon the basic physical principle of absorption.

Absorption of the radiation by the chromospheres must take place in order for a biological reaction to occur. The energy provided in the radiation absorbed by the target tissue undergoes a transformation with several possible outcomes: photo thermal (increase in temperature), photomechanical (thermal expansion producing sound waves), or fluorescence (emission of photons at another wavelength). In photo depilation, a photo thermal effect is sought in order to raise the temperature of the follicular structure and thus destroy it. Each chromophore has the capacity to absorb certain wavelength. This is a very important fact, as it is the absorption profile of the chromophore that will determine which wavelength must be used to treat it. Therefore, need to know at which wavelength the absorption peaks of each chromophore occur. Melanin is the target chromophore in photodepilation. This intracellular pigment is characterized by high absorption coefficient for all wavelength in the visible spectrum but in an inverse relation to the wavelength, meaning the absorption coefficient decreases as the wavelength increases (Fig.5). The wavelength of the radiation used is important not only because it determines the specificity for a given chromophore, but also because penetration depth is dependent upon this. At wavelength within the low absorption index of water (400 to 1000nm), as the wavelength increase, dispersal within the dermis decreases, increasing the depth of penetration at the wavelength (Fig 6).

Figure 4: Diagram showing the different physical phenomena that occur when skin is irradiated with a light source

Figure 5: Diagram showing the relationship between wavelength and the absorption coefficient of melanin
Environmental safety of lasers: There are other than the risk of exposure to laser beam, which is a significant risk of the laser system itself, such as electric shock caused by high exposure to electrical materials used. For the purpose of laser prevention, follow these steps.

1. When handling lasers or entering the lasers laboratory, special glasses must be bounced to reduce the exposure of the laser beam and the glasses must be chosen for each wavelength.

2. If the laser is turned on the laboratory light should be as high as possible to keep the pupil opening as small as possible to minimize the possibility of the laser beam entering the eye.

3. To product skin and skin of the laser rays risk to be reinstated thick white boat to reduce the capacity of laser bases. It also wears gloves to maintain the skin of the radiation.

4. Be sure to check the electrical system of the laser system and inspect it accurately and may not stand on the floors or metal surface when operating the system.

5. In laser laboratories, appropriate wall petitions are required to prevent direct exposure to laser radiation when entering the laboratory.

6. Laser lab workers warn of solitary work and individual survival when running the system.

7. The absorbent radiation barriers should be placed in front of the scattered laser beam.

8. The laser system should be provided with self-control circuits so that the system cannot be operated unless the environment conditions adequate.

9. Periodic medical examinations should be conducted for laser workers to check on their health and to protect the environment from the spread of harmful rays, which cause many diseases.

When using laser beams incorrectly affect human health and the environment, which leads to the spread of radiation and this leads to the incidence of various cancers. When lasers are used by non-specialist, the patients’ health may be affected. These rays may reach the eye, which is the sensitive organ in the human body. Therefore, laboratory safety conditions and necessary guidelines should be used when entering the laser beam to product the person from harmful radiation and also the non-spread of these rays in the environment, which leads to pollution of the environment so it is necessary to use the radiation correctly by specialists, ensuring the safety of people and live in a safety environment.

**Conclusion**

This middle age female presented with burn scar in right check perioral area and right side of neck. In the (1st) cessation the scar is large and hard in consistency after (7 cases) the scar become smaller in size and softer in consistency and the ugly appearance become better especially in right double chin area and perioral area.
This patient presented with scar in right. Shoulder with hyper and hypopigment of laser the skin after cessation of laser the scar in right. Upper arm disappear and scar in right. Shoulder become smaller and softer in addition the patient feel better movement in the joint.

This young patient presented with burn scar and hypergiment in the face. In (1st) cessation, there is hypertrophic scar in right. nasolobail fold and tip of nose with hypergimen in left. Nasolabail fold after (7 cases) the hypertrophic scar in the tip of nose disappeared and right. Nasolabial scar become smaller and smoother.

The Relation between Some Genetic Traits (Ptc Tasting, Tongue Rolling, Earlobe Attachment and Dental Occlusion in Iraqi Adults

Jinan E. Saloom1, Sami K. Al-Joubori1, Sara M. Al-Mashhdany1

1Department of Orthodontics, College of Dentistry, University of Baghdad, Baghdad, Iraq

ABSTRACT

This study aimed to determine the possible relation among three genetic traits named phenylthiocarbamide (PTC) tasting ability, earlobes attachment, and tongue rolling ability together with class I, class II and class III dental malocclusion.

The study was undertaken amongst 81 dental students of college of dentistry of Baghdad university aged (18-25), (52 female & 29 male) with different anteroposterior dental malocclusion to determine their phenylthiocarbamide (PTC) tasting ability, earlobes attachments configurations and tongue rolling ability, for these non-parametric variables, chi-square and percentage tests were used to examine differences among groups.

The prevalence of (PTC) tasting ability was higher in all dental classes and being higher in male group of Cl I, Cl II and female group of Cl III sample, the prevalence of free un-attached earlobes is higher in all dental classes being highest in Cl III sample, the prevalence of tongue rolling ability is higher in all dental classes except for female group of Cl III sample who are mostly non curler. These variables showed statistically significant gender differences (P ≤ 0.05), Cl III dental malocclusion showed specific distribution pattern of the studied genetic traits suggesting for a possible genetic link among them.

Keywords: Malocclusion, (PTC) tasting, Earlobes attachments, Tongue rolling.

Introduction

Anthropometric characters have been depended for racial classification for so many years, however the use of genetic characters bring about special advantages of helping to understand the dynamic of human population for understanding the human diversity, many polymorphic genetic markers have been used (1-3). The determination of gene frequencies for ear lobe, tongue rolling and the ability to taste phenylthiocarbamide (PTC) and the variation of dental occlusion is of interest to the human population geneticists. Genetic diversity between human populations can be detected by means of analysis of variation in these characteristic (3).

The ability to taste PTC (Phenylthiocarbamide), an organic compound is also known as phenylthiourea (PTU)is an organosulfuruthiourea containing a phenyl ring, it has an unusual property that either very bitter or is being tasteless, it has been known to be a bimodal autosomal trait inherited in a simple Mendelian recessive gene that codes for a taste receptor on the tongue (2-6), the PTC gene was discovered in 2003 (2). The people who can taste it are having a dominant genetic trait and the test to determine PTC sensitivity is one of the most commonly used genetic tests on humans (6). About 70% of the people can taste PTC (2).

There are two common forms (or alleles) of the PTC gene, one of the common form is a tasting allele, and the other is anon tasting allele each of these allele codes for a bitter taste receptor protein with slightly different parts of their shapes, since all people have two copies of each gene, combination of the bitter gene variants determine whether someone finds PTC intensely bitter, somewhat bitter, or being without taste at all (3,6).

DOI Number: 10.5958/0976-5506.2019.03270.4
Earlobe attachment is considered as a continuous trait, if the earlobe hangs free, they are detached, if they attached directly to the side of the head, they are attached earlobe. Some scientists have reported that this trait is due to a single gene for which unattached earlobe is dominant trait and attached earlobe is recessive trait, other scientists have reported that this trait is probably due to several genes (7).

Tongue rolling is considered as an inherited trait, described as the ability to turn up the lateral border of the tongue into u-shape, it is also known as tongue curling. The dominant gene is responsible for tongue rolling ability, while the inability to roll the tongue is a result of a recessive gene. In 1940, the famous geneticist Alfred noted that about 70% of the people of European ancestry were able to roll up the lateral edges of the tongue, while the remaining lack this ability (2,8).

The aim of this study is to determine the relationship among the genetic traits of PTC phenylthiocarbamide tasting ability, earlobe attachments configuration, tongue rolling ability and anteroposterior dental malocclusion in Iraqi adult sample.

Materials and Method

A measurement of PTC tasting ability, earlobe attachment configuration, tongue rolling ability and its relation to dental occlusion in a sample of (81) Iraqi dental students from the college of dentistry of Baghdad university, (52 female, 29 male), their age ranged (18-25) years, consist of (31 class I, 30 class II, 20 class III dental occlusion).

The sample of this study was collected from the students of college of dentistry of Baghdad university, they were selected to meet a special criteria, which were:

1. Full set of permenant teeth (excluding the 3rd molar).
2. Normal appearing teeth, no badly carious teeth and no missing or extracted teeth.
3. No large restoration or fixed replacement.
4. No history of previous of orthopeadic, orthodontic or facial trauma.
5. No gross asymmetries in the dental arches and face.

Examination and dental tools: Dental mirrors, kidney dish, antiseptic solution (spirit 75%), with the individual was seated on a dental chair, the intraoral examination was done for each person to check the criteria that should be present.

The dental occlusion was examined and classified into (9):

1. Class I or neutocclusion—the mesiobuccal cusp of the upper first molar occludes with the mesiobuccal groove of the lower first molar, discrepancies of up to half a cusp width either way were also included in this category.

2. Class II or distocclusion—the mesiobuccal cusp of the lower first molar occludes distal to the Class I position, which is subdivided into:
   - Class II division 1—the upper central incisors are proclined or of average inclination and there is an increase in overjet.
   - Class II division 2—the upper central incisors are retroclined. The overjet is usually minimal or may be increased.

