Indian Journal of Public Health Research & Development

EXECUTIVE EDITOR

Prof Vidya Surwade
Associate Professor, Dr Baba Saheb Ambedkar, Medical College & Hospital, Rohinee, Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. Dr. Abdul Rashid Khan (Associate Professor) B. Md Jagar Din, Department of Public Health Medicine, Penang Medical College, Penang, Malaysia
2. Dr. V Kumar (Consulting Physician) Mount View Hospital, Las Vegas, USA
3. Basheer A. Al-Sum, Botany and Microbiology Deptt, College of Science, King Saud University, Riyadh, Saudi Arabia
4. Prof. Shashank Bhide (Associate Professor) Public Health and Community Medicine, University of Buraimi, Oman
5. Pr. G R Viveki (Professor & Head) Department of Pathology, International Medical University, Bukit Jall, Kuala Lumpur
6. Kartavya J. Vyas (Clinical Researcher) Department of Deployment Health Research, Naval Health Research Center, San Diego, CA (USA)
7. Dr. PK Pokharel (Community Medicine) BP Koirala Institute of Health Sciences, Nepal

NATIONAL EDITORIAL ADVISORY BOARD

1. Prof. Sushanta Kumar Mishra (Community Medicine) Institute of Medico-legal Publications, New Delhi-110019
2. Dr. D.K. Srivastava (Medical Biochemistry) Jamia Hamdard Medical College, New Delhi
3. Dr. M Srirababu (General Medicine) GSL Medical College, Rajahmundry, Andhra Pradesh
4. Prof. Pankaj Datta (Principal & Prosthodontist) Indraprastha Dental College, Ghaziabad

NATIONAL SCIENTIFIC COMMITTEE

1. Dr. Anju Ade (Associate Professor) Navodaya Medical College, Raichur, Karnataka
2. Dr. E. Venkata Rao (Associate Professor) Community Medicine, Institute of Medical Sciences & SUM Hospital, Bhubaneswar, Orissa
3. Dr. Amit K. Singh (Associate Professor) Community Medicine, VCSG Govt. Medical College, Srinagar – Gaghal, Jammu
4. Dr. R G Viveki (Professor & Head) Community Medicine, Belgium Institute of Medical Sciences, Belgium, Karnataka
5. Dr. Santosh Kumar Mulage (Assistant Professor) Anatomy, Raichur Institute of Medical Sciences Raichur (RIMS), Karnataka
6. Dr. Gouri Ku. Padhy (Associate Professor) Community and Family Medicine, All India Institute of Medical Sciences, Raipur
7. Dr. Ritu Goyal (Associate Professor) Anaesthesia, Saraswathi Institute of Medical Sciences, Panchsheel Nagar, New Delhi
8. Dr. Anand Kalaskar (Associate Professor) Microbiology, Prathima Institute of Medical Sciences, AP
9. Dr. Md. Amirul Hassan (Associate Professor) Community Medicine, Government Medical College, Ambedkar Nagar, UP
10. Dr. N. Girish (Associate Professor) Microbiology, VIMS&RC, Bangalore
11. Dr. BR Hungund (Associate Professor) Pathology, JNMC, Belgaum.
12. Dr. Sartaj Ahmad (Assistant Professor) Medical Sociology, Department of Community Medicine, Swami Vivekananda Subharti University, Meerut, Uttar Pradesh, India
13. Dr. Sumeeta Soni (Associate Professor) Microbiology Department, B.J. Medical College, Ahmedabad, Gujarat, India

    Footballers ..........................................................................................................................................................252
    Jibi Paul, M.S. Nagaraj, John Solomon

52. Evaluation of Muscular Endurance among Dentists ..................................................................................................258
    Abigail, Jothi Priya, Gayatri Devi

53. A Study of the Evolution of Medical Education in Ancient India ..............................................................................262
    Joyshree Das

54. Effectiveness of Structured Exercise Program on Functional Capacity and Quality of Life in Grade III
    Chronic Obstructive Pulmonary Disease Patients .................................................................................................266
    Juhi Karne, Poovishnudevi T., Monisha R.

55. Trends in Hyperbaric Oxygen Therapy .....................................................................................................................271
    K.T. Moly, Ravi Sankaran, Linette Roy, Maya J. Nair

56. Role of p53 and p21 Polymorphisms in Cervical Cancer Risk among Rural Population of South-
    Western Maharashtra: A Case-Control Study .............................................................................................................277
    Kailas D. Datkhile, Madhavi N. Patil, Pratik P. Durgawale, Anand Gudur, Rashmi A. Gudur

57. An Explorative Study to Prevent the Incidence of Inpatient Falls in a Tertiary Care Hospital ...............................282
    Kayalvizhi Ashok, Khyathi G.V.

58. Probiotics and Oral Health: A Review .............................................................................................................................287
    Khurana Suchi, Jodalli Praveen, K.M. Ramya, Arora Pallak
59. Effectiveness of Acupressure Therapy among Patients with Low Back Pain in Selected Acupuncture Clinics at Mangaluru .................................................................................................................................292
   Liji Sara John, Gireesh G.R., Anju Ullas, Shashikumar Jawadagi

60. Awareness about Blood Donation Process and Transfusion Transmitted Malaria in a Tribal District of Odisha, India ...................................................................................................................................................297
   Pallavi Mishra

61. Reproductive and Sexual Health Knowledge and Utilization of Services among Adolescents: A Review Based on Available Literature ..................................................................................................................303
   Pooja Yadav, Nageshwar V., Prabhu J.

62. A Retrospective Study to Understand the Clinico-Social Profile of Neonatal Deaths in a Teaching Hospital ...........................................................................................................................................307
   Soumyashree M.N., R.G. Viveki, Sunanda Halki

63. Hoarding Disorder Effects and its Management ..........................................................................................................................312
   R. Sree Raja Kumar

64. Analysis of Trunk Muscle Activity in Hemiplegia During Sitting on Two Different Unstable Surfaces ......315
   Indira Sharma, Radhika C.M., Sivakumar R., N. Venkatesh

65. Physical and Psychological Health Issues among the Night Shift Workers ...........................................................................................................................................320
   M. Sripriya, S.N. Sugumar

66. Insomnia–Some Issues and Remedical Measures ..........................................................................................................................324
   G. Raguram, S.N. Sugumar

67. Socio–Economic Conditions of Industrial Workers in Theni District of Tamil Nadu .................................................329
   S. Saravanan, M. Ramesh, S.N. Sugumar, S. Chandrachud

68. The Pattern of Rural Employment in India ..........................................................................................................................334
   S. Sudha, S. Jansi Rani

69. Clinical Spectrum of Idiopathic Inflammatory Demyelinating Disorders in a Tertiary Care Centre in North–West India ...........................................................................................................................................338
   Soumya Darshan Nayak, C.M. Sharma, B.L. Kumawat, D. Khandelwal, R. Yadav, Samir Sahu, Soumya Nanda

70. Factors Associated with Fear of Falls in Indian Elderly: A Systematic Review ..........................................................................................................................345
   Sampada Dhavale, Sonia Singh, Raju K. Parasher

71. Green Marketing in Food Industry and Impact on Health Issues ..........................................................................................................................350
   Sayeeda Jabeen S., M. Kavitha

72. Burnout: “Lived Experience” of Working Mothers: A Phenomenological Study ..........................................................................................................................354
   Sejal K. Darbar, Kalpana Sawane

73. Prevalence of Cognitive Impairment among Elderly ..........................................................................................................................359
   Elizabeth Jacob, Sheela Pavithran, Priya Vjaykumar
74. Prevalence of Shoulder Girdle Dysfunction in Computer Users with Non-specific Neck Pain

Singh Neeraj, Kumar Pragya, Parasher K. Raju

364

75. Comparison of Antimicrobial Efficacy of Chlorhexidine Mouthwash, Lemongrass (Cymbopogon) Oil and Neem (Azadirachta indica) Oil Against Oral Microflora: An In Vitro Study

Subhashree Mohapatra, Sri Sakthi Doraikannan, Meignana Arumugham Indiran, Pradeep Kumar Rathinavelu

369

76. Assessment of Microhardness of Enamel Carious Like Lesions After Treatment with Nova Min, Bio Min and Remin Pro Containing Toothpastes: An In Vitro Study

Subhashree Mohapatra, R. Pradeep Kumar, I. Meignana Arumugham, D. Sri Sakthi, P. Jayashri

375

77. Effect of Present Day Video Games on Adolescent Cognitive Abilities

Sujatha Bhat, Liegelin Kavitha Bernhardt, Ashmitha Thinakaran, Leevyadhashiny Ganasan, Pirativ Rao Jagathesa Rao

381

78. Development of Frame Work to Minimize Waste in the Surgical Unit of a Tertiary Care Hospital

Suvenitha D., Shalini D.

386

79. Antifungal Sensitivity of Candida Sp. Isolated from Skin Infections at a Tertiary Care Teaching Hospital

Chandan Das, Shrikant Kumar Dhar, Debasmita Behera

392

80. Effectiveness of Emotional Freedom Techniques: A Pilot Study

Deepak Krishnamurthy, Anil Sharma

397

81. Effectiveness of Warm Footbath on Quality of Sleep among Elderly

Linju Prasad, Gireesh G.R., Hezil Reema Barboza, Shashikumar Jawadagi

402

82. Selfie Taking Behavior among College Students: A Cross Sectional Study

Arijit Kundu, Lipilekha Patnaik, Sumitra Pattnaik, Trilochan Sahu

408

83. A Study on Human Resource Development Climate Survey in Selected Public Sector Banks in Special Reference to Thiruvannamalai District

K. Indira, M. Vetrivel, P. Jagatheesan

412

84. To Compare Tympanoplasty with Temporalis Fascia and Tragal Perichondrium in Patients with Chronic Suppurative Otitis Media

Mannuru Khaleel Basha, Ganesh S. Khairmode, Abhay D. Havle

417

85. Reducing Fertility Rate: A Threat Leader States

Meenakshi, Tushinder Preet Kaur

420

86. A Correlational Study on Knowledge and Practice of Fluid and Electrolyte Administration among Staff Nurses of Selected Hospitals at Mangaluru

Melvin Jacob, Shashikumar, Jobin, Hezil Reema Barboza

426

87. Analysis of Pattern and Extent of Substance Abuse/Dependence: An Institutional Study

Suman Deshwal, Minakshi Vashist, Rajiv Gupta

429

88. Health Seeking Behavior among the Mothers of Under Five Children with Upper Respiratory Tract Infection

N. Siva, Baby S. Nayak

434
89. Prevalence of Depression among Elderly in the Urban Field Practice Area of Rajarajeswari Medical College and Hospital: A Cross Sectional Study ................................................................. 436
A.C. Shyam, Naveen Kumar P., Bhanushree

90. Method for Early Detection of Breast Cancer: A Technical Review .................................................. 441
A. Amir Anton Jone, T. Anita Jones Mary Pushpa, Navin M. George, K. Martin Sagayam, Suresh Subramanian, P. Esther Jebarani

91. A Study of the Engineering Maintenance Services of a Tertiary Care Hospital ........................................ 446
A P Pandit, Shithil Birthi,

92. Effect of SAQ Training on Vital Capacity and Peak Expiatory Flow Rate among School Students of Rural Area ........................................................................................................ 450
Anindya Bhowmik, Sandeep Kumar

93. A Study of Knowledge and Awareness Regarding Pulmonary Tuberculosis in Patients Under Treatment for Tuberculosis in Tuberculosis Unit Ambala City (Haryana) ........................................................................ 455
Harshpreet Singh, Anu Bhardwaj, Zahid Ali Khan, Anshu Mittal, Muzamil Nazir, Parul Jain

94. Effectiveness of Active Release Technique Versus Myofacial Release Technique on Patients with Plantar Faciitis: A Comparitive Study .................................................................................. 460
Arul Pragassame S., Mohandas Kurup V.K., R. Santhose Kumar

95. Patient Expectation Survey: An Adjunct to Successful Delivery and Reception of Health Care Services ... 466
Arunima Chauhan, Kaldeep Singh Shekhawat, Harshpriya, Sarah Yazmeenbinti Yahya, Hani Hazreenbinti Abdul Rahman Raja

96. A Feasibility Study of Skill Transfer to Female Health Worker in Screening of Cervical Cancer and Breast Cancer ........................................................................................................ 472
Radhika Joshi, Asha K. Pratinidhi, Vaishali Vhawal, Pandurang Chougule, Sujata Kanetkar, Sunita Tata, Satish Kakade

97. Immediate Effect of Post Deep Neck Flexors Endurance Test on Neck Reposition Accuracy in Smartphone Addictors ........................................................................................................ 476
Emmy Bucyana, Ayyappan Jayavel, Ndahiriwe Chance Christian

98. Gender Dynamics in Morality of Alcohol Addict and Non- Addict Young Indian College Students .......... 481
Bhawani Singh Rathore, Uma Joshi

99. Role of Ultrasound in the Characterization of Thyroid Nodule in Correlation with Fine Needle Aspiration Cytology ........................................................................................................... 486
Bikramaditya Swain, Sudhansu Sekhar Mohanty, Binit Gupta, Gitanjali Satpathy

100. A Study of Impact of Voice of Customers for Admissions Department of a Quaternary Care Hospital ...... 492
A.P. Pandit, Sandhya Sharma

101. Effect of Combination of Active Stretching and Deep Breathing Exercise for Pectoral Group of Muscle Tightness in Breast Feeding Mother ........................................................................ 501
Neha Kadam, Javid Sagar
102. To Determine Spectrum of MRI Imaging in Vertebral Artery Dissection: A Radiological Study ...............505
   P R Shaha, Manisha Luhana

103. A Study to Assess the Iodine Level in the Salt and Salt Preservation Practices among Homemakers of Selected Households at Mangaluru ..................................................................................509
   Reziya Hafeez, Leena K.C., Ananda S., Devina E. Rodrigues

104. An Analysis of Agricultural Development in Tamilnadu with Special Reference to Madurai District........513
   S. Thangamayan, Premalatha, S. Chandrachud

105. A Study on Problems Faced by Sipcot Industrial Labours in Reference to Cuddalore District.............518
   M. Vetrivel, K. Indira

106. Reducing Fertility Rate: A Threat to Leader States ........................................................................524
   Meenakshi, Tushinder Preet Kaur

107. A Qualitative Study to Assess Selected Psychosocial Experiences of Clients Admitted in Step Down Wards at Selected Hospitals Hyderabad, A.P.................................................................530
   Beulah Jasmine Rao

108. Cost Analysis of Intra Operative Anaesthesia Services in Tertiary Care Hospital ...............................533
   C. Lakshmi Venkatesh, Aileen J., Narendranath V

109. Prediction of Heart Diseases Using Hayes Process Macro Serial Mediation Model 6 ......................538
   Ruchi Mittal

110. Effectiveness of Information Booklet on Knowledge Regarding Methicillin-Resistant Staphylococcus Aureus (MRSA) among Staff Nurses .....................................................................................544
    Anuja Varghese, Gireesh G.R., Janet Prima Miranda, Shashikumarjawadagi

111. Maternal and Perinatal Outcome in Patients with Meconium Stained Liquor in First Stage of Labour: A Retrospective Study ........................................................................................................550
    Tanu Bhati, Sunil Takiar, Kalpna Kulshrestha, Sukla Debbarma

112. Salivary pH as a Factor in Oral Health and its Correlation with Diet .............................................554
    Swathy S., Muralidharan. N.P.

113. An Analytical Study on Physical Activity, Functional Capacity and Sleep Health in Patients with Type 1 and Type 2 Diabetes ..................................................................................................559
    V. Prithiha, T. Senthil Kumar, N. Venkatesh, S. Sridevi

114. Title: Knowledge, Attitude and Practice Regarding Hepatitis B Infection among Nursing Staff of Tertiary Care Hospital in South India ........................................................................564
    Pallavi A. Potdar, Ashutosh B. Potdar, Vivek R. Raikar

115. Effectiveness of Puppet Show on Knowledge about Child Safety Based on Learning Styles among School Children at Udupi District in India ...........................................................................570
    Josvita Sandra Fernandes, Anice George, Manjula

116. Impact of Blood Pressure on Cognitive Functions of Middle-Aged Male and Female Individuals ..........576
    K. Amritha Mahalingam, Manjunatha Aithala, Lata Mullur
117. Prevalence of Work Related Musculoskeletal Disorders among Sugarcane Farmers in Muzaffarnagar, India.
Shahrukh Chaudhary, Zuheb Ahmed Siddiqui, Prachi Tiwari, Junaid Jameel

118. Effectiveness of a Training Program on Improving the Knowledge, Attitude and Skill in Providing Cardiopulmonary Resuscitation (CPR)—An Interventional Study.
Swapnil Thulung, Melita Sheilini, Soumya Christabel

119. Comparative Evaluation of the Effectiveness of Apron with Mandarin Collar and Open Collar in Prevention of Microbial Contamination on Street Clothing.
Yashaswini Shetty, Ashwini Hegde, Srikant N, Ashwin Rao, Karuna Y M, Anupama Nayak P

Yogesh Mohan, Anbarasu K., Aishwarya K., Aishwarya S. P., Timsi Jain

121. Maternal Deaths in Transkei Region of South Africa a Case Report.
B.L. Meel

122. Sudden Death in a Road Traffic Accident: A Case Report.
B.L. Meel

123. The Role of Dermacyn Solution in the Treatment of Infected Diabetic Foot Ulcers in Basrah: A Randomized Clinical Trial Study.
Abdulhussein K. Marzoq, Raya Habeeb Abdulimam

124. Determinants of Exclusive Breastfeeding Duration on Infants in Girimaya Community Health Center Pangkalpinang City.
Ade Devriany, Novidiyanto, Bohari

125. Ethical Issues in Relation to Evidenced-Based-Medicine and Hippocratic Oath.
B.L. Meel

126. The Effect of Periapical Radiography X-Ray Radiation on Platelets, Leukocyte, Hemoglobin and Mean Corpuscular Volume (MCV) in Mice (Mus Musculus).
Bayu indra Sukmana, Huldani, Harun Ahmad, Hilyatul Auliya, Chelsy Oktavia, Anugrah Qatrunnada Hakim, Yenny Salmah

127. Radiation Doses from Computed Tomography Practice in Regional Hospital Center Hassan II of Agadir, Morocco.
Bouchra Amaoui*, Slimane Senghouldi, Mustapha Massaq, Mohamed Aabid, Oum Keltoum Hakam, Abdelmajid Choukri, Abdennasser El Kharras

Decha Pinkaew, Khanittha Wonglangka, Tharnwimol Intachai

Deswinda, Rizanda Machmud, Yusrawati, Ahmad Syafruddin Indrapriyatna

_Candra Ferdian Handriyanto, Moh Badrus Sholeh, Nyoman Anita Damayanti_

218. The Effect of Exercise on Activity Daily Livings and Happiness Level amongst the Elderly Population in Thailand

_Chomlak Kongart, Yuttachai Likitjaroen, Surasak Taneepanichskul_

219. Assessment of Pre and Post Training Nursing Documentation Program for Nurses in Accident and Emergency Hospital

_Delan J. Qader, Faruk H. Faraj_

220. Relationship between Training on Employee Performance

_Devita Tintasari, Swasti Niramaya, Nyoman Anita Damayanti_

221. Premarital Screening to Determine High-Risk Pregnancy: A Systematic Review

_Dewi Puspitaningrum, Nuke Devi Indrawati, Indri Astuti Purwanti_

222. Different Grades of BMI is Correlated with Left Atrium and Ventricle Structure in Patients with Hypertensive Heart Disease

_Meity Ardiana, Rofida Lathifah, Makhyan Jibril Al-Farabi, Muhammad Satya Bhisma_

223. Relationship Analysis of Factors with Implementation Measures Collaboration Effective Nurse in the HA Thalib Hospital Kerinci Indonesia 2018

_Moza Suzana, Suharizal, Lili Fajria_

224. Seroprevalence Rates of Typhoid Fever among Children in Endemic Areas, South Sulawesi, Indonesia

_Ressy Dwiyanti, Mochammad Hatta, Rosdiana Natzir, Sutji Pratiwi, Muhammad Sabir, Yadi Yasir, Rizki, Amelia Noviyanthi_

225. Clinical Profile and Outcome of Juvenile Autoimmune Hepatitis in Iraqi Children

_Mohammad Fadhil Ibraheem_

226. Deleted
227. The Role of 3D CISS MRI in the Evaluation of Primary Trigeminal Neuralgia
Mohammed abd Kadhim, Rasha Muzahim Rasheed, Bashar Talib Huweidy

228. Serum Levels of Oxidative Stress Biomarkers in Patients Obsessive Compulsive Disorder in Tikrit City, Iraq
Mohammed Amer Mohammed, Nihad Nejres Hilal, Ahmed Hashim Al Ani

229. Comparative Study of Lipid Profile in Sedentary and Active Hypertension Population of Maharashtra
Mohammed Salahuddin, Mohammed Ubaidullah Sayeed

230. Study of Role of Serum Proteins in Viral Hepatitis in Maharashtra Population
Mohammed Ubaidullah Sayeed, Mohammed Salahuddin

231. Vitamin D Receptor Polymorphisms and Correlated with Some Chronic Diseases among Iraqi Women
Nadhim M.H., Haider Turky Al-Mousawi, Nktel Faaz Nassir Al-Saad, Qabas Neamah Al-Hajjar

232. Estimation of Serum Level of Micro RNA 224 in Different Stages of Hepatocellular Carcinoma
Nady Mahmoud Semeda, Hala Ibrahim Mohammed, Zeinab Mostafa Saad, Wael Soliman

233. Histopathological Changes of Mice Immunized by Serratia Marcescens Whole Cell Sonicated Antigens
Nasr T. Mohammed

234. Effect of Healthy Special Exercises of Interval Lactic Technique in the Development of Bearing the Performance, LDH Enzyme, and Schematic Action for Young Football Players Health
Ahmed Murtada Abdulhussein, Fadhil Daham Mansour, Khalid Mohammed Ridha

235. The Effect of Perceived Quality and Perceived Sacrifice to Perceived Value at Inpatient Installation of Dr. Soetomo Hospital Surabaya, Indonesia
Florentina Joestandari, Stefanus Supriyanto, Joni Wahyuhadi, Ade Nurma Ruditya, Alexander Patera Nugraha

236. Reduction and Fixation of Orbital Floor Fracture Using Trans-Antral Balloon Technique: A Case Report
Aly Gomaa, Khaled Barakat

237. Determination of Some Human Enzymes Activities in Presence of Titanium Oxide Nanoparticles
Amer Hasan Abdullah, Manal Sadiq Hammoodi, Emad Mahmoud Eltayef, Abeer H.M. Safaryan

238. Creating Value by Service Experience to Increase Health Service in hospitalized South Sulawesi Hospital, Indonesia: A Literature Review
Armin, Alimin Maidin, Indahwaty Sidin, Fridawaty Rivai, Burhanuddin, Muhammad Safar, Risnah

239. Investigation of Infectious Stages of Intestinal Parasites and Fungal Spores which Contaminated Nails of Some Students in Tikrit University, Iraq
Ashraf J. Mahmoud Zangana, Ruaa H. Latif Dunia A. Huseen

240. The Significance of Vimentin and Matrix Metalloproteinase-9 in Oral Squamous Cell Carcinoma in Relation with Tumor Depth and Prediction of Lymph Node Metastasis in South of Iraq
Aws Rassul Hussain Al-Salih

241. Comparative Study of Two Different Telescopic Crown Materials Retaining Lower Partial Overdenture
Ayman H. Amin, Gehan Fikry, Fardos N. Rizk, Amr B. Ismail
XVIII

242. Renal Protective Effect of Quercetin on Cisplatin-Induced on Some Blood Parameters and Nephrotoxicity in Male Rats ................................................................. 1220
Baida R. Ali

243. Factors Influencing Professionalism of Nurses in Community Based Non-life Insurance Company in South Korea ................................................................. 1225
En-Ju Song, Bo Young Kim

244. Studying TMJ Changes After Using Twin Block Appliance for the Treatment of Class II Cases ................. 1231
Ahmed Abdel Monem Abdel Emam, Wael Mohamed Mubarak Refai

245. Deleted ..................................................................................... 1235

246. Organized Activities in Peer Groups Improve Mental and Social Well-Being in Adolescents: A Qualitative Study ............................................................................. 1239
Suhermanto, Bagong Suyanto, Windhu Purnomo, Rahma Sugihartati, Oedojo Soedirham, Sutinah

247. Occupational Asthma Severity among Flour Mill Workers and Adherence to Preventive Guidelines ...... 1245
Shaban M.M., Abdou N.M., Abdel Rehim A.I.

248. E. Coli Bactria Deactivation by Plasma Jet with Replica Plate Technique .................................................. 1251
Rana Talb Mohsen, Farkad Hawas Musa, M.D.T. Al-Gabore

249. Pulmonary Rehabilitation for People with Pulmonary Tuberculosis: A Concept Analysis Based on Walker and Avant Approach ................................................................................. 1255
Nur Akbar, Astuti Yuni Nursasi

250. Physiological Mechanisms of Rehabilitation in Vegetative Vascular Dystonia ........................................ 1261
Vladimir Yurevich Karpov, Svetlana Yuryevna Zavalishina, Angela Valerievna Romanova, Tatyana Mikhailovna Voevodina

251. Assessment of Nurses Staff Knowledge Regarding Chest Pain Management and Respiratory Maintains in Cardiac Care Unit ................................................................................. 1266
Younus Khudthur Baeex, Shelan Qahrman Shakor, Suhailah Mohammed Ali

252. Morphological and Molecular Study of Contracaecum Larvae with a New Record of Contracaecum Septentriorale in Al-Sanaf Marsh Southern Thi-Qar Province, Iraq .................................. 1271
Zainab Abd-Ali Mohammad, Mohammad Kareem Hbaiel

253. Anthropometric with Thryroxine Hormons in Iraqi Women ....................................................................... 1277
Zainab Abdul Wahed Naji

254. Isolation and Identification of Pathogenic Bacterial Species from Refrigerators in Basrah City, South of Iraq .......................................................................................................................... 1282
Zainab Alag Hassan, Rashid Rahim Hateet, Abdulameer Abdullah Al-Mussawi

255. Motivation for Choosing Medicine as a Career, among Students of Baghdad Medical College ............. 1286
Zuhair A. Al-Johar, Aya Ahmed Ridha, Donia Saad Zidan, Dalya Mahir Salih
256. Thyroid Dysfunction and Abnormal Uterine Bleeding

Tara Hasan Al-Bajalan, Srwa Ismael Khalid

257. Prevalence of Helicobacter Pyloriin Children with Type 1 Diabetes Mellitus and its Association with C-peptide and HbA1c

Thanoon Yahya AL-Azzawi, Ahmed Sattar Abood, Mohammed Shaker AL-Awady

258. Congenital Heart Defects in Children and the Main Approaches to Rehabilitation After their Surgical Treatment

Vladimir Yurevich Karpov, Svetlana Yuryevna Zavalishina, Angela Valerievna Romanova, Mikhail Nikonorovich Komarov, Viktor Ivanovich Sharagin

259. Genotoxic and Teratogenic Effects of Mycophenolate Mofetil in Mice

Wajdi Sabeeh Sadeq, Ruida Watheq Neama

260. Toxic Effects of Acute Cadmium and Lead Exposure in Rat Blood, Liver, and Kidney

Wasan Najim Abdul-Sada

261. Celiac and Thyroid Diseases in Some of Iraqi Patients with Juvenile Rheumatoid Arthritis

Wisal Salman Abd, Najah Salman Abd

262. Sequence Analysis of Telomerase RNA Component (TERC) in Iraqi Patients with Breast Cancer Using Bioinformatics Method

Wissam Lateef Abdullah, Abbas Abdullah Mohammed

263. Validity and Reliability of the Indonesia Version of HIV Treatment Adherence Self-Efficacy Scale (HIV-ASES) in Men who have Sex with Men in West Sumatra

Yafi Sabila Rosyad, Hema Malini, Rika Sarfika

264. The Association between Meaning in Life and Adherence to Antiretroviral Therapy (ART) of HIV-Seropositive within Men who have Sex with Men (MSM); Mixed Method

Yafi Sabila Rosyad, Hema Malini, Rika Sarfika

265. Prevalence of Lower Back Pain among Health Care Providers Working in Operation Rooms in Mosul City Hospitals

Rami Ramadan Allo, Tameem Thamir Mayouf, Mohammed Tariq Ali

266. Positive Deviance Against Malaria Events in Majene District

Arsunan, A. A., Indra Dwinata, Januar Arifianto, Muhammad Akbar Nurdin, Aisyah

267. Genetic Identification of Aplocheilus Panchax from the Waters of West Papua Using Molecular Approach for Preventing the Spread of Malaria

Lutfi, Hermawaty Abubakar, Marhan Manaf, Ida Lapadi, Muhammad Dailami

268. The Effect of National Health Care and Motivation of Maternity Mothers in Health Care Facilities in the Working Area of Bantilang Health Center East Luwu Regency in 2018

Nilawati Uly, Suhra Surdin

269. The Effect of Granisetron and Ondansetron on Hemodynamic During Cesarean Section Under Spinal Anesthesia

Syafri Kamsul Arif, Ahmad Nur Islam, Alamsyah A.A., Muh. Ramli Ahmad, Syafruddin Gaus, Hisbullah

298. Role of Genetic Polymorphisms of Angiotensin Converting Enzyme to Cardiovascular Endurance in Men Ages 13-14 Years After Fartlek Training for 3 Months ................................................................. 1519
Fatoni, Haerani Rasyid, Rosdiana Natsir, Ilhamjaya Pattelongi, Andi Ihsan², Adam Mappaompo², Sudirman²

299. The Expression of miR-21 and miR-29c in Blood Plasma of Nasopharyngeal Carcinoma Patient Post-Chemoradiotherapy .......................... 1523
Eka Savitri, Indira Maharis, Abdul Kadir, Riskiana Djamin, Sofia Mubarikaand, Tirta Wardana

300. Audiometric Profile of Fishermen Using Motor Boat in Barombong Village, Makassar ......... 1530
Muhammad Anwar, Eka Savitri, Trining Dyah

301. Implementation of Partnership between Midwives and Traditional Birth Attendants Inkotabaru District.. 1535
Anggrita Sari, Adriana Palimbo, Angga Irawan, Sukamto, Isda Herlina

302. Risk Factors and Criminogenic Needs of Indonesian Inmates ............................................................. 1540
Hasnida, Etti Rahmawati, Juliana Irmayanti Saragih, Namora Lumongga Lubis

303. Vitamin D Receptor Gene Polymorphism Fok 1 and Vitamin D (25-OH)D Status in Type 2 Diabetes Mellitus Patients with Pulmonary Tuberculosis .......................................................... 1545
Wahiduddin, Agung Pranoto, Sudjarwo, Ni Made Mertaniasih

304. An Overview of Socio-Cultural Factors on the Utilization of Antenatal Care Services in Bajonese Pomalaa, Southeast Sulawesi ........................................ 1550
Fatmah Afrianty Gobel, A.M. Multazam, Andi Asrina, Ella Andayanie

305. Utilization of Mother and Child Health Services in Bajo Transport in the Coastal Area of Hakakutobu Village, Pomalaa District ......................................................... 1554
A.M. Multazam, Fatmah Afrianty Gobel, Ella Andayanie, Andi Asrina

306. Influence of Customer Value on BPJS Patients with IUR Cost Satisfaction in Hospital of Makassar City 1559
Marwah Thaha, Amran Razak, Indar, Fridawaty Rivai

307. Determinant Factors Affecting the Development of Motor, Cognitive and Socioemotional Children Ages 18-12 Months in the District Jeneponto, Indonesia .................................................. 1564
Sarih Karmila, Siradjuddin Saifuddin, Abdullah Tahir, Hadju Veni

308. Analysis of Human Platelet Antigen (HPA) in Thrombocytopenia Patients ........................................ 1570
Rachmawati Muhiddin, Nelly, Asvin Nurulita, Tutik Harjiandi, Moch Hatta, Mansyur Arif

309. The Application of Nesting and the Light Protective Cover of Incubator to the Stability of Oxygen Saturation and the Pulse of Low Birthweight Babies in the Newborn Intensive Care Unit in RSU Undata Palu, Central Sulawesi ........................................ 1576
Andi Fatmawati Syamsu, Aminuddin
310. Effectiveness of Flipchart Toimprove Knowledge and Attitude about Tuberculosis on Mandar Etnic in Majene District West Sulawesi .................................................................................................................. 1582
Madjid Abdul, Muh Syafar, Arsunan, A.A., IdaLeida Maria, Muh Tahir Abdullah, Syamsiar S. Russeng, Anwar Mallongi

311. Accelerative, Effective and Efficient Tuberculosis (TB) Response to TB Elimination on 2035 in Medan Year 2017 ........................................................................................................................................ 1587
Syarifah, Tukiman

312. Behavior of Tuberculosis Pulmonary Disease Prevention (Tb Paru) South Sulawesi .............................................. 1592
Herman

313. Children’s Nutrition Status 7-12 Months Based on Age, Education and Job of their Mother in South Sulawesi ...................................................................................................................................... 1598
Hastuti, Hadju Veni, Citrakesumasari, Maddeppungeng Martira, Tanzia Ikee, Abdullah Tahir

314. The Effect of Health Social Determinant on the Life Quality of Pregnant Mother .......................................................................................................................... 1604
Muhammad Anwar, Saifuddin Sirajuddin, Ridwan Amiruddin, Ridwan Thaha, Toto Sudargo, Anto J. Hadi

315. Implementation of Partnership between Midwives and Traditional Birth Attendants in Kotabaru District 1609
Anggrita Sari, Adriana Palimbo, Angga Irawan, Sukamto, Isda Herlina

316. Socio-Cultural Transformation through the Process of Internalizing Values in Early Childhood Education in Makassar City (An Ethnographic Study of Education) ........................................................................................................................................................................ 1614
Juwanita Sahid, Nurul Ilmi Idrus, Hamka Naping, Munsi Lampe

317. Risks Assessment of Silica Contamination on the Communities Living Surround the Cement Industry, Pangkep Indonesia ........................................................................................................ 1619
Anwar Mallongi, Stang, Syamsuar Manyullei, Muhammad Fajar Natsir, Ratna Dwi Puji Astuti, Annisa Utami Rauf

318. Overview of TB Patients and their Behavior in the Buginese and Makassarnese South Sulawesi............. 1623
Najamuddin Andi Palancoi, Alimin Maidin, Ridwan Amiruddin, Burhanuddin Bahar

319. Possible Role of BK Polyomavirus in Prostate Cancer ................................................................................................................................. 1628
Asmaa M.S. Al-Bayati, Zaid Mohammed Sulaiman, Maad Mohammed Sulaiman, Muhammad Abdullah Alazzawy

320. A Meta-heuristic to Generate Rules for the Diagnosis of Heart Disease in Maysan Teaching Hospital .... 1633
Gesoon J.K. Al-Abbas
321. The Effect of Different Concentrations of the Blue-Green Algae Water Extract Anabaenaoryzae on the Adult Beetle (Calosomainquisitor) Order: Coleoptera for 24 Hours and 48 Hours after Treatment in Samarra, Iraq ................................................................. 1639
Atheera Hamid Jasim Al-rahmanny, Harith Ahmed Mustafa

322. Learning Cardiopulmonary Resuscitation (CPR) Using an Interactive Method for Students of an Elementary School in Indonesia .............................................................................................................. 1642
Bintari Ratih Kusumaningrum, Ika Setyo Rini, Nikma Afifi Rosida

323. Concentrations of Lead, Cadmium and Mercury in Cord Blood and Prematurity in the Sidi Bel Abbes Region (West of Algeria) ............................................................................................................. 1647
Bouhadiba Hadjer, DEMMOUCHE Abbassia, Menadi Norreddie, Mai Hichem, Ferrag Dalila, Zine Charaf Khalloua, Bekhadda Hadjer

324. The Potency of Private Practitioners on Tuberculosis Cases Finding and the Factors Associated in Surabaya City, East Java, Indonesia ........................................................................................................... 1654
Chatarina Umbul Wahyuni, I Wayan Gede Artawan Eka Putra, Hari Basuki Notobroto, Abdul Rohim Tualeka

325. The Effect of Family Assessment of Less Chronic Energy (LCE) Pregnant on Nutritional Status of Pregnant and Baby Birth Size ........................................................................................................... 1659
Demsa Simbolon, Antun Rahmadi, Jumiati

326. Safe Concentration of Mercury (Hg) Exposure in Fish Consumed by the Residents of Bulawa Subdistrict, Bone Bolango District, Gorontalo Province, Indonesia ................................................................. 1665
Deviyanti Wahyu Zati, Abdul Rohim Tualeka, Siprianus Singga, Pudhi Rahmawati, Syamsiar S Russeng, Atjo Wahyu, Ahsan

327. Evaluation of Abutment Health Related to Two Different Retention Methods of Maxillary Obturator (Randomized Control Trial) ........................................................................................................... 1670
Doaa Tawfik Hassan, Hamzawi AG, Mohamed Mohamed Fata, Gehan Fekry Mohamed

328. Antibacterial Activity of Silver-Nanoparticles Synthesized Using Trichoderma Harzianum .............. 1675
Ehab Y. Jabber, Mohamed M. Abdul Hussein

329. Incidence of Bacterial Vagniosis and Aerobic Vaginitis before and after Pessary Insertion in Indonesia 1680
Eighty Mardiyan Kurniawati, Faria Toma, Harry Parathlon, Gatut Hardianto, Azami Azinar Denas, Kartuti Deborah, Firas Farisi Alkaff

330. Mother’s Independence Model within Caring for Low Birth Weight Babies at Home after Hospital Care Based on Mother Factors, Family Support, and Social Support ................................................. 1685
ErlinaSuci Astuti, Nursalam Nursalam, Shrimarti Rukmini Devy, Risa Eitka

331. The Evaluation of My Home My Village Method to Support the Complete Basic Immunization Programme in Surabaya, Indonesia ............................................................................................................ 1691
Fariani Syahrul, Hario Megatsari, Ratna Dwi Wulandari, Arief Hargono, Kurnia Dwi Artanti

332. Safe Concentration of Benzene on Workers at Public Gas Stations around Diponegoro University Semarang, Indonesia ........................................................................................................................ 1697
Fatin Zuhra, Abdul Rohim Tualeka, Dimas Triyadi, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu, Ahsan

333. Operations Strategy as a Strategic Reconciliation towards a World Class University in Indonesia ...... 1703
Febriana Wurjaningrum, Armanu, Fatchur Rohman, Mintarti Rahayu
334. Analysis Factors Related to Coronary Heart Disease Prevention in Families by Adolescents:  
A Cross-Sectional Study ................................................................. 1708  
Fitriah Fitriah, Mustofa Haris, Mufarikah, M. Hasinudin, Nursalam Nursalam

335. Risk Factors of Gonorrhea Infection among Indirect Female Sex Workers (IFSW) in Indonesia 2015 .. 1714  
Frans Landi, Nuning Maria Kiptiyah

336. Occupational Stress Due to Additional Tasks of Procurement of Goods and Services in  
Provincial Health Office, East Java, Indonesia ............................................. 1719  
Hafidh Maulana, Mochammad Bagus Qomaruddin, Oedojo Soedirham

337. Healthy Reflection of Behavior Modification Strategies on Snatch Lift Technical Performance for  
Students of the College of Physical Education and Sports Sciences .................. 1724  
Haidar Hassan Karam, Alaa Khaldoun Ziedan

338. Evaluation of Serum Lysyl oxidase and Calreticulin as Biomarkers in patients with  
Chronic Kidney Disease ................................................................. 1730  
Haitham S. Hamadi, Mohamed I. Hamza, Arif S. Malik

339. Differences in Consumption of Flavonoid Phytochemicals Toward Total Cholesterol and Ldl-Cholesterol  
Levels in Dyslipidemia and Non-Dyslipidemia Groups of Minangkabau Ethnic Women .............. 1736  
Hermita Bus Umar, Diah M. Utari

340. Dental Caries and Treatment Needs in Relation to Nutritional Status among Kindergartens  
Children in Tikrit City, Iraq ................................................................. 1742  
Hind Thyab H. AL-Nassary, Ahlam Taha Mohammed

341. Evaluation of Implant Stability in Three Implants Supported Milled Bar Mandibular Overdenture Cases:  
A 1-Year Follow-up Clinical Trial ..................................................... 1748  
Hussein Abdel Hady Hussein, Amr Mohamed Ismail Badr, Emad Mohamed Tolba Mahmoud Agamy,  
Gehan Fekry Mohamed

342. Comparison between Anterior Colporrhaphy with Kelly’s Plication and Tension Free Vaginal  
Tape–Transobturator Approach (TVT-O) in the Treatment of Mild Stress Urinary Incontinence .......... 1754  
Inas Taha Ahmed, Maha Abdul-Allah Rashid, Osama F Qaisi

343. Evaluation of Some Enzymes, Hormones, Other Related Biochemical Parameters in Sera and  
Follow up of Women after Treatment of Breast Cancer ........................................ 1760  
Jamal A. ALJabbar Attawi, Nazar Ahmed Naji Abed.