3. Class III or mesiocclusion—the mesiobuccal cusp of the lower first molar occludes mesial to Class I position.

PTC tasting threshold was determined by using serial dilution method of Harris and kalmas (1949) (10) a stock solution containing 0.13% phenylthiocarbamide was prepared in distilled water and serial dilutions were made up to the number fourteen, the least diluted solution was numbered as dilution number 1 and the most diluted solution was numbered (14). If an individual could not taste any solution including no.14, then he or she was designed as a non-taster, threshold level for PTC were recorded for both gender.

The shape of earlobe was classified into either free or attached, the ability to roll the tongue was classified into either curlers, so the subject would be able to curl the tongue into a U-shape or non-curler who could not roll his or her tongue.

Results

Table (1) showed the distribution of the genetic traits amongst the sample of class I malocclusion in
which a higher percentage of the sample have the ability to taste a bitter phenythiocarbamide (PTC), being greater in female than male patients and high statistically significant difference were found between gender in this respect.

For the presence or absence of free un-attached ear lobes, the result showed a higher percentage of the sample have free un-attached ear lobes, being higher in male than female patients with statistically significant difference between gender in this respect. For the ability or inability to roll the tongue, the result showed a higher percentage of class I malocclusion have the ability to roll the tongue, being greater in male than female with statistically significant difference between genders in this respect.

Table (2) showed the distribution of the genetic traits amongst the sample of class II malocclusion in which a higher percentage of the sample have the ability to taste a bitter phenythiocarbamide (PTC), being greater in male than female patients and high statistically significant difference were found between gender in this respect.

For the presence or absence of free un-attached ear lobes, the result showed a higher percentage of the sample have free un-attached ear lobes, being higher in female than male patients with statistically significant difference between gender in this respect. For the ability or inability to roll the tongue, the result showed a higher percentage of male were curler, having the ability to roll the tongue, while a higher percentage of female were non-curler with statistically significant difference between genders in this respect.

Table (3) showed the distribution of the genetic traits amongst the sample of class III malocclusion in which a higher percentage of the sample have the ability to taste a bitter phenythiocarbamide (PTC), being higher in female with statistically significant difference were found between gender in this respect.

For earlobes attachment, all the studied sample have free un-attached ear lobes, with statistically significant difference between genders; For the ability or inability to roll the tongue, the result showed a higher percentage of male were curler, having the ability to roll the tongue, while a higher percentage of female were non-curler with statistically significant difference between genders in this respect.

Table (4) showed the distribution and comparison of the three tested variables in male patients with different anteroposterior dental malocclusion, it was observed that the ability to taste the bitter phenythiocarbamide(PTC) was higher in class II malocclusion, the prevalence of free un-attached ear lobes was higher in class III malocclusion; while the ability of tongue rolling was higher in class I and class III malocclusion than class II malocclusion with statistically significant differences between them.

Table (5) showed the distribution and comparison of the three tested variables in female patients with different anteroposterior dental malocclusion it was observed that the ability to taste the bitter PTC was higher in class III malocclusion, the prevalence of free un-attached ear lobes was higher in class III malocclusion; while the ability of tongue rolling was higher in class I malocclusion.

Table 5: Distribution and comparison of PTC taste, ear lobe and tongue roll among different malocclusions in the female group

**Discussion**

The present study was aimed to determine the possible relation among PTC taste ability, tongue rolling ability and the earlobe attachment configuration with different anterioposterior malocclusion class I, II and III.

**Phenylthiocarbamide (PTC) tasting ability and anteroposterior dental malocclusion:** PTC tasting ability is regarded as a classic and important genetic marker in different genetic investigations, 79% of the studied sample have the ability to taste a bitter phenylthiocarbamide (PTC), as it is revealed as a dominant genetic trait that was conveyed through a single dominant gene responsible for the taste perception on the tongue (11) and this come in agreement with other studies (12); a higher percentage of PTC taster was found among male group of class I, class II malocclusion and among female groups of class III malocclusion; this variation between gender might be due to their different genetic make up coming along with their classic inherited pattern that vary in different gender.

The higher percentage of tasting ability was lie at level 7 dilution for both male and female and this come in agreement with Hussain etal (13).
Earlobes attachment configuration and anteroposterior dental malocclusion: It was observed that the incidence of free earlobe is higher than attached earlobe in all dental malocclusion classes and in all sample and this is agree with other study (14).

As free unattached ear lobe has an autosomal dominant path of inheritance while attached ear lobes have a recessive mode of inheritance (15), However the gender differences in this trait suggesting the effect of genetic variation on earlobe attachment area configuration between them.

Tongue rolling and anteroposterior dental malocclusion: The percentage of the ability to roll up the lateral borders of the tongue into a tube shape is higher in male than female all dental classes than the inability to roll the tongue, except female group of class III dental malocclusion in which higher percentage of them were non curler. Tongue rolling is a result of an autosomal dominant gene with simple Mendelian inheritance, and might be learned or developed (16). Gender differences in the prevalence of this trait suggesting the genetic variation in the overlapping of motor innervation of both extrinsic and intrinsic muscle although this has not been studied.

Conclusion

There is no specific combination pattern among the genetic traits of PTC tasting ability, tongue rolling and earlobes attachment configuration come along with the class I, class II dental malocclusion, while in class III malocclusion there is a possible link among the studied genetic traits of phenylthiocarbamate (PTC) tasting ability, tongue rolling ability, earlobes attachments configuration and class III dental malocclusion.

Combination of Gold Nanoparticles Conjugated Lectin and Using it for Development the Antibacterial Activity of Lectin Purified from *Acinetobacter baumannii*

Sahira Nsayef Muslim¹, Alaa Naseer Mohammed Ali¹

¹Department of Biology, College of Science, Mustansiryiah University, Iraq

ABSTRACT

Lectins are glycoproteins of non-immune source which take a large range of use in medical area. In the present search a new strain, *Acinetobacter baumannii c₁₃* took from chicken carcasses samples gave the top production level of lectin by microscopic glass slide and microtiter plate methods. Lectin was purified to similarity by ammonium sulfate at 35% capacity followed by DEAE -cellulose ion exchange chromatography and sephadex G-150 gel filtration chromatography with 45.3 fold of purification and a harvest of 57.1%. Au nanoparticles was made by laser ablation and conjugated to lectin by method of pulses. The Au nanoparticles conjugated lectin led to development of lectin action versus each tested UTI affecting in contrast with ciprofloxacin antibiotic that used for therapy of UTI inflammation and purified lectin, where Au nanoparticles conjugated lectin look great effectiveness versus *Enterobacter* sp. followed by *Salmonella* sp. and *Streptococcus* sp. in contrast with the more tested bacteria. Thus Au nanoparticles conjugated lectin can be used as a suitable antibacterial agent for the action of growing urinary tract infections.

Keywords: *Acinetobacter baumannii*, lectin, Au nanoparticles

Introduction

*Acinetobacter* species are common, free-living saprophytic(1), ubiquitous in nature and can be found in different environmental sources such as hydrocarbon contaminated areas, activated sludge, sewage, dump sites(2), also found on vegetables, animals, humans and in the soil, water, and source foods(3). *Acinetobacter* species have emerged as an important nosocomial pathogen due to its capability for survival in the hospital environment on a wide range of dry and moist surfaces (4).

The term of nanoparticles refers to any particle that has three dimensions in nanometer scale and contains small enough a number of constituent atoms or molecules (5). The metal nanoparticles such as Ag, Au, Cu and Pt NPs considered a great interest source because of their novel electrical, optical, physical, chemical and magnetic proprieties (6). Au nanoparticles have important applications in different fields due to their physical and chemical proprieties that depending on their shape and size. The reduction of HAuCl₄ with different reduction agents and in presence of some stabilizers led to synthesis of Au nanoparticles (7). The goal in modern nanotechnology field may to obtain metal nanoparticles by using environmentally friendly methods. A popular top-down approach by pulsed laser ablation in liquids (PLAL) is an alternative method for conventional chemical reduction methods, it used for making of nanoparticles from a target absorbed in fluid where an intense laser beam lead to break down the bulk materials to smaller particles. Laser ablation technique has many advantages like simplify, leads to safe and stable handling of the colloids without by-products and impurities and needs less time and low cost (8).

Lectins in the beginning called hemagglutinins or agglutinins because their abilities to agglutinate of human and animal erythrocytes. Lectins are various group of proteins or glycoproteins of non-immune source. Lectins is a useful tool in several fields such as immunology, cell biology, molecular biology, membrane structure,
pharmacology, cancer research, clinical chemistry and genetic engineering due to their chemical properties and used as anti-tumor, anti-insect, antiviral, antibiotic and antifungal drug.

**Materials and Method**

**Samples collection and bacterial analysis:** Fifty five samples of chicken carcasses (1g) was diluted gradually into 100 ml NaCl 0.85% solution and according to this method. *Acinetobacter baumannii* isolate was set by Vitek 2 system by using Vitek GNI card (bio Mérieux, France) according to the producer’s commands.

**Lectin production**

**Semi-quantitative analysis:** This test was done by method that discard by.

**Quantitative hemagglutination assay:** The numerical screening was thru in microtiter plate as discarded by.

**Estimation of protein content:** The protein content of lectin was fixed by using the method of and using bovine serum albumin as a standard.

**Extraction and purification of lectin:** The special bacterial isolate was grown on (CFA) described by(13) at 37°C for 24 hour, then cells was gathered by centrifugation at 8000rpm for 30 min, washed twice and re-suspended in 0.02M (PBS) pH 7.2. Cells were upset by glass beads for 50 min at 4°C by the vortex. Remaining full cells and cell membrane fragments were detached by centrifugation 8000rpm for 20 min. The causing supernatant was used as the starting point to form the hem agglutination activity of lectin in crude cell extracts.

The supernatant was fractionated with ammonium sulfate at concentrations 20-80% saturation and using the method of.

**Preparation of Au nanoparticles by laser ablation:** Au nanoparticles was prepared by laser ablation by method.

**Characterization of Au nanoparticles:** The shaped Au nanoparticles was established by UV-visible spectrophotometer by method left to wet at room temperature for 30min. The slides were then examined.

**Conjugation and Characterization of purified lectin and Au nanoparticles by pulses method:** The pellets of Au dropped in 4 ml of purified lectin at 4°C to save away from enzyme damage and vibrated by using laser ablation method at 1 Hz replication rate with 40 pulses, fluence (14.44 J/cm2) and wavelength of 1064 nm then hem agglutination action was premeasured.

The filtered lectin and Au nanoparticles conjugated purified lectin by pulses methods by.

**Detection of antibacterial activity:** The Kirby-Bauer disc diffusion method was worked for discovery of antibacterial action of ciprofloxacin, Au nanoparticles, purified lectin, Au nanoparticles conjugated purified lectin by pulses method in Mueller- Hinton agar plates. Twenty bacterial isolates including *Streptococcus sp.*, 3 *Staphylococcus aureus*, 3 *Klebsella pneumonia*, 4 *Escherichia coli*, 2 *Pseudomonas aeruginosa*, 3 *Enterococcus sp.*, 2 *Serratia marcescens* and 2 *Salmonella* sp. isolated from urinary tract infection were immunized in liquid culture and incubated for 24 hrs at 37 °C, these bacterial isolates were then spreaded on Mueller - Hinton agar plates. Sterile blank paper discs (6mm diameter) immersed in Au nanoparticles and purified lectin, separately, for 1 h besides to ciprofloxacin that used as 30μg antibiotic disc were placed on the surface of the plates then incubated at 37 °C for 24 h. A transparent ring around the paper disc revealed antimicrobial activity and the inhibition zones around discs were measured in millimeters.

Kirby-Bauer disc diffusion method was repeated as stated above for discovery the antibacterial activity of Au nanoparticles conjugated purified lectin by pulses method. The same bacterial isolates that isolated from urinary tract infections were used. After the incubation period, the diameter of inhibition zone was calculated with millimeter.

**Results and Discussion**

**Isolation of Acinetobacter baumannii:** Twenty (36.3%) *Acinetobacter baumannii* isolates happened got out of 55 samples of chicken carcasses.

Acinetonacters have been frequently isolated from eviscerated chicken carcasses and other poultry meats. *Acinetonacter* constituted 22.7% of the total microflora of chicken carcasses.

**Lectin production:** The results of semi-quantitative analysis revealed that 16 *Acinetobacter baumannii* isolates gave hemagglutination activities plus the
isolate *Acinetobacter baumannii* c\textsubscript{13} presented upper hemagglutination level. Also in measureable analysis the hem agglutination actions in microtiter plate were revealed in these bacterial isolates and *Acinetobacter baumannii* c\textsubscript{13} showed higher hemagglutination value against O\textsuperscript{+} blood group equals to 64 U/ml.

In a paper reported by\textsuperscript{(17,18)} discovered that the purified lectin from *Acinetobacter baumannii* led to agglutinate blood group O\textsuperscript{+} in the first degree followed by B\textsuperscript{+} in the second degree, but lesser levels of hem agglutination exposed for blood groups A\textsuperscript{+} and AB\textsuperscript{+}. *Acinetobacter baumannii* has type1 Pilli that have the capability to hem agglutinate the erythrocytes that have mannose and this type of pilli considered from the the vectors of virulence that facilitate the adhesion of bacteria to epithelial cells\textsuperscript{(19)}.

**Purification of lectin:** The crude extract was consumed then crude enzyme solution precipitation process by 20-80% saturation of solid ammonium sulfate and found that 35% saturation led to increase the specific activity to 62.28U/mg. Dialysis step was consumed to delete the impurities and unwanted proteins and loaded on DEAE cellulose that equilibrated and washed with 0.02M (PBS) pH 7.2. The adsorbed enzyme was eluted with a slope of sodium chloride ranging from 0.1 to 0.5M with the same buffer. The elution headed to appear three protein peaks with hem agglutination action in the second peak (figure-1a). After collection of the active fractions these fractions loaded on Sephadex G-150 that was previously washed with 0.02M (PBS) pH 7.2. The elution with the same buffer showed two peaks of protein with hemagglutination activity in the second peak (figure-1b). The lectin was purified with 57.1% a yield, 45.3fold of purification and a specific activity of 616.8U/mg protein as shown in table (1).

Glass beads have different advantages in cells disruption such as easily, inexpensively, multiply samples can be used at the same time with a high attentiveness of protein. vortex beading is similar to sonication in extraction of the periplasmic proteins, since the sample and beads are blended and placed on a vortex to induce mechanical throbbing under cooling conditions reported that the lectin was purified to homogeneity from *Acinetobacter baumannii* by ammonium sulfate at 35% saturation followed by QAE-Sephadex ion exchange chromatography and sephadex G-200 gel filtration chromatography with a retrieval harvest of 72.72% and 40.76 fold of purification. An ammonium sulfate fractionation, gel filtration and preparative isoelectric focusing were spent for purification of cholera lectin produced by *Vibrio cholerae* strain CA401 to apparent homogeneity with specific activity of 110 U/mg and a yield of 0.02%\textsuperscript{(20)}.

TEM technique: The TEM technique was used to see the shape and size of Au nanoparticles Figure(2a) It has a spherical shape with an average size of 25nm compare with TEM technique was used to see the shape and size of the purified lectin and Au nanoparticles. Figure (2b) showed that purified lectin had a good distribution in the size of 75 nm. In contrast, Au nanoparticles conjugated purified lectin by pulses with the size of 92 nm figure (2c).

![Figure 2: TEM images of (a) Au nanoparticles (b) purified lectin, (c) Au nanoparticles conjugated purified lectin by pulses method](image)

Characterization of purified lectin and Au nanoparticles conjugated purified lectin by pulses method: The Au nanoparticle-lectin conjugation can remain observed from maximum absorption spectra with wave length by the red shift from (320.3 nm) to (376.9 nm) (figure- 1b). This indicated When the Au nanoparticle formed by pulses the shell thickness of the lectin protein shell created around the Au nanoparticle increased and led to a red shift in the peak wave length. These results reflect the conjugation of purified lectin with the Au nanoparticle. Compere with The absorption spectrum of the Au nanoparticles was calculated by a UV–visible spectrophotometer in the wavelength range 300 to 900 nm as shown in figure (3a). At wavelength about 312nm.

![Figure 3: a- Absorbance of Au nanoparticles thin films; b-Absorbance of purified lectin and Au nanoparticles conjugated lectin by pulses method](image)

Detection of antibacterial activity for purified lectin, Au nanoparticles and Au nanoparticles conjugated purified lectin by pulses method: For discovery of antibacterial activity of purified lectin, Au nanoparticles conjugated purified lectin and Au nanoparticles was learnt in Muller Hinton agar against different causing UTI
infection. The effects revealed that ciprofloxacin showed high effectiveness with high diameter of inhibition zone was reached to 16 and 16.3 mm for Enterobacter sp. and K. pneumoniae, respectively. In contrast, it revealed no effect toward Gram-positive tested bacteria (figure-4).

The calculations demonstrated that Au nanoparticles and purified lectin had antibacterial activity anti UTI causing. The Au nanoparticles had higher effectiveness than the purified lectin with great inhibition zone (21 and 20.5 mm) against Enterobacter sp. and Salmonella sp., respectively, while the diameter of inhibition zone reached to 18 and 16.5 mm, respectively against the same types of bacteria. When the purified lectin was conjugated to Au nanoparticles by pulses, the antibacterial activity was increased with high effectiveness (high diameter of inhibition) for all tested Gram-positive and Gram-negative bacteria in comparison with ciprofloxacin antibiotic, Au nanoparticles alone and purified lectin alone(figure-8) and Enterobacter sp had higher activity with higher diameter of inhibition zone of 25 mm as shown in figure (5). So that we can conclude that pulses method was the best method for enhancement purified lectin activity to maximum level for treatment of UTI infections.

Figure 4: The diameter of inhibition zone for UTI causing pathogens

Figure 5: The inhibition zones that produced by Au nanoparticles, purified lectin and Au nanoparticles conjugated lectin against Enterobacter sp.

Conclusion

Au nanoparticles conjugated lectin can be worked as a useful antibacterial agent for the action of rising urinary tract infections.