344. Arthroscopic Coblation for Temporomandibular Joint Disc Release ........................................ 1766  
Khaled I Barakat, Diaa El Saied

345. The Influence of Halloysite Nanotube Addition on Some Properties of Room Temperature  
Vulcanized Maxillofacial Silicone before and after Simulated Aging ....................... 1770  
Khalid A. Al-Obaidi, Mohammed Moudhaffer M Ali

346. Effect of Computer Related Ergonomics Intervention on Knowledge and Practice of  
Primary School Children ............................................................... 1776  
Lamiaa Saad Abdallah, Nagah Mahmoud Abdou, Afaf Ibrahim Abd Elrehim

347. Plasma Leptin and Insulin Resistance Correlation with Obesity in Pre Pubertal Children .............. 1782  
Leersia Yusi Ratnawati, Bambang Wirjatmadi, Merryana Adriant, Roedi Irawan
348. Safe Concentration of Lead in Community Drinking Water in the Tapak River Area, Tugu City District, Semarang ................................................................. 1787

   Mahfiro Risky Safitri, Abdul Rohim Tualeka, Puspito Raharjo, Pudji Rahmawati, Syamsiar S Russeng, Atjo Wahyu, Ahsan

349. Finding of Helicobacter Pylori through Biopsy Trials to Gastro-intestinal Region Infections in Iraq Patients ................................................................. 1792

   Mariam Kareem Ali, Jaafar Sataar Shia

350. Analysis of Maternal Deaths Trends in Bojonegoro, Indonesia ...................................................... 1798

   Mariya Ulfah, Budi Prasetyo, Lutfi Agus Salim

351. Psychophysiological Aspects of the Development of Alcoholism ...................................................... 1803

   Mikhail Mikhailovich Basimov, Dmitriy Vladimirovich Semenov, Natalya Sergeevna Varfolomeeva, Natalya Vladimirovna Belyakova, Elena Alekseevna Petrova, Vera Vladimirovna Pchelinova, Mikhail Valerievich Tarasov

352. The Process of Finding the Meaning of Life as an Important Component of the Pathogenesis of Alcoholism ................................................................. 1808

   Mikhail Mikhailovich Basimov, Dmitriy Vladimirovich Semenov, Natalya Sergeevna Varfolomeeva, Natalya Vladimirovna Belyakova, Elena Alekseevna Petrova, Vera Vladimirovna Pchelinova, Angela Valerievna Romanova

353. Rehabilitation Potential of Physical Activity Complex with Elements of Sports and Health Tourism in Case of Dysfunction of the Cardiovascular System in Adolescence .......................................................... 1814

   Mikhail Nikanorovich Komarov, Svetlana Yuryevna Zavalishina, Alexander Alekseevich Karpushkin, Andrey Valentinovich Malyshev, Elizaveta Sergeevna Kumantsova

354. The Effectiveness of Consuming Fruit and Vegetable on Potassium and Blood Pressure in Overweight Youth ................................................................. 1819

   Mohammad Jaelani, Meirina Dwi Larasati, Yuniarti, Sunarto, Choiroel Anwar

355. Prediction of Crime Risk Behavior among Early Adolescences .......................................................... 1824

   Mohammad Nasir Bistamam, Nor Hafifah Abdullah, Nurul Hasyimah Mat Rani, Samsiah Mohammad Jais, Md Azman Shahadan, Pau Kee

356. The Effectiveness of the (Healthy Physical-Skills) Exercises in the Development of Fitness and Balance as well as the Accuracy of Performing of Both the Skills of Preparing and Receipting of the Volleyball .. 1830

   Mohammed Dhayeamohammed, Tarik Dhayeamohammed, Rawaa Abdulkareem Farhan

357. Effectiveness of Health Educational Program on Nurses’ Knowledge Concerning of Developmental Hip Dysplasia at Al-Wasiti Teaching Hospital in Baghdad City .......................................................... 1835

   Mohammed H. Burhan, Khatam M. Hattab

358. Relationship of K3 Training and K3 Supervision with Sop Compliance in Building Workers (A Case Study of Surabaya Bridge Infrastructure Project) .......................................................... 1841

   Nabylla Sharfina Sekar Nurriwanti, Noeroel Widajati

359. Factors Affecting the Occurrence of Stunting in Indonesia ................................................................. 1845

   Nailul Izza, Windhu Purnomo, Mahmudah

360. A Study of Job Burnout among Faculty Teacher at Kirkuk University .......................................................... 1851

   Nashwan Nadhim Hasan, Faisal Younus Sameen, Fakher Abobaker Ahmed Gli, and Kasim Sakran Abass

427. Role of Some Enzymes in Early Diagnosis of Ovarian Cancer ................................................ 2206
   Tamara A. Subhi, Firas A. Hassan, Alaa Hussein j Al-qaisi
428. Antibacterial Activity of Zinc Oxide Nanoparticles and Poly (B-hydroxybutyrate)/ZnO
   Bionanocomposites Against Escherichia coli .................................................................... 2210
   Zaman salmon, Wejdan R.taj Al-deen
429. The Relationship between Postmenopausal Women and Some Hormonal Changes ......................... 2216
   Kadhem Mohammed Sabae
430. Osteoporosis Knowledge and Osteoprotective Behavior among Female Patients Attending Dxa Clinic:
   A Cross-Sectional Study ............................................................................................... 2220
   Heba M. Attash, Harith Kh. Al-Qazaz, Layth A. Al-Hajjar
431. Isolation and Identification of Dermatophytes Causing Dermatophytosis in Hilla City, Iraq .......... 2225
   Nibras AA Hindy, Abed-Ali A Abiess
432. Dental Plaque as a Probable Helicobacter Pylori Reservoir .................................................... 2231
   Muayad Mahdi kadhum, Hasanain Khaleel Shareef
433. Exploration of Potential Link between Prevalence of Irritable Bowel Syndrome and
   Seropositivity for Helicobacter Pylori ........................................................................ 2236
   Hasanain Abdulhameed Odhar, Ahmed Fadhil Hashim, Douha Hassan Obaid, Ruba Samer Majeed,
   Omaima Abbas Habeeb, Nooralhuda Mohammed Abdalhadi
434. The Anti Inflammatory Effect of Pumpkin Seeds Oil in Treatment of Gingivitis; Clinical Study .......... 2241
   Ahmed Adel Othman, Muntaha Fawzi Saleh, Taih Mahdi Saleh

435. Relationship between Testosterone and Body Mass Index, Hirsutism, Alopecia, Acne, Type of Menstrual Cycle, and Levels of Interleukin-1β, Interleukin-17, Interleukin-27 and Interleukin-35 for Infertile Women with Polycystic Ovary Syndrome ................................................................. 2245
   Sundus Fadhil Hantoosh

436. Assessment of TNF-a, IL-17, IL-33, TGF-b, and Dopamine in Iraq Depressed Women with Chronic Toxoplasmosis Infection ...................................................................................................................................................................................... 2252
   Maha mahmood shaker, Hazima Mossa Alabassi, Sabah A. Hameid A. Rahman

437. Down-Regulation of Circulating MicroRNA-205 as a Potential Biomarker for Distinguishing Prostate Carcinoma from Benign Prostatic Hyperplasia ......................................................................................................................................................... 2257
   Adel Mosa AL-Rekabi, Shoroq Mohammed AL-Temimi

438. Investigation of the MEP4 Gene of the Fungalysins Gene Family (MEP 1-5) in Isolated Skin Fungus from Primary School Students ................................................................................................................................................................. 2263
   Abbas Abdul Hussein Mohi, Majid Kazem Al Shibli

439. Laboratory Administration of Clinical Trachoma Cases Caused and Ruled by Musa domestica in Mesopotamia ..................................................................................................................................................................................................................................................................................................................... 2269
   Abdul-Samad Uleiwi Hassan, Anaam Mehdi Dawood, Zahraa Falah Abd-Alaali

440. Evaluation of Neutrophils Activity and Function in Type II Diabetes Mellitus Patients’ Blood Samples2272
   Huda Taher Ali, Weam S. Al-Hamadany, Salah Abd-Al kader Omran

441. The Effect of the Use of the Self-Programming Method in Cognitive Achievement and Learning the Handling Skills of Football Students ......................................................................................................................................................................................... 2276
   Mohsen Mohammed Hassan, Ali Mohammed Jawad Al-Sayegh, Obeis Abed Wahid

442. The Level of Ambition and its Relation to the Cognitive Achievement of Students in Volleyball ........ 2281
   Hussein Abdel-Zahra Abdel-Yamah, Khalil Hamid Mohammed Ali, Hassanein Jabbar Rahi Asadi

443. The Effect of Stopping Training in Some Physical and Functional Variables and Sending Table Tennis2287
   Marwan Abdulhamed Yousif, Zeyad Mishaal Farhan, Aarif Abdul Jabbar Hussain

444. Study of Variables in the Ratio of Creatine in the Blood of Short, Medium and Long Distance for Runners 2293
   Zaid Samsam Turki Sulyan, Mahmood dawood Salman, Saddam Mohammed Fareed Rageh

445. Molecular Investigation of Aminoglycoside Modifying Enzyme among Aminoglycoside-Resistant Uropathogenic Escherichia Coli Isolates from Najaf Hospitals, Iraq ......................................................................................................................................................................................... 2298
   Khadeeja Obaid Alm’amoori, Zainab Jaber Hadi, Ali Muhsin Almohana

446. Simulation of the Warfarin Drug-Binding Nano-Metal Induction for Serum Albumin ..................... 2304
   Hasan Tuhmaz Hamad

447. The Creative Leadership of the Heads of Sports Clubs in the Middle Euphrates from the Point of View of its Members ..................................................................................................................................................................................................................................................................................................................... 2308
   Ahmed Faris Hadi Abd Ali, Saddam Mohammed Fareed Rageh

448. Inter-Pregnancy Interval and its Association with Autistic Children .................................................. 2312
   Hajir Salem Muhsen, Sijal Fadhil Farhood Al-Joborae
449. The Role IL-16 rs11556218 T/G Gene Polymorphism with the Risk of Osteoporosis in a sample of Iraqi Postmenopausal Women ........................................................................................................................................... 2318
Mohammad Shakir Atiya, Da’ad Ali Hussain

450. The Impact of the Educational Program on the Woods Model in Learning the Skills of Serve and Receiving Volleyball Students ........................................................................................................................................... 2323
Sahira Mohammed Abdulameer, Luma S. Hamoodi, Intisar Owaid Ali

451. Capability of Diffusion-Weighted Magnetic Resonance Imaging in Differentiating between Atypical Hemangioma and Malignant Lesions ........................................................................................................................................... 2328
Ashwaq Khalil Hashim, Osamah Ayad Abdulsattar

452. Association of the 3’UTR188CT Polymorphism of Lectin-Like Oxidized Low Density Lipoprotein Receptor-1 (LOX-1) Gene with Risk for Acute Coronary Syndromes in a Group of Iraqi Population . 2335
Amal Abbas Hammoodi Alsadi, Mohammed A. M. Albayatib, Moayed Basheer Hamid

453. Oxytocin Level and Depression Risk in Elderly Iraqi Population ........................................................................................................................................... 2341
Noor K. Habash, Meena M. Abdul−Hussain, Khalid M. Jasim, Ammar L. Khazaal

454. Study the Activity of 14-3-3 Eta Protein among Ankylosing Spondylitis Patients ........................................................................................................................................... 2345
May Yahya Al- Ma’amouri

455. Prevalence of Endodontically Treated Teeth in Baghdad Sub Population ........................................................................................................................................... 2348
Nadeen Jamal Abdulredah, Farah Salahaldeen Abbas

456. Study the Inflammatory Biomarkers of Acute Coronary Syndrome Patients in Wasit Province ........... 2352
Sama Ali AL-Rubaie, Mohammed R.S.Altattab, Alaa A. AL-Kinani

457. The Impact of Nd-YAG Laser on Salivary Streptococcus Mutans and Lactobacilli in Vitro ............... 2358
Khamaal IM. Al-Hasnawi, Nada Jafer MH. Radhi

458. The Activity of 5-Flurouracil Metabolizing Enzyme Dihydropyrimidine Dehydrogenase(DPD) and its Association with Tumor Progression and Markers (CEA, CA19.9) in Patients with Colorectal Cancer 2363
Hadel Kareem AL-Rubaiawi, Raid J. Mohamed

459. Diagnostic Values of Complete Blood Count in Patients with Urinary Tract Infection ..................... 2368
Thekra Ahmed Hamada AL-Tikrity, Marwa Tariq Ahmed Al-Douri, Mohammed Mohsin Abdul- Aziz, Usama Mohmmad Abbas Al-Jeboori

460. Evaluation of CK20 and CD8 Tumor Markers in Patients with Colorectal Cancer by Using Immunohistochemical Technique ........................................................................................................................................... 2374

461. Detection of Tn917 Carrying erm(B) Gene in a Clinical Isolates of S. pyogenes ...................................... 2380
Hanan Raheem Hassooni, Hameed M. Jasim, Abbas Aboud Farhan, Adil Hassan Alhusseiny

Mohamed Sadiq Ahmed, Luay Azez Merhij, Ahmed Jarullah Abdullah

463. Effect of Closure of Peritoneum on Early Postoperative Outcome and Operating Time During the First Cesarean Section ........................................................................................................................................... 2391
Suaad Rodan Shoelef
464. Doppler Finding in Renal Parenchymal Disease Correlated with Histopathological Finding .......... 2395
   Jinan Hussein Mohammed, Talib Atiyah Salman

465. Changes in FreeT3;T4 Thyroxine and Thyrotropin in Hemodialysis and Non-Dialysis Chronic
   Renal Failure Patients ..................................................................................................................... 2400
   Yasamin Abdul-Amer kadhum, Dalal Abd Al-Sattar Asaad, Ali Shalash Sultan

466. The Culture of Terrorism Da’ashi and its Implications on Iraqi Society Medical Anthropology Study 2405
   Salwan Fauze Abed AL- Aobide, Habib Hashim Abid Ali

466. The Effect of Using Competitive Exercise in Motor Fitness and Speed of Transition for
   Football Players (Junior Class) ........................................................................................................... 2410
   Majid Mohammed Mukhilif, Fouad Hammad Asil, Mustafa Haepel Shallal

467. Effectiveness of Electromedian Exercises to Develop Visual Attention, Perception of the
   Environment and Reaction of Football Players .................................................................................. 2415
   Asaad Ali Safih, Saba Shaker Farhan, Raafat Abdulhadi Kadhim

468. AgNps as Antibacterial Agent Against Klebsiella pneumoniae Isolated from Wond Infection .......... 2419
   Khamael H. Obaid

469. Study of Hepatitis C Virus (HCV) Genotypes in Al-Muthanna Governorate, Iraq .......................... 2423
   Salam Allawi Hassan, Wisam Salih Abbood

470. The Impact of an Educational Field for the Development of Perceptual-Kinetics and Skill of
   Passing Cub’s Football ....................................................................................................................... 2429
   Aban Abdul Kareem Mezher, Diaa Gaber Mohammed

471. The Impact of Compound Exercises in the Development of Some Perceptions of The Environment for
   Football Youth ................................................................................................................................... 2434
   Hussein Hamzah Najm, Diaa Gaber Mohammed, Hussein Salih Najm

472. Serum Levels of Lipocalin-2 and Prostate Specific Antigen in Patients with Prostate Cancer;
   A Comparative Study .......................................................................................................................... 2440
   Karwan A. Muhammad, Khudhair A. Khudhair, Salam S. Ahmed

473. Practicing, Attitudes and Beliefs of Physicians at Al-Emamain Medical City towards
   Seasonal Influenza Vaccination ......................................................................................................... 2445
   Nibras Alaa Hussain, Berg J. Hadi Al-Yasserri

474. The Effect of Learning Style by Playing Directly in Learning the Skill of Passing Football at the
   Age of (13-14) Years .......................................................................................................................... 2451
   Ali Qais Habeeb Majeed, Samer Abdulhadi Ahmed, Ahmed Murtada Abdulhussain

475. Prevalence of Cutaneous Leishmaniasis in Babylon Province, Iraq ............................................ 2456
   Alaa Jabbar Tahama AL-Jubbouri, Hayam Khalis Al-Masoudi, Wessam Ali Amin

476. Accurate Scoring According to the Brain Sovereignty of Handball Players .................................. 2462
   Ali Hussein Ali, Amer Hussein Ali, Mohammed Oudah Zaal

477. Audio Skills and Their Impact on the Development of Response Speed for Handball Goalkeepers ..... 2467
   Asaad Ali Safih, Raafat Abdulhadi Kadhim, Saba Shaker Farhan
478. Academic Personality Assessment Form for Fourth Stage Students Faculty of Physical Education and Sport Sciences Karbala University

Hassan Ali Hussein, Ammar Hasan Abdal Redha, Ali Noaman Trad

479. Self-Organized Learning Strategies and their Relationship to the Complex Thinking of Kindergarten Students

Nour Sabbath Lafa, Iman Abbas Ali AL-Khafaf

480. The Impact of an Accelerated Learning Program on the Development of the Skill Level of Snatch Punch for Boxing Students

Mohammedhussein Hayder Hamwud, Wissam Salah Abdul Hussein, Samir Abdul Hady Ahmed

481. Selective Screening of Inborn Errors of Metabolism in Baghdad Al Karkh/Al-Ielam Sector

Mithal Abdulkareem Abdoun, Raghad abd ulkareem

482. The Impact of Adding Silanated Pearl Powder on Some Properties of Heat Cured Acrylic Denture Base Material

Safa G. Dekan, Raghdaa K. Jassim

483. The Skill of Personal Effectiveness and Management of the Profession as a Function to Predict the Adequacy of the Management of the Game for Volleyball Coaches

Oras Neamah Hasan, Kadhim Habeeb Abbas, Saeed Hussein Hasan

484. Toxic Effects of Sodium Benzoate on the Rat Testes

Ban Thabit Al-Ani, Rana R. Al-Saadi, Hikmat Fakhri Wassef

485. Investigation the Role of Lactobacillus ssp. on Entamoeba histolytica Pathogenesis

Zainab Sameer Sabti, Shatha Khudaier Abbas, Nibras Nazar Mahmood

486. Estimation the Level of Survivin in the Serum of Iraqi Patient with Gallbladder and Liver Disorders

Mohammed Kadhim AL-Kafajee, Zainab Thamer Showait AL-Asady

487. The Effect of Socioeconomic Level on Dental Caries among Preschool Children in Baghdad City

Mariam F. Abo Nayla, Athraa M. Alwaheb

488. The Effect of Mouth Wash Containing Alcohol on Force Degradation of Colored Elastomeric Chains

Reem Atta Rafieeq Al-Ani

489. Serum Levels of Adrenomedullin in Women with PCOS before and after Rosuvastatin Treatment

Mohammed T. Dawood, Salam S. Ahmed, Hassan K. Rajab

490. Training According to The Required Calories as a Function of Muscular Work and its Impact on the Development of Some Physical Abilities and the Achievement of Long Distances Running 5000 Meters

Nabeel Muttlak Nasser, Suhail Jassem Almsalmawi, Maher Abdulhamza Hardan Al_Alwani

491. Indications of Intra-Vitreal Anti-VEGF

Zeena Adnan Abd

492. Sera Troponin-I Levels in Rheumatoid Arthritis Patients

Mayada Noori Iqbal

493. The Effects of Obesity and Mothers’ Education Levels on the Periodontal Health Status of Iraqi School-Aged Children

Maitha Sameer Kadhim, Basma Fathi Alanbari, Sanaa Rasheed Abd Al-Aaloosi, Mohammed Jasim AL Juboori
494. Comparison of Anti Mullerian Hormone in Working Women with Different Social Class in Babylon City, Iraq  ................................................................. 2563
   Hanan Abdul Jabbar Al-Taee

495. Role of Interleukin-12 Cytokine in the Cellular Response to Mycobacterial Disease .......................... 2567
   Raafat M. Al-Enzi, Jawad Kadhim Tarrad, Moshtak A. Wtwt

496. Impact of Breast Feeding Duration on the Presence of Candida in Relation to Nonnutritive
   Sucking Habit among Group of Iraqi Children .......................................................... 2570
   Ohud Faik Taha, Aseel Haidar M. J. Al Haidar

497. The Occurrence of Certain HDV Genotype in Patients with Chronic Hepatitis and
   Hepatocellular Carcinoma .................................................................................. 2575
   Nawfal Saeed Amen, Dawood S. Dawood, Safaa Abd Alrazaq

498. Organizational Loyalty and its Correlation to the Creativity of Members of the Federations in
   Tennis Games in Iraq ......................................................................................... 2581
   Munaf Abdulazeez Mohammed, Anees Hussein Ali, Ali Mohammed Jawad Al-Sayegh, Hayder Naji
   Habash Alshawi

499. Leeches Review: Biology, Ecology and Medical Important ......................................................... 2586
   Nebrass Faleh, Zaid Naji Hassan, Maan Abdul Azeez Shafeeq

500. The Personality of the Obsessive and Their Relation to the Motivation of Achievement of
   Volleyball Players .............................................................................................. 2591
   Hameed Shamkhi Ghazi

501. Building the Predictive Scale for the Psychological Efficiency of the Athletes Students at
   Al-Furat Al-Awsat Technical University ............................................................. 2596
   Hameed Shamkhi Ghazi

502. Lymphocytosis and Increases in Complement Protein C3 Level in Women with Polycystic
   Ovarian Syndrome ......................................................................................... 2602
   Sahlah Kh. Abbas, Aseel Sh. Abdulllah

503. The Prevalence of PCOS in Infertile Women According to Clinical Features and its Associated
   Hormonal Changes in Al-Hilla City, Iraq .......................................................... 2607
   Ban Amer Mousa

504. The Role of Minimum Fluid Requirement Post Laparoscopic Cholecystectomy in Comparison to
   Open Cholecystectomy ...................................................................................... 2612
   Al-Shammari AJ, Al-Zubaidi SA, Al-Zubaidi SA

505. Estimation of the Efficacy and Safety of Totally Real-Time Ultrasonography-Guided Percutaneous
   Nephrolithotomy: A Single Center Study ................................................................ 2618
   Ahmed Abdul Ameer Alwan, Ahmed Hamza Abd, Hussain T. Ajeel

506. The Effect of the Use of Parachutes and Gloves in Some Kinetic Variables and the Completion of a
   Swimming Pool (50M) Free for the Armenian Club .............................................. 2622
   Tabarek Mohammed Salman, Nada Mohammed Ameen, Mawahib Hamid Al-Jubouri

507. The Impact of Problem Solving Strategy in Developing the Technical Performance and Accuracy of the
   Skill of the Serve Facing from the Top (Tennis) Volleyball for Students ..................... 2627
   Nuha Yousef Hashem Abbas, Rawa Allawi Kazim, Mahmoud Nasser Radi
508. Effect of Battle Ropes Training in Some Components of Health Fitness and Vision of the Body Image of Women Aged (30-35) Years ................................................................. 2633
Raghda Hassan Ibraheem, Sahira Razzaq Kadhem, Suhad Qassim Saeid

509. The Cytotoxic Effect of Zinc Oxide on Colon Cancer Cell Lines in Vitro ........................................... 2638
Shihib Ahmed Jasim, Nihad A. Saleh

510. Comparison between WBCs, RBCs and HGH Levels for Iraqi AML Patients Pre and Post 3- and 7- Treatment within Four Age Groups Segmented Based on Growth Levels .................. 2643
Ishtar Imad, Abdulameer N. Ghaloub, Mehemt Ozaslan, Alaa F. Alwan

511. The Relationship between Peak Systolic Velocity of Thyroid Gland Arteries and Thyroid Stimulating Hormone Level in Diffuse Goiter Patients ................................................................. 2648
Laith F. Farman Al-Hialy, Mohammed A. Mahmood

512. The Role of microRNA 122, MCP-1 and TGF-β1 as Diagnostic Biomarkers for Endometriosis .......... 2652
Ekhlas Saddam Falih, Suhad Hassan Aubaid, Wala’a Taha Yousif

513. Assessment of Health Related Quality of Life in Children with Nephrotic Syndrome in Iraq—A Comparative Study ................................................................................................................. 2657
Uday Khalid Abdul Jabbar Al Qaisy, Shatha Hussain Ali, Iyad Hussein Ali

514. The Use of Erubium Yag (Er:YAG) Laser to Treat Burns and Study Laser Effect on the Enviroment .. 2663
Jamal Suheel abd, Hana Hasan k, Ahmed Jumaah Mhawes, Hayder Hasan Ali, Enass Mohammed Abdulzahraa

515. The Relation between Some Genetic Traits (Ptc Tasting, Tongue Rolling, Earlobe Attachment and Dental Occlusion in Iraqi Adults ................................................................. 2668
Jinan E. Saloom, Sami K. Al-Joubori, Sara M. Al-Mashhdany

516. Combination of Gold Nanoparticles Conjugated Lectin and Using it for Development the Antibacterial Activity of Lectin Purified from Acinetobacter baumannii ................................................ 2674
Sahira Nsayef Muslim, Alaa Naseer Mohammed Ali

517. Functional Neurological Disorder at Al-Diwaniyah Teaching Hospital ......................................................... 2680
Sahar Albermany, Abdul-Zahra Al-Khafaji, Rose Jihad Kadhim

518. Immunogenetic Study of Pediculus humanus capitis Associated with Typhus Fever in Iraqi Patients .. 2686
Salah Mahdi Hassan, Youmor M. Jameel, Abdulrazzaq Neamah Zghair, Nazar Sh. Mohammed

519. Impact of Dental Caries on Quality of Life of Primary School Children aged 8-10 Years in Al-Najaf City, Iraq ................................................................. 2690
Zahraa M. Alshmaa, Athraa M. Alwaheb

520. Purification of Protease from Aspergillus fumigatus ........................................................................ 2696
Thakra Ahmed Hamada, Hadeel Mizher Youmus, Raghad Saad Abdulkareem

521. Using a Proposed Program to Develop Some Physical and Motor Abilities for Students with Slow Learning ......................................................................................... 2702
Ali Khalid Mukhlif, Basim Obaid Moharib, Mustafa Habib Shalal

522. The Effect of Learning Exercises Through Flexible Circles on Learning Some of the Composite Skills of Futsal Football for Students ................................................................. 2707
Mazin Hashim Hammood, Rashad Tarek Yousef
523. Effects of Special Exercises on the Sand on Some Blood Cells, Heart Measurements and Physical Abilities of Advanced Futsal Players ................................................................. 2713
   Adnan Ghethan Digham, Ameen Khazal Khuzai

524. The Impact of an Educational Program According to the Model 4MAT to Learn the Skill of Attack in Numerical Epee for Students Fencing ................................................................. 2718
   Zahraa salim Hussain, Wissam Salah Abdul Hussein, Amer Hussein Ali

525. Efficacy of Nano-Hydroxyapatite on Enamel Surface of Primary Teeth Following Exposure to Liquid Medications in Comparison with Sodium Fluoride: An in Vitro Study ........................................ 2722
   Hassan NM, Jafar ZJ

526. Effect of Orthodontic Force on Salivary Levels of Lactate Dehydrogenase Enzyme ........................................ 2728
   Suha Ali Abdul Ameer, Akram Faisal Alhuwaizi, Hayder F Saloom

527. Effect of Staining and Brushing on the Surface Roughness of White Spot Lesions Treated with Resin Infiltration Technique ................................................................. 2734
   Karar M. Hussein, Abdulla M.W. Al-Shamma

528. Evaluation of Salivary Melatonin and Periodontal Parameters in Type II Diabetic Patients with Chronic Periodontitis: A Comparative Study ........................................ 2740
   Rusul Subhi Hassan, Suzan Ali Salman

529. The Role of Extracellular Superoxide Dismutase (Ec-SOD) Gene Polymorphism in Motor Neuron Damage of Type 2 Diabetic Peripheral Neuropathy Patients of Babylon Province-Iraq ........................................ 2746
   Haider K. Zaidan, Asma’a H. Mohamed, Ali H. Al-Saadi

530. The Value of Metformin in the Treatment of Hidradenitis Suppurativa in a Cohort of Iraqi Patients .... 2752
   Asmaa abdulJaleel Swadi, Akeel Hamed Jabur

531. Design and Implementation of Physiology Lab Management Blood Analysis System ....................... 2757
   Ahmed Saleem Abbas, Awfa Hasan Dakheel, Ali Hasan Dakheel

532. The Effectiveness of the Model of Active Thinking in the Collection of History and Creative Thinking among Students of the Fifth Grade Literary ........................................................................ 2764
   Doaa Abdel Karim Rahim, Jinan Mohammed Abdul Jassim, Anas Hanza Aljilawi

533. Effectiveness of an Educational Program on Nurses Knowledge about Chemotherapy Hazards at Al-Habbobi Teaching Hospital in Al-Nasiriyah City ........................................ 2769
   Hussein Kadhim Abd Ali, Wissam Jabar Qassim

534. In Vitro Assessment of Some Properties of Biocompatible Polymer Dental Implant Consisting from Poly Ether Ketone (Peek) and Silicon Carbide Nanofiller ........................................ 2772
   Mustafa Mahdi Jassim, Thekra Ismael Hamad

535. Occurrence of Asymptomatic Bacterial Urinary Tract Infection and Susceptibility Profile among Students of Medical Technical Institute-Baghdad ........................................ 2778
   Najah Ali Mohammed

536. Prevalence of Levels of Examination Anxiety among Undergraduate Students of the Colleges of University of Thi-Qar, Iraq ............................................................................. 2784
   Rasha Dakhel Abdullah, Maan Hameed Ibrahim Al-Ameri
537. Influence of the Cross Linking Agent “Proanthocyanidins” on the Push-Out Bond Strength of Fiber Posts Cemented with a Self-Adhesive Resin Cement ................................................................. 2788
Hamid Kasim, Abdulla M.W. Al-Shamma

538. Effectiveness of Instruction Program on Pregnant Women’s Practices regarding Anemia at Primary Health Care Centers in Baquba City ................................................................. 2793
Qadessia Mahmood Dawood, Rabea Mohsen Ali

539. Knowledge of Iraqi Midwives and Nurses about Hepatitis C Virus at Maternity Hospitals in Baghdad City 2798
Hawraa Hussein Ghafel

540. The Impact of Strategic Defense in Attainments and Growing the Mind Thinking for the Students ..... 2804
Qais Talib Abdul-Zahraa, Firas Saleem Hayawi, Hamdan Mahdi Abbas Al-Juburi

541. Assessment Nurse’s Knowledge toward Nursing Management for Patients Post Cholecystectomy in Kirkuk City Hospitals .................................................................................. 2809
Tholfikar Haider Selman Hussein, Khalida Muhammad Khudair

542. Cholinesterases Activities in Diabetic and Hyperlipidemic Patient .................................................... 2812
Ahmed A.J. Mahmood, Musab M. Khalaf, Adnan A. Zainal

543. The Impact of the Formal Strategy of the Theory of Cognitive Burden in Acquiring the Concepts of Middle School Students .................................................................................. 2817
Nada Khudair Ali al-Shammari, Hamdan Mahdi Abbas Al-kraee, Abbas Karim Abd al-Khafaji

544. Effect of Black Seed Oil on Some Physiological Parameters in Female Rats Treated with Aflatoxin B1, B2 2822
Athraa Harjan Mohsen, Israa Harjan Mohsen

545. Rehabilitation Program Impact in the Treatment of Injury to the Cruciate Ligament of the Knee Joint Care of Five Players Lounges .................................................................................. 2828
Nagham Salman, Aseel Naji

546. The Proportion of the Contribution of Some Muscular Capabilities of the Arms to the Accuracy of the Performance in Foil ..................................................................................... 2833
M. M. Mohamed Qais Mubder, Noor Hatem, Kamil Malykh Hussein

547. The Impact of the Strategy of the Three-Step Interview in the Rugby Thinking and the Accuracy of the Performance of the Skill of Students .................................................................. 2838
Fadya Abdul-Hussein Kadhim, Nihad Mohammed Alwan

548. Measuring the Therapeutic Calendar of the Elbow Joint According to the Rate of Change of Rehabilitation Exercises ......................................................................................... 2843
Dr. Imad Kadem Yasser, Dhulfiqar Ali Abdul Hussein

549. Effectiveness of an Instructional Program on Promoting Lifestyle of Patients with diabetes Mellitus type 2 at Diabetes and Endocrinology Center in Missan City ........................................ 2848
Sarah Falah Hassan, Khalida Alwan Mansur

550. Outcomes of Laparoscopic Appendicectomy in Al-Diwanyiah Teaching Hospital ............................ 2854
Zaman Alrekabi, Muayad Alkafaji, Shakir Abid Jassim

551. Thyroid Hormone Changes in Early Pregnancy Bleeding Versus Normal Healthy Pregnancy ............. 2859
Samah Radhi Lateef
552. Impact of Danger Signs During Pregnancy Upon Pregnancy Outcomes among Pregnant Women in Al-Diwania City ................................................................. 2865
   Fatima S. Baker, Hala S. Abdulwahid

553. The Exercises by Limbs Efforts Unilateral Bilateral and its Impact on Indicators of Electrical Activity Muscular Capacity and Long Pass of Football to Reduce Bilateral Deficits for Young Players 2870
   Khalid Oudaah Gshayyish, Habeeb Shaker Jebur, Riyadh Hassan Salah

554. The Kinetic Compatibility of the Upper and Lower Limbs and their Relation to the Skill Level of Tennis for the Emerging Players ............................................................... 2875
   Wafaa Faeq Hammoodi, Aseel Naji

555. Serum Lipid Profile in Healthy Collegian Women During Consumption of 25 and 13 G of Ukrainian Walnut 2879
   Noran jameel Ibraheem, Ghadeer hamid AL-Ardhi

556. The Association between (CT60) Cytotoxic T-lymphocyte Antigen-4 Gene Polymorphism with its Plasma Levels in Alpecia Areata Patients ................................................................. 2882
   Sarah Isam Al-Rubaye, Abdulsamie Hassan Alta’ee, Zena Saeed Al-Fadhily

557. A Study for Detection the Causes of Vaginal Bleeding in Pregnant Women at 1st Trimester in Bint al-Huda Teaching Hospital at al-Nasiriyah City, Iraq ................................................................. 2886
   Doaa Sami Rashash, Sinaa Saber Kadhim, Wahran Hassan Mohammad

558. Analysis of Meiotic Genes Under Different Temperatures ........................................................................ 2892
   Zena Faris Alwash

559. Using the Level of Serum YKL-40 as an Indicator to the Pathogenesis of Allergic Asthma and Helminths Infection ........................................................................................................ 2898
   Narjis Abdul Rahman Oudah, Kareem S. Ched Al-Teea, Ahmed A. Mohammed

560. Assessment of Anxiety Level among Women Prepared for Cesarean Section at Babylon Hospitals .... 2905
   Ali A. ALHataab, Amina Abd AL-Hassan Jabur, Tabark Sattar Skhail, Diyar Ghaleb Abdul Kadhim, Zahraa Fouad kadhim, Khalid Salman Abdul Sada

561. Biofilm Producing by Staphylococcus aureus and Lactobacillus spp. Isolated from Urogenital Tract Infections of Women ...................................................................................... 2909
   Oruba K. Al-Bermani, Zainab H. Alsaadi

562. The Impact of Reading Comprehension Skills and building Standards Typical according to Thinking Creative ................................................................. 2914
   Hind Abd-AL Reeda, A. M. D Riyad Hatif, Mohamed Abd -AL Hassan

563. The Impact of Teaching Critical Thinking Skills to Develop the Habits of Mind for Students .......... 2918
   Alaa Abduladeem Abdulabbas, Muna M.A. Al-Khateeb

564. Investigation of Bioactive Natural Compounds of Diplotaxis cespitosa Using FTIR Spectroscopic Profile and Evaluation of its Anti-Bacterial and Anti-Fungal Activity ........................................ 2923
   Amenah Kadhim Murad, Ali Hussein Deman Al-Khafaji, Imad Hadi Hameed

565. Detection of Bioactive Compounds of Celosia argentea Using Fourier-transform Infrared Spectroscopic Profile and Evaluation of its Anti-fungal Activity ........................................... 2930
   Abeer Fauzi Al-Rubaye, Lena Fadhil Hamza, Imad Hadi Hameed

Gross Motor Skills in Children with Autism Spectrum Disorder and Attention Deficit Hyperactive Disorder

A. Sheba Swarnarajam, Sheila Christopher

1Research Scholar, 2HOD & Associate Professor, P.G. & Research Department of Rehabilitation Science, Holy Cross College (Autonomous), Tiruchirapalli, India

Abstract

Background: Movement plays an essential role in children’s lives. Typically developing children achieve motor skills effortlessly, while children with ASD and ADHD demonstrate a plethora of developmental challenges. In clinical practice, an explicit intervention module addressing motor deficits of these children has been greatly overlooked as they appear active and agile. Hence, this study intends to explore the gross motor skill deficits in children with ASD and ADHD.

Materials and Method: Children with ASD (n = 10) or ADHD (n = 10) belonging to the age group of 3-10 years were recruited for the study as per the inclusion criteria. All children were selected from Madurai Child Development Centre, a pediatric rehabilitation centre in Madurai, India. The Test of Gross Motor Development-2 was employed to analyze the gross motor dysfunctions in children with ASD and ADHD.

Results: Significant association between age and object control skills in ASD children was found between the ages 3-6 years & 7-10 years. Significant association between age and locomotor skills as well as object control skills was elucidated in ADHD children. A definite association in locomotor and object control skill performance between boys and girls among ASD and ADHD was found.

Conclusion: Children with ASD and ADHD demonstrate a plethora of gross motor skill challenges that subsequently thwarts their dexterity, self-care and overall function.

Keywords: Gross motor skill, Motor development, Autism Spectrum Disorder, Attention Deficit Hyperactive Disorder.

Introduction

Movement plays an essential role in children’s lives to play, explore and learn. Typically developing children achieve gross motor skills effortlessly, while children with ASD and ADHD frequently battle with their motor skill performance that subsequently thwarts their dexterity, play and overall function. ASD and ADHD are complex disorders that are often misunderstood owing to their heterogeneous nature and the complexity of the conditions.

Autism Spectrum Disorder is characterized by a range of social and communicative impairments as well as repetitive behaviours. Although, motor impairment is not a part of the diagnostic criteria for ASD, a few research literature have reported motor challenges in children with autism. Similarly, the National Research Council Educating Children with Autism also affirms presence of marked motor difficulties. Children with Attention Deficit Hyperactivity Disorder (ADHD) are characterized by persistent symptoms of inattention and/ or hyperactivity-impulsivity that are maladaptive and inconsistent with their developmental level. Several studies however, support presence of reduced motor skills in these children.

Recent studies have reported that children with ASD and ADHD frequently display problems in their gross motor performance. Comparative studies too indicate that children with Pervasive Developmental Disorders and other psychiatric disorders perform poorly on gross motor tests than typically developing children. Hence, the present study descriptively analyzes the gross motor skill capacity of children with ASD and ADHD belonging to 3-10 years of age.
study of this kind would encourage parents, educators, therapists and clinical practitioners to be sensitive about early motor delays that could possibly point towards multiple complications at a later stage.

Materials and Method

Aim: To study the gross motor skills in children with Autism Spectrum Disorder and Attention Deficit Hyperactive Disorder

Objectives:
1. To analyze the locomotor and object manipulation skills of children with ASD and ADHD.
2. To compare the locomotor and object control skill performance in children with ASD and ADHD between the ages 3-6 years & 7-10 years
3. To compare the locomotor and object control skill performance between boys and girls among ASD and ADHD

The subject sample included 20 children with an established diagnosis of either ASD or ADHD as per DSM-5 diagnostic criteria. 10 boys and 10 girls belonging to the age group of 3-10 years formed the universe. The inclusion criteria for the study were children belonging to both genders having no history of any chronic disease or apparent ambulatory disability. They were able to follow simple 2 step instructions and had no visual or hearing impairment. Furthermore, all children attended some form of schooling and lived with their biological parents in either rural or urban family setups. None of them were on any prescribed psychotropic medication or intervention. All children were selected from Madurai Child Development Centre, a pediatric rehabilitation centre where the study was carried out. The centre is located in Madurai city in the state of Tamil Nadu, South India.

A quasi-experimental research design was adopted to recruit the sample. The Indian Scale for Assessment of Autism (ISAA), ADHD Rating Scale IV-Preschool (ADHD RS-IV-P), Vanderbilt ADHD Diagnostic Parent Rating Scale (VADPRS) were used for diagnostic screening of the subjects and the Test of Gross Motor Development-2 was employed to analyze the gross motor skills (Locomotor and Object control skills). Participants performed the test as described in the TGMD-2 Examiner’s Manual\(^{13}\). Scores were calculated from the sum of two trials of each subtest. Maximal possible score for locomotion and object control is 48. Raw scores were collected and subjected to statistical analysis.

Findings

Results: Recent studies, have pointed out that children with ASD and ADHD presented with problems in their gross motor performance \(^{11-12}\). The present study besides pointing out the presence of dysfunctions in locomotor and object control skills of children with ASD and ADHD, also categorizes them based on their performance level and compares them on parameters such as age and gender. Children with low performance on gross motor skills were found to score less than the median while scores of high performers fell on the median and above.

Children with ASD and ADHD showed no significance with regard to Locomotor Skills. Based on total percentage, ASD children’s locomotor skills are high when compared to ADHD. This could be related to the more number of low performers on the ADHD category and presence of co-morbid autistic features in these children.

No association between age and locomotor skills in ASD children was noted. (P value = 0.91). Based on total percentage, all children in the age group of 7-10 years showed high performance (30%) in locomotor skills and more number of children in the age group of 3-6 years showed low performance (40%). This finding seems to disclose that children can show some degree of progress with age regardless of a definite intervention.

A significant association between age and locomotor skills in ADHD children (P value > 0.01) was found. Based on total percentage, more number of 3-6 years children demonstrated low performance (60%) while all children in the age group 7-10 years showed high performance (30%) in locomotor skills. This again underlines the pressing need for early intervention.

A significant association between age and object control skills among ADHD children (P value < 0.05). Based on total percentage, all children in the age group 7-10 years showed high performance (30%) in object manipulation skills while more number of children belonging to 3-6 years children displayed low performance (50%). Parents’ denial of problem and delay in seeking intervention could also be viewed as a reason for this consequence.
3. To compare the locomotor and object control skill performance between boys and girls among ASD and ADHD

</tbody>
</table>

Among the ASD children, a significant difference between male and female was identified in locomotor skills (P value < 0.01). However, a small degree of insignificance was found in object control skills between the genders. This could be attributed to the small sample size and the heterogeneous complex nature of the condition. However, based on mean score, male children displayed better locomotor and object manipulation skills than female children. ADHD children showed a definite significant difference (‘P value’ < 0.05) between genders in both locomotor and object control skills. Based on mean score, male children have better locomotor and object control skills than female children.

**Discussion**

Gross motor skills are elementary for development of more complex and intricate movements. Typically, children develop motor skills naturally as they explore their environment but children with neuro-developmental disorders such as ASD and ADHD demonstrate poor sensory processing, motor and adaptive skills\(^{(14-15)}\). The present study revealed no association between children with ASD and ADHD with regard to locomotor skills and object manipulation skills. However, based on total percentage, locomotor skills are high among children with ASD versus ADHD. This could be due to the increased distribution of high performers among the ASD group of children and presence of co-morbid autistic symptoms among the low performing group of ADHD children. Literature studies\(^{(16-17,9)}\) elucidate that although these two disorders seemed quite distinct in terms of their description, they did present a variety of motor skills deficits.

Many researches carried out in the western countries have reported that motor delays in children with ASD become more pronounced with age\(^{(18)}\). However, in this cross-sectional study, children belonging to an older age group demonstrated slightly better motor skills than the younger children. Older children with ASD performed better in tasks involving object control skills even without a specialized intervention module. Likewise, age was found to be significantly associated to both locomotion and object control among ADHD children. The researcher infers this finding to the educated and dedicated parents at MCDC with adequate internet accessibility. Further, funding for one’s own family is a norm in India owing to poor access to supports from the state\(^{(19)}\). Significant association between age and gross motor skills in ADHD children displayed low performance (60%) among preschoolers. This again underlines the pressing need for early problem identification and early intervention during the developmental window that could ameliorate later symptoms of a range of conditions. On comparison of locomotor and object control skill performance, boys in general, performed significantly better than girls in both the ASD and ADHD groups. Literature\(^{(20)}\) cites that boys tend to show higher levels of physical activity than girls from the time they are infants until later in life. Biological and hormonal influences begin in the womb when a foetus with an XY chromosome pattern develops an increased level of testosterone. Although both boys and girls produce testosterone and oestrogen, the quantities are different making the males stronger in nature. Besides boys in India being the preferred gender,
are generally fed and cared for much better than girls due to various beliefs linked to economic support and karmic duties.

**Conclusion**

This study concludes that significant gross motor skill deficits exist in children with Autism Spectrum Disorder and Attention Deficit Hyperactive Disorder that would subsequently impair their occupational performance in learning, play and self care. Neuroscience research\(^{(21)}\) reveals that the brain function and behaviour can be altered through neuroplasticity in response to enriched environmental experiences. Ayres Sensory Integration advocates that active engagement in carefully guided sensori-motor activities\(^{(22)}\) would promote adaptive changes in children- Thus, promising better progress and prognosis. Parents caring for these children also undergo much stress and confusion which could affect the entire family. An intervention module that would address both child-related as well as parent-related needs is proposed for future research. The investigator trusts that this study will enlighten both parents and the related health professionals to understand the gross motor dysfunction in children with ASD and ADHD and offer constructive prospects in future research to promote further elucidation on the topic.

**Ethical Clearance:** This study was undertaken with the consent from the parents of the participating families.

**Conflict of Interest:** Nil. However written parent’s consent was obtained from the children’s parents prior to the study.