Functional Neurological Disorder at Al-Diwaniyah Teaching Hospital

Sahar Albermany¹, Abdul-Zahra Al-Khafaji¹, Rose Jihad Kadhim¹
¹College of Medicine, University of Al-Qadisiyah, Diwaniyah, Iraq

ABSTRACT

Background: Functional neurological disorder (conversion disorder) is defined as a psychiatric illness in which a neurological or general medical condition can not explain symptoms and signs affecting voluntary motor or sensory function. The aim of current study was to study the sociodemographic characteristics of patients with functional neurological disorders, to demonstrate the frequency of symptoms of functional neurological disorders and to study the stressors of life events in such patients.

Method: One hundred patients were diagnosed according to DSM5 diagnostic criteria of FND at Al-Diwaniya Teaching Hospital in the Psychiatry unit and Emergency department between 1st, January 2018 and 1st, October 2018. Then, all patients were assessed with a semi-structured interview to demonstrate their sociodemographic backgrounds and stressor events.

Results: Majority of subjects were females (70%) at an age range of 21-30 years (45%), married (48%), unemployed (70%), educated up to secondary school (70%), urban resident (60%), rent house (65%) and came from extended family (60%). Common presenting symptoms were motor (56%), visceral (22%), mixed(12%) and sensory (10%). Significant stressors were found approximately in all patients and the most common one was social problems (35%) followed by financial problems (26%).

Conclusion: Functional neurological disorder is more common in females, low socioeconomic background and low literacy level and when there are significant stressors. Most common presentations were motor symptoms.

Keywords: functional neurological disorder, stressors, motor symptoms, social problems, financial problems.

Introduction

Conversion disorder, also known as functional neurological symptom disorder (FND) (¹,²), is defined as a psychiatric condition in which symptoms and signs affecting voluntary motor or sensory function cannot be explained by a neurological or general medical condition (³). Psychological factors, such as conflicts or stress, are thought to be associated with the disorder. The term conversion disorder was coined by Sigmund Freud, who emphasized the occurrence of certain symptoms that are not better explained by organic diseases and reflect unconscious conflict (⁴). The term conversion refers to the substitution of a somatic symptom for a repressed idea (⁵).

FND is relatively rare, with most cases diagnosed after age of 7 years; the incidence increases with age and has a female preponderance (⁶-⁸).

Clinical features: The most common FND symptoms are paralysis, visual disturbances and speech problem. FND may be more correlated with passive-aggressive, dependent, antisocial and histrionic personality disorders. Depressive and anxiety symptoms often associated with FND and affected patients are in danger of suicide (⁹).

Motor Symptoms: These include abnormal movements, gait disturbance, weakness and paralysis. Gross rhythmical tremors, choreiform movements, tics

DOI Number: 10.5958/0976-5506.2019.03272.8
and jerks may be present. These movements generally worsen when attention is called to them. One gait disturbance seen in FND is astasia-abasia, which is a wildly ataxic, staggering gait accompanied by gross, irregular, jerky truncal movements and thrashing and waving arm movements. Patients with these symptoms rarely fall; if they do, they are generally not injured. Other common motor disturbances are paralysis and paresis involving one, two or all four limbs, although the distribution of the involved muscles does not conform to neural pathways. Reflexes remain normal; patients have no fasciculation or muscle atrophy, electromyography findings are normal.

**Learning Theory:** Regarding conditioned learning theory, a conversion symptom can be seen as a classically conditioned learned behavior; symptoms of illness learned in childhood, are called forth as a means of coping with an otherwise impossible situation.

**Aims of the study:** The aims of current study were to study the sociodemographic characteristics of patients with functional neurological disorders, to demonstrate the frequency of symptoms of functional neurological disorders and to study the stressors of life events in such patients.

**Patients and Method**

**Setting:** The study was performed in the Emergency Department and Psychiatry Unit at Al-Diwaniyah Teaching Hospital during the period from 1st, January to 1st, October 2018.

**Sample selection:** The total studied sample was 100 patients, who were referred to the Psychiatry Unit. After initial assessment; examination and routine investigations were done in the Emergency Department to exclude any organic causes. Some consulted the Psychiatry Unit directly. All of them achieved the diagnosis of FND according to diagnostic criteria of DSM5. We used a sociodemographic scale to demonstrate the characters of patients and also demonstrate symptoms frequency and stressors and life events in such patients.

**Results**

**Socio-demographic characteristics of participants:** Table (1) showed Socio-demographic characteristics of the patients.

**Distribution of study sample according to relation of socio-demographic factors and gender:** Table (2) showed that frequencies were higher in married females (38%), educational level was most commonly secondary school in both sexes and accommodation rent and the urban residency in both sexes with significant differences, while the family structure criterion showed that most patients had extended families, but was statistically non-significant.

**Symptoms of FND:** Table (3) showed that motor symptoms were the most common symptoms (56%) followed by visceral symptoms (22%), mixed (12%) and sensory symptoms (10%).

**Distribution of the symptoms in both sexes:** Table (4) showed that syncopal attack had the highest frequency in females, while in males the motor symptoms including weakness or paralysis and pseudoseizure were most frequent symptoms.

**Distribution of study sample according to stressors frequency:** Table (5) showed that the most common stressors expressed were social problems (35%), financial problems (26%) and the death of a relative (12%).
In our study, we found that most of patients consulted either the Emergency Department or the Psychiatry Unit with sudden onset of loss of function or different varieties of physical complaints making patients with FND more likely to present first to the Emergency Department or primary care physician \(^{(12)}\). This supports the idea of introducing psychiatric services early in the process of diagnosis \(^{(13)}\).

Socio-demographic and clinical characteristics of patients: FND affected different age groups, but the most common age group affected was between 21 and 30 years representing about 45% of total cases. In a study by \(^{(14)}\), the most affected age group was between

Discussion

In our study, we found that most of patients consulted either the Emergency Department or the Psychiatry Unit with sudden onset of loss of function or different varieties of physical complaints making patients with FND more likely to present first to the Emergency Department or primary care physician \(^{(12)}\). This supports the idea of introducing psychiatric services early in the process of diagnosis \(^{(13)}\).
18 and 29 years representing about 57% of total cases, which was comparable to our study. Another study by \(^{(15)}\) reported that the most common age affected was 22-40 years, which was similar to the findings of our study. However, some studies showed even higher incidence in this age group, whereas other studies suggested a higher incidence in late thirties \(^{(16)}\).

In this study, FND affected females more commonly than males \((70\% \text{ vs. } 30\%)\), respectively, suggesting that women in Iraqi society may be having more social difficulties than men. In a study conducted by \(^{(17)}\) reported that females represented \((78.4\%)\) and males \((21.6\%)\) which was similar to our study. In a study by \(^{(18)}\) they found that 82.12% of affected cases were females and 17.89% were males.

Regarding marital status, the most common group was the married group in both sexes. Published studies gave different percentages of married individuals presented with FND. For example, \(^{(19)}\) showed that 32% of affected female patients were married and \(^{(12)}\) showed that 78% were married, suggesting that increased responsibility toward family and children with limitations of financial resources.

Regarding education, the majority of cases had just reached to secondary school, this was greatly consistent with the emphasized finding of the lower educational level that is associated with FND in literature and other studies \(^{(18,20)}\).

Regarding employment, our study revealed that \((70\%)\) were unemployed and \((30\%)\) were employed. In a study conducted by \(^{(18)}\) they found that 7.9% were employed and 92.05% were unemployed \(^{(18)}\).

In terms of residency, we found that \((60\%)\) belonged to urban community, and \((40\%)\) to rural community. A previous study \(^{(21)}\) found that \((81.8\%)\) belonged to urban community, while the remaining \((8.7\%)\) lived in the rural community.

The high occurrence of FND in urban areas may be explained by more stressful life events and more responsibilities related to harsh living conditions.

Regarding accommodation and family structure we found that most patients lived in a rented house and came from extended families where there was high tension, interrelated problems and life events in such crowded families.

**Presenting Symptoms and symptom groups:** It is likely that in eastern culture, physical symptoms are more acceptable and patients presenting their distress in the form of FND are more likely to get medical attention. This cultural approval of symptoms is an important factor that determines mode of reactions towards stress \(^{(22)}\).

Individual symptoms were motor symptoms \((56\%)\) (pseudo seizure \((19\%)\), muscle weakness or paralysis \((17\%)\), speech problem \((10\%)\) and abnormal body movement \((10\%)\)), visceral symptoms \((22\%)\), syncopal attack \((12\%)\), swallowing problems \((10\%)\), mixed symptoms \((12\%)\) and sensory loss in the form of visual disturbance \((10\%)\). This was nearly similar to a study by \(^{(17)}\) who found that the most common presentation was with motor type of symptoms \((54.1\%)\) followed by visceral \((32.3\%)\) and mixed \((11.3\%)\), while only \((2\%)\) had sensory symptoms. A majority of patients presented with motor symptoms in the form of pseudo seizures followed by paralysis or muscle weakness and aphony by a study conducted by \(^{(21)}\). Other studies conducted by \(^{(24)}\) found that classic symptoms such as pseudo seizures, paresis, limb paralysis and aphony or dysphonia were the commonest presentations. Another study conducted by \(^{(12)}\) revealed that motor symptoms were the most common clinical presentations. In another study by \(^{(25)}\) found that the most common presentations were pseudo seizures followed by motor symptoms. Moreover, it was suggested that asymbolic representation of emotions when the patient is unable to express in words \(^{(26)}\).

Regarding presenting symptoms in both sexes the most common presenting mono symptom in males was motor symptom in the form of weakness and paralysis, they involved being unable to move a limb or a leg. This weakness usually involves whole movements rather than muscle groups (i.e. weakness affects the extremities more often than ocular, facial or cervical movements), but in females it was syncopal attack which was also the most common symptom in females in this study. We observed that their vital signs were normal, no pallor in contrary to vasovagal syncope (in which there is loss of consciousness, pallor and change in the vital signs which was the finding reported by Don Eastmead and edited by \(^{(27)}\).

**Significant Stressors:** We observed that approximately most of the cases had obvious stressors. Obtaining the stressor also depends on the presenting problems and chronicity of the condition. This might lead to adaptation to the stressor by developing coping mechanisms \(^{(29)}\).
The bodily symptoms of FNDS may be an adaptive way of expressing the difficulties faced by the person in a stressful situation that is accepted by society (30). This can be one of the reasons that the manifestation of symptoms in FND differs significantly from west to east worldwide.

In this study, we grouped stressors into seven major groups according to stressful events of the patients. Social problems, financial problem, death of relative, legal problems, school problem, physical illness related to them or their family and undetermined. In comparison with other studies especially those conducted in developing countries e. g in the study by (15) the majority of the patients (24%) had in-law’s problems and (23%) had love problems, others reported family relationship problems, study-related stress, etc. Also, in the study by (12) social problems were the most common preceding stressors (40%) followed by school-related problems (30%), while exam/school-related factors were the major precipitating factors in younger ages. In the study by (25) they found that interpersonal difficulties with family and academic problems were the most importantly identified precipitants.

**Conclusion**

Functional neurological disorder is more common in females, low socioeconomic background and low literacy level and when there are significant stressors. Most common presentations were motor symptoms.

Immunogenetic Study of *Pediculus humanus capitis* Associated with *Typhus* Fever in Iraqi Patients

Salah Mahdi Hassan¹, Yousor M. Jameel², Abdulrazzaq Neamah Zghair¹, Nazar Sh. Mohammed¹

¹Department of Medical Laboratory Techniques, College of Health and Medical Technology, ²Department of Medical Laboratory Techniques, Medical Technical Institute, Medical Technical University, Baghdad, Iraq

ABSTRACT

**Background:** *Pediculus humanus capitis* is one of the ectoparasites which lead to transition of Typhus fever. Rickettsial infections which affect the vasculature cause nonspecific signs and symptoms making it difficult to diagnose the disease clinically. This study was performed to investigate the genetic sequence of these external parasites and the possibility of their development that may make them more dangerous to transfer many pathogens to the human body.

**Method:** In this study, 200 patients of school students (65 males and 135 females) with their ages ≥18 years were enrolled. In addition, 8(4%) of them were infected with rickettsiosis. All the patients were tested for detection of IGM and IgG anti- Rickettsia antibodies by ELISA and IFA techniques.

**Results:** The serum titers for Anti- Rickettsia Antibodies (IgG) were 1/128, 1/256 and 1/512 among 8 of them as 2(25%), 4(50%) and 2(25%), respectively. The COI gene was detected with 552bp. The primers used F- AGCTCATTTGTTCAAGGCGG and R TACCAACACCCTCCAGCAAA with sequence size 827.

**Conclusion:** There was a 100 percent similarity between USA strains and Iraqi strains of the Bene Bank, indicating that the lice have not been developed.

**Keywords:** *Pediculus humanus capitis*, *Typhus* fever, Gene sequence, Antibody titer, ectoparasite.

Introduction

Lice are ectoparasites that play the role of a vector that is able to transmit Typhus through their bite [1]. Lice are traditionally assigned into two orders; Anoplura (sucking lice) and Mallophaga (chewing lice) [2,3]. *Pediculus humanus capitis* which is known as head louse is an obligatory hematophagous ectoparasite of human belonging to the Anoplura order, P. ediculidae family. Its life cycle includes eggs that hatch in 5-10 days. Mediterranean spotted fever (MSF) is caused by *R. conorii* and it is endemic rickettsiosis of southern and eastern Europe as well as parts of Africa and Asia [4]. It is mainly transmitted by the tick *Rhipicephalus sanguineus*. Most clinical cases are therefore noted in rural areas. Our ecological and epidemiological comprehension of MSF has experienced important advances in the last 10 years as the disease has emerged and reemerged in different countries [4,5]. A Thai strain (TT-118) is most closely associated with a rickettsia identified in Amblyomma cajennense tick in southern Texas [6]. Rickettsial infections which affect the vasculature cause nonspecific signs and symptoms making it difficult to diagnose the disease clinically [6]. Development of effective diagnostic methods for targeted early anti-rickettsial treatment was hindered by the spread of *Rickettsia* and *Orientia* dynamics with their early limited bacteremia stage and resulting antibody emergence [7]. This study was performed to investigate the genetic sequence of these external parasites and the possibility of their development that may make them more dangerous to transfer many pathogens to the human body.
Materials and Method

A total of 200 patients aged ≥18 years with recent tick bites were asked through local public media to bring the tick, after detachment, to their primary healthcare centre (PHC). In this study, 200 participants were included from 1st, September 2018 to 1st, April 2019. A recombinant 56KDa type-specific typhus antigen was used in the wells for IgM and IgG detection by ELISA. According to the instructions of the manufacturer, typhus Detect IgM ELISA kit from InBios International Company (Seattle, WA, USA) was used to test patients’ sera at 1:100 dilutions. The absorbance was read at 450nm and the results were recorded as positive or negative. The OD cut-off value was fixed at 1.0 following the recommendations of determining the endemic cut-off titer in the kit protocol.

Statistical Analysis: The statistical analysis of the results was performed using an t-test and chi-squared test.

Results

Table 1 showed the serological assay of IFA and anti-IgM-IgG antibodies sensitivity and specificity of Rickettsiosis. In addition, serum titers for Anti-Rickettsia Antibodies (IgG) were shown in Table (2).

**Discussion**

Lice are external parasites that transport typhus fever to human body. This parasite spreads heavily in rural areas which lack health care as well as densely populated areas with low-income [3]. Samples were taken from school students and 8 of them had typhus fever. In this study, ELISA technique was conducted to determine the IgM and IgG anti-Rickettsial antibodies to identify the chronic and acute infections of the disease [8]. The IFA method was also used, but the titration of IgG was very dull. This study was performed to investigate the genetic sequence of these external parasites and the possibility of their development that may make them more dangerous to transfer many pathogens to the human body [9]. By primers LEFT PRIM AGCTCATTTGTTCAAGGCGG and RIGHT PRIMER TACCAACACACCCTCCA GCAAA, the mitochondrial gene was identified for the COI gene. The gene in mitochondria of this parasite may be responsible for vital activities of *Pediculus humanus capitis* (COI) Cytochrome Oxidase subunit gene [10]. The Phylogram map of *Pediculus humanus capitis* showed that the Iraqi strains and the USA strains were identical. According to the genetic analysis carried out for the genetic tree, it was confirmed that there was no genetic mutation occurred [11]. However, the pathways that may occur on local strains from these external parasites should be monitored. *Rickettsia* is one of the pathogenic bacteria that cause human’s typhoid fever. The cause of their transmission from infected to healthy people via absorbing blood n by lice and transmitting the disease to other patients [12]. As demonstrated by this study, after genetic analysis of the lice themselves, which are harmful to humans, it was found that there was no genetic transformation occurred to this parasite to be more dangerous to transport other species of bacteria, viruses or even malaria [13].

**Conclusion**

There was a 100 percent similarity between USA strains and Iraqi strains of the Bene Bank, indicating that the lice have not been developed.

Impact of Dental Caries on Quality of Life of Primary School Children aged 8-10 Years in Al-Najaf City, Iraq

Zahraa M. Alshmaa¹, Athraa M. Alwaheb²
¹Dentist, Al-Najaf, Ministry of Health and Environment, Iraq; ²Professor, Preventive Dentistry, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Dental caries is the most common oral diseases affecting human beings throughout the world particularly in childhood. It has been recognized that children’s quality of life is related to their oral health status. The aim of current study was to investigate the impact of dental caries on quality of life of primary school children. Methods: The total sample composed of 1200 children aged (8-10) years selected randomly from different primary schools in Al-Najaf governorate. WHO 2013 index was used for assessment of dental caries experience and OHRQoL questionnaire was distributed among children.

Results: Data from current study showed that the prevalence of dental caries was 98.00% for total sample, no significant differences were seen between OHRQoL questionnaires and dental caries experience DMFT of permanent teeth except questions concerning Children’s school were significant, while a significant relation was seen in primary teeth.

Conclusion: Primary schools children in Al-Najaf were found to have a high prevalence of dental caries and this disease was found to have an effect on quality of children’s life. Hence, this survey highlighted the need of children for dental health education programs and public as well as school preventive measures among those children.

Keywords: Quality of life, Dental caries, School children, DMFT, OHRQoL.

Introduction

Dental caries most commonly affects children, the impact of oral conditions on children’s life includes difficulty with chewing, oral pain, missed school days due to their cumulative dental caries experience and changes in emotion e.g. being upset and worrying about being different as well as anxiety or distress about their mouth (1).