**Source of Funding:** Self

The Evaluation of the Accuracy of a Completely Limiting Tooth Supported Stereolithographic Surgical Guide in Dental Implant Placement Using Superimposition Protocol of Pre-Operative and Post-Operative CBCT Data: A Clinical Study

Ajitha Suresh Kumar¹, Sanjna Nayar²

¹Post Graduate Student, ²HOD, Department of Prosthodontics, Crown and Bridge, Sree Balaji Dental College and Hospital, BIHER University

Abstract

The aim of this study was to evaluate the accuracy of a completely limiting tooth supported stereolithographic surgical guide, with sleeve structure incorporated into the design, for computer-guided dental implant placement in partially edentulous patients using the superimposition protocol using preoperative and postoperative CBCT data.

Materials and Method: 10 implants were placed in 8 consecutive patients using a stereolithographic surgical guide. Postoperative CBCT was taken 6 months after the surgery, 3D accuracy of implants position using a completely limiting tooth supporting surgical guide at the entry point, apex, and angle deviation was measured using an inspection tool software. Chi-square test was used to compare the accuracy of the planned and the placed implant positions. A value < .05 was considered significant.

Results: The mean coronal deviation was .4390°, the sagittal deviation was .2424° and the mesial shift was .1980mm with a standard deviation of .23459° in the coronal, .26632 in the sagittal and .16315mm in the mesial shift. The statistical analysis demonstrated no significant difference between the implants placed when comparing the bony entrance point and angulations in coronal, mesial and sagittal directions (p < 0.05).

Conclusions: The completely limiting tooth supported surgical guide used has proved high accuracy for implant insertion.

Keywords: Guided Implant Surgery; 3D Printing; Virtual Planning; Prosthetically driven implantology.

Introduction

Implant dentistry has gained vast prospective in our daily dental practice, its success depends upon correct designing and execution leading to its correct placement within the bone. This position and angulation of the implants should be done meticulously and the surgical guide aids in achieving perfection in executing this. A surgical guide should be translucent, rigid, stable, and may be simple to sterilize and to insert within the patient’s mouth. Thomas J. Balshi in 1987 explained that the employment of surgical guide stents greatly enhances the surgeon’s ability to quickly and accurately verify fixture location and long axis angulation."1.

These surgical guide designs vary in their design on whether or not they are for absolutely edentulous ridges or partly edentulous ridges or partly edentulous ridges. the design of the surgical guide conjointly depends on wherever the surgical guide takes support. Either it should be tooth supported, mucosa supported or a bone supported surgical guide2.

Cone Beam computed axial tomography permits elaborated preparation for the surgical placement of dental implants beneath prosthetic concerns. Computer-
Aided surgery techniques were prompt for achieving an exact implant position\(^3,4\). With the support of CBCT, medical care and rapid prototyping engineering a surgical guide that satisfies all the necessities may be factory-made. During this guide the implant is placed through the guide, thereby using laptop guided surgery in dentistry. CBCT has drastically modified the state of affairs in dental treatment planning\(^5,6\).

There are several studies on guided implant surgery associated this was an observational study done using the Dio implants (DIO Digital Corporation Korea). This study involves placing implants in precise angulation, employing a flapless, fully limiting style of a stereolithographic surgical guide with an aim to achieve good osseointegration, excellent biologic seal of prosthetically driven implants, with less post-operative discomfort to the patient.

**Materials and Method**

This study was done in 8 consecutive partially edentulous patients (3 women and 5 men, age ranged between 25 and 35 years), who had Kennedy’s class III classification, requiring dental implant placement, were a total of 10 implants, this clinical study was conducted, between August 2017 and November 2018, in accordance with Institutional Ethical Committee Sree Balaji Dental College and Hospital with Ref No SBDCH/IEC/08/2017/2.

Patients with limited bone volume requiring a bone graft, limited mouth opening (impossibility of using a surgical template) were excluded in the study.

**Examination phase:** Patients examined in the outpatient screening were explained about the implant procedure. Ideal cases were selected and were briefed about the procedure. Written consent of each patient was obtained for participation in the study and also for implant placement.

**Pre-operative phase:**

- Impressions: An ideal polyvinyl siloxane impression (3M ESPE Express XT Putty Soft), was made of the maxillary and mandibular jaws of the patient
- Bite registration: Patient’s occlusion was registered using cad bite registration material (Virtual Cad Bite Registration Ivoclar Vivadent). Trios 3 shape scanner can also be used instead of impressions and models.
- CBCT: A CBCT of maxillary and mandibular jaws in disocclusion was made.
- Once the models were scanned both the STL and DICOM files were merged for virtual Planning. The die stone models were scanned using THE 3shape scanner. The DICOM file and the scanned data of the models are merged and a STL file was created. Virtual Planning of Implant Positions Using Implant Studio Software (3 Shape) was done. (figure 1)
- 3D printing of the surgical guides: Once the planning was approved the 3D printing of the surgical guide was done using 3D Printer ProJet MJ 3600.

**Operative phase:** The surgical guide and the drilling protocol were followed as given by the manufacturer. Each implant planning comes with a drilling protocol as per the DIO NAVI master kit as this system has a specific sleeve incorporated drill. The protocols of the guided surgery were followed in the surgical phase. The surgical guide is sterilized with 2% chlorhexidine gluconate. The patient was prepared for surgery by swabbing the intraoral and extraoral sites with povidone iodine. The surgical guide was first placed in the patient’s mouth and checked for its fit (figure 2). The surgical procedure as given by the protocols of guided implant surgery were followed (figure 3, figure 4). The first drill was the tissue punch drill in which the tissue was punched out as in the tissue punched out verified in and then consecutive drilling was done and the sleeve was incorporated in few drills as specified in the drilling protocol given by the manufacturer. Abutment profile drill was the last drill before implant placement. The implant was placed and the torque was checked with the hand wrench. The gingival former was also placed through the surgical guide. Neither complications nor unexpected events occurred during implants insertion in all the cases.

**Analysing phase:** Loading protocol was performed as follows: all 10 implants were planned to be delayed loaded with screw-retained or cement - retained metal ceramic prosthesis (after 6 weeks’ healing period). No implant was lost at 6 months’ follow-up, meaning a 100% survival rate. Postoperative CBCT 6 months later to the preoperative CBCT after removing the gingival former was made. The analysis was done using superimposing pre - operative CBCT and post -operative CBCT and the software implant studio. The analysis was done in the mesial section (figure 5) and coronal section (figure 6) and in sagittal section (figure 7). Statistical analyses were performed using SPSS VERSION 21.
Results

Among the ten implants which were inserted in 10 partially edentulous patients: 5 in the maxilla and 5 in the mandible using tooth-supported surgical guide. All the variables involved in the study were expressed in terms of frequency and percentage. Cross tab was used to assess the statistical relationship between the coronal deviation, sagittal deviation and mesial deviation. Chi-square test was employed to assess the association. $P = 0.05$ was taken as significant. Among the mandible and the maxilla were compared in the. The mean coronal deviation was $0.4390^\circ$, sagittal deviation was $0.2424^\circ$ and mesial shift was $0.1980$mm with a standard deviation of $0.23459^\circ$ in coronal, $0.26632^\circ$ in sagittal and $0.16315$mm in mesial shift (table1) The statistical analysis demonstrated no significant difference in the implants in coronal sagittal and mesial directions ($p < 0.05$) (table 2).

Discussion

This study used a static guided surgery as explained by Jung et al\(^7\). In this type, the surgical guide is manufactured and is used during the surgical phase while in the dynamic guided surgery the surgery is guided in real time. The only disadvantages are, when the patient had very less intraoral mouth opening, it was difficult to place the guide and to accommodate the handpiece without any interference. Many authors have supported this statement that it’s important to check for mouth opening particularly in dentate cases.

For tooth supported surgical guides all previous studies presented high accuracy while using a rapid-prototyped surgical guide. Gilbarto Sammartino et al (2004)\(^8\) considered using stereolithography in guide manufacturing. The current study also used a surgical guide which was manufactured with stereolithographic technology.
Immediate loading can be done as the guided surgery helps to determine the precise occlusion prior to surgery but this study followed a delayed loading protocol but the gingival former was used to create the gingival cuff. This was in order to facilitate postoperative -CBCT. Obviously, the absence of factors such as incision, flap reflection, determination of implant location, drill depth control, and suturing procedures contribute to reduced surgical time in the flapless computer -guided surgery. Corina Cristache et al published the superimposition protocol and has mentioned a validation study is required for comparing error analysis using post operative-CBCT versus intraoral optical scans should be performed in order to evaluate the potential errors arising from impression making (error of the optical scanner), superimposition of the surfaces, segmentation of implants in the software, error calculation algorithm, and so forth. Thus, this study was done for evaluating planned and placed implants insertion was designed. In accordance with this, two STL files of pre and post CBCT were superimposed using the implant studio software, which then calculates the matrix, the treatment plan was set as the reference. This protocol was used by Turbush turkyilmaz et al. in an in vitro study. Literature presents a limited number of studies that discuss the variables capable of causing deviations. Marlière, et al. studied the accuracy computer -guided surgery dental implant between the virtually planned position and implant placement using stereolithography guides and said that it can be emphasized that during acquisition, processing, and manipulation of images, an error of approximately 0.5 mm may occur, and incorrect configurations in software can generate slight deformations in surgical guides, varying from 0.1 to 0.2 mm.

Amaral, Daniel et al in 2018 in a systematic review addressed clinical studies, different computer -guided surgery systems and their clinical relevance which may be useful to warn the surgeon that safety margins to consider should refer to clinical situations.

Some errors could also occur during the manufacturing of the surgical guide in the phase of surgical simulation on the software, in the precision of the prototyping machine, in the properties of the stereolithography material used, in the fit between the cylinders of the guide, Manufacturing errors of the guide can have a cumulative effect, which can generate unfavourable clinical results. However, errors are not exclusive of the workflow process and/or the product itself (stereolithographic surgical guide). The type of surgical guide (dento supported, muco supported with or without bone supported fixation), as well as morphological factors of the peri implant tissues (bone type: cortical or medullary, thickness of gingival mucosa), may interfere in the accuracy between what was planned and the actual outcomes of dental implants placement. Another important aspect to highlight is the bone structure itself, which if predominantly medullary (maxilla) would have a greater impact on the deviations between planning and execution. This is due probably to lower resistance to torque, when compared to cortical bone, which in turn causes more pronounced deviations in the position of the dental implants. The use of completely limiting stereolithographic surgical guide along with shank modified drills and including sleeve while preparing the osteotomy site is an appropriate method in placing the implants in an accurate position to achieve a successful prosthetically driven prosthesis to be in harmony with the stomatognathic system.

Conclusion

It is concluded in this study that the guided implant surgery with proper planning gives significant options in different locations and angulations within safe limits when considering the anatomy. This method provides precise angulations in coronal, sagittal and in mesial sections for restoring a successful prosthetically driven implant rather than the conventional method. The surgical phase is very comfortable for the patient and to the dentist with consuming very little time. The quality of the bone influences the accuracy of the angulation. Some discrepancies are seen in the entry point which is clinically insignificant and also statistically it was insignificant. Further evidence on many levels of this guided implant surgery with site specificity is needed. Future studies can be focused on evaluating the accuracy, fine-tuning the process and assessing the success of guided implant surgery in larger scale can be done.

An Audit to Pain Management of Lower Segmental Caesarean Section in a Tertiary Care Hospital

Amrita Panda1, Lingaraj Sahu1, Bhaskar Thakur2, Gunupuru Bharat1

1Associate Professor, Department of Anesthesiology, 2Assistant Professor, Department of Research and Publication Cell, Kalinga Institute of Medical Science, Bhubaneswar, Odisha

Abstract

Background: Women undergoing caesarean delivery present a unique set of challenges to the anesthesiologist in terms of postoperative pain management. The transversus abdominis plane block is an effective method of providing postoperative analgesia in patients undergoing abdominal wall incisions. Accordingly, this retrospective study was conducted and analyzed.

Method: Patients who underwent elective lower segment caesarean section under sub arachnoid block in last 3 months were scrutinized and 100 eligible records found. Categories into who received the transversus abdominis plane block (TAP Group) at the end of surgery and another was who did not receive the TAP block (Control group).

Results: From control group 26 patients complained of pain during first 4 hours, 43 during 8 hours and all 50 complained of pain within 12 hours. Similarly in TAP group 4 patients had complained of pain during first 4 hours, 16 within 8 hours, 29 within 12 hours, 42 within 16 hours. In TAP group 46 patients required rescue analgesics twice or less and 4 required thrice but none of them demanded more than three times whereas in the control group 7 patients demanded twice, 36 demanded three times and 7 of them demanded four times. The ‘p’ value < 0.01 was found to be statistically significant between all the groups.

Conclusion: TAP block is easy to perform under ultrasound guidance with minimal complications and side effects and it provides effective analgesia and holds good as part of a multimodal analgesia regime for patients undergoing lower segment caesarean section.

Keywords: Lower segmental caesarean, Postoperative pain management, Transversus abdominis plane block.

Introduction

Women undergoing Lower Segmental Caesarian Section (LSCS) delivery present a unique set of challenges to the anesthetist in terms of postoperative pain management (1). The aims of postoperative pain management are to provide subjective comfort, inhibit nociceptive impulses and blunt the neuroendocrine response to pain thus enhancing early restoration of function. Early mobilization is a key factor to prevent the risk of thromboembolic disease and the need to be pain free to take care of the newborn and breastfeed them effectively (2). The Transversus Abdominis Plane (TAP) block is a recently described approach to providing analgesia to the anterior abdominal wall. TAP block is a regional anesthetic technique that blocks abdominal somatic afferents, however the analgesic benefit of TAP block for LSCS delivery remains controversial (3, 4). In considering of it was first reported by Rafi in 2001, the TAP block could be leading report as a peripheral nerve block to the anterior abdominal wall (T6-T11). The TAP block has been a subject of controversy with regarding to utility, indications and more fundamentally how best to place the block and its precise mechanism of action (5). Eventually, the outcome are encouraging and
most studies have demonstrated clinically significant reductions of postoperative opioid requirements and pain, as well as some effects on opioid related side-effects like sedation and postoperative nausea vomiting (7). In view of the continuing increase in LSCS rates identified around the world and the need to expand the knowledge on the occurrence and characteristics of pain experience in the immediate postoperative period, this present study was developed to make a research on the women’s perceived quality of pain during this time (5).

Methodology

A total number of 204 patients, who underwent elective lower segment caesarean section under SAB between September 18 to November 18, were considered for further analysis. Out of this 78 patients were without TAP block and 50 patients were given transversus abdominis plane block at the end of surgery. The patients who did not receive TAP block, of them 76 were given SAB without adjuvants 26 were ASA 3 and 2 refused SAB. These 28 patients were excluded from further analysis. As per the protocol of the institute in the postoperative ward patients were given 1 gram of paracetamol at 2 and 12 hours of sub-arachnoid block. If any patient complained of pain, the visual analogue score (VAS) was assessed and when it was more than 3 than 50 mg of tramadol was administered intra venously. This data was recorded independently by the two authors and analyzed retrospectively. The primary objective was to find out the association of field blocks with postoperative pain control in patients after LSCS. The time required for first rescue analgesic demand, the total requirement of rescue analgesics and the VAS score were taken as an indicator for this. The secondary objectives were to compare the side effects such as postoperative nausea vomiting, sedation and patient satisfaction among both the groups. A 100 ASA-2 class patients between age group 18-40 years posted for elective LSCS were included in the study. The exclusion criteria were patients with known cardiovascular, hepatic, or renal dysfunction, patient refusal for regional anaesthesia, failed sub-arachnoid block (SAB), adjuvants used in SAB, any coagulopathy or known drug allergy or hypersensitive reaction. All the patients received standard premedication according to the institution protocol with ranitidine and metoclopramide intravenously before shifting the patient to the operating room for elective LSCS. Those patients in whom no adjuvants were used in SAB were included in the study. The time of SAB, the height of block, the surgical duration were noted for data analysis. At the end of the procedure only willing patients were given bilateral transversus abdominis plane block using 20 ml 0.2% ropivacaine on each side. In the postoperative ward patients received 1 gram of paracetamol at 2 and 12 hours of sub-arachnoid block. If any patient complained of pain, the visual analogue score (VAS) was assessed and when it was more than 3 than 50 mg of tramadol ws administered intra venously. All the patients were followed by an independent observer for a period of 24 hours duration at intervals of 0-4 hours, 4-8 hours,8-12 hours,12-16 hours,16-20 hours and 20-24 hours. Pain scores were assessed as the primary outcome using the Visual Analogue Scale. The total cumulative amount of rescue analgesia and frequency of analgesic requirement on demand were noted. Incidence of postoperative nausea vomiting and sedation were noted.

Sample size and Statistical Analysis: Statistical analysis was done using chi square test. Differences were considered to be statistically significant when the ‘p’ value was found to be < 0.05.

Results

There was no significant difference in the demographic characteristics between both the groups with respect to age, weight, Height of SAB, and duration of surgery. That in the control group pain in patients without TAP block started early, out of fifty patients 26 complained of pain within first 4 hours, 43 patients within 8 hours and all 50 patients complained of pain within 12 hours. Similarly in the group where TAP block was given only 4 patients had complaints of pain within 4 hours,16 patients within 8 hours,29 patients within 12 hours,42 patients within 16 hours. The ‘p’ value < 0.01 is highly significant between both the groups (Table 1). The mean VAS was lower in the block group as compared to the control group in the first 12 hours (Table 2). The frequency of analgesic requirements is low in the TAP group. During the first postoperative day 46 patients required twice or less time and 4 patients required thrice but none of them demanded more than three times in the group where block was given. Where as in the control group 7 patients demanded twice, 36 patients demanded analgesics three times and 7 of them demanded four times. The ‘p’ value < 0.01 was found to be statistically significant between both the groups (Table 3). Total rescue analgesia required during the first 24 hours showed a 36.42% decrease in the group of patients who received the block as compared to the control group. Two patients from control group were...
having post-operative nausea and vomiting and were treated with metoclopramide. None of the patients complained of sedation from both the groups and no complications of procedure like bowel injury or femoral nerve palsy were noted. At least for the first 12 hours patients were more satisfied in the group who received the transversus abdominis plane block than those who did not (Table 4).

Discussion

This work substantiates that patients complained of postoperative pain following lower segment caesarean section early in the group of patients where field block (transversus abdominis plane block) was not given as compared to those in which the block was given. Moreover, there was less number of patients who complained of postoperative pain in the early hours in the group where field block was administered as compared to the group where the block was not administered. In this study, the visual analogue pain scores were lower in the block group as compared to the control group in the first 12 hours. Furthermore, present results are quite similar to a another study conducted by Sinha et al. where transversus abdominis plane block resulted in a significant reduction of pain visual analogue scores over the first 24 hours postoperatively\. A study conducted by Ammar Mahmud et al pain Visual Analogue Pain score was significantly lower at the postoperative period of 2 hours, 4 hours and 12 hours which is similar to our results\. Therefore the pain impulse following lower segment caesarean section may arise from two components mainly somatic and visceral\. The somatic pain arises from the anterior abdominal wall due to incision. The peripheral nerves that carry signals following lower segment caesarean section are thoracolumbar nerves ranging from T10-L1 with varying contribution from T9-L2\. Consequently, the regional analgesic technique that aims to provide parietal wall pain relief following lower segment caesarean section should block all these nerves. Thus, the transversus abdominis plane block performed at the midaxillary line in the subcostal area provided the conduction blockade of thoracolumbar nerves arising from T10-L1 during 50% of the time and T11-L1 in 100% of the time\. In according, TAP block group of patients the parietal wall anesthesia was more complete as it blocked the pain impulse from both the skin and subcutaneous tissue and from the rectus muscle. The visceral pain impulse from the uterus reaches the spinal cord through the sympathetic fibres through the inferior hypogastric plexus which were not blocked by the regional anesthetic technique. Therefore, all the patients in both te groups required some dose of systemic analgesics to attenuate the visceral pain. Thus, the frequency of rescue analgesics required in the first 24 hours was low in the in the group with the block as compared to the control group. Also the number of patients who out demanded rescue analgesics was low in the block group as compared to the control group. The mean analgesic requirement in the block
group was lower than the control group and there was a 36.42% decrease in the analgesic requirement in the field block group during the first 24 hours of surgery. In this present study report is also quite similar to various other studies where there is decreased requirement of postoperative opioids like tramadol as shown by Sinha et al, Ammar Mahmoud et al\(^{(9,10)}\) However, in a study conducted by Eslamian et al for postoperative analgesia in lower segment caesarean section patients, the maximum tramadol consumption was 150mg in the TAP block group and 400 mg in no block group. The mean tramadol consumption in a 24 hour period was only 75 mg in TAP block group while it was 250mg in patients who did not receive tramadol, as quite similar as to this study.\(^{(14)}\)

There were no side effects such as, postoperative nausea vomiting and sedation among the patients of both the groups. There were no complications of the TAP block such as, bowel injury, trauma or femoral and nerve palsy or local anesthetic toxicity.

**Limitations of our study:** This is a retrospective analysis of recorded data so chances of missing vital data are excessive. In some cases feedback was collected after 3-4 months, so validation of satisfaction of data not reliable.

**Recommendation:** The authors would like to suggest that there is the a need to develop new and well designed randomized control trial to compare different approaches, drugs, doses and volumes for the same intervention, aiming to answer the current questions and assess the effects of transversus abdominis plane block in current routine clinical practice, as the clinical utility of the current approaches to the blockade of these nerve afferents, such as abdominal field blocks is limited and the degree of block achieved can be unpredictable.

**Conclusion**

TAP block is easy to perform under ultrasound guidance with minimal complications and side effects and it provides effective analgesia and holds good as part of a multimodal analgesia regime for patients undergoing lower segment caesarean section.

**Conflict of Interest:** There is no conflict of interest

**Ethical Clearance:** The ethical clearance is approved by Institutional Ethical Committee, KIMS Hospital, Bhubaneswar (KIIT/KIMS/IEC/15/2019)

Evaluation of Phytochemical Analysis and Antimicrobial Activity of Citrus Latifolia Peel Extract

Arunava Das\textsuperscript{1}, M. Vasundra\textsuperscript{2}, V. Vinotha\textsuperscript{2}, P.S. Sanofer\textsuperscript{2}, J. Bindhu\textsuperscript{3}

\textsuperscript{1}Associate Professor, \textsuperscript{2}III Year Biotechnology Students, \textsuperscript{3}Research Associate, Molecular Diagnostics and Bacterial Pathogenomics Research Laboratory, Department of Biotechnology, Bannari Amman Institute of Technology, Sathyamangalam, Erode District, Tamil Nadu, India

Abstract

\textit{Citrus latifolia} accounts for its phytochemical activity, these bioactive compounds result in the antioxidative, anti-inflammatory, anti-microbial effects that can serve mankind. The aim of the present work investigates the presence of the bioactive components present in the Methanol extracts of the \textit{Citrus latifolia} peel and examines its potent antimicrobial and antioxidant activity. The plant material was dried and extracted in the soxhlet extractor and was concentrated using rotary evaporator. The extract was then tested for the anti-oxidant activity using DPPH assay and antimicrobial activity using well diffusion method. The extract was then lyophilized and analyzed for the presence of potent bioactive compounds using GCMS technique. The DPPH antioxidant profiling of the methanol extract of \textit{Citrus latifolia} peel showed maximum radical scavenging activity compared with the IC50 of Ascorbic acid. The extract showed inhibitory antimicrobial activity against \textit{Escherichia coli}, \textit{Pseudomonas aeruginosa}, \textit{streptococcus pyogenes}, and \textit{Listeria monocytogenes}. The GC-MS analysis reveals the presence of eighteen compounds such as alcohol, acid-esters, aromatic acids, furanone, polyester, coumarins, hypoxanthine, that is responsible for the anti-oxidation and anti-microbial effect of the \textit{Citrus latifolia}. The investigation from this study has concluded that the methanol extract of \textit{Citrus latifolia} will be the alternative medication to such threat full pathogens.

\textbf{Keywords:} \textit{Citrus latifolia}, anti-microbial activity, anti-oxidant activity, GC-MS.

Introduction

Recent advancement in the plant technology provides a threshold for the development of different plant-dependent antimicrobial drugs against drug-resistant human pathogenic microorganism using different plant-derived extracts, one among them is citrus species identified with 80% of antioxidant profile. \cite{1} They are also rich in nutrients and active bio compounds which have a tendency of healing and pain-relieving ability. Most of the dietary antioxidants available in markets are derived from plant\cite{2}, The citrus fruits have a high content of various plant-derived secondary metabolites called phytochemicals which is responsible for the different medical properties like high aromatic content, antitoxic content, antioxidant profile, refreshing property and citric acid content, vitamin C content which can be formulated as a medicine for various disorders and disease occurrence.\cite{3} The Eos of \textit{citrus latifolia} specified to have anti-inflammatory property against the experimental mouse models.\cite{4} The evaluation of cytotoxicity and genotoxicity of \textit{citrus latifolia} are also provided a better result on the cancer cell lines so it is found to have the anticancer activity.\cite{5} Their juices also act as an antidote to relieve pain and inflammation resulting from stinging corals, Bitting aroids Furthermore the citrus fruits are also been used in Ancient Ayurvedic field in many different countries like china, japan, Korea, India to treat indigestion, cough, inflammation, skin allergies, ringworm infection, maintain blood pressure, to reduce weight and also to treat nausea.\cite{6} The phytochemicals like flavonoids,
carotenoids, ascorbic acid, citric acid, terpenoids, coumarins, phenolic acids, limonoids, alkaloids present in the citrus species owe to the different medicinal properties. These phytochemicals are further studied to have anticancer activity, antibiotic activity, anti-inflammatory effects, anti-inflammatory effects, cardiovascular protective effects, neuroprotective effects, hepatoprotective effects, antibesity effect. It has been identified that citrus fruits provide 80% of antioxidant property. [8] Antibiotic resistance in the microbes have shown a great increase thereby increasing the pathogenicity of the organism. [9] The citrus species possess the natural antimicrobial agents it is studied that the essential oils of citrus species are antimycotic, antibacterial, against the certain fungal species like Candida albicans, Candida tropicalis and against some bacterial species like Escherichia coli, Listeria monocytogenes strains, etc. [10,12] Present research focuses on the evaluation of antimicrobial activity, antioxidant activity and phytochemical assays of the methanol extract of Citrus latifolia, the extracts were also which is extended to identify the different medicinal applications and uses of Citrus latifolia, which serves as a threshold for the evaluation of phytochemical based drugs for the different targeted disorders and diseases, that plays a key role in the medical pharmacy.

Materials and Methodology

Plant material: The fresh Citrus latifolia fruits are collected from the sathyamangalam market and the collected fruits were transferred to the lab using sterile plastic bags. The peels were removed and washed with warm distilled water and air-dried in the hot air oven at 40°C for 36 hours, pulverized in a mixer grinder, sieved and the fine powder was stored in a nontoxic polythene bag.

Preparation of plant extract: The powder mass of 10g was packed in a Whatman® high-performance cellulose extraction thimbles purchased from Sigma-Aldrich and subjected to the soxhlet extractor apparatus. The 80% Methanol is used as the solvent for the extraction and cycling conditions were 50°C for 7 cycles. The extract was then condensed by using rotary evaporator BUCHI Rotavapor® R-300. The concentrate is used for all the followed experiments. [11]

GC-MS Analysis: Gas chromatography-mass spectrometry (GC-MS) is a diagnostics method that works under the principles of gas chromatography and mass spectroscopy which is used for the detection and quantification of different molecules and its structure within the test solution. The extracted samples were subjected to the GC–MS (Perkin Elmer model: Clarus 680) which is combined with the mass spectrometer (Clarus 600 (EI) analyzed using (TurboMassver 5.4.2) software. At a constant flow rate about 1ml/min, a carrier SSSSgas such as helium was used to separate the components. The temperature of the injector was adjusted to 260°C while performing the experiment. The extracted sample of 1µL was injected into the equipment the temperatures of the oven were 60°C (2 minutes); followed by 300°C at the rate of 10°Cmin⁻¹; and 300°C for 6mins. The conditions of the mass detector were: the temperature of the transfer line was 240°C; and ionization mode electron impact at 70eV, the duration time of scan interval is 0.2sec and scan interval is 0.1sec. The fragments from 40 to 600Da. The spectrum of components was corresponding to the database of the spectrum of established components gathered in the GC-MS NIST library. [12]

Phytochemical Screening: Mayers reagent (1ml) was added to 3ml of extract and shaken well, the white precipitate at the bottom indicates the presence of alkaloids. 10ml of the extract of the plant was added with 1% HCl. The red precipitate deposition in the bottom indicates the presence of phlobatannins. Triterpenoids in the extract were indicated by Salkowski test in which 5 drops of concentrated sulphuric acid was added to the 2 ml of extract, shaken well allowed to stand. The appearance of the greenish-blue color indicates the presence of triterpenoids. Presence of flavonoids in the extract was indicated by alkaline reagent test. In this few drops (3 drops) of 10%, NaOH solution was added to 1ml of extract, indicated by an intense yellow color, which disappeared on the addition of a few drops of dilute acid. Lipid confirmation was carried out by adding 0.5 N alcoholic potassium hydroxide to 10ml extract along with a drop of Phenolphthalein. The mixture was heated on a water bath for 1 hour the confirmation of foam or soapy layer indicates the presence of lipids. 2ml of chloroform and few drops of concentrated sulphuric acid were added to the 5ml extract, the upper layer in the test tube appear red white. The sulphuric acid layer appears with greenish fluorescence, indicates the presence of steroids. Extract of 1ml was added with 1ml of chloroform, mixed well and left for 5 minutes, after 5 minutes 1ml of concentrated Sulphuric acid was added, the appearance of grayish layer indicates the presence of Terpenoids.
**Antioxidant Profile**

DPPH (free radical scavenging) Assay: DPPH (2, 2-diphenyl-1-picryl-hydrazyl-hydrate) is a method to find the antioxidant activity. It measures the radical scavenging of the plant extract through redox reaction, the violet color of the DPPH turns to pale yellow color due to the hydrogen donation by the antioxidants present in the extract, then the amount of antioxidant property is calibrated by the colorimeter, the 1.0 mM DPPH was added to the various concentrations of the samples, it was dark macerated for about 30 minutes, the respective color change from violet to yellow indicates the presence of antioxidants, which was later examined using spectrophotometer 517nM by using ascorbic acid as a standard.\[^{[13]}\]

\[
\% \text{ of inhibition} = \left[ \frac{A_0 - A_1}{A_0} \right] \times 100
\]

\[A_0\] is absorbance of control solution (the solution without sample)

\[A_1\] is absorbance of sample/standard

**Antibiogram Evaluation:** The Antibiogram refers to an antibiotic sensitivity test. The antimicrobial activity of the extract was analyzed by using well diffusion tests. The four bacterial species were selected, two species which are gram-positive and two species which are gram-negative. The Agar well Diffusion antimicrobial Assays specified above was followed in order to get the better MIC values and its zone of inhibition. The preparation plates include the autoclaving agar stock (Mueller Hinton agar) purchased from Himedia laboratories. The sterile agar plates were inoculated with the bacterial strains of interest two gram-negative bacteria (Escherichia coli, Pseudomonas aeruginosa) and two gram-positive bacteria (Streptococcus pyogenes, Listeria monocytogenes) which was then streaked by a sterilized cotton swab with the respective strains, the agar plates were punctured by using a good puncture injector. The different concentrations of the extract were pipetted into the well and incubated for 24 hours at 37°C and Zones of inhibition values are calculated.\[^{[14]}\]

**Results and Discussion**

The results have shown the *Citrus latifolia* antimicrobial activity and the antioxidant activity of *Citrus latifolia* has a potential role in the pharmaceutical world. Predominantly all the plants possess antioxidant activity that is responsible for the arresting of different reactive oxidative species from damaging the DNA.\[^{[15]}\] The DPPH assay has demonstrated the potent results for the different concentration levels which the curvy increasing graph. Ascorbic acid was used as the standard to compare with the different concentration samples and IC50 (inhibitory concentration) was calculated for both sample and standard Graph shows the anti-oxidation property versus concentration of *C.latifolia* (sample). The capacity of extracts to scavenge the DPPH radical was estimated according to the procedure described.\[^{[16]}\] The bacteria tested showed the positive results towards the antimicrobial susceptibility. Altogether, the results suggest that there is a possible contribution of the components present in *C. latifolia* with the antioxidant property is one of the factors that take part in the antimicrobial activity.\[^{[17]}\] The minimum inhibitory concentration assay conducted in nutrient agar using solvent extract are reported in table I for *Pseudomonas aeruginosa* Streptococcus pyogenes, Listeria monocytogenes, Escherichia coli respectively, all the microbes showed the positive antimicrobial sensitivity.\[^{[18]}\] The study shows that the peel of citrus latifolia is a potent antimicrobial agent against skin flora like *Pseudomonas* and *Streptococcus* is a skin microbiota, which can be furthermore implemented as a medication for the various skin infections.\[^{[19]}\] Phytochemical screening of the methanol extracts of the *Citrus latifolia* is analyzed through various phytochemical assays to identify the presence of the respective phytochemicals in the extract. GCMS analysis of methanol extract of *Citrus latifolia* showed the presence of the following compounds as shown in table 2 respectively.\[^{[20]}\] The analysis showed that the extract contains eighteen bioactive compounds that include mostly such as alcohol, acid-esters, aromatic acids, furanone, polyester, coumarins, hypoxanthine, that accounts for the anti-oxidation and anti-microbial effect of the *Citrus latifolia* species.\[^{[21]}\]

Conclusion

This study has revealed that the methanol extract of *Citrus latifolia* has a potential antimicrobial and antioxidant activity. The biomolecules of methanol extract of the peels of *citrus latifolia* were contrary to specific bacteria which can be supplemented as the potent drug for the various diseases. Meanwhile, the purification and identification technology of the plant photochemistry play a major role in the separating and identification of biomolecules that is responsible for the anti-oxidation property which can be a threshold for the development of anti-oxidant drugs.

Prevalence of Autoantibodies and the Clinical Spectrum of Disease in an Indian Patient Subpopulation with Lichen Planus

Balkrishna Pralhadrao Nikam1, Dhanraj D. Chavan2, Nischhal Shrivastava2, Namita Narkhede2

1Assistant Professor, 2P.G. Resident, Department of Dermatology, Krishna Institute of Medical Sciences Deemed to be University, Karad

Abstract

Background: Lichen planus is a chronic mucocutaneous inflammatory disease which frequently involves the oral mucosa. The present study was conducted to assess prevalence of auto antibodies and clinical spectrum of lichen planus.

Materials & Method: The present study was conducted on 82 patients of lichen planus of both genders. A thorough clinical examination was performed. 5 ml of blood was drawn in a sterile syringe with all aseptic precautions. Antibodies including anti-nuclear antibody, anti-desmoglein 1 antibody, anti-desmoglein 3 antibody, anti-keratinocyte antibody, anti-mitochondrial antibody and anti-thyroglobulin antibody were assayed in serum samples by indirect immunofluorescence according to commercially available testing kits.

Results: Out of 82 patients, males were 24 and females were 58. Age group 11-20 years had 5 males and 15 females, 21-30 years had 8 males and 26 females, 31-40 years had 6 males and 10 females, 41-50 years had 3 males and 4 females and > 50 years had 2 males and 3 females. The difference was significant (P < 0.05). ANA was positive in 14, DSG- I in 15, DSG- III in 24, AKA in 27, AMA in 45 and TGA in 32. The difference was significant (P < 0.05).

Conclusion: Authors found that most common auto- antibodies found was AMA, AKA and DSG- III.

Keywords: Auto- antibodies, Desmoglein, Lichen planus.

Introduction

Lichen planus is a chronic mucocutaneous inflammatory disease which frequently involves the oral mucosa. In the majority of patients with oral lichen planus (OLP) there is no associated cutaneous lichen planus or lichen planus at other mucosal sites.1 This may be called “isolated” OLP. This disease has most often been reported in middle-aged patients 30-60 years of age and is more common in females than in males. OLP is also seen in children, although it is rare.2

The etiology of lichen planus is poorly understood and autoimmunity is proposed. Recent evidence suggests the role of humoral immunity in the pathogenesis of lichen planus.3 This study mainly focuses on the immunological profile of lichen planus patients from western India to understand the etiopathogenesis of lichen planus from an autoimmune point of view by detecting various autoantibodies such as anti-nuclear antibody, antidesmoglein 1 antibody, anti-desmoglein 3 antibody, anti keratinocyte antibody, anti-mitochondrial antibodies and anti-thyroglobulin antibody.4

OLP was first described clinically by Wilson in 1869 as a chronic mucocutaneous disorder. Cutaneous lichen planus is recurrent, itchy and not contagious. Concomitant disease involving the scalp, nails, esophageal mucosa, larynx and conjunctivae occurs much less frequently. In many patients, the onset of OLP is insidious, and patients are unaware of their oral condition.5 The present study was conducted to assess prevalence of auto antibodies and clinical spectrum of lichen planus.
Materials & Method

The present study was conducted in the department of Dermatology. It comprised of 82 patients of lichen planus of both genders. All were informed regarding the study and written consent was obtained. Ethical clearance was obtained prior to the study.

General data such as name, age, gender etc. was recorded. A thorough clinical examination was performed. 5 ml of blood was drawn in a sterile syringe with all aseptic precautions. Antibodies including anti-nuclear antibody, anti-desmoglein 1 antibody, anti-desmoglein 3 antibody, anti-keratinocyte antibody, anti-mitochondrial antibody and anti-thyroglobulin antibody were assayed in serum samples by indirect immunofluorescence according to commercially available testing kits. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

Discussion

The pathogenesis of lichen planus has not yet been fully elucidated. However, an autoimmune etiology with cellular immunity playing a role is postulated. The steps involved in the pathogenesis of lichen planus include recognition of the lichen planus specific antigen by CD4+ T cells and NK cells, cytotoxic T cell activation and keratinocyte apoptosis. Other mechanisms which may possibly be operative in the pathogenesis of lichen planus include activated fibrinogen cascade, neoangiogenesis and nonantigen- mediated mechanisms, including activation of matrix metalloproteinases and mast cell degranulation. Many studies hypothesizing the role of circulating antibodies have been described in lichen planus recently.

We found that out of 82 patients, males were 24 and females were 58.

Kinjyo et al found that 65 (65%) patients showed the presence of at least one of the six auto antibodies while 35 (35%) tested negative for all six of them. Positivity of anti-keratinocyte antibody in 26 (26%), anti-nuclear antibody in 22 (22%), anti-desmoglein 1 antibody in 19 (19%), anti-desmoglein 3 antibody in 16 (16%), anti-mitochondrial antibody in 9 (9%) and anti-thyroglobulin antibody in 6 (6%) patients was detected. It was observed that 55 (71.4%) patients of cutaneous lichen planus, 6 (46.1%) patients of mucosal lichen planus and 4 (40%) patients of cutaneous and mucosal lichen planus overlap showed presence of at least one autoantibody.

We found that age group 11-20 years had 5 males and 15 females, 21-30 years had 8 males and 26 females, 31-40 years had 6 males and 10 females, 41-50 years had 3 males and 4 females, and > 50 years had 2 males and 3 females. The clinical evaluation of the oral lesions is based on the six clinical forms described by Andreason as reticular, papular, plaque, atrophic, erosive, and bullous. Mucosal lesions, which are multiple, generally have a symmetrical distribution, particularly on the mucosa.
of the cheeks, adjacent to molars, and on the mucosa of the tongue, less frequently on the mucosa of the lips (lichenous cheilitis) and on the gums (the atrophic and erosive forms localized on the gums manifest as a desquamative gingivitis), more rarely on the palate and floor of the mouth. However, this clinical appearance of desquamative gingivitis. A study by Parodi et al\textsuperscript{10} described the prevalence of stratified epithelium-specific antinuclear antibodies directed to an antigen of 70 kd in patients with various forms of lichen planus. Carizossa, Elorza, Carnacho\textsuperscript{11} found anti-nuclear antibodies in high proportion (40% using rat esophagus as substrate and 27.6% using monkey esophagus). These anti-nuclear antibodies exhibited a speckled pattern and were more frequently encountered in erosive lichen planus patients. Chang et al\textsuperscript{12} had reported the frequency of anti-mitochondrial antibody as 1.6%; anti-thyroglobulin antibody positivity as 21.3% among oral lichen planus patients. The presence of anti-nuclear antibody, anti-gastric parietal cell antibody, anti-thyroglobulin antibody and anti-thyroid microsomal antibody were also reported in oral lichen planus.

**Conclusion**

Authors found that most common auto-antibodies found was AMA, AKA and DSG-III.

Patterns of Head Injury in Geriatric Eastern Indian Population in Computed Tomography: A Retrospective Study

Bikramaditya Swain¹, Ranjan Kumar Sahoo², Manoj Kumar G³

¹Assistant Professor, ²Associate Professor, ³Junior Resident, Department of Radiology, KIMS Bhubaneswar, Odisha

Abstract

Background and Purpose: Head injury is the common cause of mortality and morbidity in elderly in a developing country like India. Data of geriatric head injury epidemiology is scant in literature in Indian population. The purpose of the study was to assess the pattern of Computed Tomography (CT) findings in head injury patients at the tertiary referral centre in eastern India.

Method and Materials: CT image data of 234 geriatric patients (more than 60 years of age) with head injury between January 2016 to June 2019 duration were retrieved from radiology data storage and analysed by two radiologists for pattern of head injuries, anatomical distribution and age, sex predilection.

Results: Male to female ratio was 2.9:1 and common cause for trauma was road traffic accident (RTA) (65.8%) followed by falls (31%). Extra axial lesions (75.5%) were most common finding. SDH was the most common pattern among all (60%) followed by contusion (16%). Temporo-parietal bone was most commonly involved skull bone fracture.

Conclusion: The prevalence of traumatic head injury in elderly is high in the study. Head injuries more common in males than females. Extra axial lesions are most common findings with SDH as the most common pattern seen in elderly.

Keywords: Computed Tomography, subdural haemorrhage, trauma, brain, injury.

Introduction

Head injury is the commonest cause of morbidity and mortality worldwide including developing countries like India. Head trauma includes injury to scalp, skull, meninges and brain. National Centre for Injury Prevention and control, USA, reported that around 1.7 million people got treatment related to head injury in united states alone with high morbidity and mortality.

WHO stated that head injuries will cross many diseases to become the major cause of death and disability especially in elderly persons more than 60 years and account for 25% of all injury deaths and 30% of injury related hospitalization and is estimated that it will become third largest cause of disability adjusted life years lost world wide by 2020.

Falls are responsible for more than one-third of all Traumatic Brain Injuries (TBIs) within the general population and more than 60% of all TBIs among people older than 65 years.

Patients over age 75 years have the highest rates of both TBI-related hospitalization and death.

As India’s elderly population is increasing it is a significant public health importance to know various patterns of head injury, incidence, sex predilection and thus in determining appropriate treatment in timely manner.

It also challenges clinicians of various specialities, as head injury patients are commonly encountered in the emergency department and for healthcare providers in
primary care, surgical specialties, nonsurgical specialties, allied health. Thus nearly all medical professionals need to have a robust understanding of various patterns of head injury.

There is no sufficient data in India on the contribution of head injury to trauma-related mortality and morbidity especially in elderly and various imaging patterns.\(^7\)

The frequent use of anticoagulants for comorbid conditions in this population leads to an increased risk of haemorrhage, even with low-velocity head trauma. A high index of suspicion for intracranial haemorrhage is thus warranted, as these patients may present with vague neurological complaints and a normal physical examination. This study done to know the patterns of traumatic head injuries (THI) in the Department of Radiology of our institution and common causes of the trauma, the age and sex distribution of the elderly patients. The study will also help in understanding the burden of head injury and help concerned public health bodies to take appropriate steps to control it.

**Materials and Method**

It is a retrospective and descriptive study done by retrieving the image data from Picture Archiving and Communication System (PACS) over a 4-year period (January 2016 to June 2019) in the department of Radiology of our institution, a tertiary referral centre in eastern India. All head injury patients of age more than 60 years referred to the Radiology Department for CT head during this period were included in the study.

CT head examinations were done using the General Electric (GE) 64-slice multidetector CT scanners. A multislice protocol with 3.5-4 mm slice thickness from the skull base to the vertex was utilized. Image data were analysed both in bone and brain parenchyma tissue windows, and images were reformatted into sagittal, coronal, and oblique plane with 3D reformation. The radiological features of the CT Images were assessed and documented. The demographic data of the patients were also recorded. Participants with congenital abnormalities of the head and face were excluded from the study. All the selected images were based on preselected inclusion criteria set for this study, such as presence of full identification parameters (age, sex, clinical indications, detailed diagnostic findings showing soft tissue and bony involvements). Images without the sufficient data were excluded.

The data were analysed by IBM SPSS (Statistical Package for Social Sciences) software version 22 for Microsoft windows. Descriptive frequency analysis was done with results presented in text, figures, and tables.

**Results**

234 CT Image data of patients who had head injury were evaluated. Males were commonly involved compared to females with a ratio of 2.29:1 (Table-1). Age group between 60-96 years were included in the study with mean age of 71.08 ± 8.27 (mean ± standard deviation). (Table-2). Road traffic accident (RTA) was the leading cause of head injury which constitutes 65.8%, followed by fall 31.6 %, violence (0.8%) and unknown in 1.7% cases. 55 % of patients presented to hospital for CT scan within 7 days. Out of which only only 18 (13%) patients had CT scan done within the first 24 h of the injury. Out of 234 patients 38 (16.23%) had mild scalp injury with no significant intracranial findings and considered as normal. 196 (83.7%) had intracranial findings which were mentioned in the Table-2. Skull bone fractures found in 71 patients (30.3%). Fracture of temporo-parietal bone, parietal, temporal, frontal and occipital bone were seen in 40.3%, 19.3%, 19.3%, 11.29% and 9.6% respectively.

Out of 234 cases, 148 (63.24%) cases had extra axial haemorrhage and 48 (20.51%) had intra axial haemorrhage. Subdural Haemorrhage (SDH) alone was found in 90 cases (38.4%), subarachnoid haemorrhage in 17 (7.2%), and extradural haemorrhage in 2 (0.8%) cases.

Brain parenchymal contusion alone seen in 33(14.1%) cases, contusion associated with SDH in 17(7.2%), combination of SDH and EDH in 1 (0.42%), contusion with EDH in 3 (1.28%), combination of contusion, SAH, SDH and IVH in 10 (4.27%) cases were seen out of 234 cases. 13(5.5%) patients had associated cerebral oedema and 25(10.68%) patients had pneumocranium. Paranasal and mastoid collection were seen in 12 (5.12.%) cases. Few patterns of intracranial hemorrhages and skull bone fractures are depicted in Figure-1.

Figure-1. Acute on chronic subdural hemorrhage over bilateral fronto-parietal convexity (A), intraventricular hemorrhage and bilateral sylvian fissures subarachnoid hemorrhage (B), left fronto-parietal acute extradural hemorrhage and pneumocephalus (C) with right temporal bone fracture (D) are noted in different patients.

Discussion

One-fourth of global deaths due to TBI occurs in India. In geriatric patients falls are the most common cause of hospital admission and intervention, most of them are secondary to intracranial injury. Elderly are more susceptible to trauma due to age-related comorbidities such as visual impairment, gait abnormalities, degenerative joint disease, and cognitive impairments. The prevalence of road traffic accidents is increasing in India and is due to poor and bad road conditions, bad driving, not following traffic rules, poor vehicle conditions. Driving under the influence of alcohol contributes to significant number of RTA. Many patients might be on numerous medications including antiplatelet agents and/or anticoagulants. Even trivial trauma causes intracranial injury. Out of all imaging modality, Computed Tomography (CT) remains the most useful initial imaging tool due to its sensitivity for acute haemorrhage and fractures. The average duration between the injury and CT scan was almost within 1 week in most of the patients. Very few patients underwent CT within 24 hr. This may be due to unaffordability, distance from the hospital and lack of...
knowledge and awareness regarding the role of CT in the head injury by patients and relatives. In the present study it is found that males are more affected (69.6%) than females (30.34%) and is probably due occupation and activities which predisposed to trauma and injuries compared to the females. The most common cause of head injury in our study are related to road traffic accidents (65%) followed by fall (31.6%), violence (0.8%) unknown in 1.7 % cases. Subdural hematoma was the most common pattern of intracranial hemorrhage in our study. Hawley et al.16 and Røe et al.18 opined that males were more affected than female and subdural hemorrhage was the most common pattern of intracranial hemorrhage but the fall at home was the most common cause of head injury in elderly people in their study.

In the present study around 83.7% had findings and 16.23% were having normal CT findings. Intracranial haemorrhage was the most common finding. Extra axial haemorrhage corresponds to 63.24% of all cases and rest was intra axial haemorrhage. Adeyekun et al.14 studied patterns of injury in CT which included all age groups and opined that intracerebral haemorrhage is the most common form of intracranial bleed and Ohaegbulam et al.15 opined that cerebral contusion was the most common finding which is different to this study in elderly. This change in pattern might be due to inclusion of all age groups in their studies. Skull fractures were found in 71 patients (30.3%) of which temporo-parietal bone involvement was seen commonly. In few cases fracture of the skull base is seen and was associated with paranasal sinus collection. SDH is found out to be the most common pattern seen in elderly after trivial trauma, followed by brain parenchymal contusion in our study.

The limitation of the study: Our study included smaller number of geriatric cases. However, study with more number of sample is required for better analysis and statistical correlation.

**Conclusion**

Subdural hemorrhage was the common pattern of intracranial hemorrhage in elderly. Road traffic accident was the common etiology followed by fall at home. Male were more affected by head injury than female.

Shetty Memorial Institute of Dental Sciences, NITTE (Deemed to be University), Mangalore, India

Abstract

Objective: The aim of the present study was to assess the antimicrobial activity of orthodontic adhesive mixed with silver nanoparticles (SNPs) in varying concentrations.

Material and method: SNPs were prepared by using the chemical reduction method and characterized using UV-Vis Spectrophotometer, Fourier Transform Infrared Spectroscopy, and Scanning Electron Microscopy. The synthesized SNPs were mixed with commercially available orthodontic adhesive Transbond™ XT in varying concentrations (1%, 5% and 10%, n = 20 each) w/w and were formed into disc shaped specimens and incubated with Streptococcus mutans MTCC 497 and Lactobacillus acidophilus MTCC10307. The Disc Diffusion test was performed to examine the growth inhibition zones. Adhesive discs without silver nanoparticles were used as control (n = 20). The data was interpreted statistically with Kruskal-Wallis test followed by Tukeys Post Hoc analysis and Mann Whitney U test. P < 0.05 was considered statistically significant.

Results: The characterization of reduced silver ions by UV spectroscopy showed surface plasma resonance band around 400nm. SEM study showed particles with roughly spherical shape with less than 100 nm size. The present study showed that the orthodontic bonding adhesive with SNPs showed higher antimicrobial activity against Streptococcus mutans and Lactobacillus acidophilus as compared to the control group even in low concentration of 1% (P < 0.05). The adhesive mixed with SNPs in varying concentrations exhibited higher zone of inhibition in Streptococcus mutans compared with Lactobacillus acidophilus (P < 0.05).

Conclusion: The present study showed that the orthodontic bonding adhesive with silver nanoparticles showed excellent antimicrobial activity against Streptococcus mutans and Lactobacillus acidophilus even in low concentrations.

Keywords: Antimicrobial, Lactobacillus acidophilus, nanoparticles, orthodontic, Streptococcus mutans.

Introduction

Nanotechnology is a riveting field of science that is concerned with manipulation of materials at an atomic scale, where in various disciplines of natural sciences interweave at nanoscale making it viable for interdisciplinary applications. When particles are created in nanometers remarkable changes in their properties are observed as a consequence of the quantum effect of the nanoscale. Thus, evolutions in the field of
nanotechnology and nanomaterials have brought its benefits into the realm of medical and dental sciences.

Oral hygiene of patients undergoing fixed orthodontic therapy is usually compromised which increases cariogenic bacterial counts and decreases the salivary pH. The oral cavity of patients undergoing fixed orthodontic appliance therapy, exhibits new foci of plaque on the enamel in proximity to the orthodontic attachments with more colony forming units of *Streptococcus mutans* and *Lactobacilli*. This may lead to post-orthodontic treatment decalcification, appearance of white spot lesions and caries. Study done by Lim et al. demonstrated that there is an increased bacterium on the adhesive than on the bracket material itself. This has led to new research in the development of innovative orthodontic adhesives containing various nanomaterials intended to reduce bacterial colonization and thus inhibit formation of white spot lesions and caries.

Nanoparticles of silver, gold, hydroxyapatite have been identified to have superlative antimicrobial properties and their addition to dental or orthodontic materials have shown to be effective against oral pathogenic microbiota without compromising their physical properties. Addition of Silver Nanoparticles (SNPs) with the orthodontic adhesive paste or primer system have shown to produce inhibition zones against *Streptococcus mutans, Lactobacillus acidophilus, Streptococcus sanguinis*, proving their effectiveness as antibacterial agents.

Development of clinically admissible and efficient orthodontic bonding adhesives with anti microbial traits can be undertaken only if their antimicrobial efficacy in optimum concentrations can be established.

The aim of this study was to determine the effect of silver nanoparticles (SNPs) in varying concentrations on the antimicrobial properties of orthodontic adhesives and assess the concentration to be added to obtain maximum antibacterial effect against oral cariogenic pathogens like *Streptococcus mutans* and *Lactobacillus acidophilus*.

**Material and Method**

**Materials used:** Materials used were Silver Nitrate (HIMEDIA, India), Trisodium Citrate (COBA Chemie Pvt. Ltd, India), Transbond™ XT (3M Unitek, USA) and Mueller Hinton Agar (HIMEDIA, India).

**Methodology**

**Preparation of Silver Nanoparticles in varying concentrations:** Chemical reduction method as proposed by Fang et al. was used in this study for the preparation of silver nanoparticles. 1 mmol of silver nitrate was dissolved in double distilled water and boiled; to which 1% trisodium citrate was added drop wise and mixed vigorously. The solution was heated until the colour change to pale brown was observed. Silver nanoparticles thus obtained were dried and prepared for further study.

**Characterization of silver nanoparticles:** The characterizations of nanoparticles were done using UV-Vis-NIR Spectrophotometer (Shimadzu UV-3600), Scanning Electron Microscopy (EVO MA18 with Oxford EDS(X-act)) machine with magnification of 10.00K and FTIR Spectrometer (Thermo Scientific™ Nicolet™ iS20).

**Incorporation of silver nanoparticles into orthodontic adhesive and preparation of composite discs:** The synthesized silver nanoparticles were mixed with commercially available orthodontic adhesive Transbond™XT1%, 5% and 10% w/w concentrations (n = 20 each) using a Vortex Machine (REMI Cyclo/Vortex Mixer, CM-101). The minimum concentration (0.5µg/ml) of SNPs for effective antibacterial activity as recommended by Greulich et al. and Shahrokh et al. was added to every 1mm orthodontic adhesive using a graduated pipette. The prepared paste was formed into disc shaped specimens. This was done by filling teflon molds of 5mmx2mm dimensions which were placed on glass slides and light cured (3M ESPE Elipar™ S10, USA) for 20s from each side. Plain Transbond™ XT discs (n = 20) were also prepared. The obtained discs were sterilized using gamma radiation.

**Antimicrobial Activity**

**Preparation of the bacterial culture:** Freeze dried *Streptococcus mutans* MTCC 497 and *Lactobacillus acidophilus* MTCC 10307 were revived in specific media and incubated to obtain sub cultures.

**Disc Diffusion Method:** The disc diffusion test was performed to measure the inhibition zones produced by the antibacterial agents. Mueller Hinton Agar plates were swabbed with *Streptococcus mutans* and *Lactobacillus acidophilus* suspensions. Orthodontic adhesive discs
containing (0%, 1%, 5% and 10%, n = 20 each) silver nanoparticles were placed on the plates equidistant from each other. Agar plates containing Lactobacillus acidophilus were incubated anaerobically and plates containing Streptococcus mutans were incubated at 37°C for 24 hours following which growth inhibition zones were measured. The test was repeated three times.

**Statistical Data:** Statistical analyses of values were performed with descriptive statistics and inferential statistics like Kruskal-Wallis test followed by Tukeys Post Hoc analysis. Mann Whitney U test was used to compare the efficacy of Silver Nanoparticles between the two organisms. The statistical analyses were performed using SPSS software version 16. P < 0.05 was considered statistically significant.

**Results**

**Characterization of silver nanoparticles:** The characterization of reduced silver ions was determined by UV Spectroscopy showing surface plasma resonance band around 400nm (Figure 1).

The Scanning electron microscopy (SEM) study showed particles with roughly spherical shape with nanometer sizes (Figure 2).

The functional groups were studied with Fourier Transform Infrared Spectroscopy (FTIR) analysis. Symmetric bands at 1600 cm⁻¹ to 1300 cm⁻¹ indicated the presence of NO group (Figure 3).

**Antimicrobial activity:** Commercially available orthodontic adhesive was used as the control which did not produce any inhibition zones against both Streptococcus mutans and Lactobacillus acidophilus. These results are in conformity with the study done by Choi Kwonyong et al. [18] Table I shows the statistical results of the antimicrobial activity of all the adhesive groups against Streptococcus mutans as compared with the control group and among each other.

Discussion

Fixed orthodontic appliances have been shown to increase the risk of enamel decalcification, appearance of white spot lesions and subsequent caries development.\(^3\,19\) Orthodontic adhesives have been reported to retain pathogenic bacteria like *Streptococci* and *Lactobacilli*.\(^7\) Addition of various antimicrobial agents to the orthodontic adhesive systems has proven to enhance their antimicrobial activity.\(^20\)

The use of nanotechnology and the quantum effect of nanomaterials in the field of orthodontics have brought a revolutionary change in the oral scenario of patients undergoing orthodontic therapy.
Over the years Silver Nanoparticles have been synthesized by both chemical and biologic method. Studies have proven their antimicrobial properties as they have larger surface area in spite of their small particle size making them potent antibacterial agents even in smaller concentrations.\cite{21,22}

In this study we added silver nanoparticles in varying concentrations to commercially available orthodontic adhesive Transbond\textsuperscript{TM} XT in order to study their antimicrobial property against \textit{Streptococcus mutans} and \textit{Lactobacillus acidophilus}; and thereby assess the most effective concentration to be added. As Transbond\textsuperscript{TM} XT is considered the gold standard light cure orthodontic adhesive, it was selected as the control adhesive in this study.\cite{23}

The results of the disc agar diffusion test showed that addition of 1\%, 5\%, 10\% SNPs to commercially available orthodontic adhesive not only showed inhibition zones against \textit{Streptococcus mutans} effectively, but also demonstrated a significant increase in the efficacy of adhesive with 1\%SNPs thus exhibiting superior antibacterial effect in small concentrations. On the other hand all three concentrations of SNPs when added to adhesive provided antibacterial activity against \textit{Lactobacillus acidophilus} but there was no statistical significance seen among the groups. Previous studies show that Silver and Hydroxyapatite Nanoparticles (Ag/HA) in 1\%, 5\%, 10\% concentration when added to orthodontic adhesive or primer, produced bacterial growth inhibition zone and particularly addition of 5\% Ag/HA was effective from an antimicrobial aspect.\cite{12,23}

In the present study, adhesive containing 1\% SNPs showed maximum inhibitory activity toward \textit{Streptococcus mutans} and \textit{Lactobacillus acidophilus} as compared with adhesive containing 5\% and 10\% SNPs. Comparing the efficacy of adhesives with SNPs against the two organisms showed that they are more effective towards \textit{Streptococcus mutans} as compared to \textit{Lactobacillus acidophilus}. These results are in conformity with Kasraei et al.\cite{24} The results of our study concur with previous literature that proves the effectiveness of SNPs as antibacterial agents,\cite{25} even after mixing with the composite resin or adhesives.\cite{12-14}

The present study proves the effectiveness of SNPs added in low concentrations to orthodontic adhesives as an antimicrobial agent, reducing any possibilities of dose related nanotoxicity and aiding in maintenance of good oral health in patients undergoing orthodontic therapy.

The only drawback we observed on the of addition of SNPs to orthodontic adhesive is the colour change of the adhesive, hindering esthetics.

**Conclusion**

The present study displayed that the orthodontic bonding adhesive with Silver Nanoparticles showed higher antimicrobial activity against \textit{Streptococcus mutans} and \textit{Lactobacillus acidophilus} in low concentrations which in turn will avert the formation of white spot lesions and further progression of dental caries.

However these being an in-vitro study, further clinical studies are required to confirm the beneficial effects in terms of superior esthetics, mechanical properties and good antimicrobial properties before the product is made commercially available.

Evaluation of Carbapenem-Resistant Genes and Colistin Susceptibility in Gram Negative Organisms from Clinically Significant Samples

Dhanyashree Rai¹, Pooja Rao², Sevitha Bhat², Udayalaxmi Jeppu³

¹Post graduate, Department of Microbiology, Kasturba Medical College, Manipal Academy of Higher Education, Mangalore, Manipal, Karnataka, India. ²Associate Professor; Department of Microbiology, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, Karnataka & Manipal McGill Center for Infectious Diseases, Prasanna School of Public Health, Manipal Academy of Higher Education, Manipal, Karnataka, India, ³Associate Professor, Department of Microbiology, Kasturba Medical College, Manipal Academy of Higher Education

Abstract

Introduction: The rapid global spread of carbapenem-resistance in microorganisms is a threat to the health system. This study aims to evaluate carbapenem resistance in different bacterial isolates like *E coli*, *Klebsiella pneumoniae*, *Acinetobacter* and *Pseudomonas* species and detection of genes conferring the carbapenem resistance in bacteria using Multiplex PCR.

Materials and Method: A total of 101 clinically significant samples from the various patients such as blood, urine, pus, sputum, aspirates, and tissue were collected. Antibiotic susceptibility testing done by standard Kirby Bauer disc diffusion & Vitek 2 system. MIC values of Colistin for all the isolates was determined by Broth Microdilution method. Detection of carbapenemase genes was done by using Multiplex PCR.

Results: The most prevalent Carbapenem resistant organism was *Klebsiella* species(53%). NDM gene was the highest of all the other carbapenemase encoding genes detected constituting up to 68%. Out of these 15, 12 *Klebsiella pneumoniae*, 2 *Acinetobacter* species, and 1 *Escherichia coli* harbored the NDM gene. The prevalence of OXA-48, VIM and IMP genes were about 9%. There were 2 IMP and 2 OXA-48 genes each was found in *Escherichia coli* and *Klebsiella* species. The carbapenem resistance encoding gene KPC was found only in the single isolate of *Acinetobacter* isolated from blood culture. The organisms showed higher resistance to Colistin(56%).

Conclusion: Evaluation of bacterial resistance to carbapenems contributes to know the appropriate treatment available, and the reduction of morbidity, mortality and dissemination of resistance. Detection of the genes conferring Carbapenem resistance helps in the study of resistant mechanism.

Keywords: Carbapenem resistance, *Klebsiella pneumoniae*, Carbapenemases.

Introduction

Antimicrobial resistance (AMR) in Gram-negative bacteria (GNB) is a significant cause of severe infections across the world with increasing morbidity and mortality rates. The increasing resistance for beta-lactam groups of antimicrobials is a big concern¹. It is mainly due to the presence of beta-lactamases that are present on the mobile genetic elements, which causes its widespread². Carbapenem-resistant gram-negative bacilli especially
those belonging to Enterobacteriaceae family, Acinetobacter baumannii and Pseudomonas aeruginosa are an emerging cause of nosocomial infections. These bacteria are difficult to treat due to the high levels of antibiotic resistance they exhibit and are associated with high mortality. The production of carbapenemase enzyme is the most common method of resistance acquired. The presence of these resistant organisms has limited the choice of appropriate antibiotic therapy. Therefore it is important to monitor these resistant genes in different bacterial strains to prevent the spread of the resistance and thereby to prevent the infections. The objectives of the study are evaluation of the carbapenem resistance in Gram negative bacilli isolated from various clinically significant samples and detection of carbapenem resistance genes by using molecular method PCR.

Materials and Method

A 6-month cross-sectional study where a total of 101 samples were collected from November 2018 to April 2019. The samples such as blood, urine, pus, sputum, aspirates and tissue were collected from Kasturba Medical College Hospital, Attavar and Ambedkar circle. Only E.coli, Klebsiella pneumoniae, Acinetobacter, and Pseudomonas isolates resistant to carbapenems by disk diffusion & Vitek 2 system were considered in this study. The results were analyzed based on the recommendations of the Clinical Laboratory Standards Institute (CLSI 2018) guidelines. The following antibiotic discs (Himedia, Mumbai) were used-Amikacin (10mcg), Ceftazidime (30mcg), Cefaperazone / sublactum (75/30mcg, Ciprofloxacin (5mcg) Cotrimoxazole (25mcg), Gentamycin (10mcg), Piperacillin (100mcg), Piperacillin/Tazobactam (100/10mcg), Ertapenem (10mcg), Imipenem (10mcg), Meropenem (10mcg), Ticarcillin (75mcg), Tigecycline (15mcg), Netillin (30mcg), Nitrofurantoin (300mcg)

MIC values of Colistin were determined for all the isolates using Broth Micro dilution method. Detection of carbapenem resistance genes in gram negative organisms was done using multiplex PCR. The presence of carbapenemase encoding genes was determined using primers VIM, IMP, OXA-48, KPC and NDM obtained from Sigma Aldrich Pvt.Ltd,(Table 1)

The DNA from various clinical samples was extracted according to CDC protocol using boiling method. For the master mix - Ready mix Taq PCR reaction mix (Sigma Aldrich, US) with MgCl2, in which the respective primer sets i.e. Forward (F’) as well as Reverse(R’) added. Multiplex PCR reaction mix consisted of 12.5μl of ready to use mastermix, 2.5μl of primer mix, 7.5μl of nuclease water, and 2.5μl of DNA in a final volume of 25μl. Amplification was done using cycling conditions, initial 10 min denaturation step at 95°C followed by 35 cycles of 45 s of denaturation at 94°C, 45 s of primer annealing at respective temperature, and 50 s of primer extension at 72°C. Following the last cycle, an additional 7 min extension step at 72°C in Rotor gene-Q (Qiagen, Germany). The amplified product was detected by using 2% agarose gel electrophoresis in 1X Tris Acetate EDTA Buffer. The gel stained with 0.5mg/ml ethidium bromide and visualized under UV transilluminator. Quality control: Positive control: K. pneumonia ATCC BAA 1705 & K. pneumonia BAA 1706 (negative control) was used.

The study samples were collected from the samples that were received routinely in the laboratory. It was not collected separately for this project; hence, informed consent from the patients was not required, and Institutional Ethics Committee, Kasturba Medical College, Mangalore, approved to conduct this study.

Statistical analysis done by using Statistical package SPSS V.20.0 (SPSS Inc., Chicago, IL, USA). Results are summarized as frequency tables, and percentages were worked out. Antibiotic susceptibility percentage and association was calculated by descriptive study analysis and Chi-square test, respectively.
Results

Out of 101 various clinically significant samples received, Carbapenem resistance (CR) was seen highest in urinary tract infection (31.6%) followed by wound infection (21%) and respiratory tract infections constituting 22%. Blood stream infections comprised of upto 7.9%.(Table 2)

Among 101 Gram negative bacilli isolates, *Klebsiella* was the major pathogen isolated constituting 53 (58%), 18 *Acinetobacter* species, 15 *Escherichia coli* and 16 *Pseudomonas* species. A male preponderance was seen among the patients constituting 62% of the total sample, females comprised of 38%. Maximum patients were from the age group 61-70 years, and broadly, most patients belonged to 21-80 years of age. The study used samples which are resistant to at least one of the carbapenems among Ertapenem, Imipenem, and Meropenem.

The antibiogram pattern in our study revealed that overall the organisms were more resistant to Ciprofloxacin, Gentamycin, Cefoperazone/sulbactam and moderately susceptible to Amikacin, Piperacillin and Piperacillin/Tazobactam, Ticarcillin, Tigecycline, Netillin. The Colistin MIC values were determined and highest resistance was found in *Klebsiella* species (57%). *E.coli, Acinetobacter* and *Pseudomonas* species were sensitive to Colistin (Table 3).

</table>

The prevalence of NDM gene was high when compared to the other carbapenemase encoding genes constituting up to 68%, i.e., 15 out of 22 isolates showed the presence of NDM genes. Out of these 15 strains, 12 were *Klebsiella pneumoniae*, 2 were *Acinetobacter* species and 1 *Escherichia coli* with the NDM gene. The presence of 2 IMP and 2 OXA-48 genes each was found in two different isolates *Escherichia coli* and *Klebsiella* species. The carbapenem resistance encoding gene KPC was found only in the single isolate of *Acinetobacter* isolated from blood culture. However, we could not find any carbapenem resistance genes in *Pseudomonas* species. The total mortality rate was 21% i.e, 21 out of 101 patients expired. Among which the mortality rate was higher in males.
**Discussion**

The incidence of carbapenem-resistant Gram-negative bacilli is on the rise all along the globe, posing a huge public health threat\(^\text{10}\). During the last 10 years, carbapenem resistance has escalated among *Enterobacteriaceae* bugs such as *Klebsiella* species and *Escherichia coli* apart from *Pseudomonas* and *Acinetobacter* species\(^\text{11}\). Out of 101 Carbapenem resistance (CR) was seen highest in urinary tract infection (31.6%) followed by wound infection (21%) and respiratory tract infections constituting 22%. Blood stream infections comprised of up to 7.9% which was found to be similar in another study.\(^\text{12}\) In another study, *E. coli*, *Klebsiella* spp, *P. aeruginosa* followed by *Acinetobacter* spp was the pattern seen. Maximum patients were from the age group 61-70 years, and broadly, most patients belonged to 21-80 years of age with male preponderance which was synchronous with a study conducted at Ghana hospital.\(^\text{13}\)

In an Indian multicenteric study, amikacin & Carbapenems were the only agent which showed moderate activity.\(^\text{1}\) In a study performed by Solanki et al., Hyderabad, out of 100 carbapenem resistant isolates,\(^\text{37}\) were having NDM gene including 25 strains of *Klebsiella* spp and 12 strains of *E. coli*. This was synchronous with our results showing that the *Klebsiella* spp. harboring NDM gene outclassed the other isolates with NDM gene. On the other hand, they found only 1 KPC gene, which was an isolate of *E. coli* whereas our study showed the presence of KPC in a single isolate of *Acinetobacter* spp. isolated from blood culture.\(^\text{12}\) Another study performed by Atul Garg et al., in Lucknow, it was observed that among the 312 carbapenem-resistant bacteria the most common isolate was *Pseudomonas aeruginosa* (24%) which is in contrast to our study. On multiplex PCR, 90.3 percent carbapenem-resistant isolates were positive for carbapenemase gene NDM (63%) followed by VIM (18.4%). The KPC gene was not isolated in this study, NDM and OXA were co-observed in 20 per cent isolates.\(^\text{14}\)

However remaining organisms could be having other mechanisms of Carbapenem resistance like hyperproduction of AmpC and ESBL, porin loss and efflux pump mediated resistance and some of the isolates was susceptible to either of the Carbapenems. This study showed a slow rise of resistance in colistin and the mechanism of resistance being MCR-1 gene mediated or others which is out of scope from our study.

The total mortality rate of the patients diagnosed with Carbapenem resistant bacterial infections was 21%, i.e., 21 patients out of 101 expired, including 15 males and 6 females. Although the presence of carbapenem resistance genes was found in 5 expired cases, and the remaining cases showed recovery from the infections despite the presence of carbapenemases. A similar study conducted by Sahin et al., and the mortality rate was 58.1%.\(^\text{16}\) Prolonged ICU stay, diabetes mellitus, invasive procedures, Catheters are the risk factors associated with the Carbapenem resistant Gram negative bacilli infections.\(^\text{17}\) To get an indication of the association between the presence of carbapenem resistant genes in clinical isolates with mortality, simple association analysis between the two was conducted. The results showed that patients with any one of five carbapenem resistant genes in their specimens had a mortality rate of 24% (5 out of 21 cases). In comparison, the patients without any carbapenem resistant genes actually had a mortality rate of 76% (16 out of 21). The difference in the mortality between patients with and without the presence of the carbapenem resistance genes was not statistically significant.

**Conclusion**

Carbapenems are often considered last resort antibiotics in the treatment of infections due to multidrug-resistant organisms. It is therefore mandatory to maintain the clinical efficacy of carbapenems by early detection of various enzymes. Detection of carbapenemase producing organisms using different methodologies demonstrates variations in the sensitivity and specificity across different geographical regions. This genotypic study helps us in the evaluation of carbapenem resistance genes in Gram- negative bacilli isolated from various clinical samples from a tertiary health care setup in Mangalore and shows that NDM is the most prevalent gene found among various Carbapenem resistant Gram negative bacterial isolates especially in the *Klebsiella* species, and the rate of isolation of KPC gene was extremely low which indicates that the prevalence of the gene is lesser compared to other regions. This study signifies the importance of assessing the predominant carbapenemase enzymes seen in a specified geographical region. Also, other antibiotics such as colistin and tigecycline should be tested to provide alternative therapy. The rise in polymyxins resistance is of high concern. More studies should be done to determine the evolution and molecular epidemiology of these isolates.

Abstract

Quality human resource is directly related to the economic development of a nation. Health care options with the rural poor are still highly inaccessible in India due to the economic condition of majority populations and inadequate public health care facilities. The study looks at the possibility of microfinance as an alternative option for financing health care in lower Brahmaputra valley of Assam. The study observes that there has been a considerable improvement in the health conditions of the Self Help Group beneficiaries in the study area. However, there is lots of scope to enhance the quality of manpower in the study area by broadening the health care options through microfinance. Setting up of a welfare fund at the SHG level is appreciable in order to make microfinance a medium of health care requirements.

Keywords: Health, Self Help Group, Human Resource Development, SHG Bank Linkage Programme.

Introduction

The economic prosperity of a nation is negatively affected by poverty. Poverty is directly related to poor health condition in a society. Department for International Development (UK) advocated for reducing the poverty rate in developing countries to enhance the quality of life as that will gradually lead to build strong human resource. Poverty and health inequalities are inextricably linked. Poverty impacts on individual’s health, including the ability and opportunity to engage in health-seeking and health promoting behaviour. Despite all the appreciable trends, in the context of aftermath of global economic momentum, escalation of health care costs and due to the inelastic nature of the fiscal resources of the state, the necessity of alternative sources of financing healthcare is inevitable.

Finance helps the poor to be at par with the rest of the economy as it grows. Microfinance is a powerful tool against poverty. Microfinance is one example of an intervention that can give a considerable impetus through poverty reduction and its associated vulnerabilities including the fundamental determinants of health disparities.

Microfinance includes savings, credits, insurance and remittance. Microfinance has the ability to increase the earnings of poor people and improve their health status. Non-availability of formal finance and exorbitant interest rate of informal finance made the entry of microfinance smooth in rural India. Various studies have analysed the relation between microfinance and health status of beneficiaries. However, so far as the knowledge of researcher goes no such study has tried to analyse the relation between microfinance and health status in the lower Brahmaputra valley of Assam. Therefore the current study is an attempt to analyse the role of microfinance in the health status of the beneficiaries in lower Brahmaputra valley of Assam.

The paper is divided into 5 sections. The first section is the introduction while the second section discusses the methodology. Section 3 discusses the measures of health and section 4 discusses the status of women health post joining SHG. And section 5 concludes the paper.

Methodology

The objective of this paper is sought to be fulfilled through the analysis of the primary data. The unit of
the study comprises of the selected members of Self Help Group (SHG) linked to Assam Gramin Vikash Bank (AGVB) under SHG Bank Linkage Programme (SBLP). A structured questionnaire is used for collecting responses and for drawing conclusions for the study. The samples for the study are selected from five districts namely Barpeta, Baksa, Nalbari, Kamrup (R), Kamrup (M) and of the Lower Brahmaputra Valley. A total of 340 samples are collected from 340 households from 170 SHG.

For analysing the objective, data from the questionnaire that is designed to analyse the health status of women post joining SHG are used. The health conditions of women SHG beneficiaries is analysed with the help of a few assertions. The respondents are asked to express their opinion (either agreement or disagreement) in a five-point Likert Scale on the statements (assertions) on health status. These statements are checked for internal reliability and consistency using Cronbach’s Alpha Coefficient and then the exploratory factor analysis is used.

To measure whether microfinance through SBLP has enhanced the health condition of the rural poor, descriptive statistics is used. The percentage of people in agreement to better health condition post joining SHG is given in terms of frequency.

**Findings of the Study**

For the present study, the basic indicators of health are analysed. An analysis of the health status variables can give a picture of the physical health of people in rural India particularly in the context of the lower Brahmaputra Valley of Assam. As such the results for the same are presented in the sections that follow.

Measuring the Internal Consistency and Reliability of the Construct

In order to measure the consistency and reliability of the instruments used for the present study, Cronbach’s alpha (α) is calculated.

**Table 1: Overall Reliability Statistics for Constructs for Health Indicators**

<table>
<thead>
<tr>
<th>Reliability Statistics</th>
<th>Health Indicators</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cronbach’s Alpha</td>
<td>.815</td>
</tr>
<tr>
<td>No. of Items</td>
<td>12</td>
</tr>
<tr>
<td>No. of Cases</td>
<td>340</td>
</tr>
</tbody>
</table>

Source: Calculated by the author from Primary data

As seen from table 1 Cronbach Alpha (α) is estimated to be .815 for all the 12 assertions relating to Health Indicators. This can be considered to be in a very good range. The overall value of alpha (α) for Health Indicators indicates that the assertions made respectively for each form of health condition positively contribute to the overall reliability of the study. As such the assertions are retained for further analysis.

Exploratory factor analysis is used to club the assertions into meaningful conclusions. But before that as a part of preliminary analysis, some prerequisite tests to measure sampling adequacy and multicollinearity was done.

**Table 2: Measures of Sampling Adequacy for Health Indicators**

<table>
<thead>
<tr>
<th>Sampling Measure</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kaiser–Meyer–Olkin measure of sampling adequacy</td>
<td>.717</td>
</tr>
<tr>
<td>Bartlett’s test of Sphericity</td>
<td>(Approx. Chi Square) 1.764***</td>
</tr>
<tr>
<td>Df</td>
<td>66</td>
</tr>
</tbody>
</table>

Source: Calculated by the author from Primary data

***: significant at the 0.01 level (2-tailed)

For the study the Kaiser–Meyer–Olkin measure of sampling adequacy for health variables is 0.717. This falls in the recommended values of minimum 0.5. Thus it can be concluded that the sample size is adequate. The Bartlett’s test of Sphericity tests the null hypothesis that the original correlation matrix is an identity matrix and has a significance value less than .05. The Bartlett’s test is significant (p < .001) for the data for all the forms of health status and thus factor analysis can be considered appropriate for the present study.

The results of exploratory factor analysis finds out the items that cluster on the same components suggest that component 1 represents “Children and Health”, component 2 represents “Obstetrics Health” and component 3 represents “Health and Hygiene”. Among these 3 factors, “Children and Health” explains the highest amount of total variance with a total variance of 24.529.

Amongst the four variables comprising “Children and Health” namely “Increase in regular vaccination”, “Reduction in falling sick of infants”, “Reduction in school absent days of children” and “Increase in
medical checkup”, “Increase in regular vaccination”, has the highest factor loading of .853 closely followed by “Reduction in falling sick of infants” with a loading of .800. Thus it can be inferred that SBLP can increase SHG member’s consciousness towards the importance of vaccination of their children’s as a result of the exposure they get after coming out of the house for various training programmes.

Health Status Post Joining SHG: The health status is measured through 12 variables with the help of descriptive statistics and it is seen that the overall respondents out of 340 who agreed to have been benefited with better health condition post joining SHG stands at 62%. However, the difference is observed between the 12 variables of health. Encouragingly, most of the respondents i.e. 320 out of 340 has stated that there has been a decrease in open defecation post joining SHG because of the increase in financial flow to the household and increased knowledge about health hazard. This change is also due to the exposure that women SHG members gets after coming out of the periphery of house for petty business. This is closely followed by 288 respondents (i.e.85%) respectively agreed about reduction in falling sick of infants post joining SHG. On contrary to this only 8% family members of the respondents have increased the use of sanitary pads post joining SHG. This suggests that use of sanitary napkin at the time of menstruation is still considered as a cost saving option in villages.

Conclusion

On the basis of exploratory factor analysis 4 factors are found to be important which can affect the health condition of SHG beneficiaries. Further under health conditions, “Children and Health” explains the highest amount of total variance. From this it can be inferred that SBLP has helped its members to increase awareness about the health of children’s. Majority of respondents have also revealed that they have become more health conscious after joining SBLP.

The study has found that there has been a positive impact of microfinance on the health condition of SHG members. However the Government should provide more subsidised loans through SBLP to the members for further improvement in the quality of human resources in India through better health conditions. Additionally, setting up of a welfare fund at the SHG level will be highly beneficial for the SHG members.

Ethical Clearance: It is a research article.

Correlation of Age, Sex, Waist Circumferences with Thyroid Disorders in Metabolic Syndrome Patients

Gunjan Kumar Mandal1, Suvarna Prasad2, B.K. Agrawal3

1Ph.D. Student, Department of Biochemistry, 2Professor & Head, Department of Biochemistry, 3Professor, Department of Medicine, MMIMSR, Mullana, Ambala, Haryana, India

Abstract

Objectives: Metabolic syndrome (MetS) is a cluster of several metabolic disorders including hyperglycemia, reduced high density lipoprotein cholesterol, raised triglyceride level in serum, hypertension and abdominal obesity. Thyroid dysfunction (TD) was found to be more frequent between patients with metabolic syndrome. MetS and its related components are associated with functional and morphological alteration of the thyroid gland.

Method: The present study was conducted at the MM Institute of Medical Sciences and Research. The study includes 300 patients with MetS as a case and 300 healthy volunteers as a control. MetS was diagnosed according to international diabetes federation. Thyroid status was correlated with age, sex and waist circumference (WC) amongst metabolic syndrome patients.

Results: In our study thyroid disorder are common in the age group between 51 and 60 years of age of MetS patient and are very common in females MetS patients. WC between 100-109 cm are more common in MetS patients having thyroid disorder.

Conclusions: Our study found that females had higher risk of thyroid disorders in MetS patients. More over aging and increase in waist circumferences is an important risk factor for thyroid disorder in MetS patients.

Keywords: Age, Sex, Waist circumference, Metabolic syndrome, Thyroid disorders.

Introduction

MetS is a group of signs and symptoms which include abdominal obesity, insulin resistance, and elevated blood pressure (BP). It is related to cause risk of chronic kidney disease, Type 2 Diabetes Mellitus, cardiovascular disease (CVD) and these diseases are important cause of mortality 1. Early identification of MetS is important because it raises the risk of CVD between 1.5 to 1.8 times more and raise relative risk of coronary artery disease and 4.2 fold a death 2. In persons with MetS, the prevalence of CVD increases 2-3 folds3.

International Diabetes Federation (IDF) defines MetS, as central obesity (defined as WC ≥ 90 cm for men and ≥ 80 cm for women) along with presence of any two of the following 4.

- Systolic blood pressure (SBP) ≥ 130 mm Hg or diastolic blood pressure (DBP) ≥ 85 mm Hg.
- Increased fasting blood Sugar (FBS) ≥ 100 mg/dl.
- Increased triglyceride: ≥ 150 mg/dl.
- Decreased high density lipoprotein cholesterol (HDL-C): < 40 mg/dl in men, < 50 mg/dl in women.

Fast economic development with accelerating change in lifestyle, urbanization, nutrition, reduced physical activity and socio-economic status play key roles in the dramatic acceleration of MetS 5. Age, sex, and WC are important factors, involved in the development of MetS. Sex wise variation of MetS prevalence has been noticed. According to some reports increased prevalence occurs...
in men, whereas other showed increased prevalence in females. Increased MetS prevalence has been observed with increase of age. Prevalence of thyroid disorder has been observed in female MetS patients and the prevalence increases with increase of age.

WC provides a simple and practical anthropometric measure for assessing central adiposity and significant number of studies have reported strong relations between WC, obesity related health risk. Lately it has been reported that WC is better predictor of metabolic abnormalities than percent fat measured by bio-impedance method in elderly whites. It is important to further investigation whether WC is a better anthropometric marker than accurately measured percent fat for adiposity related health risks in different ethnic groups.

AIMS and Objectives:

1. Measurement of waist circumference of MetS patients of different age and sex.
2. Investigation of serum T₃, T₄, TSH, FT₃, FT₄ levels in (age and sex matched) MetS patients.

Materials and Method

The study has been conducted between February 2017 to August 2018

Study Area: The present study was conducted in the Department of Biochemistry in collaboration with Department of Medicine, Maharishi Markandeshwar Institute of Medical Sciences and Researches, Mullana, Ambala, Haryana, India.

Study Population:

Group 1: 300 subjects with metabolic syndrome.

Group 2: 300 healthy Volunteers controls (age and sex matched) without metabolic syndrome.

Informed consent has been taken from the participants included in the study.

Inclusion Criteria:

- Patients with Metabolic syndrome above 18 years of age.

Exclusion Criteria:

- Thyroid disease
- Familial hyperlipidemia
- Renal disease
- Pregnancy
- Any history of liver disease
- Lactation
- Oral contraceptives
- Recovery from non thyroidal illness
- Cushing disease
- Patients with history of chronic drug use (steroid treatment, antidepressant and anti psychotic drug user)

Waist Circumference Measurement: WC was measured with a tape in a horizontal plane, mid way between the inferior margin of the ribs and the superior border of the iliac crest.

Sample Collection: 5 ml of blood sample was aseptically collected as per the standard guidelines and protocol. Serum was allowed to separate and subsequently analyzed for various parameters.

Serum T₃, T₄, TSH, FT₃, FT₄ was assayed by chemiluminescence immunoassay Method.

Statistical Analysis: Data obtained was analysed by using SPSS 21 version software and results was compared in cases and controls. P value < 0.05 was taken as significant at 95% confidence intervals. Student’s t-test and pearsons correlation coefficient was used to find the association between thyroid profile and various components of MetS.

Result

The total number of patients in our study were 600 (100%) out of which 300 (50%) were healthy controls subjects and 300 (50%) were MetS patients. Among 300 patients with MetS in the study, 102 (34.0 %) were male and 198 (66.0 %) were female. Similarly there were 300 control subjects, out of which 102 (34.0 %) were male and 198 (66.0 %) were female.