It is essential to evaluate the impact of dental caries on quality of life on those children, taking their own perceptions into account. Given that, at the age of eight years, children consider health to be set of emotional and somatic symptoms, they have the ability to report all health aspects using same criteria as attractive as using with adults (2). Iraq is one of the developing countries that exhibited an increase of dental caries prevalence and severity. Some previous studies found that dental caries prevalence is low, while other studies reported high prevalence (3,4). Some studies showed that dental caries had negative impact on quality of life for children and for their families including nutrition aspects, educational alterations and behavioral oral symptoms (5).

As a consequence, assessment of oral diseases impact on daily life of children is very important because oral diseases not only limit their current functioning and psychosocial well-being but may also compromise their future achievements and development as well as difficulty in chewing process, resulting from dental caries severity in children (6).

Oral health-related quality of life (OHRQoL) indicated the impact of oral health on individual’s daily functioning, wellbeing and quality of life (QoL). During
childhood oral diseases can have a negative impact on the child’s life (7).

Therefore, this study was conducted on group of primary school children 8-10 years old living in Al-Najaf governorate to find out the impact of dental caries on the quality of their life.

Method

A sample of 1200 primary school children (600 boys and 600 girls) 8-10 years old were selected randomly from urban areas in Al-Najaf city, from different schools distributed in the city. The study received approval from the Research Ethics Committee of the College of Dentistry/University of Baghdad, Iraq.

Oral health related-quality of life was recorded by 20 questions (OHRQoL questionnaire) (8) which are sub-grouped into four domains: the first part included questions about the mouth and teeth (Q1. Pain in the teeth or mouth in the past 4 weeks? Q2. Sore spots in the mouth in the past 4 weeks? Q3. Pain in the teeth when drinking cold drinks or eating foods in the past 4 weeks? Q4. Bad breath in the past 4 weeks? Q5. Needed longer time than others to eat the meal because of the teeth or mouth? Q6. Had a hard time biting or chewing food like apples, corn on the cob or steak because of the teeth or mouth? Q7. Had a problem sleeping at night because of the teeth or mouth? The second part included questions about the feelings (Q8. Been upset because of the teeth or mouth? Q9. Felt frustrated because of the teeth or mouth? Q10. Been shy because of the teeth or mouth? Q11. Been concerned what other people think about the teeth or mouth? Q12. Worried that is not as good-looking as others because of the teeth or mouth? The third part included questions about school (Q13. Missed school because of the teeth or mouth? Q14. Had a hard time paying attention in school because of the teeth or mouth? Q15. Not wanted to speak or read out loud in class because of the teeth or mouth? The fourth part included questions about child being with other people (Q16. Tried not to smile or laugh when with other children because of the teeth or mouth? Q17. Not wanted to talk to other children because of the teeth or mouth? Q18. Not wanted to be with other children because of the teeth or mouth? Q19. Stayed away from playing with children because of the teeth or mouth? Q20. Other children teased or called names because of the teeth or mouth?

Intra oral examination of dental caries status was recorded according to WHO 2013 (9) using CPI probe. Dental caries was measured by DMFT/S for deciduous teeth and DMFT/S for permanent teeth.

The statistical data analysis was approached by using statistical package (SPSS) version 23.0 in order to analyze and assess the results of this study through application of descriptive data analysis (frequencies and percentages). Inferential data analysis were used to test hypotheses by accept or reject it, which included Spearman Rank Correlation test, analysis of variance and significance at $P \geq 0.05$.

Results

Results showed that the prevalence of dental caries was 98.00% for the total sample. The (mean ± SE) dmft for deciduous teeth was equal to (5.479 ± 0.084) and for dmfs, it was (12.954 ± 0.273), while concerning permanent teeth, the (mean ± SE) DMFT was (1.86 ± 0.047) and for DMFS, it was (2.16 ± 0.063).

Significance of the relation between dmfs and educational levels of father and mother revealed $P$ values of 0.423 and 0.407, respectively. In addition, the relation of DMFS with the educational levels of father and mother revealed $P$ values of 0.076 and 0.837, respectively.

Significant differences were seen between OHRQoL questionnaire and dental caries experience dmfs of primary teeth. Some pain questions were highly significant, the question about sore spots in the mouth (the dmfs $P$ value was 0.004) and the question about child had a hard time chewing food (the dmfs $P$ value was 0.009). Also, the question about child had trouble eating foods (the dmfs $P$ value was 0.007).

No significant differences were seen between OHRQoL questionnaire and dental caries experience. DMFS of permanent teeth except the question about finding the child in the school (Not wanted to speak or read out loud in class because of your teeth or mouth) had significant difference (DMFS $P$ value was 0.168; Tables 1, 2, 3 and4).

Not significant at $P \geq 0.05$. *: Significant at $P < 0.05$.

**Discussion**

In this study, the prevalence of dental caries was found to be (98%) for primary school (8-10) years old children. This percentage was more than that reported in a study done in Brazil (10) and more than some Iraqi studies (3,11,12,13). The high prevalence of caries recorded in this study may partly be attributed to lower fluoride level in drinking water in Iraq that was ranging between 0.12-0.22 (14) and may also be related to other factors related to socioeconomic condition and living style of families (15). For the diagnosis and recording of caries-experience, DMFS/dmfs indices were used in present study. These indices allow measurement of past caries-experience, indicated by missing and filled fraction, and present caries, by the decayed fraction. In addition, DMFS and dmfs indices allow measurement of dental caries by severity. The (mean ± SE) DMFS value was (2.16 ± 0.063) and that for dmfs was (12.954 ± 0.273) compared with other Iraqi studies (17,18).

This study also showed that the mean of DS fraction (2.11) was higher than MS and FS components of DMFS index and the mean of ds fraction (8.752) was higher than ms and fs components of dmfs index, which was an indication of a poor dental treatment. MS fraction (0.02) was higher than FS fraction (0.04) and ms fraction (4.2%) was higher than fs fraction (0.7%), which indicated that even if treatment is present, it is directed toward extraction rather than restoration. This result was in agreement with other studies (11,16,12). No statistically significant differences were found between genders regarding impact on OHRQoL, unlike other studies on children from different age groups. There may be several reasons for that, including the fact that most children in this study were in the mixed dentition phase. The recently erupted anterior permanent teeth did not have enough time to exhibit signs of the disease and the anterior primary teeth most affected by early childhood caries and more related to facial appearance had already exfoliated. Perhaps, the results could be different if esthetic had been affected by dental caries in the anterior region of the mouth, as shown by other studies with older children (19,20).

In this study, the OHRQoL has no significant difference with caries experience of permanent teeth except the question about finding the child in the school (Not wanted to speak or read out loud in class because of your teeth or mouth) had significant difference. Also, the study showed that there was significant difference in the relation of OHRQoL questionnaire to dental caries experience of primary teeth.

**Conclusion**

This study highlighted the need of children for preventive measures and dental health education as well as improvement of dental knowledge and attitude towards good oral hygiene.
Acknowledgment

The authors would like to thank all participants in the study and Dr. M. Galib for helping in data analysis and statistical work.

Purification of Protease from *Aspergillus fumigatus*

Thakra Ahmed Hamada¹, Hadeel Mizher Younus², Raghad Saad Abdulkareem¹

¹College of Medicine, ²College of Dentistry, Tikrit University, Iraq

ABSTRACT

**Background:** Protease enzymes are considered one of the virulence factors for many types of microorganisms, including *Aspergillus spp*. The aim of current study was to evaluate proteases enzymes in clinical isolates of *Aspergillus fumigatus*.

**Method:** Isolates of *Aspergillus fumigatus* were inoculated at bromocresol purple agar and then colonies that gave clear zones were further evaluated for protease enzyme production. Then purification of protease was done by using more than one step via different purification techniques.

**Results:** We found that 39 isolates out of 41 isolates of *Aspergillus fumigatus* were able to produce protease enzyme, while 2(4.9%) isolates were unable to produce protease.

**Conclusion:** *Aspergillus fumigatus* species that were isolated from human are more efficient in protease production than *Aspergillus* that are isolated from other source.

**Keywords:** *Aspergillus fumigatus*, protease enzyme, bromocresol purple agar chromatography.

Introduction

*Aspergillus. fumigatus* secretes a variety of enzymes, such as proteases, that help invasion of host tissue. Proteases assist establishment inside the host by degrading protein barriers at the lung epithelium (¹). Protease has been identified as a potential virulence factor since strains producing more protease are more virulent (²). An additional large group of putative virulence factors are enzymes.

Proteases are able to hydrolyze ester bonds present in phospholipids, which are the major component of host cell membranes. Moreover, secretion of proteases was elevated in clinical isolates of *A. fumigatus* (³). *Aspergillus fumigatus* isolates need to obtain nutrients by degradation of collagen and elastin, which constitute the main compounds of the lung (⁴). The major protease under neutral conditions is the rine alkaline protease ALP with the ability to proteolyses elastin. Nevertheless, strains without ALP cause the same mortality rate in a mouse model compared to those with ALP. Other enzymes without proteolytic activity are also important for *A. fumigatus* in causing disease (⁵-⁸), catalases and peroxidases are needed by the organism to counter attack reactive oxidative species like H₂O₂. Deletion of four enzymes involved in peroxide breakdown leads to strains that are more sensitive to this reactive oxidative molecule but not to phagocytosis (⁹). In general, it has to be stated that pathogenicity of *A. fumigatus* appears to be multifactorial and cannot be assigned to one single trait (¹⁰). The aim of current study was to evaluate proteases enzymes in clinical isolates of *Aspergillus fumigatus*.

Materials and Method

**Screening the ability of *A. fumigatus* for protease production:** One drop of spore suspension of *A. fumigatus* isolates was inoculated on bromocresol purple agar. The plates were incubated at 25°C for 4 days (triplicate of each isolate). Colonies that displayed clear zone around growth were selected for further experiments and transferred to fresh plates. The ability of protease production was calculated according to (¹¹).

**Secondary screening for protease production:** Secondary screening was carried out for the five isolates which gave high diameter zone on protease production.

medium. So that, $5 \times 10^6$ inoculums were transferred to 25mL of sterile casein production medium and incubated at 30°C under shaking conditions for three days. Cells were harvested by filtering the broth with cellulose filter; subsequently, 1ml of this culture was transferred to 100ml of casein broth and incubated under the same conditions for 12 hours. The culture was centrifuged at 12000rpm for 25min at 4°C and the supernatant was collected in fresh flask (12). The filtrate was used as the crude enzyme and protease activity was determined according to the method described by (13).

Protease activity of filtrate was determined by adding 0.1ml of crude enzyme to 3ml of casein prepared and incubated at 37°C for 20 minutes. After incubation, 2ml of 1.5M trichloroacetic acid was added to the reaction mixture to stop the reaction, then the mixture was centrifuged at 4000rpm for 15-20 minutes, the enzyme activity was measured in the supernatant. One protease unit (IU) is defined as the enzyme amount that causes 0.01 per minute increase of absorbance at 280nm under experimental conditions.

**Determination of protein concentration:** The protein concentration in the standard filtrate was assayed after following the same steps of the known protein concentration and depending on the standard curve of bovine serum albumin as follows:

Stock solution of bovine serum albumin was used to prepare gradual concentrations of bovine serum albumin (0, 20, 40, 60, 80, 100mg/ml). Specific activity of crude protease was calculated according to the equation mentioned by (12).

A volume of 10µl from each concentration of BSA was added to sterile test tubes, then 250µl of 1N NaOH and 5ml of coomassie blue G-250 were added to each tube and mixed gently, and then it was left to stand at room temperature for 5 minutes followed by reading absorbance at 595nm.

Standard curve of bovine serum albumin was drawn by plotting the relationship between bovine serum albumin concentrations and absorbance at 595nm (14) as shown in Figure (1).

![Figure 1: Standard curve of bovine serum albumin for determination of protein concentration](image)

**Purification of Protease:** Protease produced by the selected *A. fumigatus* isolate, that gave high enzymatic activity, was purified by more than one step using different purification techniques as mentioned below:

**Dialysis of enzyme:** Crude enzymes were dialyzed against potassium phosphate buffer (pH=7, 0.05M) using dialysis tube for 24 hours with three increments of substitutions. Enzyme activity and protein concentration were determined.

**Ion exchange chromatography DEAE-Cellulose Preparation:** DEAE-Cellulose column (2×23cm) was prepared according to (13) by dissolving 20 grams from DEAE-Cellulose resin in 1 liter of distilled water. Then, beads were left to settle down washed several times with distilled water until clear appearance. The suspension was filtered through Whitman No.1 Buchner funnel. The resin was then re-suspended in 0.25M sodium, filtered again and washed several times with 0.25M hydrochloric acid solution by distilled water before it was equilibrated with potassium phosphate buffer (pH=8, 0.05M).
Sample loading: After column equilibration, concentrated enzyme was transferred and poured gently onto surface of the column, then washed by potassium phosphate buffer to displace unbinding proteins (wash). Fractions were eluted at a flow rate of 3ml/fraction and the optical density for each fraction was measured at 280nm. Enzyme activity for each fraction was determined according to (16). Other proteins bound to the column were eluted by gradient concentrations of NaCl (0.1-0.5M) dissolved in 0.05M potassium phosphate buffer solution (pH= 8.0). The relationships between eluted fractions, optical density at 280nm and protease activity were blotted. The fractions with high protease activity were pooled together and kept frozen for the last step of purification by gel filtration chromatography.

Gel filtration chromatography

Preparation of Sepharose 4-B column: Sepharose 4-B column was prepared according to instruction of the Pharmacia Fine Chemical Company. Five grams of the gel (Sepharose 4-B) were suspended in 1 liter of 0.1M potassium phosphate buffer, then suspension was left in a water bath at 90°C for 5 hours to ensure the swelling of gel beads with gentle agitation from time to time. Then, the gel was degassed, packaged gently in a glass column (1.6x43cm). The column was equilibrated using the same buffer at a flow rate of 20ml/hour for 24hrs.

Sample loading: After column preparation, 5ml of the enzyme solution obtained from the elution fractions of ion exchange chromatograph was added gently to column surface and eluted using 0.1M potassium phosphate buffer (pH= 8.0) with flow rate of 20ml/hour (5ml for each fraction). Optical density (at 280nm), and enzyme activity (U/ml) were determined in each fraction. Fractions represented protease activity were pooled and kept at 4°C for further experiments.

Screening for A. fumigatus hemolysin producers: One drop of spore suspension (5*10⁶) A.fumigatus of each isolate was inoculated on sheep blood agar (SBA). The plates were incubated at 37°C for 7 days (triplicate of each isolate). The evidence of hemolysin in the medium indicated by the presence of clear hemolysis in the medium and considered as a positive result. Mean of hemolytic diameter were calculated in each plate (16).

Results and Discussion

Screening of A. fumigatus isolates for protease production: In order to select the efficient isolate for protease production, screening of A. fumigatus isolates had been achieved on bromocresol purple medium contained casein as sole source of nitrogen.

Thirty nine isolates (95.1%) out of 41 A. fumigatus isolates were able to produce protease on bromocresol purple medium (Figure 1), whereas 2(4.9%) isolates were unable to produce protease (Figure 2). All protease-producer isolates of A. fumigatus included in this study gave a clear zone but at different ratios.

The five selected isolates with high protease production were secondary screened for protease production using casein liquid medium.

Significant differences were shown (P<0.001) between specific activities of the five protease-producing isolates. A previous study (17) demonstrated that a strain of A. fumigatus isolated from a case of human Aspergillosis produced more protease activity than other strains from non-clinical sources.
Fungal isolates in present study were also capable of growing on bromocresol medium and produced visible clear zones around and beneath colonies. The ability of *A. fumigatus* isolates to produce protease may due to proteolytic activity of these isolates. Another study suggested that casein is a useful substrate for the assay of crude protease. However, other studies have reported that there was variability in detecting the ability of clinical isolates to produce protease as a virulence factor.

**Protease purification using ion exchange chromatography:** Protease extracted from *A. fumigatus* was purified by ion Exchange chromatography using DEAE-Cellulose, an anionic exchanger. This matrix was used for purification because it has high capacity for bioseparation, easy to prepare, multiple uses in addition to simplicity to separate different biomolecules.

According to these findings, anionic exchanger DEAE-Cellulose was used for purification of protease from *A. fumigatus*. A portion of 3ml of partially purified protease concentrated with sucrose was applied onto surface of column gel matrix (DEAE-Cellulose). Then column was washed and equilibrated with equal volume of 0.05M potassium phosphate buffer solution (pH= 8.0) to wash unbound proteins (uncharged and positively charged proteins) in protease crude extract. The bound proteins (negatively charged) were then eluted using linear gradient concentrations of sodium chloride ranged between 0.1-0.5M. Results in Figure (3) showed that no protein peak appeared in the washing step, while there were four protein peaks appeared after elution with gradient concentrations of sodium chloride. All these protein peaks in washing step were detected by measuring the absorbance at 280nm for each eluted fraction.

Figure 3: Ion exchange chromatography for purification of protease produced from *Aspergillus fumigatus* using DEAE-Cellulose column (2×23cm) with a flow rate of 20ml/hour.

Results also showed that the third peak eluted in fraction numbers 80 to 84 had protease activity that reached 558.0U/ml. Fractions represented protease were collected and pooled, then protein concentration, protease activity and specific activity were estimated. Results in Table (1) showed that the maximum protease activity and specific activity in the protease concentrate were 554.8U/ml and 154.1 U/mg, respectively, with 13.7% yield 2.03 fold. Partially purified protease obtained from ion exchange chromatography step was further purified by gel filtration chromatography technique. Due to the dependence of ion exchange chromatography basically on charge difference principle, the presence of enzyme in the elution step confirmed that protease, produced by *A. fumigatus*, was negatively charged.
Gel filtration chromatography: Gel filtration chromatography technique was the next step used in the purification of protease produced by *A. fumigatus*, after purification by ion exchange chromatography technique. A volume of 5ml of partially purified protease was applied on Sepharose 4-B column (1.6×43cm) which was previously equilibrated with 0.1M potassium phosphate buffer (pH= 8.0). Sepharose 4-B column has separation limits ranged between (5000-600000 Dalton) which allow ability of separation with high degree of purification (19). Furthermore, gel filtration is the simplest and mildest of all chromatography techniques and separates molecules on basis of differences in molecular size (19). Proteases were eluted thought the column matrix in a flow rate of 20ml/hour. Protein peaks were detected by measuring the optical density at 280nm using UV-VIS spectrophotometer. Results in Figure (4) showed that only one peak represented protease activity appeared after elution with potassium phosphate buffer. Fractions representing protease activity were pooled, and then protein concentration, protease activity and specific activity were measured in 20ml of enzyme concentrate.