The table 1 shows that in MetS patients in age group of 21-30 years, 4 patients are in euthyroid state, in age group of 31-40 years, 25 patients are in euthyroid state, 5 patients have hypothyroidism, 5 patients have hyperthyroidism, 10 patients have subclinical hypothyroidism and 5 patients have subclinical hyperthyroidism. In the age group of 41-50 years, 49 patients are in euthyroid state, 15 patients have hypothyroidism, 3 patients have hyperthyroidism, 14 patients have subclinical hypothyroidism and 1 patient have subclinical hyperthyroidism. In the age group of 51-60 years, 52 patients are in euthyroid state, 13 patients have hypothyroidism, 3 patients have hyperthyroidism, 16 patients have subclinical hypothyroidism and 1 patient have subclinical hyperthyroidism. In the age group of 61-70 years, 35 patients are in euthyroid state, 10 patients have hypothyroidism, 3 patients have hyperthyroidism and 17 patients have subclinical hypothyroidism. In the age group of 71-80 years, 5 patients are in euthyroid state, 3 patients have hypothyroidism and 1 patient have subclinical hypothyroidism. In the age group 81-90 years 1 patient are in euthyroid state.

Table 2: Correlation of thyroid status with sex distribution amongst metabolic syndrome patients:

The table 2 shows the sex wise thyroid status in MetS patients. From the table it is evident that, in male group, 61 patients are in euthyroid state, 20 patients have hypothyroidism, 5 patients have hyperthyroidism and 16 patients have subclinical hypothyroidism.

Similarly in female group, 110 patients are in euthyroid state, 26 patients have hypothyroidism, 13 patients have hyperthyroidism, 42 patients have subclinical hypothyroidism and 7 patients have subclinical hyperthyroidism.

</table>

The table 3 shows that in MetS patients having waist circumferences between 80 and 89 cm, 9 patients are in euthyroid state, 3 patients have hypothyroidism, 2 patients have hyperthyroidism, 1 patient have subclinical hypothyroidism and 2 patients have subclinical hyperthyroidism.

In patients having waist circumferences between 90 and 99 cm, 54 patients are in euthyroid state, 13 patients have hypothyroidism, 19 patients have subclinical hypothyroidism and 2 patients have subclinical hyperthyroidism.

In patients having waist circumferences between 100 and 109 cm, 85 patients are in euthyroid state, 21 patients have hypothyroidism, 5 patients have hyperthyroidism, 27 patients have subclinical hypothyroidism and 3 patients have subclinical hyperthyroidism.

In patients having waist circumferences between 110 and 119 cm, 18 patients are in euthyroid state, 9 patients have hypothyroidism, 5 patients have hyperthyroidism and 9 patients have subclinical hypothyroidism.

In patients having waist circumferences between 120 and 125 cm, 5 patients are in euthyroid state, and 2 patients have subclinical hypothyroidism.

Discussion

It was noted from the results that among 102 male patients, 61 patients have euthyroid state, 20 patients have hypothyroidism, 5 patients have hyperthyroidism and 16 patients have subclinical hypothyroidism.

Thyroid dysfunction was predominantly seen in female patients. Out of 198 female patients, 110 patients are in euthyroid state, 26 patients have hypothyroidism, 13 patients have hyperthyroidism, 42 patients have subclinical hypothyroidism and 7 patients have subclinical hyperthyroidism.

The two groups were similar in their distribution of age. Our study shows that in MetS patients of age group from 21-30 years have no thyroid disorder. In age group of 31-40 years, 25 patients have thyroid disorder, out of which, 5 patients have hypothyroidism, 5 patients have hyperthyroidism, 10 patients have subclinical hypothyroidism and 5 patients have subclinical hyperthyroidism. In age group of 41-50 years 33 patients have thyroid disorder, out of which, 15 patients have hypothyroidism, 3 patients have hyperthyroidism, 14 patients have subclinical hypothyroidism and 1 patient has subclinical hyperthyroidism. In age group of 51-60 years, 37 patients have thyroid disorder, out of which, 13 patients have hypothyroidism, 17 patients have subclinical hypothyroidism and 1 patient has subclinical hyperthyroidism. In age group of 61-70 years, 30 patients have thyroid disorder, out of which, 10 patients have hypothyroidism, 3 patients have hyperthyroidism, 17 patients have subclinical hypothyroidism. In age group of 71-80 years, 4 patients have thyroid disorder, out of which, 3 patients have hypothyroidism and 1 patient has subclinical hypothyroidism.

Our study shows that metabolic syndrome occurs most commonly in 51-60 years of age. In this age group 29.7% patients (89 patients) have MetS and in this age
group thyroid disorder are also very common in our study. In H K Tamang et al study showed that the people of age group of 40-60 years, had a higher prevalence of MetS which is in accordance with other study done in south Asian 9. Our study shows that subjects of age group of 41-50 years suffering from MetS occupy the second position in respect of prevalence. In this age group 27.3% (82 patients) have MetS. MetS patient in the age group of 61-70 years occupy the third position in order of prevalence. In this age group 21.7% (65 patients) have MetS. Subjects (patients) of age group of 21-30 years, 71-80 years and 81-90 years suffer less from MetS. In the age group of 71-80 years, 9 patients (3%) have MetS. In the age group of 21-30 years, 4 (1.3%) patients have MetS and in the age group of 81-90 years, 1 (0.3%) patients has MetS.

In our study 141 metabolic syndrome patients had WC between 100-109 cm, 94 patients had WC between 90-99 cm, 41 patients had WC between 110-119 cm, 17 patients had WC between 80-89 cm and 7 patients had waist circumference between 120-125 cm.

In our study, out of total MetS patients having WC between 80-89 cm, 8 patients have thyroid disorder. Out of this 8 patients, 3 patients have hypothyroidism, 2 patients have hyperthyroidism, 1 patient has subclinical hypothyroidism and 2 patients have subclinical hyperthyroidism. Out of total MetS patients having WC between 90-99 cm, 40 patients have thyroid disorder, out of which 13 patients have hypothyroidism, 6 patients have hyperthyroidism, 19 patients have subclinical hypothyroidism and 2 patients have subclinical hyperthyroidism. Out of total MetS patients having WC between 100-109 cm, 56 patients have thyroid disorder, out of which 21 patients have hypothyroidism, 19 patients have subclinical hypothyroidism and 2 patients have subclinical hyperthyroidism. Out of total MetS patients having WC between 110-119 cm, 23 patients have thyroid disorder, out of which 9 patients have a hypothyroidism, 5 patients have hyperthyroidism and 9 patients have subclinical hypothyroidism and 9 patients have subclinical hyperthyroidism. Out of total MetS patients having WC between 120-125 cm, have subclinical hypothyroidism.

**Conclusion**

Our study advocate that age, sex, WC is directly related to thyroid disorder in metabolic syndrome patients. In our study, it is evident that thyroid disorder and MetS are correlated and thyroid disorder (hypothyroidism or hypothyroidism developed in 43% MetS patients. Our study found that females had higher risk than male. More over aging is an important risk factor for MetS. Our result suggests the necessity of monitoring thyroid function test in MetS populations, especially elder women. For prevention of the dreadful diseases like DM, CV disease etc and better management of MetS patients.

Emotional Intelligence and its Correlation with Academic Performance of Dental Undergraduates

Harsh Parmar1, Pronob Sanyal2, Dhirajkumar Mane3, Ketki Kulkarni1, Shailaja Patil4

1Intern BDS, 2Professor and HOD, Department of Prosthodontics, School of Dental Sciences, 3Statistician, Directorate of Research, 4Clinical Psychologist, Psychiatry Department, Krishna Institute of Medical Sciences “Deemed to be University”, Karad, Maharashtra, India

Abstract

Background: Now days, Emotional intelligence (EI) has been strongly associated parameter for the health care providers, which includes dental practitioners also. EI have been inter-linked with variables such as Psychiatric, Physical and Satisfaction levels.

Aim & Objectives: The aim of this study was to determine and correlate EI scores and academic performance(AP) among undergraduate dental students.

Material & Method: This was a quantitative cross sectional study among total of 260 1st to 4th year BDS students enrolled at school of dental sciences, Krishna Institute of Medical Sciences “Deemed To Be University”, Karad (KIMSDU), in the academic year 2018-2019. The study tool used was Emotional Intelligence Scale (Situational) by Dr. P. Srinivasan and Mr. K. Murugesan which included demographic and EI based questions. The response rate was almost 92% that affects quality of results.

Result: It was found that EI was significantly associated with AP with p < 0.05.

Conclusion: This study proves that emotional skills development will enhance AP of medical undergraduates in Western Maharashtra.

Keywords: Emotional intelligence, emotional intelligence scale, dental students, dental education, academic performance.

Introduction

Emotional intelligence (EI) is defined as the ability to monitor one’s own and other people’s emotions, to discriminate between different emotions and label them appropriately, and to use emotional information to guide thinking and behaviour and to manage and/or adjust emotions to adapt to environments or achieve one’s goals. [1] EI constitute of interpersonal and intrapersonal intelligence. Differentiating between emotions has been found to help guide people’s actions and enhance their problem-solving skills. Interpersonal intelligence is the outer intelligence one uses to understand and manage relationships with the other people. This is important for developing qualities like empathy and building up effective relationships. Intrapersonal intelligence is the inner intelligence one uses to know and understand oneself which is important for self-awareness, self-regulation and self-motivation. It can be postulated that management of interpersonal and intrapersonal emotions is vital for an individual’s success in academic and professional fields. Those with higher EI have greater mental health, job performance and leadership skills and therefore are more likely to understand, regulate and manage emotions better both in themselves and in the others. [10] Improving EI has beneficial effect on academic, social and personal well-being of an individual. It constitutes of over-all development of an individual.

In the evaluation of EI, the following six components have been identified: self-awareness, self-confidence, self-control, empathy, motivation, and social competence. Self-awareness refers to individuals’ ability to recognize their own feelings and how their actions could potentially affect others. Self-confidence gives individuals the assurance that they are smart and professional, while individuals’ confidence that they can accomplish their goals, maintain their composure, and stay collected even in frustrating situations comes from self-control. Empathy allows someone to understand the feelings of another and know how to appropriately respond. Having motivation contributes to the continual pursuit of success not only in individuals’ careers, but in their personal endeavours as well. With social competence, effective and appropriate communication occurs due to enhanced social skills. The combination of these components provides an overall evaluation of EI.

Evidence indicates that in clinical practice, EI is related to improved empathy in medical consultation, better doctor-patient relationships, better clinical performance, and higher patient satisfaction. These findings highlight that EI plays a critical role in making a balanced doctor who is competent in practicing both the art and the science of medicine and thus preventing them from becoming victims of the inevitable stress associated with the medical profession.

Since dental students are expected to acquire diverse academic and clinical competencies and interpersonal skills, in the five-year dental education program in India, dental students pursue four years of study, followed by a clinical internship in the final year. In this study we decided to focus on the relationship between EI and AP of students from first to final year examination, for two reasons. Firstly the exams are considered to be the most emotionally demanding period for dental student. Secondly a higher level of EI is more likely to enhance AP at the examination.

The aim of this study was to assess students’ EI and its associated factors and to determine if there was an association between their EI and AP.

**Materials and Method**

The Study was conducted during the period of September 2017 to January 2017 in school of dental sciences (SDS), KIMSDU, Karad, Maharashtra, India. The study was approved by Institutional Ethics Committee of KIMSDU, Karad. Permission was obtained from the head of the institution of SDS, KIMSDU, Karad. The study used a quantitative cross-sectional research design. All first to fourth year undergraduate dental students of SDS were invited to participate in the study. After participants were provided with detailed information about the voluntary research study and an opportunity to ask questions, participants provided written consent.

The study tool used was Emotional Intelligence Scale (Situational) by Dr. P. Srinivasan and Mr. K. Murugesan which consisted of a questionnaire with two parts. The first part addressed demographic factors. Demographic variables were age, gender, Living area, marital status, educational Qualification and AP. The second part included a structured questionnaire on EI. It consisted of 40 questions, to assess domains of EI which are self-awareness, social awareness, self-management, and relationship-management. The questions consisted of different situations and the options were different reactions to these situations. There was no time limit for completing the scale. It was emphasized that there is no right or wrong answers to the statements. The statements were designed to understand the differences in individual reactions to various situations. No statements were to be unanswered as it would cause errors in interpretation of the EI. From the answer scale Raw score was obtained which was checked with Z-score and by the Z-score interpretation helped to obtain Grade and level of EI which ranged from A to G(Extremely High to Extremely low). The reliability was established by split half method and Cronbach’s alpha method and was found 0.62 and 0.71 respectively and validity was established by comparing two EI scales and 0.92 was significance between both scores.

Total 260 students from first to final year participated in the survey. A self-administered questionnaire was distributed after the students were informed about the nature of the study and assured that their responses would be confidential. Participation was voluntary and no other incentive was given. Participants took about 15 minutes to 20 minutes to complete the questionnaire but there was no time limit. For analysis of EI score of all the four domains were added to get the raw score which was checked with the z-score to get the grade and level of EI. For Academic score analysis, marks of the university exams were recorded which were converted to percentage so all the participants can be analysed equally and a fair result was obtained.
Statistical Analysis: All data were in form of hard copy was entered in Excel data sheets. Then all excel data were cooked in IBM SPSS (Statistical Packages for Social Sciences) 20.0 software for analysis and drawing conclusions. Here the correlation between academic performance and Emotional Intelligence was calculated by using Pearson’s correlation. Also the various parameters of emotional intelligence comparisons year wise were done by using ANOVA (Analysis of Variance). For comparing two independent groups we used unpaired t-test.

Hypothesis: There is a significant relationship between the emotional intelligence and academic performance of students

Result

Total 260 BDS students participated in this study, out of that 52 were males and 208 were females. Proportion of participation of female students were higher as compared with males, out of 52(100%) male students max. 22(43%) students were perusing 1st year of BDS, 12(23%) students were perusing 2nd year of BDS, while 10(19%) students were perusing 3rd year of BDS and 8(15%) students were perusing 4th year of BDS. Among 208(100%) female students’ 56(27%) students perusing 1st year of BDS, 59(28%) students were perusing 2nd year of BDS, while 10(19%) students were perusing 3rd year of BDS and also 34(17%) students were perusing 4th year of BDS. * Significant when P < 0.05

About 1st year students it (r = 0.01828, p > 0.05) means there was no statistically significant difference of academic score and EI. According to 2nd year students (r = 0.01125, p > 0.05) there was no statistically significant difference of academic score and EI, also in 3rd & 4th year students (r = -0.1117, P > 0.05) and (r = 0.2543, p > 0.05) respectively. In 3rd and 4th year students there was no statistically significant difference of academic score and EI. Positive value of correlation shows that academic score increased if score of EI increased. [See in Table 2]

</table>

*Significant when p < 0.05

Here from 1st to 4th year of BDS the mean score of EI of female students was high as compare to male students. There was no statistically significance difference among males and females students from 1st to 3rd year as p > 0.05. This suggests there was no relation between EI of male and female students of 1st, 2nd, 3rd year BDS Students. For 4th year BDS student we can say mean EI score of female students was statistically significant while compared to male students. The p < 0.05 shows there was statistically significance difference in 4th year BDS students between males and females in EI. [See in Table 5]

*Significant when p < 0.05

While comparing AP of 1st to 4th year among male and female students in BDS, here by above table (p > 0.05) hence we can say that there was no significant difference in their AP. [See in Table 6]
Discussion

The healthcare practitioners have specified as concoction of expertise clinician and a server directorate towards care givers. One’s EI may reflected by aptitudes for a service and caring. This study revealed that EI was an associated predictor of AP at BDS examination amongst SDS, Karad, Western Maharashtra which may be due to the huge size of data. On the other hand, Wijekoon CN et al. in their study has observed EI was independent variable for AP. But it was nearly same a response rate by Wijekoon CN et al. almost 92% which increases efficacy and quality of study. The other strength of this study is the concept EI performance which gives deeper encyclopaedia about a behaviour of student’s towards real life settings. We considered the 1st to 4th BDS examination results as our main study objective because it is considered to be the major summative assessment faced by the dental undergraduates. This result could indicate the significant presence of a direct EI effect on AP in dental education. Our study confirmed that EI was positively associated with AP. Similarly, our study suggests that certain parameters of EI are related to AP. Our study results highlighted the important link between the EI and AP of dental undergraduate. A very few number of study published before in India especially in western Maharashtra and also in Asian countries on this theme and it has found an association between higher EI and better performance during examinations.

This study revealed that out of 260 participants 52 were males and 208 were females. Proportion of participation of female students was higher as compared with males. Majority of the study had shown that the female student participant was more in such studies. Similarly, Kumar Amit et al. in their study male to female ration were 1:1.9. In our study the Pearson’s correlation between EI and AP was positive means there was definite functional relationship between EI and AP. But, statistically not significant likewise almost all of the study done in the past reflected this result. The findings of this study done in dental students strengthen the findings of the previous study which discussed about the fact of the link between EI and AP. Higher EI may count several reasons for the better AP. Ranasinghe et al. reported that among medical undergraduates from a different university in Sri Lanka, self-perceived stress score was lower in those with higher EI. Joseph et al. has reported that EI positively predicts performance in emotionally demanding situations.

Interpersonal EI is also important for nurturing positive relationships with the health care providers in the hospital, which in turn facilitates a smooth process of learning. Our findings with regard to the relationship between EI and AP are in keeping with the findings of several previous studies from different countries including India, USA, and Malaysia. The study done by Ranasinghe et al. has demonstrated the same trend. It is also worth mentioning that we did not use longitudinal data in our analyses of AP.

Conclusion

Among the dental undergraduates of the selected SDS, both EI and AP from 1st to 4th year BDS examination were higher among females as compared to males. Independent of gender, AP was better in those who were more emotionally intelligent. This study proves that emotional skills development will enhance academic performance of medical undergraduates. This proves our hypothesis that there is a significant relationship between EI and AP of students. Hence it is suggested to enhance EI of students by various techniques.

Influence of Aging on Cardiovascular System in Elderly Male and Female Healthy Subjects

I.N. Mitra\textsuperscript{1}, Lily Walia\textsuperscript{2}, B.K. Aggarwal\textsuperscript{3}, Gurdev Goyal\textsuperscript{4}

\textsuperscript{1}Student, Department of Physiology; \textsuperscript{2}Professor and Head, Department of Physiology; \textsuperscript{3}Professor, Department of Medicine; \textsuperscript{4}Associate Professor, Department of Physiology, MMIMSR Mullana, Ambala, India

Abstract

Objective: This Study Helps to find out the Significant changes of cardiovascular functions in Case of Male and Female Subjects with advancing age.

Material and Method: The Present Study Was Undertaken On Elderly 65 Years and Above Healthy, Non Smoker Subjects of Both Sexes. Subjects Were Selected Randomly From Puran Hospital OPD at Medicine Department, Paonta Sahib, H.P and MMIMSR Hospital, Mullana, Ambala, Haryana. The Cross Sectional Study Was Conducted On 1000 Subjects With Equal Number of Male and Female. The Mean Age of Male was 74.46 ± 8.41 And Mean Age of Female Was 73.59 ± 8.32. We Have Taken Healthy and Clinically Fit Subjects Those Who are 65 Years and above age. Cardiovascular Parameter Like - Blood Pressure that is Systolic Blood Pressure, Diastolic Blood Pressure, Pulse Pressure, Mean Blood Pressure and Heart Rate was Taken to conduct the Study.

Result: There Was Significant Correlation of age with Blood Pressure that is Systolic Blood Pressure, Diastolic Blood Pressure, Pulse Pressure, Mean Blood Pressure and Heart Rate.

Conclusion: All These Cardiovascular Parameter Correlate Significantly with advancing age.

Keywords: Aging Related Changes, Myocardium, Blood Vessels, Vascular Function, Blood Pressure, Heart Rate.

Introduction

Physiological declines in multiple systems in older adults is a new field of geriatric research. Ageing process is associated with progressive constriction of the homeostatic reserve of every organ. Aging can be defined as progressive accumulation of random molecular defects within tissues and cells. Physiological changes occur with aging in all organ systems. Growing older related modifications to cardiovascular concerned in particular lower in rates of the heart, extraction of oxygen, stiffening of the arteries, vasoconstriction, systolic blood pressure elevation, myocardial thickening, diastolic filling rate discount, in rhythmic rates alterations, and prolongation of movement capacity had been described in advance by exclusive researcher.\textsuperscript{1}

Getting older has usually been associated with accelerated casual Systolic Blood Pressure (SBP) and Diastolic Blood Pressure (DBP) and with reduced Heart rate (HR). In research of BP using intra-arterial and non-invasive ambulatory tracking techniques, older hypertensive and normotensive subjects have been observed to show extra variability for BP.\textsuperscript{2,3} It’s miles concept that the age-associated modifications in variability are related to changes inside the baroreflex and sympathetic/parasympathetic manipulate of the cardiovascular device. BP variability has been discovered to be an independencytance issue for cardiovascular morbidity and the price and severity of target-organ damage.\textsuperscript{4,5}

The “physiological” age-related increase in blood pressure can be a confounding element inside the dedication of age consequences on blood pressure variability. Definitely, incidence of hypertension with a conservative definition of blood pressure above 140/90mm Hg in patients aged above 65 years is better than 40%.\(^6,7\)

Many studies have proven that the maximum exercising coronary heart rate declines with age.\(^8,9\) Getting old is associated with adjustments in pacemaker tissue, a decrease in the responsiveness of autonomic cardiovascular reflexes, a decline in the intrinsic heart rate, and reduced adrenergic receptor sensitivity.\(^10-12\)

Results of cross-sectional studies, blood pressure increases with age. Each systolic and diastolic blood pressure tended to grow with age.\(^13,14\) The upward push of blood pressure with age is not an integral part of the aging process.

Presently, the aged represent a big and fast-growing percentage of the population that demanding situations cardiovascular research. Like hypertension, ageing has been shown to boom blood pressure variability. Coronary heart rate variability, however, decreases with increasing age and blood pressure. Because blood pressure rises with getting older.\(^15\)

The most important physiological changes associated with aging are of increase in Diastolic and Systolic Myocardial stiffness, perhaps due to increased interstitial decrease interstitial fibrosis in the myocardium. There is a increased stiffening of arteries with age, especially of the thoracic aorta, leading to an increased after load of the heart.\(^16\)

A progressive increase in blood stress after the first decade of life has long been seemed as a normal effect of ageing and was the foundation for ignoring the presence of hypertension in the elderly. Moreover cardiovascular disease was more frequent cause of death and morbidity in the hypertensive subjects older than 65 years of age than in the younger subjects.

Atherosclerosis clearly increases with aging. Raised fibrous plaques that contain lipid, atheromas, of the abdominal aorta increase linearly from onset by age 70 years. Myocardial infarction from coronary artery disease will increase with age and despite the fact that many risk factors are recognized, but age itself is probably the most significant.\(^17\)

The aim of this study was to establish cardiovascular values for normal, healthy elderly male and female people aged 65 and above population.

**Material and Method**

The present study was undertaken on elderly 65 years and above healthy subjects of both male and female. Subjects were selected randomly from Puran Hospital OPD at medicine department. Paonta Sahib, H.P. and MMIMSR Hospital, Mullana, Ambala, Haryana.

Cardiovascular Parameter like - Blood Pressure that is Systolic Blood Pressure, Diastolic Blood Pressure, Pulse Pressure, Mean Blood Pressure and Heart Rate was taken to conduct the study. The cross-sectional study was conducted on 500 male and 500 female elderly equally healthy subjects, those who were 65 years and above age. A written informed consent was obtained.

**Inclusion Criteria:**

1. Healthy individual without athletic training
2. Aged population 65 years and above age but clinically fit.

**Exclusion Criteria:**

1. All the subjects 65 years and above age with sign and symptoms of disease.
2. Subjects having on medication but clinically not healthy.

**Result**

The data was analysed by using SPSS version 20.0 for windows. Mean and standard deviation (SD) was calculated and reported for quantitative variables. The Spearman correlation coefficient was calculated of cardiovascular function parameters Systolic Blood Pressure, Diastolic Blood Pressure, Pulse Pressure, Mean Blood Pressure and Heart Rate. A p-value of < 0.01 was considered statistically highly significant, value < 0.05 was considered statistically significant and that > 0.05 was considered statistically non-significant.

There is positive correlation found in between age and systolic Blood Pressure, Diastolic Blood Pressure, Pulse Pressure, Mean Blood Pressure and Heart Rate. All these cardiovascular parameters significantly altered with age (Table 1 and Table 2).

Discussion

Aging is a progressive failure of body’s homeostatic adaptive response resulting in increased vulnerability to environmental stress and disease. The physiological sign of aging are gradual deterioration in function and capacity to respond to environmental stress. Aging is a general physiological on-going process and despite intensive research the mechanism of aging are still to be explored.\textsuperscript{18}

In this study the positively correlation was found between cardiovascular parameter like Systolic Blood Pressure, Diastolic Blood Pressure, Pulse Pressure and Mean Blood Pressure with age, and significant. Heart rate is not significantly correlated with age. These findings are similar to those of F Jaquet, IB Glodstein and D Shapiro, University of California, Los Angeles, CA, USA. According to their study SBP and DBP levels were significantly higher in the elderly group compare to normal. Age has been associated with increased blood pressure variability.\textsuperscript{19}

In our study Heart rate is not correlated with age significantly. This study is also similar with a study conducted by Laurence Fluckiger, Jean –Marc-Boivin, et al. those who reported that there was short term heart rate variability is impaired whereas Blood pressure variability is little affected by the aging process subject with normal blood pressure. This study also shows continuous negative correlation between age and spectral component of heart rate variability. The result suggest that the sympathetic and vagal components of heart rate are equally affected by aging.\textsuperscript{20}

The aspect of study by John B. Kostis, M.D., Abel E. Moreyra, M.D. et al., suggest that the fat that age did not affect the difference in heart rate between day and night also implies that variation in activity were not the only reason for the decline of maximum heart rate with age. Another cause may be decline in the capacity of the sinus node to increase the heart rate.\textsuperscript{21}

Overall blood pressure variability at rest does not increase with aging. This study is suggested by Dark P. Veerman, Ben P.M. Imholz et al. In other studies it has been found that ambulatory blood pressure variability is increased in the elderly. In their study the difference between the antioscillatory influence of heart rate which decreases with aging is less important at rest than in ambulatory conditions.\textsuperscript{22}

Other study by Mohamed Nabil Alama, who measured cardiovascular efficiency by blood pressure. According to their study with aging the baroreceptors become less sensitive which clear that many older people have hypertension.\textsuperscript{23}
Conclusion

The outcome of present study indicates that SBP, DBP, PP and MBP are significantly correlated with age but heart rate is not significantly changes with increase age. It indicates that cardiovascular function were dependent or number of factors. The result s obtained have both clinical and public health significance for evaluating the changes due to aging.

CVS is associated with many complex changes during aging both in structure and function. Which leads to alterations in of the cardiovascular physiology CVD and cardiac reserve diminishing, heart thickened and stiffens were increased by aging. There little diminishing in contractility of myocardium.

Incidence and Profile of Gross Congenital Malformations in a Tertiary Care Hospital in North India

Jagjit Singh Dalal¹, Rohit Kapoor², Sandeep Jhajra³, Manish Gupta⁴

¹Associate Professor, ²Junior Resident, ³Assistant Professor, ⁴Senior Resident, Department of Neonatology, Pt. B. D. Sharma Post Graduate Institute of Medical Sciences, Rohtak, Haryana

Abstract

Background: With better management of nutritional deficiency and infectious diseases, congenital malformations are becoming important cause of perinatal and infant mortality and morbidity in developing world. Due to lack of National Birth Defect surveillance the true magnitude of births affected by congenital anomalies in India is unknown. Need for data regarding congenital malformations arises so as to get the burden and to assess their impact on health and rehabilitation services in a developing country like India.

Objectives: To determine the incidence and profile of congenital malformations among live births at a tertiary care hospital in North India.

Method: A prospective analysis was carried from November 2016 to October 2018. All live borns during study period were included. Diagnosis of congenital malformations was based on clinical examination of newborn. Other investigations like Xray, ultrasonography of skull and abdomen and two dimensional echocardiography were done where required to rule out other associated anomalies.

Results: During the study period, there were 22,460 live births. Among them, 265 had congenital malformations resulting in an incidence of 11.8 per 1000 live births. Out of these, 245 babies had single and 20 babies had multiple congenital malformations. Out of these, 54.71% babies were males and 30.9% were preterm. Most of the mothers were multiparous (75%) and in the age group of 20-30 years (81.3%). The most common system involved was central Nervous system (20.75%) followed by cardiovascular system (20.75%) followed by gastrointestinal system (17.35%) and gastrointestinal system (15.84%). Meningomyelocele (10.5%) was the commonest anomaly in central nervous system.

Conclusions: The incidence of congenital malformations in our study was found to be 11.8 per 1000 live births. The most common system involved was central nervous system.

Keywords: Gross Congenital Malformations, Incidence, tertiary care hospital, Neonate.

Introduction

With improved control and better management of infections and nutritional deficiency diseases, congenital malformations are now becoming major cause of perinatal and neonatal morbidity and mortality in developing countries¹². According to CDC report, about 3% of all live births in USA are born with congenital malformations.³ True burden of the number of births affected by congenital malformations in India is unknown due to lack of a National Birth Defect surveillance. Worldwide, incidence of congenital malformations is 3-7%, however, geographic and ethnic variations exist between countries. In India, 2.5% infants are affected at birth accounting for 8-15% of perinatal and 13-16% of neonatal mortality⁴. Congenital anomalies constituted the fifth largest cause, being responsible for an estimated 9% of neonatal deaths in the year 2010⁵.
Need for data regarding congenital malformations arises so as to derive the estimates of their magnitude and to assess their impact on health and rehabilitation services in a resource limited country like India. Many of these conditions may be potentially preventable or treatable through simple low cost interventions like folic acid supplementation.

Aims and Objectives

To determine the incidence and profile of congenital malformations among live births at a tertiary care hospital in North India.

Material and Method

A prospective analysis was carried out in Neonatal Services from November 2016 to October 2018. All live born during study period were included. Diagnosis of congenital malformations was based on clinical examination of newborn done by pediatrician at the time of birth. Detailed history and physical examination was done. Various imaging modalities like radiography, ultrasound and MRI were done as per requirement. The anomalies diagnosed on pre-natal ultrasonography were confirmed clinically or by appropriate radiodiagnostic method soon after birth. Other investigations like radiography, ultrasonography of viscera, skull and 2D-echocardiography as and when required were done to rule out other associated anomalies. The neonates were managed accordingly either medically or surgically. Congenital malformations were divided into central nervous system (CNS), musculoskeletal, gastrointestinal, genitourinary, cardiovascular (CVS), respiratory, ear/eye/nose and multisystem disorders.

Results

During the study period, there were 22,460 live births. Among them, 265 had congenital malformations resulting in an incidence of 11.8 per 1000 live births. Out of these, 245 babies had single and 20 babies had multiple congenital malformations. Out of these, 54.71% babies were males and 30.9% were preterm. Most of the mothers were multiparous (75%) and in the age group of 20-30 years (81.3%). The most common system involved was Central Nervous system (20.75%) followed by Cardiovascular system (17.35%) and Gastrointestinal system (15.84%). Meningomyelocele (10.5%) was the commonest anomaly in central nervous system (Table 1).

Discussion

Increased incidence of anomalies in countries like India may be contributed by causes like inadequate periconceptional folic acid, low birth weight or intake of teratogenic drugs in pregnancy and consanguineous marriage. The causes of congenital abnormality may be genetic in 30–40% and environmental in 5–10% cases. Chromosomal abnormality constitutes around 6% of the genetic causes, single gene disorders constitutes about 25%, and multifactorial factors in about 20-30%. And the cause is not known in about 50%. A previous study from north India reported GCMF in 47 (1.64%) births with incidence of anencephaly (44.68%), talipes equinovarus (17.02%) and meningomyelocele.
Un-booked (2.07%) mothers had higher risk of malformation in-comparison to booked (1.01%); pre-term birth (5.13%) vs. term (0.73%); cesarean section (4.36%) versus vaginal delivery (0.62%). Also malformation was slightly higher in females, female: male ratio of 1.35:1. Our study included only live births they included all cases.

Congenital anomalies in babies were significantly associated with maternal factors like consanguinity, maternal age, previous child with gross congenital malformation, severe anemia and history of previous abortions. CTEV is the commonest congenital anomaly observed in musculoskeletal malformations. One study from east India reported incidence of musculoskeletal anomalies 4.4/1000 live birth. The incidence of CTEV in this study was 3 per 1000 live births, which was slightly higher than other Indian studies. Our study also shows CTEV as most common musculoskeletal anomaly. The Incidence was 0.84 per 1000 live birth. As per systemic review the live birth prevalence of hospital based studies in India for central nervous system 28.93 (95% CI 13.64–44.22), Musculoskeletal system 79.38 (95% CI 32.32–126.44), Cardiovascular system 23.04 (95% CI 4.69–41.39), Gastrointestinal system 37.72 (95% CI 26.41–49.03), Genitourinary system 28.41 (95% CI 16.18–40.65). The incidence of congenital malformations in our study was found to be 11.8 per 1000 live births, which is consistent with studies conducted in various parts of our country.

In our study, out of all malformations central nervous system anomalies constituted around 20.75% followed by Cardiovascular system (17.35%) and Gastrointestinal system (15.84%). The incidence of congenital malformations was found to be higher in multiparous females (75%). Our study had a limitation of being an exclusive hospital based study specially dealing with risk pregnancies. Big population based studies are required to know the actual prevalence and profile of congenital malformations in the population. The high rates of neural tube defect are noteworthy. To reduce neonatal and infant mortality, interventions should include pre-conceptional supplementation of folic acid, particularly in high-performing states. Designing of public health programs that incorporate folic acid supplementation into newly married couple counselling as well as those planning families has a role. Simultaneously, we must maintain a Birth Defects Registry which will be easily accessible. Knowledge about essential maternal care during pregnancy, fortification of food products of daily use, increasing awareness about congenital malformations and knowledge about the consequences of consanguineous marriages need to be enlightened to reduce the incidence of congenital malformations.

Conclusion

The incidence of congenital malformations in our study was found to be 11.8 per 1000 live births. The most common system involved is central nervous system followed by cardiovascular and gastrointestinal.

Attitude Towards Mental Illness among the Adolescents in Selected Colleges of Udupi District

Jeeva M.V., Michelle J.M., Preethika, Manjula

Abstract

Introduction: Mental illness refers to a group of disorders that affect the way a person thinks, feels and acts. The attitudes of the general public towards people with mental illnesses have been described as negative, stigmatizing, uninformed and fearful.

Objective: To determine the attitude of college students towards mental illness as measured by rating scale, to find the association between attitude and selected demographic variables like age, gender, religion, type of family, source of information and mental illness among the family members and to find the opinion about the informational leaflet on mental illness.

Methodology: The study was carried out among 173 adolescents aged between 16-19 years from selected Colleges. The colleges were selected by simple random technique and subjects by convenient sampling.

Results: Out of 173 subjects, (41.0%) were of 17 years old. Majority (52.0%) of the subjects were females and (90.8%) of them belongs to the Hindu religion. Majority (63.6%) were from nuclear family and all of them were from rural area. Most (39.3%) of them reported health personnel as the source of information. Only 2.3% subjects reported having mentally ill client in their family. Among 173 subjects, majority (54.9 %) had moderately favorable attitude and (45.10%) had favorable attitude. None of the subjects had unfavorable attitude. There was no significant association between mental illness and age ($\chi^2 = 4.669; p > 0.05$), gender ($\chi^2 = 0.031; p > 0.05$), type of family ($\chi^2 = 0.119; p > 0.05$), religion ($\chi^2 = 0.554; p > 0.05$), source of information ($\chi^2 = 0.904; p > 0.05$), and any family members suffering from mental illness ($\chi^2 = 0.040; p > 0.05$). Opinionaire on leaflet on prevention and management of mental illness revealed that, 57.4% of them strongly agreed that it is a good source of learning, agreed that the leaflet gave them sufficient knowledge(61.8%) and the information was very useful(61.3%).

Conclusion: The attitude of the adolescents were favorable towards caring for mentally ill people. Information leaflet will help in improving the attitude of adolescents towards mental illness.

Keywords: Attitude, Mental illness, Adolescents and Informational leaflet.

Introduction

Mental illness refers to a group of disorders that affect the way a person thinks, feels and acts. Attitude has long been known to influence behavior. The attitudes of the general public towards people with mental illnesses have been described as negative, stigmatizing, uninformed and fearful. More disturbing are the researchers indicating the societal knowledge and the attitudes towards people with mental illness may not have changed substantially in the past 30 or more years. Mental illness is estimated to affect approximately one
in five persons in the United States. Depression ranks first among illnesses that cause disability in the United States. It is a chronic, debilitating illness that occurs 2 to 3 times more frequently in women than in men and has a peak onset during the child-bearing years. Depression is the second leading cause of hospitalization for women of childbearing age in the United States. Anxiety and substance abuse commonly precede the onset of major depressive disorder and can be an indication for depression screening\(^1\). Gureje O, Lasebikan VO, Oluwanuga OE, Olley BO, Kola conducted a community survey to determine the knowledge and attitude in Nigeria among 2040 participants who were selected using multi-stage cluster sampling technique. The respondents commonly endorsed cause of mental illness was a belief that it could be due to possession by evil spirits (\(t = 30.2\%\)) following this trauma (\(t = 29.9\%\)), stress (\(t = 29.2\%\)) and hereditary (\(t = 26.5\%\)) were the possible causes. The study concluded that the stigma of mental illness is widely spread in Nigeria and the attitude towards mental illness is greatly fueled by notions of causations that suggest that the affected people are responsible for their illness and by fear.\(^2\) Mental illness still generates misunderstanding, prejudice, confusion and fear. People may be less willing to offer support and empathy if someone is suffering from mental illness rather than a physical health problem. The stigma is at times worse than the illness itself and to provide this knowledge to the adolescents the stigmatizing attitude can be reduced to some extent.\(^3\)

**Materials and Method**

In this study, the colleges were selected by simple random sampling and subjects by convenient sampling. The research tools used were, Tool 1: Demographic Proforma and Tool 2: Rating scale on attitude towards mental illness. Content validity of the tools was established by obtaining suggestions from seven experts. Reliability of the attitude scale was established by using Cronbach’s alpha. The tool was found to be reliable with value \(r = 0.8\). Pilot study was conducted to assess the feasibility of the study. Data were collected in selected colleges of Udupi district after taking the administrative permission. An informed consent was taken from the participants before administering the tool. The analysis was done based on the objectives of the study.

**Ethical consideration:** Administrative permission and ethical clearance were obtained before data collection. Informed consent from the participants obtained before conducting the study.

**Statistical Analysis:** The data were analysed using Statistical Package for the Social Sciences (SPSS) version 16.0. Frequency and percentage was computed to analyse the sample characteristics. The Chi-square test was used to find out the association between attitude scores and the demographic proforma

**Results**

Out of 173 subjects, (41.0%) were of 17 years of age. Majority (52.0%) of the subjects were females and (90.8%) of them belongs to the Hindu religion. Majority (63.6%) were from nuclear family and all of them were from rural area. Most (39.3%) of the subjects reported health personnel as the source of information. Only 2.3% subjects reported having mentally ill client in their family. Among 173 subjects, majority (54.9%) had moderately favorable attitude and (45.10%) had favorable attitude. None of the subjects had unfavorable attitude.

There was no significant association between mental illness and age (\(\chi^2 = 4.669; p > 0.05\)), gender (\(\chi^2 = 0.031; p > 0.05\)), type of family (\(\chi^2 = 0.119; p > 0.05\)), religion (\(\chi^2 = 0.554; p > 0.05\)), source of information (\(\chi^2 = 0.904; p > 0.05\)), family members suffering from mental illness (\(\chi^2 = 0.040; p > 0.05\)).

Among 173 subjects, most (57.4%) of the subjects strongly agreed that the information leaflet on prevention and management of mental illness is a good source of learning. Majority of them agreed that it’s interesting to read (64.2%) and is very useful (61.3%).

Discussion

The present study findings showed that, among 173 subjects, majority (54.90%) had moderately favorable attitude. None of the subjects had an unfavorable attitude. Singh AJ et al, conducted a study to assess the attitude of Indian urban adults towards mental illness and found that 73% considered mental patients as dangerous and difficult to understand, 79% considered as botheration in the neighborhood. Only one third of the respondents agreed that mentally ill patients can be of some use to the society, 85% favored the assignment of the jobs to the ex mental patients, 84% asserted that they have no hesitation in working with such people, 55% did not favor to have marital alliance and 64% did not favor ex mental patients to be tutors to their children. The study further revealed that 88% had a sympathetic attitude towards the patients and 74% were against harsh treatment or stern attitude towards mental patients. These findings support the findings of the present study. [4]

Gureje OS et al conducted a study to assess the attitude towards people with mental illness and the study revealed that most of the people were afraid to have a conversation with someone known to have a mental illness and a few would consider such a person for friendship. The closer the intimacy required for the interaction, the stronger the communities desire to keep a safe distance. Thus less than 4% considered marrying anyone with mental illness. These findings support the findings of the present study. [2]

Chiu MYL and Chan KKL, conducted a study to assess the discrimination with people with severe mental illness (SMI) revealed that more than half of all the respondents (55%) believed that the behavior and thinking of family members of the people with SMI were weird, 38% thought that siblings of people with SMI would also developed psychiatric problems while 41% thought that this would also be the case for their spouses, 74% thought that people with SMI should see a psychiatrist. [5]

Jane K, Calton T, Caroline F, conducted an exploratory study to explore the feasibility of a randomized controlled trial of the effects of two anti-stigma films on attitudes to serious mental illness and psychiatry among 82 medical students in Nottingham. The study findings revealed that, majority (n = 37; 80%) were White European; 28 (60%) had previous contact with a person diagnosed with a serious mental illness. there was a significant change in score in the intervention group over the three time points (n = 23, d.f. = 2, P = 0.026), with scores demonstrating a significant decrease from baseline to post-intervention (z = –2.614, P = 0.009) suggesting that students’ attitudes were less stigmatizing after the intervention. The study concluded that, Intervention films significantly improved general attitudes to serious mental illness and social distance, with a trend towards reducing perceived dangerousness. These effects appeared to attenuate during the students’ clinical placements, suggesting a possible interaction with their clinical experiences. [6]

Limitation of the Study: The study is limited to selected colleges of Udupi district. Therefore generalization of the study can be done only to the similar population.

Conclusion

The attitudes of the adolescents were favorable towards caring for mentally ill people. Information leaflet or any intervention will help in improving the attitude.

A Clinico-Epidemiological Analysis of Seropositive Cases of Tropical Infections and their Co-Infection in Tertiary Care Hospital in South India

Kristel Bhalla¹, Pooja Rao², Radhakrishna Manipura²

¹Undergraduate, ²Associate Professor, Department of Microbiology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Manipal

Abstract

Aim of the study: Tropical infections with similar presentations, makes diagnosis difficult. To determine the seroprevalence and clinic-epidemiological profile of malaria, dengue, typhoid, rickettsia and leptospirosis in clinically suspected patients and their co-infection to ease in the diagnosis and treatment.

Material & Method: The laboratory information system and medical records was accessed to find the rates of seropositivity and clinical epidemiological records for the above diseases during the study period. The data was entered and analyzed using statistical software Statistical Package for Social Sciences (SPSS) Version 11.5 and any significant associations were analyzed by using the Chi-square test.