Results in Table (1) showed that there was an increase in both activity of purified enzyme (732.4U/ml) and specific activity (228.8U/mg) with a purification fold 3.02 with an increase in the yield of protease (24.2%).

In another study, (26) found that purification of protease from *Aspergillus terrus*, using Sephadex G-100 and Sephadex G-200 as a second step (after ammonium sulfate precipitation), gave the highest specific activity of 158.11U/mg protein and 128 fold of purification with 17% yield.

Purification of protease produced by *Streptomyces spPDK 2*, using dialysis, precipitation with ammonium sulfate 45-85%, Sephadex G-50 gel filtration and Sephadex G-200 gel filtration, gave a maximum specific activity of 63.0U/mg.

On the other hand, protease from *Enterobacter aerogenes*, purified by a simple method involving sonication of the crude cell mass, then by gel filtration with Sephacryl S-100 as the separating material followed by ultrafiltration.

This procedure gave 10-fold of purification with a specific activity of 55U/mg protein and recovery of 54% (17).

**Conclusion**

*Aspergillus fumigatus* species isolated from human are more efficient in protease production than *Aspergillus* isolated from other source.

Using a Proposed Program to Develop Some Physical and Motor Abilities for Students with Slow Learning

Ali Khalid Mukhlif¹, Basim Obaid Moharib², Mustafa Habib Shala³
¹Faculty of Physical Education and Sports Sciences, University of Anbar, Iraq; ²Department of Physical Education and Sports Sciences, Al Maarif University College, Iraq

ABSTRACT

Background: There is no doubt that childhood is one of the most important stages of human life and the most dangerous because it is a formative stage in which the personality traits and behavior of the individual are determined, and that attention to this stage is a comprehensive concern not framed by immediate needs. The aim of current study was to develop a proposed curriculum to develop some physical and dynamic characteristics of the slow learners, and to know its impact as an appropriate attempt to contribute to raising the level of our children and achieve balanced growth of physical, psychological, social and mental abilities.

Method: The research sample was selected from students intentionally slow learners aged 7-9 years from the School of Mercy civil, Anbar province. The number of the selected sample was 27 students of both sexes make up the selected percentage (51.92%) of the original community of 52 students.

Results: The results of pre- and post-tests indicated that there were statistically significant differences between pre- and post-tests and in favor of the post-test in all variables identified in current study.

Conclusions: The sports activities of student in general have a great positive relationship with student's mental abilities.

Keywords: proposed program, physical ability, motor abilities, slow learners.

Introduction

There is no doubt that childhood is one of the most important stages of human life and the most dangerous because it is a formative stage in which the personality traits and behavior of the individual are determined, and that attention to this stage is a comprehensive concern not framed by immediate needs. However, through the objective thinking derived from deep studies to prepare them as well as their efforts to reach children’s abilities and talents, in order to help them make their way through life. The curricula and their methods of preparation are still a minor concept in some countries of the world.

The physical and motor abilities are one of the important pillars that we should care about in childhood to accompany the child in most of his life time as well as children in middle childhood of high mobility and ability to learn new sports skills, and their great love for the activities and sporting events that this development leads to “directing and linking the motor with the flow in movements of sports and reach the flow to the top in the third row and be lower in the first and second rows”¹.

Some children suffer from poor or slow learning ability for one reason or another such as educational, psychological, social or health reasons. It is educational that every child has the right to have a good education without any difference between people. In addition, the emphasis of modern education of attention to all children, including private, based on the principle of equal opportunities in the provision of educational services to them to reach the maximum to enable their preparations and their capabilities ².

Moreover, for the purpose of achieving an integrated understanding of the nature of their work in order to serve the educational process of special education classes for
this group of our children, mental processes are of great impact in the result of participation in motor skills.

Therefore, to the aim of current study was to prepare a proposed program for the development of some physical and dynamic characteristics of the slow learners, and to know its impact as an appropriate attempt to contribute to raise the level of our children and achieve balanced growth of their physical, psychological, social and mental abilities.

Method

The study sample was randomly selected from students of slow learning at the age of 7-9 years from Al-Rahma private School in Anbar Governorate, Iraq. They were 27 students of both sexes representing 51.92% of the original society (52 students). In order to know the nature of sample spread around its arithmetic mean, the researcher used the coefficient of variation in some variables of the study sample (length, weight and age) to find out the homogeneity of sample members. The results showed that the sample was normally distributed.

Field research procedures

Determination of physical and motor characteristics: In order to determine the most important physical and motor characteristics in the motor performance, which are required to be developed for the students of slow learning within the age group in question, the researcher surveyed the sources related to the above characteristics. The researcher prepared a questionnaire for the opinion of experts and specialists. In the fields of (science of training and learning locomotives) and the number of experts and specialists were 8. Through the presentation of qualities on them and in light of results generated by the questionnaire, the qualities that were less than (60%) were excluded because the researcher has the right to choose the suitable proportion when selecting indicators.

Tests used

First test: jogging (20m) from the high start: The objective of this test was to to measure the transition speed. The tools used to carry out it were straight path for testing, two lines for start and end for 20m, and stopwatch. participant stood behind the starting line from the high start position. When the start signal is heard, it starts at full speed from the starting line and the end line is crossed straight and the participant was given two attempts and the best one was registered. The time at which the specified distance cut was recorded.

Second test: Bend the trunk in front of the bottom of the stand: The objective of this test was to measure the elasticity of the spine. In this test, a graduated ruler (0-20 cm) vertically placed at the edge of the table, with the middle of the scale above the edge of the table and the other half under the top edge of the table or seat. From standing on the bench or table, and the feet to the two sides of the scale, the participant bends the trunk in front of the bottom so that the hand fingers become in front of the meter and from this situation the participant tries to bend the trunk to the maximum extent possible while noting that the fingers are at one level and the participant maintains his final status between (2-3) seconds without bending the knees to record the distance and give the participant two attempts to register the best. In this test, the maximum point recorded on the scale was that reached by participant with his fingertips.

Third test: Running the winding between the barriers: The objective of this test was to measure agility. Tools used for test were chairs or low chairs and stopwatch. During this test the participant stood behind the starting line, which is located between the first block distance (3m) and its width (1m). The distance between one block and another of the four meters distance was one meter. When the start signal is heard, participant runs between one block and another. The time taken for two continuous sessions was calculated.

Fourth test: Throw and receive balls: The objective of this test was to measure the ability of eye-hand compatibility. Tools used were tennis ball and a wall. During this test, the participant stood behind a drawn line on the ground, 4 meters away from the wall. The test was carried out as follows:

1. Throw the ball five times in a row with the right hand and that participant receives the ball after rebounding from the wall with the same hand.
2. Throw the ball five consecutive times with the left hand and that the participant receives the ball after rebounding from the wall with the same hand.
3. Throwing the ball five times in a row with the right hand. The ball should be received by the participant after it has been removed from the wall with the left hand. For every correct attempt, the participant was rated a score, the final grade is (15) grade.

Pretests: The tests and measurements are one of the assessment, diagnosis and guidance methods that are part of scientific work parameters based on the correct scientific basis. Tests are a means of evaluation in different curricula and plans for all levels and age groups. Tests serve as a positive indicator that contributes to achieving the goals and objectives set.

In light of this, the pretests of physical and motor characteristics of study sample were conducted on 13-14/1/2018 at 9:00 am as shown:

1. Testing physical qualities on Sunday, 13/1/2018.

On the other hand, pre technical tests for the same sample were conducted on 9/3/2002 at 9am for both groups and two days for each group as shown:

In order to create the same conditions as possible in the post-tests, it was taken account the establishment of the conditions related to tests of space and time as well as tools used and methods of implementation of the tests.

Educational program: The researcher prepared the educational program which was aimed to develop the variables under consideration for students with slow learning, taking into consideration the intensity of the educational units, depending on length of the distance, difficulty of jumping, complexity of the exercise and increasing the repetitions and rest between performances of the games used. The reason was specificity of the sample, on the one hand, and lack of achievement to break a record, on the other hand. The new thing in our current approach was that the researchers adopted games that are characterized by the nature of compatibility of muscular and nervous systems because of its positive impact on the nervous system, which will reflect the increased efficiency of students in the cognitive aspects.

Regarding validity of scientific bases used in the development of the program, the researcher drew opinions of experts and specialists and through the presentation to them to ascertain suitability of the program for students who were slow to learn in the first primary stage. The program was finalized within (10) weeks, 3 units per week and for 3 days (Sunday, Tuesday and Thursday) and (20-26) minutes of the time for each unit, specifically the main sections; the preparatory section and the final sections, however, the increase in time was made at the expense of the education side. The minimum and upper limits of these sections corresponded to variables of the atmosphere and what is required for the preparation of the exercises through the physical education teacher to implement the preparatory section and the educational aspect of the main section and the closing section.