Results: Dengue had the largest number of patients that tested positive (30%), and malaria had the least number (7%). A significant association (p < 0.05) was found for dengue for sex, place and residence and malaria for the place and residence and leptospirosis for age and sex. The most common symptoms these patients presented with were fever(98.7%), vomiting(33.6%), myalgia(49.5%) and headache(47.6%). Coinfections found in 16 patients (2.6%).

Conclusion: Among the 5 infections, dengue had the highest prevalence, and co-infections were seen mostly with dengue and other infections. Given the burden of these diseases, research for better and more accurate diagnostic modalities is required.

Keywords: Tropical infections, Co-infections, dengue, clinico-epidemiological.

Introduction

Malaria, dengue, typhoid, rickettsia, and leptospirosis are major health problems in tropical countries and are particularly endemic in South India. These infections present with acute undifferentiated fever and significant overlap of clinical symptoms which makes diagnosis difficult. Moreover, co-infections can occur. [¹, ²]

Serological method for diagnosis of these diseases remains the mainstay. [¹, ³] The study was taken up to determine the prevalence and the varied clinical presentations and the chances of existence of co-infections among these diseases.

With this background, this study was designed for a better understanding of these diseases and their diagnosis.

Materials and Method

This descriptive cross-sectional study was carried out from June 2018 to December 2018 in a study population of in patient department of clinically suspected cases of malaria, dengue, leptospirosis, typhoid and rickettsia that were admitted to the hospital.
The data collection was carried out from the laboratory information system to find the rates of seropositivity out of the total number of patients tested for the above diseases. Detection method used for malaria was Quantitative Buffy Coat, observed for presence of the Plasmodium spp. Thick and thin smears prepared from the above suspension for differentiating the Plasmodium species. Rickettsial infections detected by the Weil Felix test (PROGEN, Tulip diagnostics Pvt Ltd. Goa) Proteus antigen kit which contains Proteus OX2, OXK, and OX19 antigens. The patient’s serum was serially diluted and mixed with the progen suspension at room temperature and observed for agglutination. A titer of 1:80 and above indicates a positive test for typhoid. Widal tube agglutination test (Span diagnostic Pvt. Ltd. Bengaluru, India) was performed. Lastly, Leptospirosis and Dengue diagnosed by using PANBIO IgM ELISA (PANBIO diagnostics, Korea) in which antibodies against Dengue or Leptospira antigens in the patient sera are detected and value more than 11 panbio units are considered positive.

Next, the patient records from the medical records departments at the 2 hospitals of the clinically suspected cases of the above diseases analyzed for sociodemographic details, clinical manifestations, platelet count, creatinine, urea, AST and ALT levels as well as the prevalence of co-infections.

The data was entered and analyzed using statistical software Statistical Package for Social Sciences (SPSS) Version 11.5 and any significant associations analyzed by using the Chi-square test with a P value < 0.05 considered statistically significant.

Results

Out of a total of 6818 samples, 891, 5155, 341, 319, and 110 were tested for dengue, malaria, leptospirosis, and typhoid and rickettsia diseases respectively. Dengue had the highest number of patients that tested positive (30%), and malaria had the least. (7%). (Table 1)

Out of all the malaria cases admitted, 80.3% had vivax malaria, 11.8% falciparum malaria and 7.9% had mixed malaria with both the species being prevalent. While among the enteric fever cases, 86.4% of cases caused by Salmonella Typhi while the remaining 13.6% were due to Salmonella Paratyphi A. All the rickettsia cases were of Scrub typhus type.

Maximum dengue cases were reported in July (50.7%), Malaria (23% in July) and leptospirosis(32.7% in July). Cases throughout the 6 months with a slightly higher number of cases reported in July and August. Rickettsia and typhoid hardly showed any variation. (Figure 1)

Most of the dengue(43%), malaria(38%) and typhoid(50%) cases were seen in the age group of 26-45 years while most of the leptospirosis (51%) and rickettsia (60%) cases seen in the older age group of above 46 yrs. (Figure 2)

41.5 % of the cases reported were from Mangalore while the remaining 58.5 percent belonged to other parts of South Canara, North Canara, Kerala, and other states and 55.2% of the population was urban the remaining 44.8% was rural.

A significant association (p < 0.05) was found for dengue for sex, place and residence and malaria for the place and residence and leptospirosis for age and sex. No associations found for typhoid and rickettsia. (Figure 2 & Table 2)

The most common symptoms these patients presented with were fever(98.7%), vomiting(33.6%), myalgia(49.5%) and headache(47.6%). The fever was mostly intermittent (79.1%) and high grade (77.6%), except in case of typhoid which mostly presented with low-grade fever.

Bleeding manifestations mostly seen as conjunctival injection (22%), black/bloody stools (15%), hematuria(11%) and petechiae(10%).

The chief urinary complaint the patients presented with was oliguria (29% cases). The others had discoloration of urine(20%), burning micturition(17%) and hematuria(8%)

On examination, hypotension found in cases of Dengue, Malaria, and Leptospirosis in 6.3%, 8.6% and 4.1% of the cases, respectively. Icterus was seen in 24.5% of cases of Leptospirosis and 40% Rickettsia, while it was seen in only 0.8% and 6% of cases of Typhoid and Malaria respectively.
Per abdomen examination showed that tenderness was the maximum in leptospirosis cases (18.4%), hepatomegaly and hepato-splenomegaly were commonly seen in Rickettsia cases 20% each, and splenomegaly was most common among malaria cases (0.6%). Thrombocytopenia was high in number in cases of Dengue (72.3%), Malaria (82.9%), Leptospirosis (81.6%) and Rickettsia (80%) but only 13.6% of typhoid cases.

Highest creatinine (3) and urea (78) values were found in leptospirosis indicating deranged RFT, and highest AST (207) and ALT (172) values were found in rickettsia (172) indicating deranged LFT (Table 3).

Complications mainly seen in Rickettsia and Leptospirosis were 80% and 61.2%, respectively. Whereas Dengue (9%), Malaria (13.2%) and Typhoid (13.6%) presented with complications in very few cases.

The complications seen in Rickettsia were pleural effusion (33%), pulmonary edema (17%), Acute Renal Failure (17%), Myocarditis (17%) & pneumonia (16%). In Leptospirosis, acute Renal Failure (52%), multi-organ dysfunction (14%), Septicemia (10%), Pancreatitis (10%), Pleural effusion (7%), ARDS (7%).

Out of the 607 patients admitted, coinfections found in 16 patients (2.6%), and most coinfections found with malaria and dengue followed by dengue and leptospirosis. (Table 4)

**Discussion**

In our study, the most seroprevalent infection was dengue (30%), which is much more than the study carried out by Sushi et al. probably because the study was carried out during different years and our sample size (607) was larger than this study (100). Least seroprevalent is malaria (7%) lesser than the study conducted by Birhanie et al. these differences are probably because of a high degree of suspicion for malaria among clinicians because of its endemicity in Mangalore.
Out of the seropositive cases, the most common etiology was dengue (62.4%), followed by malaria (25%) leptospirosis (8.1%), typhoid (3.6%), rickettsia (0.8%). However, the study by Sushi et al. showed that leptospirosis (46%) was a much more common etiology than dengue (17.4%).[2] This difference is probably because our study was conducted from July to December while this study was conducted from March to August. The study by Abrahamsen SK et al., shows that the frequency of typhoid cases is similar to our study, however, malaria cases were much lower and rickettsia cases higher in frequency.[4] This is probably once again because of the difference in the study period as this study was conducted from July to August.

In our study among the malaria cases, *Plasmodium vivax* (80.3%) was most prevalent followed by *P. falciparum* and mixed malaria. This was different from the study conducted by Birhanie et al. in Ethiopia, in which *P falciparum* and Vivax malaria were detected in almost equal number followed by mixed malaria (15.1%).[1] This can be attributed to geographical and seasonal variations. The same study shows 100% prevalence of S. Typhi cases, and no Paratyphi cases incase of patients diagnosed with enteric fever, which is comparable to our study in which 86.4% cases are of S Typhi and remaining 13.6% were S Paratyphi.[1]

Our study showed that maximum dengue cases reported in July during the rainy season when mosquito breeding increases whereas the study by Leelarasamee et al. suggested that dengue cases peaked in December and Leptospirosis detected throughout the year similar to our study. This is probably because outbreaks of dengue occurred at different periods in the two studies, during the monsoon in our study and during winter in their study.[6]

Dengue was mostly found in with the male population, South Canara district and rural areas probably because this region is endemic for dengue and exposure of males to Aedes mosquito at their work place or while traveling. This is in similarity with the study by Anker M et al.[7] that showed significantly more males getting affected by dengue but is contradicted by the study conducted by Yew et al.[8] Malaria was associated with South Canara and urban population due to its endemicity in the area. Leptospirosis mostly occurred in the male population and age group of above 46 yrs which might be because males are more involved in agricultural activities and an older age group would be associated with decreasing immunity and increased susceptibility to getting infected. The middle age group seems to be more susceptible to various tropical infections.

The most common symptoms these patients came with were fever, vomit, myalgia, and headache the warning signs in Dengue which is similar to another study by Leelarasamee et al.[6] Fever was present in almost all patients which are in accordance with the other studies. Also similar to the study by Sushi SK et al. fever was mostly intermittent (79.1%) and high grade (77.6%).[21%]. Except in case of typhoid where in low-grade fever is most common feature. In our study, dengue presented with cough (15%) and typhoid with abdominal pain (36.4%), the warning signs in Dengue which is similar to another study conducted by Sushi et al.[2] Rickettsia cases present with diarrhea (40%) which is similar to the study by Phongmany et al in which it is 35% but urinary manifestations in our study are in 60% whereas in this study they are 3% of the cases probably because of the huge difference in sample size of both the studies and also because the only urinary symptom this study has considered is dysuria where as our study encompasses burning micturition, hematuria, oliguria and discoloration of urine.[5]

Hepatomegaly was present in 20% rickettsia cases in our study while in 30% cases in the study by Phongmany et al which might again be due to difference in the sample size. However both studies showed hepatomegaly in a large number of cases.[5] Thrombocytopenia is mainly found in dengue (72.3%) and malaria patients (82.9%) which was also a common finding in Dengue in another study.[9] While the most deranged RFT was seen in leptospirosis and LFT in rickettsia.

Maximum Complications were seen in Rickettsia and leptospirosis cases – as high as 80% and 61.2% respectively. The main complication in rickettsia was pleural effusion (33%) and in leptospirosis was acute renal failure (52%) similar to the study by Ramesh HK et al. in which ARF was the main complication.[10]

In our study, the prevalence of coinfection was 2.6%. Out of which maximum coinfection was seen with dengue and malaria unlike the study by Sushi SK et al in which maximum coinfection occurred with leptospirosis and typhoid.[2] Our study also had a case of malaria and typhoid coinfection, but the prevalence was much lesser than the study conducted by Birhanie et al. this is probably because of the much larger prevalence
of dengue patients in our study as compared to other diseases.[1] Co-infection of Dengue with malaria and leptospirosis was elaborated in a another study. [11] Studies have shown a high incidence of Dengue prevalence along with Typhoid illness.[12]

**Conclusion**

Among the 5 infections, dengue had the highest prevalence. *P. vivax* was the most common etiological agent for malaria and *S. typhi* for enteric fever.

Main presenting symptoms were fever, vomiting, headache, and myalgia for all the diseases. Malaria presented with a good number of cases of weakness and abdominal pain, whereas dengue presented with cough and bleeding manifestations, typhoid with abdominal pain and low-grade fever, rickettsia with diarrhea and abdominal pain and leptospirosis with bleeding manifestations.

Confections were seen mostly with dengue and other infections (most commonly dengue and malaria). Co-infection was also seen with malaria and typhoid. No deaths were reported.

The results of this study are similar to other studies but are also contraindicated by some, which means that more thorough research is still required in this area. Given the burden of these diseases, research for better and more accurate diagnostic modalities is required for prompt diagnosis and early treatment.

Correlation between Neutrophil-Lymphocyte Ratio and Proteinuria in Diabetes

Meenakshi Shetty¹, Mohammed Ahmed Hussain², Jayakumar Jeganathan¹, Pavan M.R.¹

¹Associate Professor, ²Resident, Department of Medicine, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, Karnataka, India

Abstract

Introduction: To study the relationship between Neutrophil-lymphocyte ratio and proteinuria in diabetes.

Materials and Method: This was a cross-sectional study 196 diabetic subjects. They were divided into no nephropathy, incipient nephropathy and overt nephropathy. The Neutrophil lymphocyte ratio was compared between the three groups using Mann Whitney U test. Pearson's correlation was used to compare the other parameters between the three groups.

Results: There was significant difference between the median Neutrophil lymphocyte ratios in the three groups. The median NLR in patients with ‘no nephropathy’ was 2.69 (1.64-2.53). In patients with ‘incipient nephropathy’ was 2.77 (1.81-4.65). In patients with ‘overt nephropathy’ was 3.77 (2.01-5.39). A value of 2.752 of NLR can be taken as a cut off for predicting Overt Nephropathy with 74% sensitivity and 50% specificity.

Conclusion: Being a commonly available and cheap test, NLR can be advocated as a useful screening test in diabetics to predict the development or presence of diabetic nephropathy.

Keywords: Neutrophil, lymphocyte, Ratio, diabetes mellitus, nephropathy.

Introduction

Diabetic nephropathy is one of the most common microvascular complication of long standing Diabetes Mellitus. It is imperative to develop tools and strategies that can detect proteinuria in diabetics at an early stage so that interventions to reduce the risk of progression of incipient nephropathy to overt diabetic kidney disease can be undertaken. Inflammation has an important role in the pathophysiology of diabetic nephropathy. An index has been recently generated, Neutrophil to Lymphocyte ratio (NLR) to reflect both neutrophil elevation, due to the acute state of inflammation, and lymphopenia, which happens following physiological stress. Neutrophil to Lymphocyte ratio (NLR) is the ratio of neutrophils to lymphocyte in the peripheral blood. It has been studied as a marker of inflammatory state in the body.¹ Neutrophil to Lymphocyte ratio (NLR) can be used as an inexpensive screening test in diabetics if it shows a relationship with proteinuria in diabetics. Our study aims at consideration of NLR as an inflammatory marker that can be correlated with the severity of diabetic nephropathy.

Materials and Method

The main aim of this study was to study the relationship between NLR and proteinuria in diabetic patients. The primary objective was to divide the diabetics into three groups as No nephropathy, incipient nephropathy and overt nephropathy and to compare the NLR between these three groups. The secondary objective of this study was to assess the utility of NLR as a predictive tool for diabetic nephropathy. This was a cross-sectional study done on patients with Type 2 diabetes. The sample size calculation with 90% power and 95% confidence interval came to 117 (39 in each...
Clearance was obtained from the Institutional ethics committee. Informed consent was obtained from all the participants. People with Active infection, chronic inflammatory disorders, urolithiasis and on drugs (Angiotensin converting enzyme inhibitors and Angiotensin receptor blockers) were excluded. A detailed history and examination was done on all participants. HbA1c, serum creatinine, Urine Protein-creatinine ratio, urine routine, ECG and complete blood picture were performed on all subjects. The patients were divided into three groups: 1. No nephropathy: Spot Urine Protein: Creatinine ratio ≤ 150 mcg/mg of creatinine, 2. Incipient Nephropathy: Spot Urine Protein: Creatinine ratio 150-500mcg/mg of creatinine. 3. Overt Nephropathy: Spot Urine Protein: Creatinine ratio > 500mcg/ mg of creatinine.

Statistics: For Primary objective Kruskall Wallis test and Mann Whitney U test were used as tests for statistical significance. For secondary objective ROC curve was plotted and Area under curve calculated. Pearsons correlation test was done to see the degree of correlation between NLR and Proteinuria.

Results

A total of 196 participants participated in the study. 62.8% patients were males in the study. 37.2% patients were females in the study. The maximum number of patients in our study were between the ages of 51-60 years accounting for 27% of the total studied population. 25% patients were in the age group 41-50 years which formed the second largest age group in our study. 31.6% of participants had diabetes for 6-10 years and 23% had diabetes of 11-15 years prior to the study. The maximum number of participants, 112(57.1%) were on treatment with oral hypoglycemic agents alone. This was followed by treatment with Insulin alone with 59 participants (30.1%) 23 participants were on combination of Insulin and Oral hypoglycemic agents. 40 (20.4%) patients did not have nephropathy. 78 (39.8%) patients had incipient nephropathy. 78 (38.8%) patients had overt nephropathy. There was significant difference between the median NLR values in the three groups, Kruskall Wallis test (p = 0.03). The median NLR in patients with ‘no nephropathy’ was 2.69 (1.64-2.53). In patients with ‘incipient nephropathy’ was 2.77 (1.81-4.65). In patients with ‘overt nephropathy’ was 3.77 (2.01-5.39). When compared individually (Mann Whitney U test), there was no significant difference between median NLR values of ‘no nephropathy’ and ‘incipient nephropathy’ groups (p = 0.391). However, there was significant difference in median NLR values between ‘no nephropathy’ and ‘overt nephropathy’ groups (p = 0.02), and also between ‘incipient nephropathy’ and ‘overt nephropathy’ groups (p = 0.04). Pearsons correlation was used to check for the correlation between various parameters and urine protein creatinine ratio as seen in Table 1. As NLR increased, Urine Protein creatinine ratio increased with a correlation coefficient of 0.141 which was statistically significant (p = 0.048). As creatinine increased, Urine Protein creatinine ratio increased with a correlation of 0.455 which was also statistically significant (p = 0.006). There was significant difference in serum creatinine levels in the three groups, the mean serum creatinine being 0.91(±0.31) in patients without diabetic nephropathy, 1.08(±0.45) in patients with incipient nephropathy and 2.91(±3.17) in patients with overt nephropathy. There was no significant difference between Glycated Hemoglobin levels in the three groups in our study. The mean HbA1C was 8.05(±1.68) in patients without diabetic nephropathy, 8.16(±1.75) in patients with incipient diabetic nephropathy and 8.31(±1.68) in patients with overt nephropathy. When an ROC curve was plotted between NLR and patients with Overt Nephropathy, with 95% confidence interval, lower bound of 0.597 to upper bound of 0.749 was observed with area under the curve 0.673 and was significant. A value of 2.752 of NLR could be taken as a cut off for predicting Overt Nephropathy with 74% sensitivity and 50% specificity. So, NLR can be considered as fair test for predicting overt Nephropathy in diabetic patients.

Discussion

The study was started with the premise of considering Neutrophil Lymphocyte Ratio as a useful screening test for detecting Diabetic Nephropathy. Our study showed that there was no significant difference in the NLR value when comparing patients with No diabetic nephropathy to Incipient nephropathy. However, there was significant difference in median NLR values when comparing Overt Nephropathy with the other groups. Kahraman et al.,
in their study also found a linear increase in NLR in comparison to the urinary albumin excretion. However, their study was a retrospective study. In a study done by Moursy EY et al., they found that Diabetic patients with microvascular complications had higher median NLR values when compared to Diabetic patients without microvascular complications. Khandre SA et al., studied 115 diabetic patients and found that NLR had significant correlation with urinary albumin excretion. In our study a cut off of NLR value above 2.752 was useful in predicting the presence of nephropathy. Lingling Huang et al., in their study found that a NLR above 1.758 was found to correlate with the presence of diabetic microvascular complications. There was no significant difference between Glycated Hemoglobin levels in the three groups in our study. This is consistent with previous studies done by Cüneyt K et al., which also showed no significant difference between the mean HbA1C values in patients with normoalbuminuria, microalbuminuria and macroalbuminuria. There was significant difference in serum creatinine levels between the three groups in our study. This was similar to earlier studies done by Cüneyt k et al., which also showed a worsening of serum creatinine as there was increase in degree of proteinuria.

Conclusions

There was no significant difference in the median NLR values between the ‘no nephropathy’ and ‘incipient nephropathy’ groups. However, there was significant difference in median NLR values between ‘no nephropathy’ and ‘overt nephropathy’ groups and also between ‘incipient nephropathy’ and ‘overt nephropathy’ groups. A value of 2.752 of NLR can be taken as a cut off for predicting Overt Nephropathy.

Ethical Clearance: Taken from the institutional local ethics committee before the start of the study.

Changes in the Brainstem Auditory Evoked Potentials in the Chronic Obstructive Pulmonary Disease

Monika Kamra¹, Lily Walia², Sonia Kochhar³

¹Scholar, Department of Physiology, Maharishi Markandeshwar Institute of Medical sciences and Research, Maharishi Markandeshwar University, Mullana, Ambala, ²Professor and Head, Department of Physiology, Maharishi Markandeshwar Institute of Medical Sciences and Research, Maharishi Markandeshwar University, Mullana, Ambala, ³Associate Prof, Department of Physiology, AIIMS, Bathinda

Abstract

Chronic obstructive pulmonary disease is characterized by progressive and irreversible pulmonary airway obstruction. Brainstem auditory evoked potentials (BAEPs) are the voltage changes generated in the brain. BAEPs are recorded from the ear and vertex after application of auditory click stimuli to the auditory pathway.

Aims and objectives: To find out the changes in the Brainstem Auditory Evoked Potential values in the Chronic obstructive pulmonary disorder (COPD) patients and to know the effect of severity of COPD on the same.

Materials and Method: The study was conducted in the department of Physiology, Maharishi Markandeshwar Institute of Medical sciences and research, Mullana (Ambala). There are total number of 150 subjects in our study in between the age group of 35-65yr. There are two groups: 1. Control group 2. Study group. Each group consists of 75 subjects containing both males and females.

Result and analysis: There was no significant difference in the age in control and study group. PFT parameters showed highly significant changes in the COPD as compared to control group. Wave-V shows significant prolongation in left ear (p-value 0.04) and highly significant prolongation in right ear (p-value 0.006) in COPD patients. Interpeak latency I-III of right ear showed significant prolongation (p-value 0.01) in COPD patients. I-V interpeak latency of left and right ear showed highly significant prolongation (p-value less than .001) and amplitude of wave I-Ia also showed significant reduction in COPD group (p-value 0.04). There is significant delay in latency of wave-I of left side (p-value 0.03) with increasing degree of severity of COPD. None of the other absolute wave latencies and interpeak latencies show any significant change with degree of severity of the disease.

Conclusion: In our study, there are significant changes are seen in the BAEP values in COPD patients. These significant results may be due to excessive smoking induced hypoxia which in turn affects the auditory mechanism and hence BAEP values.

Keywords: COPD, BAEP, PFT, Wave-V, p-value.

Introduction

Chronic obstructive pulmonary disease is characterized by progressive pulmonary airway obstruction. Recurrent and progressive episodes of COPD effects the normal O₂/CO₂ exchange. With advancement of age, it gets more worse. It is a major public health challenge worldwide. Globally, due to increased exposure to risk factors and aging of the population, the burden of the disease is increasing³¹.
COPD is the 4th leading cause of death in the world. In 2012, more than 3 millions people died due to COPD. By 2030, it will be the 3rd leading cause of death. A step has been taken by the US National heart, lung and blood institute and world health organisation to form a Global Initiative for Chronic Obstructive Lung Disease (GOLD). The disease is associated with various extrapulmonary manifestations like various cardiovascular, neurological and metabolic disorders. It also leads to the anxiety and depression. Excess cigarette smoking may lead to neuropathy in COPD patients due to hypoxic damage to the receptors. Auditory receptors also gets affected with developing hypoxia in COPD. Brainstem auditory evoked potentials (BAEPs) are the voltage changes generated in the brain. BAEPs are recorded from the ear and vertex after application of auditory click stimuli to the auditory system. BERA consists of five or more waveforms generating within 10msec after acoustic stimulation. These auditory click stimuli are given to assess the conduction via auditory nerve up to midbrain. They measure the functional integrity of the auditory pathway.

COPD leads to the hypoxia, hypercarbia and acidosis which further causing polyneuropathy. Recurrent and progressive episodes of COPD may lead to the non-arteritic anterior ischaemic neuropathy in middle aged people. Excess smoking affects the pontomedullary region of the brain. Smoking leads to the production of more nicotine and carbon-monoxide which affects the oxygen level to the cochlea.

BERA findings have much clinical importance in various disease like multiple sclerosis, neuropathy, diabetes mellitus etc. Many studies have evaluated the association of BERA abnormalities with COPD, but these have given variable data. There is also a lack of adequate data on BERA changes in COPD in India because of less studies have been done here. The present study was done to determine the effect of chronic obstructive pulmonary disease in BAEP findings i.e. wave latencies in ms and amplitude in μv and to study the correlation of the observed abnormalities with the severity of COPD.

**Material and Method**

The study was conducted in the department of Physiology, Maharishi Markandeshwar Institute of Medical sciences and research, Mullana (Ambala). Institutional ethics committee approval had been taken. There are total number of 150 subjects in our study in between the age group of 35-65yr. There are two groups: 1. Control group 2. Study group.

Each group consists of 75 subjects containing both males and females. Study group have 75 COPD patients containing both males and females and control group have 75 healthy subjects.

Written consent was obtained from all the subjects after explaining them the details of the study in their own language.

**Inclusion Criteria:** In the study group, those with COPD, aged 35-65 years with no past/present or family history of ear disease and deafness were included. The diagnostic method of COPD was based on GOLD criteria. In the control group, non- COPD, age matched subjects who had no past/present or family history of ear disease and deafness and who were apparently healthy were included.

**Exclusion Criteria:** Those having a positive personal/family history of any kind of ear surgery, any trauma, and disorders (e.g. Multiple sclerosis, Vitamin B12 deficiency etc), diabetes mellitus, hypertension, malnutrition, head trauma, chronic alcohol, CNS disorders (e.g. stroke, parkinsonism, epilepsy etc), any history of medication that can effect the normal functioning of CNS (antidepressants, antipsychotic, antiepileptic, sedatives, ototoxic drugs,) will be excluded from the study.

**Study Tools:** The equipment used was Allengers Scorpio EMG EP NCS software.

**Procedure:** Preliminary examination: Prior to BERA recording, history will be taken from all the participants after which they will be subjected to a complete General Physical Examination including a full ear check up. All the relevant details of the subjects will be noted in a proforma. Pulmonary function test were performed in all the subjects. Lung volumes and capacities were determined by the spirometry. The parameters assessed are FVC, FEV1, FEV1/FVC by computerized helios software. Pure tone audiometry was done prior to the recording. Complete external ear examination was done for both ears by physician. Anthropometric data was recorded and subjects were screened for any history of drug intake or medical illness which are likely to affect the BAEP study parameters based on clinical history and physical examinations including detail auditory assessment.
Recording: The subjects will be instructed to take a sound sleep in the previous night and to avoid using mydriatic/meiotic drops, at least 12 hours before the test. BERA was performed using a standardised procedure. Skin electrodes were used. Skin was prepared by cleaning. Conduction jelly was used to ensure good, stable electric connection. Left and right ears were tested separately. The scalp electrodes will be placed relative to bony landmarks, in proportion to the size of the head, according to the International 10/20 system.

Placement of electrodes: Reference electrode ($C_z$)- at vertex, Recording electrode (E)- at mastoid bone, Ground electrode ($F_z$)- at forehead or connected to the right forearm.

Automatic artifact rejection was used. Sweep velocity was 1ms. Click acoustic stimuli at a rate of 11 pulse per second at an intensity of 90 db hearing level to the ear stimulated and masking sound of 40dB in non stimulated ear was given through head phones. Electrical activity had low cut filters 100 Hz and high cut filters 3000Hz to avoid any electrostatic and electromagnetic interferences. 1000 auditory clicks were averaged. Rarefaction was chosen in those side of head phone in which diaphragm moves away during auditory clicks.

Statistical analysis: Data was analysed with the help of unpaired t-test statically and data is expressed as mean ± standard deviation. To analyse the data according to the severity of COPD, one-way ANOVA has been done.

Result and analysis: Our study comprised of 150 subjects including both males and females of age group 35-65 yrs. Subjects are divided into 2 groups- Study (COPD) group and Control group. PFT values in control group and study group with P value are shown in Table-1.

Table-1: PFT values in Control and COPD group with p-values.

Discussion

In our study there are significant changes in BERA values in COPD patients. COPD and chronic hypoxia affect the functional integrity of auditory pathway. These effects are due to hypercarbia, hypoxemia and acidosis which further causing the damage to the vasa-nervosum and further leading to polyneuropathy[8].

Study done by Hafez et al[11] and Singh et al[12] also favor our study who found delayed latencies in BAEP in hypoxic conditions. Our study results are also in accordance with the study done by Shabina et al[13] who found BAEP abnormalities in COPD patients. These results are due to damage in ponto-medullary region of brain by excess smoking. Atis et al[14] also found abnormal BAEP pattern in severe COPD patients. They showed involvement of auditory component of 8th cranial nerve and impaired brainstem function in severe COPD. Our results are in contrast to the study done by Martins et al[15] and Nakano et al[16] who found no significant difference in inter-peak latencies I-V in smokers and non-smokers and in chronic respiratory insufficiency patients in their study.

El-kady et al also favors our study who found significant changes in audiological parameters between control and COPD subgroups[17]. Study done by Howard et al also favors our study who stated atherosclerotic damage in the central nervous system due to excess smoking.[18]

Conclusion: In our study there are significant effects are present in BAEP values in COPD patients. These significant results are due to excessive smoking induced hypoxia which in turn affects the auditory mechanism and hence BAEP values. Hypoxia produced by excessive smoking may also leading to the slowing of processing of information with in the brain.

Emotional Intelligence and Happiness

Nitin Girdharwal

Associate Professor-Research, Krishna Institute of Engineering & Technology, Ghaziabad-NCR, India

Abstract

Emotional intelligence refers to understanding and managing one's own and others' emotions effectively. It is linked to a wide range of positive outcomes like higher academic achievement and better work performance. Furthermore, theory also suggests that emotionally intelligent individuals are most likely to experience a higher level of psychological Wellbeing. Thus, emotional intelligence has become an important topic of research worldwide in relation to various variables like personality, empathy, self-efficacy, interest, achievement, performance etc. The present study aimed at understanding the relationship between emotional intelligence and happiness as well as to find out the profession-wise differences in these variables. Since emotional intelligence and happiness are getting extremely important with reference to today's workplace contexts, in this study individuals from the Army, Teaching and Creative field were studied. Also, to get an increased and better understanding, a sample of college students was also included. A total of 88 participants were studied using The Assessing Emotions Scale (Schutte et al., 1998), Subjective Happiness Scale (Lyubomirsky & Lepper, 1999) and a structured open ended questionnaire prepared by the research. In the current time, where we are living in a global village, being sensitive towards ourselves as well as to our surroundings is a crucial need. Thus, this study provides various implications for enhancing emotional intelligence and happiness.

Keywords: Emotional Intelligence, Happiness, Profession.

Introduction

Emotional Intelligence: The concept of emotional intelligence first emerged during the 1990s breaking away from the rigid notions of IQ being the sole determinant of success in one’s life. The term “emotional intelligence” was coined by Mayer and Salovey in 1990.

Emotional intelligence is the ability to perceive emotions, to access and generate emotions so as to assist thought, to understand emotions and emotional knowledge, and to reflectively regulate emotions so as to promote emotional and intellectual growth” (Mayer & Salovey, 1997)1.

According to (Mayer and Salovey 1990)2, emotional intelligence refers to a set of skills that is instrumental in understanding emotions and its effective regulation in oneself and others, and the use of feelings to motivate one-self, plan and achieve greater heights in life.

Happiness: In earlier times, happiness was understood in the context of need or goal satisfaction but with changing times, the focus has shifted on the positive aspects and ways in which the positive affect can be enhanced to maintain a state of happiness.

The concept of happiness can be studied under two constructs given by Aristotle:

1. Hedonistic Approach wherein the focus is on the basic nature of happiness i.e. attaining pleasure and avoiding pain.
2. Eudaimonic Approach wherein the focus is on meaning in life and self-realization.

Relationship between Emotional Intelligence And Happiness: Emotional Intelligence and Happiness, both are positive psychology constructs. Various studies have also helped in determining a positive relationship between emotional intelligence and happiness. A study by (Chamorro-Premuzic, Bennett and Furnham (2007)3 aimed at examining the relationship between emotional intelligence, the big five personality factors and happiness. Results revealed that stability, extraversion, agreeableness and conscientiousness positively correlated with happiness and trait emotional intelligence. Also, trait emotional intelligence explained shared variance between happiness and the big five personality factors. Similar results were also obtained by (Furnham and Petrides 2003)4 in their study as they
found that there exists a positive relationship between trait emotional intelligence and happiness in the presence of the big five personality factors.

**The Present Study:** Theory and research have illustrated the importance of emotional intelligence. Emotional intelligence has implications in various domains of life as academics, health, Wellbeing, workplace performance etc. Emotional intelligence also plays a crucial role in happiness. Although the relationship between emotional intelligence and happiness has been explored before yet it has not been studied in relation to the waste context. Since various professions have distinct profile, duties and challenges hence they might also bring in differences in individuals in terms of emotional intelligence, happiness as well as the relationship between these variables. Also very few such studies have been done in the Indian context with respect to emotional intelligence and happiness especially in the context of various professions. In today’s developing world, where the world is becoming a global village, it is a priority to sort oneself emotionally and get ready to face the life stressors especially at the workplace where competition is immense. Hence, this study was carried out to find out the relationship between emotional intelligence and happiness among various professions.

**Objectives:**
1. To study the differences in emotional intelligence and happiness of people belonging to different professions.
2. To study the relationship between happiness and emotional intelligence in people belonging to different professions.

**Hypotheses:**
H1. There are no differences in emotional intelligence of people belonging to different professions.
H2. There are no differences in happiness of people belonging to different professions.
H3. There is no significant relationship between happiness and emotional intelligence in people belonging to different professions.

**Method**

**Design:** Mixed method approach was undertaken to better understand the variables of the study. Questionnaires were administered to the sample to assess the variables. An open-ended structured questionnaire was also administered. Correlation analysis, ANOVA and post-hoc analysis were carried out. Thematic analysis was carried out to analyze the qualitative data obtained from the open-ended structured questionnaire.

**Sample:** For the present study, a sample of 20 army officers, 18 teachers, 34 students, 16 individuals from the creative field were selected. A total of 88 participants were taken. Purposive sampling technique was used.

**Measures**

**Assessing Emotions Scale:** This scale is also called the Self-Report Emotional Intelligence Test, or the Schutte Emotional Intelligence Scale (Schutte et al., 1998). The Assessing Emotions Scale assesses characteristic, or trait emotional intelligence. It is a 33-item self-report inventory consisting of positively and negatively keyed items. Respondents rate themselves on the items using a five-point Likert type scale with one denoting strongly disagree and five denoting strongly agree.

**Subjective Happiness Scale:** The Subjective Happiness Scale (SHS) (Lyubomirsky & Lepper, 1999) is a 4-item scale of global subjective happiness. Two items ask respondents to characterize themselves using both absolute ratings and ratings relative to peers, whereas the other two items offer brief descriptions of happy and unhappy individuals and ask respondents the extent to which each characterization describes them. The SHS has been validated in 14 studies with a total of 2,732 participants. Results have indicated that the SHS has high internal consistency, which has been found to be stable across samples. Test-retest and self-peer correlations have suggested good to excellent reliability, and construct validation studies of convergent and discriminate validity have confirmed the use of this scale to measure the construct of subjective happiness.

**Structured Open-Ended Questionnaire:** A structured open-ended questionnaire was constructed by the researchers to study the variables in the study in detail. Four questions were formulated:
1. According to you what is happiness?
2. How important it is to understand and manage one’s emotions? Explain.
3. Do you think that how you manage your emotions influences your happiness?
4. Do you think your career/profession has an influence on your emotion?

**Procedure:** The questionnaires were administered to the participants from various professional fields i.e. army personnel, teachers, individuals from the creative field and students. After the data collection, quantitative and qualitative analysis was done.

**Results**

Correlation analysis, ANOVA and post-hoc analysis were carried out. Thematic analysis was carried out to analyze the qualitative data obtained from it. The results are presented in the tables below.

Discussion

The aim of the study was to study the relationship between happiness and emotional intelligence among army officers, teachers, college students and creative artists. Another aim was to find whether there are differences in happiness and emotional intelligence among these professions. For this purpose the data were collected using questionnaires on emotional intelligence and happiness. A structured open ended questionnaire was also used. The sample size was 88 including both males and females of different professions.

The mean score for emotional intelligence is 132.51. The mean score for happiness is 12.65.

Results show that there exists a significant positive correlation between emotional intelligence and happiness. This result is consistent with the results obtained by Furnham and Petrides (2003) which stated that positive relationship between trait emotional intelligence and happiness persisted if the big five personality factors were present. Army professionals obtained a mean score of 127.10 for emotional intelligence and 4.96 for happiness. For teachers, the mean score for emotional intelligence was 131.77 and for happiness, it was 7.62. Creative artists obtained a mean score of 132.81 on emotional intelligence and a score of 12.03 on happiness. Student’s sample achieved a mean score of 135.94 for emotional intelligence and 20.14 for happiness.

One-way AN OVA was carried out to study the profession-wise difference in both the variables and it was found out that there is no profession-wise significant difference in emotional intelligence but in terms of happiness there exist significant profession-wise differences.

Further, Post-hoc analysis for happiness was carried out to study the difference between the professions. Army personnel significantly differed with individuals in creative profession and with students. Teachers show significant difference on happiness with artists and with students. Creative professionals show significant difference with all the other three professions. Students also show significant difference with all three professions.

Thematic analysis was used for the qualitative analysis of the data obtained from responses to the structured open-ended questionnaire. The responses to the structured open ended questions were read over and over again which led to the finding of various prominent codes. Then, when the codes were categorized, various themes emerged.
Through this, various meanings of happiness developed from individuals ranging in different professional fields, which clearly reflects their personality aspects and the components which actually make them happy. Artists, teachers, as well as students correlated happiness to achievements in life. Artists gave holistic meanings to happiness by attaching notions of gratitude, love and freedom to it. For students happiness was confined to their day-to-day world of family members, friends and career.

For most of the subjects, understanding and managing emotions was clearly important so as to develop personal qualities that are socially desirable and also to maintain a balanced thinking pattern when faced with a challenge. Teachers and army professionals also related hiding of emotions to personality disorders. Participants believe that through understanding and managing one’s emotions we are able to understand and love ourselves better.

When the subjects were asked as to whether managing of emotions led to happiness, all the participants from the various professional categories positively correlated management of emotions to the expansion of happiness: positivity, and peace.

The subjects showed mixed responses when asked whether their profession has an influence on their emotions or not. Creative professionals linked emotion with their professions and stated that “emotion is in itself an art”. The answers to this question yielded four different views wherein career and emotions both influence each other in both positive and negative ways.

The qualitative analysis helped to get a wider picture of the profession wise difference in the emotional understanding and management and its further role, in happiness. Through the results a profession wise difference was observed in the subjects.

Hence, this study found a positive relationship between emotional intelligence and happiness. Also thematic analysis led to in-depth understanding of the variables under study. The study has implications in terms of understanding the positive relationship between emotional intelligence and happiness. It has also led to an increased understanding of the important role of one’s profession in one’s emotional intelligence and happiness.

The Role of Psychological Well-being in Positive Human Health

Nitin Girdharwal
Associate Professor-Research, Krishna Institute of Engineering & Technology, Ghaziabad-NCR, India

Abstract

Employment not only means financial stability but it also defines an individual’s identity. Well-being refers to a positive measure and global assessment of all aspects of an individual’s life whereas Job Satisfaction involves specific beliefs about one’s job, behavior intentions and feelings about it. Both the above constructs have an important role in predicting organizational commitment and therefore greater success at work. The objective of the present study was to understand the role of Wellbeing and job satisfaction in predicting an individual’s commitment to his/her work in Indian Organization. It was hypothesized that employees would become more committed to their organizations if they are satisfied with their current job and have positive evaluations of themselves. For this, a convenience sample of employees was taken from various organizations and was administered Organizational Commitment Questionnaire (Mowday, Steers & Porter, 1979), Minnesota Satisfaction Questionnaire (Hirschfeld, 2000) and Psychological Wellbeing Scale (Ryff, 1989). Pearson’s product moment method of correlation coefficient and multiple regression analyses were used to analyze the data. Correlation and regression analyses revealed a number of significant relationships between the above constructs. The research was concluded by briefly foregrounding some of the study’s implications and future directions.

Keywords: Job Satisfaction, Organizational Commitment, Wellbeing.

Introduction

A foremost part of a character’s lifestyles is spent at work. Employment not only means monetary balance but it also defines an individual’s identification. Employees are one of the most critical determinants that decide the success of a corporation in competitive surroundings. A character who has an effective psychological functioning and is happy with process would perform his/her responsibilities well and might be dedicated to his/her enterprise.

World Health Organization (WHO) described fitness as “a nation of whole physical, mental and social Wellbeing and not only the absence of ailment or disease” (Ryff & Singer, 1998). Psychological Wellbeing is described in terms of a common effectiveness of a character’s psychological functioning (Berkman, 1971). Recently, psychologists have focused on important components of psychological Wellbeing: hedonic and Eudaimonic (Ryan & Deci, 2001). The hedonic approach centered on happiness and described mental Wellbeing in phrases of pleasure attainment and pain avoidance. The eudaimonic approach centered as recognition & achievement of human capacity. The cause of the existing studies is at the eudaimonic approach.

Both job satisfaction and organizational commitment have a positive effect on each other. (Yucel & Bektas, 2012). Some researches recognized job satisfaction to be a component of organizational commitment whereas others stated job satisfaction to be a predictor of organizational commitment (Kovach, 1977; Porter, Steers, Mowday, & Boulian, 1974).

Psychological Wellbeing was found to be positively related to job satisfaction and organizational commitment (Wright & Bonnet, 2007). Previous researches stated that organizational commitment developed the need of belongingness in an individual for the organization which was attained through positive psychological Wellbeing.

Employees are the most vital aid for an employer. One of the biggest challenges that Information Technology (IT) industries are facing today is the potential to draw and keep high-quality human assets. Industry attrition quotes are maximum amongst...
employees having among 1 and 5 years of experience with the very best turnover charges said in India (14%), China and Switzerland (14%), The United States and Canada (10%) (Pastore, 2000). Employee turnover is affected largely through employee’s organizational dedication. If an agency wants to carry out higher, it’s far very critical to understand the extent of dedication of its employees. In the existing situation of the work way of life, psychologists are employed in organizations to understand what factors play a position in permitting employees to gain a tremendous mental kingdom and what can a business enterprise do to make employees happy with their jobs.

The choice of taking Indian IT companies as the sample for data collection for the purpose of the present research is motivated by a variety of reasons. First, there are limited researches on human resource management issues in India. Second, in today’s time, the IT sector in India is seen to have a lot of significance.

Objective of the Study: The present study helps in understanding that enhancing the optimal functioning and making the employees satisfied with their jobs would increase their commitment towards the organization. This would lead to betterment of the employees and the organization to achieve the goals at both levels. So, the objective of the research was to understand the role of psychological Wellbeing and job satisfaction in predicting organizational commitment. To fulfill the above objectives, the following hypotheses were formulated:

Hypothesis of the Study:
1. There might be a statistically sizeable relation among Psychological Wellbeing and Job Satisfaction facets with organizational commitment.
2. Psychological Wellbeing and Job Satisfaction are giant predictors of Organizational Commitment.

Method

Instruments: The following instruments were employed for data collection in the study:

Biographic Information Schedule: Biographic information schedule was used to record gender, age, marital status, educational qualifications and work experience for respondents working at various organizations.

Psychological Wellbeing Scale (PWB): It is developed by Ryff in 1989 reflecting the six areas of psychological Wellbeing: autonomy, environmental mastery, personal growth, positive relations with others, purpose in life and self-acceptance. Respondents rate statements on a scale of 1 to 6, with 1 indicating strong disagreement and 6 indicating strong agreement. Internal consistency values (coefficient alpha) for each dimension varied between 0.86 and 0.91 indicating high reliability of the scale.

Organizational Commitment Questionnaire (OCQ): It is developed by Mowday, Steers and. Porter in 1979. It was used to measure the how committed an employee is towards his/her organization. Respondents rate statements using a seven point Likert scale ranging from (strongly agree) to 7 (strongly disagree). Reliability for the OCQ has been recorded as satisfactory with alpha levels of 80 and above.

Minnesota Satisfaction Questionnaire (MSQ): It is developed by Hirshfeld in 2000. This brief version of the questionnaire was used to measure the activity pleasure of employees. It measures satisfaction with specific components of the activity. Respondents rate statements on a scale of 1 to 6, with 1 indicating strong disagreement and 6 indicating robust agreement. Reliability for the MSQ has been recorded as first-class with alpha ranges of 77 and above.

Participants: The study population consisted of males and females working in IT sector at Delhi/NCR. The data was collected using a purposive cum convenience sampling technique. The size of the total sample was 50 aged 20-50 years. The details of the demographic characteristics are presented in table 1

**Procedure:** The goal of the present research was to think about the job of mental Wellbeing and occupation fulfillment in foreseeing hierarchical duty. A purposive cum convenience sampling technique was utilized to gather a sample of 50 males and females working in an IT segment at Delhi/NCR. Members were educated about the nature and motivation behind the investigation and consent was acquired from interested members expressing that the inquiries addressed would be kept private. Likewise, they were informed that interest was totally intentional and could be ended whenever. The Organizational Commitment Questionnaire (Mowday, Steers and Porter, 1979), Minnesota Satisfaction Questionnaire (Hirschfeld, 2000) and Psychological Wellbeing Scale (Ryff, 1989) were regulated and it took roughly 15 minutes for the respondents to finish these surveys. Descriptive statistics (means and standard deviations) were utilized to investigate the information. Pearson product-moment correlation coefficients were utilized to determine the connection between the factors. A different relapse examination was directed to decide the extent of difference in the reliant variable (Organizational duty) that is anticipated by the autonomous factors (Psychological Wellbeing and Job Satisfaction).

**Result**

The present study was designed to understand the role of psychological Wellbeing and job satisfaction in predicting organizational commitment. For this descriptive and inferential statistics was used. The data was analyzed using SPSS (version 19). In Table 2, main and standard deviation of psychological Wellbeing, Job Satisfaction with their dimensions and Organizational Commitment were reported.

**Correlation is significant at the 0.01 level (2 tailed); * Correlation is significant at the 0.05 level (2 tailed)**

Person product moment method correlation was employed to see the relation between Psychological Wellbeing and Job Satisfaction facets with Organizational Commitment. These correlations are presented in Table 3. Results from Table 3 revealed significant positive relations between Psychological Wellbeing and Job Satisfaction facets with Organizational Commitment.

A multiple regression analysis was conducted to determine the proportion of variance in the dependent variable (Organizational commitment) that is predicted
by the independent variables (Psychological Wellbeing and Job Satisfaction). The findings are presented in Table 4. Results from the Table 4 indicated that the adjusted R2 was calculated as 0.70. This means that 70% of the total variability in Organizational Commitment is explained by the Psychological Wellbeing and Job Satisfaction (R2 = 0.70; F = 60.65; p < 0.05)

Discussion

The objective of the present research was to study the role of psychological Wellbeing and job satisfaction in predicting organizational commitment. The data was collected using purposive cum convenience sampling. The sample was administered questionnaires on psychological Wellbeing, job satisfaction and organizational commitment. Descriptive statistics (means and standard deviations) were used to analyze the data. Pearson product-moment correlation coefficients were used to specify the relationship between the variables. A multiple regression analysis was conducted to determine the proportion of variance in the dependent variable (Organizational Commitment) that is predicted by the independent variables (Psychological Wellbeing and Job Satisfaction).

The first hypothesis stated statistically significant relation between Psychological Wellbeing and Job Satisfaction facets with Organizational Commitment. Significant and positive relations were found on the above constructs. Similar findings were reported by previous studies.

The present research found moderate to high positive relation of psychological Wellbeing and its dimensions with organizational commitment. Having strong and trusting relationships with the colleagues is an important factor for an individual to be committed to the organization. When an individual has satisfying relationships, he/she becomes concerned with the welfare of others and this helps in reaching the organizational goals. An individual who is autonomous, able to resist social pressures and has a positive attitude towards self (self-acceptance) is more able to make independent decisions at work. He/she is clearer and more directed towards the individual and organizational goals which further helps to remain in the organization.

Job satisfaction was also located to have an excessive advantageous correlation with organizational commitment. The findings of the present research is in line with the study performed through Cheng and Stockdale (2003), Tella, Ayeni and Popoola (2007) mentioning that task pride and organizational dedication are two very relevant operating mindset, because of this that robust courting existed among the constructs and there is a few overlap of the two working mind-set while there may be an effect on other variables. Extrinsic delight had a moderate relation and intrinsic delight had a high fantastic relation with organizational dedication stating the truth that intrinsic elements have a better source of affiliation as compared to extrinsic elements. Intrinsic assets of pride rely on the person traits of the man or woman, along with the ability to use initiative, relations with supervisors, or the work that the person certainly plays; those are symbolic or qualitative sides of the process while extrinsic resources of delight are situational and depend on the surroundings (SousaPoza & Sousa-Poza, 2000; Armstrong, 2003).

The second hypothesis stated that psychological Wellbeing and job satisfaction are significant predictors of organizational commitment. The results of regression analysis revealed 70% of the total variability in organizational commitment is explained by the psychological Wellbeing and job satisfaction (R² = 0.70; F = 60.65; p < 0.05). This means that both psychological Wellbeing and job satisfaction play an important role in organizational commitment. There is only 30% contribution is of other factors in organizational commitment which is not the focus of
the present research. The finding of the present research is supported by previous review of literature that stated job satisfaction to be a predictor of organizational commitment (Kovach, 1977; Porter, Steers, Mowday, & Boulian, 1974).

Managerial Implication: The present investigation has direct ramifications for the present modern world. Whittling down rates soaring and representatives are moving starting with one association then onto the next in fast progression. This study has contributed to the existing theory of organizational behavior and is useful for research purpose. The examination expressed positive mental state and occupation fulfillment are significant benefactors in making the workers focused on their associations. Organizations can improve organizational commitment of their employees by initiating employee development programs to improve their attitude in the workplace. Furthermore, the findings of this study can be of great help in designing policies for improving organizational commitment.

Limitation of the Study: There exist constraints originating from the size just as the idea of the example. Since the example of respondents is moderately little and the example was gathered from couple of IT organizations in Delhi/NCR, this investigation should be reproduced over a bigger database of respondents to affirm the discoveries. Likewise, the example was gathered utilizing non likelihood inspecting techniques so it didn’t give a sheltered premise of speculation. In addition, self-report information could be one-sided and may not give the most substantial or exact records of a person’s conduct.

Conflict of Interest: Author declare no conflict of interest.

Online News Media Coverage of Women’s Health in India: A Content Analysis

Olive Nerurkar

Associate Prof, Symbiosis International (Deemed University)

Abstract

Women’s health is of particular concern in India as numbers involving Non-Communicable Diseases (NCD) are rising alongside Reproductive and Sexual health disorders. Women’s health must, therefore, encompass women’s sexual and reproductive health, as well as NCDs. Media coverage of issues related to women’s health plays a vital role in increasing awareness, influencing public opinion, and motivating change in health policies. Hence, this study was designed to assess news coverage of women’s health in India.

Method: Online daily news media exclusively covering health in India from June 2018- May 2019 were systematically analyzed, and articles concerning women’s health were identified. The articles were taken from two national online daily news media reporting in English language about women’s Reproductive and Sexual health and Noncommunicable diseases, and the pieces were coded and analyzed.

Results: Out of a total of 240 articles, 108 relevant to the study were identified from two online news media which enjoyed high readership. The articles were a mix of news, features, and commentary/interview. The articles covered various disease types (Reproductive and Sexual Health, CVD, Cancer, Respiratory Diseases, Diabetes, Mental Health, General Wellbeing, and Other).The article coverage included research study findings from India, international agencies / countries, or global. Prevention, diagnostics and therapy, location or context of the news, and the stakeholders were also covered. The analyses show reportage mostly covering diseases affecting women’s Reproductive and Sexual Health and Cancer. Limited information was provided on most of the significant Non-communicable Diseases like Cardiovascular Diseases (CVD), Diabetes, Chronic respiratory diseases. The rate of NCDs affecting women in India is galloping. The skew in the article coverage of conditions may create a gap in awareness about more pressing NCDs and hence may fail to influence policy actions at the governmental or industry level.

Further the articles mentioned stakeholders like the government, global/international agencies or countries, and individual. There was a lesser mention of industry. Some lost opportunities in the media coverage have been identified as lack of a balance in the articles published on diseases, lack of comprehensiveness in terms of disease burden, stakeholder role or lack of suggestions for policy changes.

Conclusion: Gaps exist in the current online news media coverage on women’s health in India, suggesting the need for more comprehensive coverage of diseases and influencing policy action of the government and industry. Through better coverage of the major NCDs, quantification of the health burden and suggestion for policy actions, the media can play a critical role in galvanizing India’s movement on women’s health. These data suggest opportunities for government and industry.

Keywords: Online news media, content analysis, women’s health in India, Non Communicable diseases and Reproductive and Sexual Health, stakeholders.

Introduction

Health is an essential factor that contributes to wellbeing and economic growth of a nation. With a total life expectancy at birth of 68.8 years (67.4 years for men and 70.3 for women), India has made significant
progress on various health parameters, yet the sector faces many challenges and barriers. While the country is still struggling with communicable diseases, NCDs have been reported to have become more threatening, causing 60 percent of the deaths in the country. NCDs are estimated to create the country a loss of USD 4.8 trillion between 2012 and 2030 and is expected to be the primary cause of mortality overtaking communicable diseases. Its insufficient health infrastructure will mar the future of India as a world economic power. A country can build a strong foundation for economic success and prosperity by investing in the health of its population.

In this context, the health of Indian women assumes prominence because of their contribution to society in their productive and reproductive roles. According to WHO 2008, Reproductive and sexual ill-health accounts for 20% of the global burden of ill-health for women as compared to 14% for men. Apart from Reproductive Health issues, women have to contend with NCDs, which are the world’s number one killer and account for 18 million deaths among women. NCDs is a significant threat to women’s health worldwide, and in developing countries affect them in their most productive years. So sustained and comprehensive action is required to tackle women’s health on both fronts sexual and reproductive health and NCDs. Media coverage on those above will help create awareness, inform about the possible policy changes and actions required by all stakeholders.

Women in poor health are more likely to give birth to low weight infants, provide inadequate care for their children, and if they are employed will be less productive. Further, in India, families depend primarily on women to provide family care. Thus poor health of women seriously affects themselves as well as their families.

Media coverage of women’s health issues plays an essential role in creating awareness, influencing individual actions that they can be taken to prevent, diagnose, and seek treatment. Policy decisions by industry, government, international agencies may also be informed by media coverage. Hence, this study was designed to assess online news media coverage of women’s health in India.

The rationale for this study: Given the role of online news media in spreading awareness about issues and problems, influencing public opinion and shaping government policy, a systematic content analysis of news stories published online in the period 2018–2019 was undertaken, to assess the news media’s prioritization of women’s health in India. Women’s health related to reproductive health and NCD formed the backdrop of the study. In light of the above, it was considered worthwhile to examine online news media relating to women’s health.

Method

Articles published by online news media in India with exclusive coverage of health from June 2018-May 2019 formed a part of the data for the study. The articles that discussed women’s health were systematically content analyzed. Total of 108 articles from two online news media covering health in India was analyzed. These online news media were reported to have good readership on health and specifically target decision makers, policymakers, and other stakeholders. The articles were downloaded from two online papers devoted to the Health sector in India, namely: ET Healthworld and E Health.

Keyword search on “women health” resulted in 240 articles. These were checked for relevance and reduced to 108. Articles were filtered out because they were covering communicable diseases, diseases affecting the general population or news about aspects not relating to the scope of study like news about awards received by individuals. All the 108 identified articles were covered by the analysis because of their relevance. Because women’s health in developing and lesser developed countries are showing the presence of high amount of non-communicable diseases (NCD) specifically the study covers NCD and Reproductive and sexual health of women in India

Coding frame for content analysis: A coding frame for content analysis was developed, and the following topics were included:

- Type of story: news, feature, commentary / interview.

A news story is short less than 300 words and written in a pyramid form. A news feature is a longer news article. Commentary is an opinion.

- Type of Diseases covered: Reproductive and Sexual health, Coronary and vascular diseases (CVD), Diabetes, Cancer, Depression, Chronic Respiratory. Other (includes specific mention of women’s condition in the context of overall health coverage of article), General wellbeing.
Non-communicable diseases (NCDs) tend to be of long duration involving a combination of genetic, physiological, environmental, and behavioral factors. The main types of NCDs are cardiovascular diseases (like heart attacks and stroke), cancers, chronic respiratory diseases (such as chronic obstructive pulmonary disease and asthma) and diabetes. For the study, the following NCDs were covered: Coronary and vascular diseases (CVD), Diabetes, Cancer, Depression, Respiratory, Other.

- **Visuals**: photos, illustrations
  Visuals consisted of photos of people, illustrations, symbols, and logos. All were clubbed under Visuals.

- **Health Status and coverage**: Research, Disease, diagnostic, prevention, therapy, and treatment.
  News is primarily aimed at informing, creating awareness, interpreting, and sometimes persuading or mobilizing opinions. Hence the following Issues in the news story were studied: Research information about the disease, Disease explanation including symptoms, diagnostic, prevention, therapy, and treatment.

- **Location**: International/global country or agency, India, and the Indian States
  News covering areas was also captured. Location: international/global country or agency, India, and the Indian States.

- **Stakeholder**: Global /International country or agency, Government (Indian or State), Industry, individual.
  News stories also mentioned stakeholders as listed above.

Since most of the coding categories were multiple responses the percent respondents add up to more than 100%.

**Results and Analysis**

The result of the content analyses is presented

**Type of Story** (Table 1): The news articles covering the year May 2018 - June 2019 were 108 in all. These articles included news (32.41%), features (43.52%) or commentary and interviews (24.07%).

% exceeds 100 as there are multiple responses

**Discussion**

This study found a significant volume of reporting on issues related to women’s health in India about NCDs and Reproductive and sexual health. But also there are significant gaps and missed opportunities that may guide future action by the media in terms of awareness creation.

Online news media reports as per the content analysis emphasize reproductive and sexual health and Cancer and appeared to have given CVD, Respiratory diseases, diabetes, mental health far lesser coverage. Is the reporting, therefore, unbalanced? Lack of reportage of major NCDs is a missed opportunity for creating awareness, influencing the informed choice, and demanding policy change when the nation’s burden from NCDs is growing. Many of the NCDs are caused by a poor selection of food, physical inactivity, and poor lifestyle choices and can be reduced by emphasizing individual action and government intervention. Consequently, the media reportage and prioritization might have the effect of misleading public attention and policy priorities for work. India’s burden of non-communicable diseases (NCDs) is escalating, the issues of multiple chronic conditions prevail, and many a time NCDs remain undiagnosed due to lack of awareness and insufficient health-care access. [6]

Media should be able to play its constructive role in creating awareness, educating people of the risks and complications that can arise out of neglect.

The study found that these two publications reported news which covered global/international, national, and news related to the Indian states. Domestic health news articles were predominantly available.

The women’s health status covered issues related to the disease, research, prevention, diagnostics, and treatment with a fair amount reported under each reflecting a reasonable balance. Most articles had photos or illustrations depicting the problem.

Most reported the government as the stakeholder, with roles of global agencies, individual and industry being reported as well. The bulk of the reports mentioned the government but a lesser amount reported industry as a stakeholder. There were, likewise, missed media opportunities for highlighting solutions to addressing women’s health by the sector.

There were, likewise, missed media opportunities for highlighting solutions to addressing women health, particularly in calling for a comprehensive health management system aimed at preventions and control and affordability. Media missed opportunities to advocate for taxes on unhealthy processed foods and call for policy changes for affordable health.

Media reporting must consider women’s health as crucial to the health of a society and should receive due importance. Media needs to emphasize the role of deliberate policy and action and recognize its role in facilitating the same. [7]

The growing non-communicable diseases affect a large portion of the population in countries like India. An affordable healthcare policy intervention has the potential to improve the status of health significantly.
and will have a significant impact on economic growth. Media needs to emphasize the importance of prevention as NCDs to a large extent, are caused by improper lifestyle choices.

Concerns have been raised by researchers about not enough research being carried out on women’s health and NCDs and are calling for a sex-disaggregated approach to health studies. They also advocate a life course approach to women’s health, deliberate policies aimed at nurturing women’s health and well-being across the life cycle for realizing the full potential of women and girls. [8]

Very few articles called for the industry to show leadership in addressing women’s health. The strengths of this study lie in the large volume of articles analyzed and the comprehensiveness and depth of the content analysis.

Nonetheless, there were some limitations to the study. The search terms were restricted to “women health” and confined to Indian online news media with a health focus. It did not cover dailies covering the general news which also might have an occasional weekly section on health. Further, the articles were restricted to only the English language. Future studies might so contemplate analysis of Indian regional media for the study of comparable problems.

Conclusion

The study identified substantial media reporting on women’s health in India covering diseases, the status of development, symptoms, diagnostics, and therapy, the contexts like location in India and international alongside stakeholders. However, news reportage appears skewed towards some diseases over others.

This study has identified the media reporting on the diseases reported to be reasonably balanced about symptoms, research, prevention, and diagnostic and therapy thus making these issues salient in the national media. The media had also identified stakeholders, but the emphasis was on government, global/international agencies, and individual.

However, there were many gaps in reporting observed. While Reproductive and sexual health and a few NCDs were generally reported, many important ones were not reported. Discussion of policy options tended not to be covered. Preventive measures were not mentioned in the context of addressing women’s health. Not only does this represent a lost opportunity to address health issues and policies to be implemented. Accountable government and industry needs to be at the forefront of health and must play an active part in advancing the health perspective in women.

Media must seek to redress many of the gaps identified in this study. Increased specificity about the burden of women’s health, including advice for the groups most vulnerable to the impacts of poor health would serve a mainly educational purpose. Greater elaboration in the media, particularly by key influencers, on the real sources of and solutions to women’s health, can help trigger policy action. Calls on the government and industry and individuals to play a more active role in the country would prove beneficial.

Migration and Displacement: The Case of Tuberculosis

Paramita Barman

Assistant Professor in Economics, Faculty of Commerce & Management, St. Xavier’s University, Kolkata

Abstract

The recent years have witnessed an enormous rise in population displacements both beyond country borders as well as within. Limited access to health services and unfavourable living and working conditions make migrants vulnerable to an array of health risks and hazards including tuberculosis (TB) infection, progression to TB disease and poor treatment outcomes. Underlying social determinants of health are the most crucial risk factors that multiply the chances of contracting TB. Also, around 40 per cent of the total number of incident TB cases globally are missed by the public health systems which have serious public health implications and are most likely to occur among populations susceptible to TB, like migrants and refugees. With respect to ‘crowd infections’ and public health emergencies like TB, the health of migrants therefore assumes a critical position. This study makes an important contribution by providing a comprehensive survey of existing evidence on how migration and displacement can increase the risk of TB infections across countries and empirically validating the same in the Indian context.

Keywords: Tuberculosis, epidemiology, risk factors, migration, displacement.

Introduction

Tuberculosis (TB) remains a public health emergency, substantially contributing to the global burden of disease. In 2017, there were an estimated 10 million incident cases of TB globally and 1.3 million TB deaths among HIV-negative people. Moreover, only 64 per cent of incident TB cases were notified to national authorities and eventually to the WHO. Treatment default has been one of the prime reasons for the rampant emergence of drug-resistant TB. TB is an opportunistic infection. Several medical conditions like HIV, diabetes, silicosis, tobacco and alcohol abuse present risk factors for the disease and are responsible for detrimental TB treatment outcomes.

Although TB is not exclusively a disease of the poor, deprivations and vulnerabilities typically associated with poverty increase the risks of infection and disease manifold. The burden of disease is in general disproportionately more among the poor with less access to healthcare whether measured by geographical and financial accessibility, availability, acceptability or quality of care.

The recent years have witnessed a rising trend in population movements, forced or voluntary, both across international borders and across country states. Globally, there are 244 million international migrants and 740 million within national territories. Migrants constitute a heterogeneous group comprising overlapping sections of migrant workers and their families moving from one location to another in search of work or better living conditions, immigrants, refugees, internally displaced persons, asylum seekers and victims of human trafficking. Exposure to new environments generally render migrants more vulnerable to an array of health risks and hazards with limited access to some of the basic social services including health.

In this era of globalisation, population mobility across countries is an underlying factor behind the emergence of public health threats that are often related to transmissible pathogens. Migrants and the displaced present a key population for a communicable disease and social affliction like TB. This paper makes an
attempt to explore the body of literature that throws light on the dynamics of migration and displacement on the epidemiology of TB. Besides providing a comprehensive survey of existing evidence on how displacement can aggravate the risk of TB infection and disease it tries to validate the association between migration and risk of TB with the help of secondary data in the Indian context.

**Tuberculosis and migration at crossroads:** The migrant status itself constitutes a social determinant of health (Fig.1) interacting with other determinants to adversely affect access to health care and health outcomes\(^8,10\).

**Fig 1: Migration cuts across social determinants of health**

**Source:** International Organisation for Migration: The TB epidemic serves as testimony to substandard living and working conditions, nutritional deficiency, low education and disease awareness and low access to health care serving as some of the critical determinants of morbidity and mortality associated with TB\(^{11}\). Although national TB control programmes worldwide have steadily brought down prevalence and mortality rates, not much has been achieved on the incidence front despite availability of effective diagnostic tools and a treatment regime. ‘Missed cases’ comprising a mix of under-diagnosed and under-reported incident cases are responsible for perpetuation of infection in the community and are most likely to occur among population subsections more susceptible to TB, like migrants and refugees. Migration as a social determinant of health increases TB related disability and deaths among migrants along all migration pathways\(^{12,13}\).

**Vulnerability of migrants to TB:** Certain conditions associated with the migrated population make them more vulnerable to TB infection and disease. Migrants in detention centres like prisons and in asylums or victims of trafficking are often forced to live in inhuman and filthy conditions lacking ventilation and proper sanitary arrangements for long periods of time. Such conditions present hotbeds for TB infection to spread and thrive. Forced displacement of people following an armed conflict or natural calamity is often associated with food scarcity and undernourishment, overcrowding in temporary shelters like camps and disruption in treatment. Occupational hazards like silicosis expose migrant workers engaged in the mining industry to a high risk of TB\(^{14}\). In case of migrants with a legal status, access to diagnostic and treatment services for TB are conditional on terms of contract, work permits and entitlement to insurance and other health allowances provided by the state or the employer concerned. However, if falling sick leads to loss of work permits, individuals may be tempted to withhold positive TB status till late to avoid the risk of being sent back. Delay in seeking care causes infection to spread. Irregular migrants fear deportation which limits their access to health services. Deportation during the course of treatment leads to treatment default and consequently drug-resistance, poor health outcomes and continued transmission of infection. Again, the typically long tenure of TB treatment with daily administration of drugs becomes a challenge when people are on the move causing breaks in the treatment continuum. The outcome may be death or development of more complicated drug-resistant TB\(^{15}\).

Risk factors for exposure to TB infection, its transmission and adverse health outcomes present themselves all along the migratory process. These may be categorised into *individual factors* like poor living and working conditions, low socio-economic status, low nutrition status, smoking and alcoholism, *sociocultural factors* like linguistic barriers, cultural differences, legal rights, fear of stigma and discrimination and low awareness regarding disease and health service entitlements and *economic burden of TB* at the level of the household involving direct costs like costs of care and opportunity costs like income loss for migrants and their families, governments and loss of remittances for home countries\(^{16}\). Thus the interplay of determinants of health and TB at multiple levels sustains the migrant population’s vulnerability to TB.

**Migration pathways:** Modern migration processes constitute junctures like *origin, transit, destination* and sometimes, *return* (Fig 2). While migrants may be otherwise fit to travel, they may be at a higher risk of getting TB infection
or developing the disease depending on the incidence of TB in their home country, conditions experienced during travel and during stay in the destination country.

Fig 2: Migration pathways

Source: International Organisation for Migration: Factors that determine the health profile of the migrant and TB risks at country of origin include the individual’s own health status, access to and availability of quality health services, prevailing socioeconomic conditions and experience of any epidemic, conflict or emergency. Journey of migrants or the transit phase plays a role in determining the TB risk of migrants especially when they undertake travel under perilous situations. For example, unlike legal migrants who would travel with requisite documents and approval as well as pre-migration health screening, irregular ones may travel on foot or by unsafe and crowded conveyance. Undocumented migrants may be held up in jail where they are forced to stay in crowded and ill-ventilated conditions with poor nutrition together with other inmates already infected. Asylum seekers and human trafficking victims who suffer physical abuse often undergo mental trauma causing them to refrain from seeking health care from both private providers and public services due to mistrust. Upon reaching destination, conditions under which migrants work and live, their socioeconomic condition, availability of health services in the host country, access to such services, affordability and acceptability, all these factors play out to influence migrants’ risk of contracting TB and eventually its treatment and outcome. Coping with a new environment may be both physically and emotionally demanding for migrants and lack of identity and obligation to abide by social norms may instigate them to take recourse to drugs or prostitution as a means to escape loneliness, frustration and social isolation. These pave way for the marginalised populations to acquire immunosuppressive conditions like HIV and eventually TB infection and disease.

Effects of migration on TB epidemiology: Migration influences the epidemiology of TB by serving as a connecting link across countries or regions within a country with varying degrees of disease prevalence and socioeconomic settings. People moving across country borders or within have different health profiles that impact access to health care, health seeking behaviour and disease burden. The burden of morbidity and mortality from TB in the low TB burden high income countries is mostly borne by foreign-born individuals who have migrated into these countries, the probable reason being reactivation of previously acquired latent TB infection in their countries of origin – low and middle income, high TB burden settings or along the migration pathway. It may be interesting to note that some of the top countries of origin for international migrants – like China, India, Bangladesh, Pakistan, Afghanistan, Indonesia, the Philippines and the Russian Federation also find place among the 30 high TB burden countries identified by the WHO. More than half of TB incidence in Europe and North America is accounted for by foreign born individuals with active case finding strategies revealing higher rates of multi drug resistant TB higher among immigrants, refugees and asylum seekers.

Migration and risk of TB: an empirical exercise in the Indian context: India accounts for more than a quarter of global TB incidence and almost a third of global mortality from TB annually. According to the estimates of the Economic Survey of India 2017, interstate migration in India was as high as 9 million annually between 2011 and 2016, and there are around 139 million internal migrants in the country. The 2001 Census of India identifies few important states with respect to inter-state migration, each of which had more than a million migrants by place of birth from both other states in India and other countries. NFHS 3 (2005-06) reports TB prevalence at household level across states in India. Table 1 shows the percentage shares of the preferred destination states in all-India in-migrant population and their percentage shares in all-India reported TB prevalence.

Table 1: Percentage shares of preferred destination states for migration in India, in all-India in-migrant population and all-India reported TB prevalence

<table>
<thead>
<tr>
<th>States</th>
<th>Percentage share of total in-migrants</th>
<th>Percentage share of reported TB prevalence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maharashtra</td>
<td>16.4</td>
<td>6.29</td>
</tr>
<tr>
<td>Delhi</td>
<td>11.6</td>
<td>1.85</td>
</tr>
</tbody>
</table>
Correlation between the share of total in-migrants and the share of reported prevalence of TB for the selected states comes out to be 0.49 (approx.) and a test of significance for the correlation yields p value = 0.06 implying significance of the test at 10 per cent level.

This small analytical exercise as a case study of India establishes a positive and significant association between migration and the risk of TB infection and disease.

**Discussion**

Health of migrants is a crucial global public health issue, especially in view of public health emergencies like TB and other infectious diseases. TB is a ‘crowd’ infection that shares its underlying drivers with the social determinants of health. Various factors at play along migration pathways may be regarded as social determinants of health that make migrants a critical population for TB. One concern with TB in migrants is the public health implication of delayed diagnosis and care seeking, if any, due to financial constraints, poor health literacy and fear of termination of employment contract and deportation. Besides worsened health outcomes for the affected population, delay in care seeking leads to uninterrupted spread of infection in the community. Development of drug-resistant TB among illegal migrants without any social protection, refugees and displaced persons due to poor treatment adherence and high default rates is another area of concern given their mobile lifestyle and possibilities of deportation while on treatment. Thus, immigration laws need to be framed exclusive of health care needs for migrants, irrespective of their legal status. Migrant workers are most often engaged in hazardous occupations that facilitate contraction of TB. Policies of the health sector need to be framed in coherence with non-health sectors like labour and immigration to support TB-related interventions across and within countries. There are health implications of migration in the host country. Recently, the rising burden of TB in Lebanon for example has been associated with a rise in the number of migrants and influx of refugees displaced in the aftermath of the conflict in Syria. It has been shown that despite their origins in a low TB setting, Syrian refugees in Jordan have higher rates of disease. While some migrants may exhibit the ‘healthy migrant’ effect, others may have pre-existing health conditions in the form of remotely acquired latent TB infection that eventually impacts the local disease epidemiology. As part of preventive measures, some destination countries make pre-migration screening and other health assessments mandatory particularly for infectious diseases like TB, for prospective legal migrants or lay down certain health conditions as entry-prohibiting. However, this poses a certain ethical dilemma with respect to the trade-off between ensuring preventive health measures for the native population and preservation of human rights. In case of irregular migrants and forced migration however, screening mechanisms prior to migration are difficult to implement.

**Conclusion**

TB management and control for migrants need to adhere to the basic public health principles of removal of disparities in health status and access to TB-related services between migrants and the host population thereby preserving health rights of migrants, reduction of TB burden in migrant population and minimization of the adverse effects of various phases of the migration process on their TB-related health outcomes. Also, pulmonary TB being a communicable disease, strategies to control it in the migrant populations need to balance the human rights of afflicted individuals with prerogatives to safeguard population health in host communities. National TB control programmes should come up with migrant-inclusive strategies like measurement and analysis of TB burden among migrants along with sensitization of health personnel towards their particular TB-related needs. Active screening for TB among refugees and immigrants and contact tracing assume
critical importance in responding to issues of under-diagnosis of TB cases, treatment non-compliance and increase in drug-resistant cases. The WHO for example recommends systematic screening for detection of active cases of TB among immigrants from settings with high TB prevalence and people in refugee camps, identifying them as ‘possible risk groups’ for TB. Also, the continuum of care must be ensured at all levels through facilitation of appropriate cross-border communication and follow-up. For the first time, the contribution of migration to sustainable development has been recognised as part of the development vision for 2030. Management strategies focusing on migration as a facilitator of TB and political commitment at national and international levels are critical for achieving the ambitious goals of the End TB Strategy and health equity including TB related targets in the era of the Sustainable Development Goals.

Introduction

Immunization is one of the most successful and cost-effective interventions. Worldwide, vaccines have saved countless lives and improved health and well-being of children. In May 1974, the WHO launched the global programme known as Expanded Programme on immunization (EPI) to protect all the children of the world against six vaccine preventable diseases (VPDs) by the year 2000. An estimated 19.4 million children under the age of one year did not receive basic vaccines. Globally, 1 in 10 infants did not receive any vaccinations in 2016. The Government of India launched Universal Immunization Programme on 19th November 1985, with the main objective of covering at least 85% of all infants against the six vaccine preventable diseases by 1990. As per the national family health survey– IV

To Study the Knowledge Regarding Immunization among Caregivers of Under Five Children in Amritsar, Punjab

Pooja Sadana¹, Kanwal Preet Kaur Gill², Manisha Nagpal², Amanpreet Kaur²

Abstract

Introduction: Childhood immunization almost guarantees protection from several diseases. Since parents are the important health decision makers of their children, their knowledge regarding immunization and their educational status have a great impact in the immunization status of their children. This study evaluates the knowledge among parents/care givers about vaccines, to understand their perception towards immunization and to identify solutions to address the knowledge gap.

Objectives: The objectives of this study were to assess the knowledge of parents or caregivers regarding immunization and to establish a correlation between socio-demographic variables and knowledge about immunization.

Methodology: The study was conducted in Sri Guru Ram Das Institute of Medical Sciences and Research, Vallah, Amritsar. Parents or care givers who came to the immunization clinic of the hospital to vaccinate their children were interviewed by a self-designed questionnaire. Each parent or caregiver’s knowledge, was assessed by giving specific scoring to selected questions in the questionnaire. Significance of difference in parameters was calculated using Chi-square test at 95% confidence interval.

Results: Out of 130 parents/caregivers studied, 6.9% of the parents/caregivers had good knowledge, 63.9% had average knowledge and 29.2% had poor knowledge about immunization. The association between knowledge and educational status (p = 0.002), type of family (p = 0.006), birth order (p = 0.030) and relation of the child with the caregiver (p = 0.020) were found to be statistically significant.

Conclusion: Majority of the subjects did not have adequate knowledge on vaccination. Socio-demographic factors had a significant influence on the knowledge of the caregiver. There is an urgent need to increase the coverage of vaccines under Universal Immunization Programme and a dire need to arrange for health education programme for all the parents regarding the importance of complete adherence of vaccination among children.

Keywords: Parents, Caregiver, Knowledge, Socio-demographic factors.

Introduction

Immunization is one of the most successful and cost-effective interventions.¹ Worldwide, vaccines have saved countless lives and improved health and well-being of children. In May 1974, the WHO launched the global programme known as Expanded Programme on immunization (EPI) to protect all the children of the world against six vaccine preventable diseases (VPDs) by the year 2000.² An estimated 19.4 million children under the age of one year did not receive basic vaccines. Globally, 1 in 10 infants did not receive any vaccinations in 2016.³ The Government of India launched Universal Immunization Programme on 19th November 1985, with the main objective of covering at least 85% of all infants against the six vaccine preventable diseases by 1990. As per the national family health survey– IV

Corresponding Author: Dr. Pooja Sadana
Associate Professor, Department of Community Medicine, Sri Guru Ram Das Institute of Medical Sciences and Research, Sri Amritsar
(2015–16) only 62.0% of eligible children were fully vaccinated. Though India had implemented the universal immunization schedule, under which immunization services are offered free in public health facilities, the magnitude of its coverage remains poor. The main reason for non-immunization is lack of knowledge and awareness among the caregivers.

Adequate knowledge regarding immunization among parents or caregivers is important for prevention of diseases in the future. On the other hand, inadequate knowledge is dangerous and may perpetrate poor vaccine uptake and underutilization of the vaccination programs.

Several studies on immunization status of children conducted in various countries have revealed that increasing parents’ knowledge regarding vaccination improves immunization status and affects success of immunization programme. Education status and other socioeconomic status of parents have a great impact on their decision regarding vaccination. Therefore, our aim of this study was to assess parent’s knowledge towards vaccination and to correlate these factors with socio demographic variables so as to improve the vaccination coverage.

**Objectives**

1. To assess the knowledge of parents or care givers regarding immunization.
2. To assess the effect of demographic determinants on the knowledge of the respondents.

**Materials and Method**

A hospital based cross sectional study was carried out in the immunization clinic of Sri Guru Ram Das Institute of Medical Sciences and Research, district Amritsar, Punjab. Study population included parents or caregivers of children from 0 to 5 years of age, who visited the immunization clinic.

The study was conducted for a period of one month starting from 15 June 2019 to 15 July 2019. A pre tested and predesigned questionnaire was administered to the study subjects after taking an informed consent from them. Parents or care givers who did not cooperate for the interview were excluded from the study. Questionnaire consisted of two parts; Section A consisted of the socio-demographic profile of the study subjects, which included age, sex, qualification of the parent, income of the family, type of family, area of residence, number of siblings, birth order and age of the child coming for vaccination.

Section B included questionnaire to assess the awareness and knowledge of immunization, as per National Immunization Schedule as followed in India, knowledge about importance of vaccination, knowledge was assessed based on the number of vaccine preventable diseases known to the respondents, age at which first vaccine is administered, side effects of vaccines, awareness regarding special vaccines.

Knowledge regarding vaccination of each study subject was assessed by giving scores to their response to eight questions. Each correct answer was given a score of ‘1’ and wrong answer was given ‘zero’ score. The maximum score was 8 & minimum score was ‘0’. Using likert’s scale the knowledge was categorized as poor (score 0 to ≤3), average (score 4 to ≤ 6) and good (score 7 to ≥ 8). Role of following parameters were assessed to understand the knowledge of parents/care givers regarding immunization such as age, sex, qualification of the parent, income of the family, type of family, area of residence, number of siblings, birth order and age of the child coming for vaccination.

Approval of college ethical committee was granted at the time of submission of the plan of the study. Data was tabulated on Microsoft Excel Sheet. The master chart was prepared and data analysis was carried out by using SPSS 22.0 version. The demographic variables were analysed by frequency and percentage. Association between knowledge with other demographic variables was found using chi-square test. Value of p < 0.05 was considered as statistically significant.

**Results**

Table 1 depicts the socio-demographic profile of the parents/caregivers. More than half i.e. 54.6% belonged to 25-34 years of the age group, 27.7% were more than 35 years and 17.7% were in the age group of 15-24 years. Females predominated as 70.8%. Regarding educational and occupational status of the study subjects, 52.3% of them were matric and above and 62.3% were unemployed respectively. Per capita income of 74.6% was less than 10000 and 83.1% belonged to joint family. As far as birth order of the child is concerned, in 59.2% cases it was second or above and in 40.8% it was first child. Among the study subjects mother predominated, i.e. 55.3%. More subjects, i.e. 65.4% were from rural areas.

</table>
Perusal of Table 3 depicts that age, sex, occupation, per capita income and area of residence and had no effect on the knowledge of the parent/caregiver where as educational status (p = 0.002), type of family (p = 0.006), birth order of the child (p = 0.030) and relation with the caregiver (p = 0.020) were significantly associated with the knowledge of the parent/caregiver.

**Discussion**

Analysis of the demographic characteristics (Table 1) of the 130 participants shows that, majority (54.40%) were in the age group 25-34 years. A study done by Mereena et al showed that a higher percentage (50.3%) of mothers belong to age group 26-30. In another study done by Patil R at Bhopal, majority of parents were between the age group of 25-35 years. Present study also shows that 62.3% of the respondents were unemployed. Similar finding was seen in the study conducted by Mugada et al in 2017.

In our study 83.1% respondents were from the joint family, a study conducted by Panari H and Anuchithra in 2015 and Sinha S et al (2018) to assess the knowledge on immunization among the mothers of under five children also showed that most of them belonged to joint family. Present study revealed that 59.2% children were of birth order second or more, similar birth order is seen by Patil R in their study. In the present study 55.3% of the children were brought to the immunization clinic by their mother, whereas 30.0% were brought by their father, almost 17.7% were being brought by their grandparents/ uncles or aunts. This is in accordance with the study done by Sinha S et al(2018).

As far as knowledge about immunization is concerned (Table 2), present study showed that 29.2% of parents/caregivers had poor knowledge, 63.9% had average knowledge and 6.9 % had good knowledge. Similar findings were reported by Jose et al (2013), Vaithilingan S (2017) and Dharmalingam et al (2017) in their studies.

In the present study (Table 3), educational status (p = 0.002), type of family (p = 0.006), birth order of the child (p = 0.030) and relation with the caregiver (p = 0.020) were significantly associated with the knowledge of the parent/caregiver.
Conclusion

The present study highlighted the knowledge of parents or caregivers on immunization. A better understanding of health issues associated with the immunization constituted a challenge for clinicians and researchers. So there is a great lot scope for exploring this area. Research should be conducted to identify the attitude and practice of mothers on immunization. Low literacy level of mothers is a matter of worry. Some of them don’t know about the diseases for which their child is being immunized, so there is a dire need to arrange for health education program sessions for mothers of under five children with main emphasis on importance of vaccination & Vaccine Preventable Diseases (VPDs). Socio-demographic factors had a significant influence on the immunization status. Hence, efforts should be focused on improving them also besides educating them about vaccines to improve their knowledge. TV, newspaper and other Medias can be also promoted as most important sources which can be used for spreading educational messages regarding vaccination. There is need to upgrade knowledge among parents so as to ensure that immunization schedule is followed properly.

Health Issue as One of the Barrier to Women Weavers

Raju Saikia

Research Scholar, Gauhati University

Abstract

Health is an important factor for the upgradation of the society as a whole. A person with a good health can contribute more to the working than a person with bad health. Weaving is one of the activities which require the use of whole body and the mental and the physical strength. Weavers are a person whose job is to weave cloth. Weaving involves using a loom to interlace two sets of threads at right angles to each other. Weaving is a method of textile production in which two distinct sets of Yarns or thread are interlaced at right angles to form a Fabric or cloth. Other methods are knitting, crocheting, felting, and braiding. The longitudinal threads are called the warp and the lateral threads are the Weft or filling. The method in which these threads are inter-woven affects the characteristics of the cloth. Weaving can be summarized as a repetition of these three actions, shedding, Picking, Beating Up or battening which are primary motion of the loom, let of motion and take up motion is a secondary motion of the loom and lastly warp and weft is the tertiary motion of loom.

The health issue can be one of the barriers to women weavers. The paper is based on primary data where it tries to focus on the health condition of the people and their impact on weaving. The primary data has been collected on the basis of simple random sampling from the district of Lakhimpur in Assam.

Keywords: Health, weavers, shedding, picking, Motion.

Introduction

Health is an important issue for nations, who are engaged in economic development. All development activities, whether economic as well as social depend upon the sound mind, health and environment. The economic pressure in the country is the most striking factor that leads to the development of women weavers. Women weavers are endowed with invaluable talent of weaving masterpieces on textiles. Women in rural areas basically take up entrepreneurship to improve their standard of living. Weavers are a person whose job is to weave cloth. Weaving involves using a loom to interlace two sets of threads at right angles to each other. One of the encouraging steps is the development of women handloom weavers and the artisans. Weaving is a method of textile production in which two distinct sets of Yarns or thread are interlaced at right angles to form a Fabric or cloth. Other methods are knitting, crocheting, felting, and braiding. The longitudinal threads are called the warp and the lateral threads are the Weft or filling.

The health issue can be one of the barriers to women weavers. The present study tries to focus on the condition of women weavers and their health condition in Assam. The paper tries to look on the women in villages of Assam who have desire to weave cloth as their spare time activity and as a income source and to focus on their hindrances.

Objective: Women weavers are blessed with the skill of weaving masterpieces on textiles, this paper
tries to look on the health as a hindrance that obstruct women weaver’s entry into entrepreneurial activity in villages of Assam.

**Research methodology:** The paper utilizes empirical investigation and interview method with rural women engaged in domestic weaving in addition to bibliographical retrospect. Thus interpretive and empirical approaches form the basis of this study. Merbil, Baligaon, Panigaon, Harmutty(Bagicha), and Bahbari villages that exhibit typical rural characteristics in Lakhimpur district of Assam have been chosen for undertaking the research. These villages are specifically selected as these villages represent a good combination of Bodo, Kachari, Deori and Assamese populations. These women folk are very well known for their textile artistry in Assam. Assamese women in rural settings also practice textile weaving. Thus woman weavers who are engaged in the production of textiles while making the study are taken as the sample for the study.

**Sample Design:** Since health is an important factor for the development of the society as a whole let us take into account the domestic women weavers and their health condition, fifty respondents from fifty households were purposively chosen through convenience sampling technique out of a total of 100 households. The most of the sample were into weaving textiles which is used for domestic purpose as well as accomplish a part for occasional sale but not considering it as a full time occupation. The same respondents belong to the lower age category of 18-35 years, middle age category of 36-45 years and upper age category of above 45 yrs. but less than 60 years. From literature studies it has been observed that women especially in rural areas engage in entrepreneurial activities at later age once they are free from domestic responsibilities like taking care of their children, their health and the activities in their home. But, the presence of artistic skills is rooted among women at a very young age. Hence, the lower age limit is set at eighteen years, as this becomes a legal age in India and thereby legal to start an individual enterprise.

**Analysis:** Health is one of the significant factors for upgradation of the economic activities or skill. Women entrepreneurship faces a series of problems especially when they belong to village settings [7]. Women in India are faced with many problems to get ahead their life in business. With respect to women weavers in the selected villages it is astonishing to observe that only 43.3% of the women weavers in surveyed villages weave for occasional sale and 6.7% respectively weave for gifting purposes. But every woman who knows to weave dedicatedly weaves for her family.

According to statistics given below, 77.1% women believe that lack of access to start up finance is a major hurdle in their endeavor. It is seen from the table one that no access to property, difficulty to secure loan due to collateral security and dependence on family members for finance are major obstacles with respect to access to finance.

Source: Field Survey

The two major factor concerns for the low assessment of loan facility is loan refunding and lack of documents to avail loan. For few women, loan is something which they never prefer over financial support from family. A respondent retort that:
there is a continual miserable condition for me. Once I have taken money to buy two pigs. [...] they did not survive due to flood. Now I am in debt and still paying for it.

But there are some who are quite ok with the idea of approaching banks for loans and do not mind the process as tedious.

For one respondent, as she exclaimed that: There are certain things have to be compromised if one truly requires loan. I do not mind waiting in queue and beg to officials for loan or for the work to be done.

In case of accessibility to raw materials like thread and dyes and infrastructural issues, we can see from the table 1 that 81.2% of respondents believe that lack of access to raw materials is one of the major obstacles in their decision to take weaving as an entrepreneurial activity. The implicit problems with respect to raw material and infrastructural accessibility are presented in Table 3 where we can see that cost and the good quality raw material are the major obstacles.

In the above table we can see that women weavers find difficulty in purchasing raw materials due to high costs. A majority (72.4%) believes that lack of availability of good quality raw materials like variety of yarns and dyes in the nearby market is a problem factor in their pursuit.

Source: Field Survey

As we can see from table 1 that regarding domestic problems only 55.4% women in villages believes that it can be a major issue for them. As compared to literature review that shows lack of support from family as a primary obstacle for women to enter into business, the picture in villages of Assam tells a different story. Table 5 shows that only 40.4% of women agreed that their family will not support them if they desire to start their own weaving business. At the same time, it is also true that women in villages cannot take business decisions on their own as is evident from responses of 58.8% respondents.

One lower age group respondent said that: My family always recommends me to have my own business since I am skilled in this work well. Not everyone is gifted with such talent and I must utilize when I know how to weave the cloth. However, I cannot decide what is good or bad on my own and I take guidance of my husband and the family member in every matter.

77.3% women believe that family responsibilities hold first place for them but at the same time they believe that it is not impossible to balance family and work life as stated by 48.5% respondents.

Table 5: Domestic problem as hindrances

Source: Field Survey

As we can see from the table 5 that there is some domestic problem in the society, since they have to do some domestic work as well. 77.3 % of respondent consider family responsibility to be their first preference then the weaving or any other activities. A respondent retorts that;
I woke early morning do all my household works [...] and works in night after all sleep.

Many women in the villages face major difficulty to take up weaving as business activity as there are many other responsibilities. Most of the women in villages rear pigs, poultry, etc. alongside agriculture which take away most of their time.

Table 6: Health Related issues as hindrance

<table>
<thead>
<tr>
<th>Health Issues</th>

<td>65.1</td>
<td>34.9</td>
</tr>
<tr>
<td>Lack of Manpower in Hospitals</td>
<td>46.6</td>
<td>53.4</td>
</tr>
</tbody>
</table>

Source: Field Survey

Some of the respondent’s retort that: After working for a longer period there is a problem with the eyesight, there is headache and sometime due to excessive time in weaving there is laziness [...] creates some domestic issues.

As we can see from the table 6 that the eyesight problem is one of the important issues among the weavers, it is seen that 72.1 % of women are facing eyesight problem. Similarly, the distance among the people and the health sector were too high as one of the respondent’s retorts that;

I was suffering from fracture in hand and when I went to the hospital after a long distance there was no doctors present in the hospital [...]

Conclusion

Weaving is one of the artistic skill presences among the people with increase in hindrances in weaving the weaving sectors are lagging behind. If the health condition of the people is up to mark they are motivated to their work or weaving cloths. A prior importance should be given for the development of the health sector of the people for the development of the economy as a whole.

Women weavers are not averse to the idea of taking up weaving as a full time occupation or enterprising. They have the inner urge or creativity and they want to prove themselves. For the up gradation of women weavers these are few significant factors that should be upgraded i.e. Health issues, finances, raw materials, training, access to markets, etc. to help such women utilize their skills productively. Various studies from time to time has focused on these persisting issues it is imperative to see that their requirements are fulfilled so that these obstacles do not hinder their entrepreneurial pursuit. If such provisions are given to our village women, we could expect more number of talented women weavers joining the commercial activity, and thereby, making the village society prosperous and self-sustainable.

Abstract

Introduction: The literature provides a clear evidence of involvement of auditory system from peripheral auditory system to auditory cortex in individuals with Type-II diabetes. Speech perception in noise, along with auditory brain stem responses (ABR) and otoacoustic emissions have been found to be affected in these individuals. The speech perception ability is affected in these individuals which can be associated with central auditory processing ability. There is a need to understand central processing ability involvement. Hence aim of the present study was to explore the effect of Type-II diabetes on temporal processing abilities like modulation detection and gap detection thresholds.

Method: The research was carried out on 40 participants, between the age ranges of 28 – 60 years, who were diagnosed as having Type-II diabetes since 5 years and compared to control age and gender matched participants without diabetes.

Results: Independent t-test was applied to assess the statistical significance between both the groups. The results reveal that the group of participants without diabetes performed better than the group of participants with type-II diabetes.

Conclusions: There is an involvement of central auditory processing ability on task of modulation detection and gap detection in participants with type-II diabetes.

Keywords: Temporal modulation transfer function, Gap detection, Diabetes.

Introduction

India is one among those nations which has the maximum proportion of individuals having diabetes, being designated the “Diabetes capital of the world”¹. American Diabetes Association (2011) has broadly identified Type I and Type II varieties of Diabetes Mellitus. In Type I diabetes, little or no insulin is produced owing to the destruction of the cells that produce insulin in the pancreas, which is not preventable². Type-II diabetes is the most common type, with more than 90% of all diabetes in the world and is generally due to excessive body weight and lack of physical activity. People with this type of diabetes produce too little insulin or the insulin they produce is of no use because their body has become resistant to insulin. These hormones regulate blood sugar in body and irregularity in production of these hormones can lead to uncontrolled diabetes, over time causing serious damage to nerves and blood vessels. Our entire auditory system is highly dependent on blood supply specially the cochlear portion. The type-II diabetes has an impact on auditory system also, both at peripheral as well as central auditory pathway. The auditory evoked brainstem response is reported to be affected in individuals with Type-II diabetes³–⁶. It has been reported that individuals with Type-II diabetes...
Their performance was compared to control group as having Type-II diabetes (Group 1) since Sticky Note. Mean- 44 years, SD- 5.3 years), who were diagnosed individuals, between the age ranges of 28 – 60 years with Type-II diabetes. The duration of the diabetes among the individuals with Type-II diabetes, owing to the damage of the nerve cells. The central auditory processing ability depends on central processing ability. Sometimes in the absence of peripheral hearing loss, there may be impact on central hearing in individuals with Type-II diabetes, worsening to the damage of the nerve cells. The central auditory processing ability through temporal modulation transfer function and gap detection can shed light on better understanding about involvement of central auditory processing ability. The speech perception is important for communication, especially in adverse listening conditions and it determines the quality of life. Hence, this study intends to study central auditory processing abilities among those individuals with Type-II diabetes who have normal peripheral hearing. The auditory processing abilities in present context include performance of the participants on two tasks i.e. gap detection threshold (GDT) and modulation detection threshold (TMTF) respectively.

**Aim and objectives of the study:** The aim of the present study was to explore the effect of Type-II diabetes on temporal processing abilities like modulation detection and gap detection thresholds. The primary objective of the research was to estimate the difference in the performance of individuals with and without Type-II diabetes on the given two tasks of temporal processing. Furthermore, the research also explored the correlation between the task performances on the two given tasks with the duration of the diabetes among the individuals with Type-II diabetes.

**Method**

**Participants:** The research was carried out on 40 individuals, between the age ranges of 28 – 60 years (Mean- 44 years, SD- 5.3 years), who were diagnosed as having Type-II diabetes (Group 1) since Sticky Note. Their performance was compared to control group (Group 2) which consisted of 40 age and gender matched participants without diabetes as screened by Canadian Diabetes screening checklist (CAN RISK). The hearing sensitivity of all the participants was found to be within 25 dB HL for air conduction and bone conduction at octave frequencies ranging from 250Hz – 8 kHz and 250Hz – 4 kHz respectively, with an air bone gap of 10 dB or less. Further, participants with normal middle ear function and minimum score of 25 on Mini Mental Status Examination were considered for the study.

**Need for the study:** The literature provides a clear evidence regarding involvement of auditory system from peripheral auditory system to auditory cortex in individuals with Type-II diabetes. Speech perception in noise, along with auditory brain stem responses (ABR) and otocoustic emissions have been found to be affected in these individuals. The central processing issue needs to be explored more as speech perception ability depends on central processing ability. Sometimes in the absence of peripheral hearing loss, there may be impact on central hearing in individuals with Type-II diabetes, owing to the damage of the nerve cells. The central auditory processing ability through temporal modulation transfer function and gap detection can shed light on better understanding about involvement of central auditory processing ability. The speech perception is important for communication, especially in adverse listening conditions and it determines the quality of life. Hence, this study intends to study central auditory processing abilities among those individuals with Type-II diabetes who have normal peripheral hearing. The auditory processing abilities in present context include performance of the participants on two tasks i.e. gap detection threshold (GDT) and modulation detection threshold (TMTF) respectively.

**Procedure:** The procedure of the entire study was carried out across two steps. The first step involved assessment of the eligibility criteria of the participants followed by their evaluation of temporal processing abilities. All the participants underwent TMTF and GDT for the assessment of temporal processing skills.

**TMTF:** In this task, a participant is expected to detect the sinusoidal amplitude modulation in a broadband noise depending upon the depth and rate of stimulus modulation. In the present study, sinusoidal amplitude modulated stimulus was presented at the modulation rate of 8Hz, 20Hz, 60Hz and 200Hz with two alternative force choice, by using staircase procedures to track threshold. Presentation of the stimuli was binaural. In Simple Up-Down or Staircase Method, the stimulus intensity is increased every time a participant fails to respond to the stimulus and is decreased when the participant responds. Temporal discrimination or resolution is the shortest time needed to discriminate between two auditory signals. TMTF is the ability to detect amplitude modulation in a sound, generally measured by having the participants indicate whenever a silent interval embedded is heard in a noise burst. In present research, the carrier was given in two consecutive intervals with silent intervals of 200ms, sinusoidally amplitude modulated in randomly chosen interval. As the threshold run was in progress, the modulation depth in dB (20 log m), was attuned by a 1 down 1-up rule. Step size was 31.5 with 48 reversals. Participants were given 3-4 practice trails before the commencement of each test.

**GDT:** White band noise was used to find out the auditory acuity of the participants. The Noise consisted of 0.5 msec cosine ramps at the beginning and end of the gap which was presented for a duration of 500 msec. Rephrase this sentence to “Inter stimulus duration was 500 ms and duration of gap was changed at step size of 2ms in the beginning, while step size was reduced...
to 1.41421 ms near threshold. Two interval alternative forced choice task was used for estimating threshold. Inter stimulus duration was 1500 msec with varied gap changes of 2 1.41421 msec step size in two interval alternative forced choice task in simple staircase method.

Statistical Analysis: The scores of the participants of both the groups across the two tasks were tabulated and subjected to statistical analysis using the SPSS 15.0 version. Independent t-test was administered to evaluate the existence of difference between the performance of both the groups across TMTF and GDT. The relation of duration of diabetes with the performance on both the tasks, among the Group 1 was evaluated by using the Pearson’s correlation.

Results

Modulation Detection Threshold: The TMTF was performed across four modulation frequencies i.e. 8Hz, 20Hz, 60Hz, and 200Hz for both the groups. The results revealed that the group of participants without diabetes performed better than the group of participants with type-II diabetes for all four modulation frequencies which means that the participants with type-II diabetes had poor ability on modulation detection ability. Independent t-test revealed statistically significant difference between the two groups across all the four modulation frequencies [8Hz-\(t(78)=3.20, p=0.002\); 20Hz, \(t(78)=3.87, p<0.001\); 60 Hz, \(t(78)=4.49, p<0.001\); 200Hz, \(t(78)=5.87, p<0.001\)]. The Figure 1 describes the mean and one standard deviation values obtained by participants of both the groups for TMTF tasks in dB.

![Figure 1: Mean and standard deviation of TMTF values of participants with and without diabetes](image)

The participants without type-II diabetes surpassed the participants with type-II diabetes i.e., participants with type-II diabetes had poor ability on gap detection and took longer time than the non-diabetes participants. Independent t-test revealed a statistically significant difference between the two groups [\(t(78)=3.08, p=0.003\)]. The Figure 2 describes the mean along with standard deviation values obtained by participants of both the groups for GDT tasks in msec.
Fig 2: Mean with standard deviation of GDT values for participants with and without diabetes

Effect of age of diabetes on TMTF and GDT scores: To understand if there exist any significant correlation of the duration of diabetes with TMTF and GDT scores for participants with diabetes, the Pearson’s correlation coefficient was performed. In Table 1, the correlation of the duration of diabetes with TMTF and GDT have been depicted.

Table 1: Showing the Correlation between the duration of diabetes and test variables

<table>

<td>0.392</td>
<td>0.011</td>
</tr>
</tbody>
</table>

The correlation coefficient correlation value disclosed that the duration of diabetes positively correlated with both the tasks. However, it reached a level of statistical significance for the GDT task only, than the performance on TMTF task.

Discussion

The presence of significant differences between the performance of participants from group 1 and the group 2 on both TMTF and GDT tasks suggests that the type-II diabetes group had a substantial influence on the temporal processing abilities compared to the group without diabetes who demonstrated greater ability. This finding indicates that though the peripheral hearing ability is with in normal limits, the central auditory processing ability was affected. Hence, it can be inferred that individuals with Type-II diabetes may have auditory processing difficulty in spite of peripheral hearing being with in normal limits. The auditory processing difficulty in present study, we attribute to Type-II diabetes as it is known to cause serious damage to nerves and blood vessels. These results are in line with the earlier observation where TMTF was affected among individuals having Type-II diabetes, who possess high frequency hearing loss. The evidence from other study have also noted that there is presence of subclinical hearing loss along with deviant auditory brainstem responses among individuals with Type-II diabetes. Speech perception abilities being significantly affected in individuals with Type-II diabetes with normal hearing is reported in previous research as well.

Though all the participants had type-II diabetes for more than 5 years in this study, a significant correlation was witnessed between their duration of diabetes and performance on various tasks. With the increase in the years of having diabetes, affected individuals exhibited lower performance on both the TMTF and GDT tasks, respectively. This could be attributed to the age linked increase in impact of Type-II diabetes on structural aspects of the central nervous system, the auditory processing and cognitive influences.

Conclusion

The present study’s results conclude that participants with type-II diabetes exhibit significant deficits in the
temporal processing abilities and gap detection abilities in spite of peripheral hearing abilities being normal. Further, there is an association amongst the duration of diabetes and the deterioration in performance on the temporal processing tasks. Hence it can be concluded that there is an involvement of central auditory processing ability on task of modulation detection and gap detection in participants with diabetes.

Impact of Dividend Announcement on Stock Returns and Market Efficiency in India

V. Shanthaamani¹, V.B. Usha²

¹Professor, Department of Management Studies, Vels University, P.V. Vaithiyalingam Road, Velan Nagar, Pallavaram, Chennai, ²Asst. Professor, Department of Economics, LRG Govt Arts College for Women, Palladam Main Road, Near Collector Office, Tirupur, Tamilnadu

Abstract

The announcement of dividend can be seen in two perspectives: if the dividend that is announced is up to expectations of shareholders, the market price of the shares will be positively affected. Whereas, if the dividend that is announced is not up to expectations of the equity investors, the market price of the shares will be negatively affected. Market efficiency is defined as the amount of time it takes for the stock market to react to announced public information. Finally, when a market is strong-form efficient, investors are unable to earn above normal returns by relying on both public and private information. This research is an attempt to find out the relationship between dividend announcement and the market efficiency. This paper explores the market reaction to dividend announcements of BSE SENSEX stocks for the period 2014-2017 using Event study methodology.

Keywords: Dividend announcement, Market Efficiency, Abnormal Return, Event study.

Introduction

Investment means commitment of funds or money to gain a return. However, this commitment of capital also has a price in terms of blocking of money and that too with a risk of losing it. The concept is applied while investing in common stock in a more precise manner. Stocks are more volatile and risky than debt securities. Before investing into common stock, an investor should keep three factors in mind nature of business, quality of management and price to be paid. These three factors will help together to decide the proportion and time of investment. In addition to these factors there are so many points to be considered before an investor finally takes a decision to invest in a particular security. These factors can be knowledge of share market, trading at stock exchanges, risk and return analysis, dividend expectations, news announcements especially dividend announcements. When a corporation earns a profit or surplus that can be put to two uses: it can either be re-invested in the business or it can be paid to the shareholders as a dividend. Many corporations retain a portion of their earnings and pay the remainder as dividend. The variation in the stock prices would be more if dividend policy is frequently changed. It happens due to the frequent reactions of investors in lieu of announcements at stock exchanges by the companies.

Market efficiency depends on the ability of traders to devote time and resources to gathering and disseminating information. Markets that are more efficient attract more investors, which translate into increased market liquidity (Osei, 1998). Investors care about market efficiency because stock price movements affect their wealth. More generally, stock market efficiency may affect consumption and investment spending and therefore influence the overall performance of the economy. This study is an attempt to examine the stock price reaction to dividend announcements by 30 companies listed on BSE SENSEX during the period 2014-2017.

Review of Literature: Balachandran Balasingham (2001) examined the share price reaction to announcement of bonus share issues of Australian companies. They found that the magnitude of price

Corresponding Author:

e-mail: apshan6@gmail.com
reaction to bonus issue announcements is statistically related to the size of bonus issues and pre-announcement effect.

Vandana Gupta (2003) in a study involving a sample of 145 bonus issues examined the announcement effects of bonus issues on equity share prices in India and concluded that the Indian Stock market was efficient in its semi-strong form.

Budhraja et al. (2004) in their study on BSE suggested that abnormal returns in stock prices around the bonus issue announcement data, over three day trading period starting one day before the announcement is significant at 95 per cent confidence level.

Mishra (2005) examined the reaction of the stock price to the information content of bonus issues and found that the stock starts showing positive abnormal returns eight to nine days before the announcement date. This could be due to the leakage of the informational content. This paper lends support to the hypothesis that Indian stock market is efficient in its semi-strong form.

Madhuri Malhotra et al. (2007) in their study has examined the share price reaction to the announcement of bonus issue for a sample of Indian companies. Bonus issue announcement yielded negative abnormal returns around the announcement date. There is a negative reaction after the bonus issue announcement conveying that the market under reacts after the announcement. It was also observed that there is no information leakage prior to the announcement.

Olatundun Janet Adeleogan (2009) assessed the speed with which share prices adjust to the information contained in dividend announcements in the Nigerian stock market and to investigate market reactions to announced changes in dividend policies by Nigerian companies and determine whether there is no overreaction or a drift. The study revealed that the mean excess returns are generally negative for all the dividend omission subsamples both before and after the date of announcement, but positive after the announcement date.

Muhammad Aamir and Syed Zulfiquar Ali Shah (2011) study dividend announcement and the abnormal returns for the event firm and its rivals. The study found that there were some firms whose abnormal return were negative on the dividend announcement date but became positive immediately after the dividend announcement date. There were some other companies, whose abnormal returns were positive on the dividend announcement date and some days before and after the announcement date. There are instances of dividend announcement day return was negative but it was positive before and after the dividend announcement date. Overall results indicate that impact of dividend on dividend announcement date and few days after were positive. These results confirm the theoretical background regarding the impact of dividend on the stock prices.

Suwanna and Thanwarat (2012) study result indicates that the stock prices move upward significantly after dividend announcements. Abnormal return (AR) and cumulative abnormal return (CAR) from the market model are statistically significantly revealed. The results confirm dividend signaling theory as the dividend announcements have significant impact on share prices.

Pradhan and Subhendu (2014) examined that there is a rise price after result but that rise in price is mainly due to market conditions rather than dividend. The increase or decrease in share price is not reflecting the amount of dividend. The CAR is positive in the long run after dividend announcement.

Rosario et al. (2016) findings show that there is an increase in the share price and has resulted in positive average abnormal return especially in the post dividend declaration period in Oman context.

Objectives of the Study:
1. To investigate the stock market reaction to dividend announcements.
2. To test the market efficiency with the announcement of dividend by a company.
3. To examine the excess or abnormal return that the shareholders expect at the time of dividend announcements.

Hypotheses of the Study:

H$_1$: There is no statistically significant difference in the response of stock price to dividend announcements.

H$_2$: Indian stock market is inefficient.

Methodology: This paper focus on the relationship between the stock prices reactions to dividend announcement by selected companies. For this purpose, secondary data were collected from BSE SENSEX which has increased dividends during 2014-2017. The data has been taken from the website of www.bseindia.
com and the Economic Times. As per the methodology a common event with different dates has been applied. The common event is the firm’s announcement of dividend. The event period is created taking the public announcement day as benchmark or day “0” 15 days prior to the public announcement date and 15 days after the date are taken into consideration. So the event period is of 31 days starts with -15th day and end with +15th days. These 31 days are referred as event period.

Daily abnormal returns for the security ‘i’ from 15 days before to 15 days after the dividend announcement has been computed as follows:

\[ AR_{i,t} = R_{i,t} - E(R_{i,t}) \]  \hspace{1cm} (1)

where,

\[ t = \text{day measured relative to dividend increase announcement day} \]

\[ AR_{i,t} = \text{abnormal return on security ‘i’ for day ‘t’} \]

\[ R_{i,t} = \text{raw return on security ‘i’ for day ‘t’ which was calculated as:} \]

\[ R_{i,t} = \frac{MP_{i,t} - MP_{i(t-1)}}{MP_{i,t}} \]

where,

\[ MP_{i,t} = \text{market price on security ‘i’ for day ‘t’} \]

\[ MP_{i(t-1)} = \text{market price on security ‘i’ for day ‘t-1’} \]

\[ E(R_{i,t}) = \text{expected return on security ‘i’ for day ‘t’ which has been estimated through market model using BSE SENSEX as follows} \]

\[ E(R_{i,t}) = \alpha_i + \beta_i * R_m - \varepsilon_i \]  \hspace{1cm} (2)

Where \( \alpha_i \) and \( \beta_i \) are the parameters of market model,

\[ R_m = \text{Return to the market (BSE SENSEX)} \]

\[ \varepsilon_i = \text{abnormal return} \]

Average abnormal return has been calculated as:

\[ AR_t = \frac{\sum_{j=1}^{N} R_{j,t}}{N} \]  \hspace{1cm} (3)

where

\[ AR_t = \text{Average abnormal returns} \]

\[ N = \text{Number of securities with abnormal returns during day ‘t’} \]

The cumulative average abnormal returns (CAR) of dividend announcement by summation of the average abnormal returns (AR) in the respective window.

\[ CAR = \sum_{t=-15}^{15} AR_t \]  \hspace{1cm} (4)

For the purpose of study, the stock prices of 30 companies are taken. The list of sample companies is displayed in Table 1.

**Results and Discussions**

For testing the market efficiency, in this study cumulative annual return (CAR) of all the thirty companies are computed. For computation of CAR, we need to first compute the average abnormal return (AR).

Source: Estimated values, *Significant at 10% level, ** Significant at 5% level, ***Significant at 1% level

The results of the table 2 shows that the market reacts positively to the increasing dividend as the investors considered the increasing dividend as positive signal of future optimum earning. Meanwhile, the signaling cannot be applied to the decreasing period where there is significant positive AR reflected by market during the days -1 and +1 in parallel with Yip (2010)[15]. The positive significant changes for AR in the day -1 might reveals a leakage of information in a short period before the official announcement and it can be considered as a short-term reaction linked to the event after the announcement (Kothari, et al., 2006)[7]. The market reaction in Indian stock market is complete within a day. This result suggest that the Indian stock market responds quickly and efficiently to the corporate news about dividend announcement. The null hypotheses $H_1$ there is no statistically significant difference in the response of stock price to dividend announcements has been rejected. The results are in line with the developed markets Gurgul et al, 2003[5]; McClusky et al, 2006[9].

Source: Estimated values, *Significant at 10% level, ** Significant at 5% level, ***Significant at 1% level

Table 3 shows that CAR values are significant for event windows (-15, 0), (-10, 0), (-5, 0), (-2, 0) at 1% level of significance and at 5% level of significance for (-15, +15) event window. It can be confirmed that the market addressed positive abnormal returns on days -1, 0 and +1. CAR value is 1.009 on the 15th day of trading, which means that stock market was inefficient over that time period. This results in the acceptance of null hypotheses $H_2$ that the Indian stock market is inefficient.
The figure 1 indicates that AR does not vary significantly. It is very clear that the AR curve follows almost a linear pattern with very negligible deviation. This means, that dividend declaration does not have much impact on average abnormal return.

In figure 2, the CAR presented 15 days before the declaration of dividend was quite lower and it got much impact day on day basis after declaration of dividend. CAR has been decreasing in the pre-announcement and post-announcement period.

Conclusion

Dividends are payments made by a corporation to its shareholder members. It is the portion of corporate profits paid out to stockholders. When a corporation earns a profit or surplus, that money can be put to two uses: it can either be re-invested in the business or it can be paid to the shareholders as a dividend. It increases wealth maximization of shareholders. This study indicates that investors do benefit from dividend announcement over the 31 period of days. After declaration of dividend the market shows inefficiency and that does not affect the stockholders.

The positive impact of dividend increase has been reflected in the Indian stock market. Findings also reveal that dividend signals good news to cause large price movements than those involving bad news. This suggests that bad news may be discounted long before the dividend announcement.

A New Ensemble Approach to Predict Breast Cancer

G. Manikandan¹, J. Poigai², R. Bala Krishnan³, B. Karthikeyan⁴, P. Rajendiran⁵

¹Senior Assistant Professor, School of Computing, ²Student, School of Computing, ³Assistant Professor, Srinivasa Ramanujan Centre, ⁴Senior Assistant Professor, School of Computing, ⁵Assistant Professor, School of Computing, SASTRA Deemed University, Thanjavur, India

Abstract

The primary objective of using a variety of Data mining techniques in health care domain is to construct a useful model that can effectively interpret the data from a cluster of medical datasets. To reveal the hidden pattern in data, Data Mining techniques and algorithms rely on a wide variety of machine learning techniques. Classification along with prediction techniques play an essential role in medical decision making. This type of knowledge-based system can aid doctors in predicting the disease accurately. The main objective of this paper is to create an ensemble of classification algorithms to classify the cancer data set with higher classification accuracy when compared with the existing classification algorithms available in the literature.

Keywords: Data mining, Classification, Ensemble Learning, Bagging, Boosting.

Introduction

Data mining is the cognitive process of divulging exciting patterns and knowledge from a huge quantity of data. All the tools and techniques used for retrieving the interesting relationships in large amounts of data come under the umbrella of data mining.¹

Classification and Prediction are the two prominent data mining techniques that play a vital role in the health care domain. Classification also is known as categorization and used to classify or place the known data in one of the preexisting classes with the help of various learning rules. If the classification model is used to prognosticate the class for new data, it would be a prediction. For effective disease prediction, physicians make use of a variety of expert systems trained by machine learning techniques.

These techniques can be broadly classified into three different categories namely supervised learning, unsupervised learning, and semi-supervised learning. Supervised learning techniques build models for relegating succeeding events according to the historical information. A wide variety of models developed using supervised machine learning techniques are available in the literature. One of the challenging tasks to the researchers is to identify an appropriate technique for constructing and implementing an efficient expert system for disease diagnosis.

Breast cancer is considered to be the second common non-skin cancer. In India, breast cancer ranks as the number one cancer among Indian females. Cancer affects nearly 1% of the female population. The medical community faces deterrence in developing guide-lines for cancer prediction due to the absence of even a single identifiable cause for this disease. Findings of the recent research, reports that 90% of patients with cancer had related symptoms long before they were diagnosed. The proposed ensemble model acts as an efficient classifier than the existing system. Boosting ensemble approach gives an accuracy of 94.13% with Naive Bayes, 95.07% with K-Nearest Neighbor (KNN) and 99.06% with Multi-Layered Perceptron (MLP).

Literature Review: A hybrid knowledge-based system that employs various machine learning techniques for diseases prediction was proposed. Disease prediction is done in this system with the use of fuzzy rules.² Fuzzy rules were generated using the regression tree algorithm. EM algorithm was used for data clustering and for dimensionality reduction PCA was used. Several

e-mail: manikandan@it.sastra.edu
experiments were conducted to evaluate the efficiency of the proposed system on various data sets like Wisconsin Diagnostic Breast Cancer and Pima Indian Diabetes. Parkinson’s telemonitoring dataset was used for validation purpose. Experimental results indicate that this integrated approach results in higher accuracy in disease prediction. The data sets used in the experiments are with known input and output parameters.

Humans with excessive glucose are said to be diabetic. According to a survey, about 415 million people in the world are said to be diabetic. The number is expected to rise to 642 million people by 2040. Still 46% of the people with diabetic are unrecognized. Most of the classification algorithms used for diabetic prediction relies on the traditional approaches namely linear discriminant analysis (LDA), quadratic discriminant analysis (QDA), and Naive Bayes (NB). Gaussian process (GP)-based classification technique was used for diabetic prediction. This process uses three different kernels namely radial basis, linear and polynomial. [3] Accuracy, sensitivity, specificity, negative predictive value, positive predictive value, and receiver-operating characteristic were the parameters used to evaluate the accuracy of the Gaussian process. Pima Indian Diabetic data set was used as input to the proposed system. From the experimental results, it is evident that the proposed system results in higher accuracy than the traditional approaches.

A new expert system for efficient classification of breast cancer disease was proposed. Clustering plays a vital role in increasing the accuracy of any disease prediction system. Expectation Maximization (EM) is used to group data in the experimental data set. Regression Trees were used to generate fuzzy rules from the data set. [4] To defeat the multi-collinearity issue in the data, the dimensionality reduction technique was utilized using Principal Component Analysis (PCA).

An online tool named HPBCR (a hybrid predictor of breast cancer recurrence) was proposed to predict breast cancer in an efficient manner. Authors have analyzed the characteristics of 579 breast cancer patients and identified the essential features using statistical feature selection method. [5] These features were further refined using Particle Swarm Optimization algorithm. 4-fold cross-validation technique was used to measure the accuracy of the proposed system. From the experimental results, it is evident that the performance of HPBCR was higher than the other tested classifiers.

The objective of this work is to find the best combination of classifiers which is suitable for a heterogeneous collection of data sets related to heart disease. Subsequently, six classifiers namely BayesianNet, Naive Bayes, Support Vector Machine, Neural Network, C4.5, and FDT are used to predict heart diseases. [6]

A framework is created for Heart disease prediction by utilizing a Naive Bayesian Order strategy. The framework extricates concealed information from an authentic coronary illness database. From the experimental results, it is found that this model is the best one to anticipate patients with coronary illness. This model is capable of answering complex inquiries, each with its very own requirements without any difficulty of model elucidation. [7]

A novel neuro fuzzy strategy is built to analyze the reality of the illness from the patient report. A summed up database is built for basic decision making from the diminished traits set, which is a yield of genetic algorithm. A four layered fuzzy neural system for proficient demonstrating and dissuading fleeting conditions under vulnerability is utilized. [8]

**Proposed System:** The objective of our proposed work is to construct an ensemble with Multi-Layered Perceptron, Naïve-Bayes, and K-nearest neighbour algorithms. Here we have given Wisconsin dataset as an input to all the three classification algorithms. Then ensemble method like Bagging and Boosting are applied to these algorithms.

**Results and Discussion**

For experimental purpose, we have used Wisconsin dataset. It has 683 instances and 9 attributes namely sample code number, clump Thickness, Uniformity of cell shape, Uniformity of cell size, Marginal adhesion, Singe epithelial cell size, Bare nuclei, Bland chromatin, normal nucleoli, Mitosis. From the Table 1, it can be inferred that boosting ensemble with Multi-Layered Perceptron method results in higher accuracy.

Conclusion

Cancer is a disease in which cells separate in an uncontrolled manner and ruin body tissue. Breast cancer is one type of cancer that forms in the cells of the breasts. Breast cancer is considered to be the most common type of cancer in women. 2 million new cases were reported in the year 2018. The suggested ensemble can render promising results in breast cancer prediction. Our approach has used Boosting and Bagging ensemble techniques with Multi-Layered Perceptron, Naïve-Bayes and K nearest neighbour algorithms which result in the precise prediction of breast cancer. We can understand from the experimental results that Multi-Layered Perceptron with boosting is the best ensemble technique for cancer prediction.

Effectiveness of a Parent Education Programme on Knowledge Regarding Home Care Management of Children with Epilepsy

Anila K.P.1, Rajee Reghunath2

1Professor, Amrita College of Nursing, AMRITA Vishwa Vidyapeetham, Kochi, 2Principal, Amala College of Nursing, Amalanagar PO, Thrissur, Kerala, India

Abstract

Purpose: To assess the effectiveness of a parent education programme on knowledge regarding home care management of children with epilepsy and compare the pre-test knowledge scores of mothers with the selected demographic variables.

Method: The research approach was quantitative and the design of the study was one group pre- test post-test. The sampling technique was convenience sampling. The sample size of the study was 30 mothers of children with epilepsy. Data was collected with the help of a structured knowledge questionnaire to assess the knowledge of mothers and the demographic details. The analysis was done by using frequency, percentage and t-test.

Results: The mean post-test knowledge score (23.26 + 3.71) is significantly higher than the mean pre-test knowledge score (14.50 + 3.62) which indicates that the mothers gained more knowledge after the administration of parent education programme on home care management of children with epilepsy. The comparison of pre-test knowledge scores of mothers with selected demographic variables (p value-0.000) shows that there is significant association between the pre-test knowledge score only in the area of education and occupation of the parents.

Conclusion: The study depicts the importance of implementing education programme for parents of children with epilepsy as it would help to improve knowledge on home care management and follow healthy practices, through which the children can build up a good quality of life.

Keywords: Epilepsy, Home care management, Children, Parents, Knowledge.

Introduction

Childhood is a unique phase of human development. Children are the important feature of every society and also the future of a nation. Epilepsy is the common neurological condition in children. Epilepsy can begin at any time of life. Although it varies from person to person, children with epilepsy generally have seizures.1

According to the World Health Organization definition, “a diagnosis of epilepsy is made in the presence of recurring seizures, at least two unprovoked ones.” Approximately 45,000 children under the age of 15 develop epilepsy each year. Population based studies have reported the prevalence rate of 3.6-4.2/1000 children in developed countries and approximately double these rates in developing countries. Beliefs, attitudes, and misconceptions toward the disease still exist, and families do not easily accept the disease and its treatment regimen. These “stigma” and misconceptions are due to lack of information and knowledge toward the disease.2

According to the International League Against Epilepsy (ILAE) 2005, Epilepsy is a disorder of the brain characterized by an enduring, predisposition
to generate epileptic seizures and by the neurologic, cognitive, psychological and social consequences of this condition.³

In India the overall “incidence” of epilepsy lies between 20- 50 cases per year per 100,000 persons in a general population. The “prevalence” rate is 500-1000 cases per 100,000 persons in the population. Going by these statistics, there will be about 2,600–6,500 new cases of epilepsy every year in Delhi alone (estimated population of 1.3 crores) and 200,000 to 500,000 new cases in the whole of India (estimated population about 100 crores) Kruskal Values test.⁴

Many epilepsies have direct impact on a child’s brain and, therefore, on their cognitive development, language and social skills. Children with epilepsy have higher rates of Attention Deficit Hyperactivity Disorder (ADHD), Learning disorders and Behavioural problems, Disruptive behaviour and Aggression.⁵

A cross sectional study conducted by Ettinger et al. among 100 epileptic, aged 6-11 years old children who visited Neurological Clinic at Queen Sirikit National Institute of Child Health depicts that prevalence of behavioural problems was 57% in epileptic children. The study results also reveals that behaviors that indicate Attention Deficit Hyperactivity Disorder (ADHD) was 58%, social problems are 32% and conduct disorders was 24% respectively. Depression is a common but frequently overlooked problem in children with epilepsy. Also found that 26% of children with epilepsy had symptoms of depression, but none had been identified or treated.⁶

Epilepsy leads to sleep problems and tiredness are reported frequently by parents of children with epilepsy, particularly in non idiopathic epilepsy. Seizures can delay sleep, lead to awakenings during the night; disrupt quality of sleep and decrease total sleep time, affects memory. Parents of children with epilepsy suffer from sleep deprivation as they regularly wake to check on their children during the night.⁷

In addition to the ‘normal’ influences of demographics, cultural, cognitive and behavioural factors in development of children with epilepsy they can also experience social incompetence at school, with their peers and in other relationships, and in group activities. The reduced social competence in girls could be due to several factors, the severity of the epilepsy, subtle cognitive defects, subclinical behavioural disorders, over protection from their family and fear of seizures which can be transmitted to children by parental anxiety and negative attitude.⁸

After headache, epilepsy is the second most common neurological condition seen by neurologists among all age group worldwide. Epilepsy is a common illness occurring approximately in one percent of the general population in South India. The knowledge about epilepsy are often clouded in mysticism, superstition and despair not only among the rural folk who constitute nearly 76.7% of the country’s population, but also among the urban people including the intelligent.⁹

The family can act as a buffer or stressor for all children with epilepsy, the stress the parent feels can affect their behaviour towards their child and the psychological impact upon the child’s adaptation to their condition. Parents may be anxious about their child’s diagnosis seeing them as different to other children. Parents can encourage dependence on them so that children do not develop their own competencies as parents can overprotect children at times being overly intrusive.¹⁰

A descriptive study was conducted by Manju et al. to evaluate the knowledge and attitude of parents of children with epilepsy toward the disease. Parents of 60 children from pediatric neurology clinic of All India Institute of Medical Sciences, Delhi were enrolled. Data on epilepsy were collected using pre-tested and validated self-developed questionnaire (α=0.85, 0.89). The mean knowledge and attitude scores of parents of the children with epilepsy were 9.82±3.9 (2-22) and 31.25±9.27 (0-40), respectively. Parents of the children with epilepsy had poor 50(83.3%, scores <60%) to fair knowledge scores (60-70%). Correlation between knowledge and attitude was found to be very weak and negative (r=−0.039, p=0.77) with few misconception related to disease and clear idea about the activities to be performed with/without caution. The study suggested that there is a need for developing information booklet and conducting educational sessions on epilepsy for the parents.¹¹

A study conducted by Radhakrishnan K, Pandian JD, Santhoshkumar T, Thomas SV, Deetha TD, Sarma PS, et al. on Prevalence, knowledge, attitude, and practice of epilepsy in Kerala. The study reveals that people with epilepsy face stigma in many communities. Stigma is referred to as a severe social disapproval of personal characteristics or beliefs that are against
cultural norms. The study was conducted among total of 1,175 mothers. Among these, 31% thought epilepsy to be a hereditary disorder, 27% a form of insanity, 40% were denied employment due to their condition, 11% of the parents did not allow their child to play with children with epilepsy and 55% of the women concealed their epilepsy during marriage negotiations. Out of those who concealed, 18% were legally divorced and 20% were separated from their spouses because of the disease. These studies reflect different aspects of stigma associated with epilepsy.12

A survey conducted at Institute of Medical Education and Research, Chandigarh in 1995 on Public awareness, understanding and attitude towards epilepsy. The report shows that 92% of persons were not read or heard about epilepsy. Most (55%) of them knew someone with epilepsy. Less percentage (18%) of them thought that epilepsy to be a hereditary disorder. 40% of them had an opinion that children with epilepsy hould not be sent to school. Half (50%) of the parents did not know the first aid during seizures.13

Lack of knowledge and misconceptions about epilepsy have been associated with parental anxiety. Children take their cues from their parents and develop worries and concerns about their epilepsy. Education about epilepsy is effective in reducing parental anxiety.14

A key element in managing these patients and their families is adequate education. Parents of children with epilepsy are at high risk of having anxiety, which correlates significantly with their quality of life. Parents’ knowledge of epilepsy is associated with lowered parental anxiety. Also, family activities are less restricted if they are more knowledgeable, and they reported less worries regarding their children. Knowledge of epilepsy also leads to less stigmatization, social isolation, and depressive symptoms. Overall, parents’ attitudes are significantly influenced by the depth of their knowledge of the disease. Therefore, misconceptions and misinformation should be identified and corrected for optimal care and management.15

The purpose of the study was to assess the effectiveness of a parent education programme on knowledge regarding the home care management of children with epilepsy among mothers as well as to find the comparison between the knowledge of mothers and the selected demographic variables.

Materials and Method

The study was conducted among 30 mothers of children with epilepsy attending Pediatric Neurology unit at AIMS, Kochi. The data collection was started after obtaining Ethical Clearance certificate from the Ethics Committee and Scientific committee of Amrita Institute of Medical Sciences and Research Centre (AIMS), Kochi. The sample was selected by convenience sampling technique based on inclusion criteria. After building rapport with the mothers, written informed consent was obtained from each subject. Data had been collected by a structured self administered knowledge questionnaire includes two sections; section A and section B. Section A consists of 12 items on sociodemographic variables and section B includes 40 items on knowledge of mothers regarding the home care management of children with epilepsy. Pre-test was done on the first day using tools and the intervention also administered on the same day. The parent education programme was a systematically developed, individual teaching session of 45 minutes duration. The session includes the areas of; meaning of epilepsy, triggering factors, signs and symptoms, investigations, medications–side effects and home care management of the child.

Statistical analysis: Statistical Analysis has done using IBM SPSS statistics 20 windows (SPSS Inc., Chicago, USA). For all the continuous variables the results are either given in mean ± standard deviation and for categorical variables as percentage. To compare the mean difference of numerical variable between two groups, two sample t-test was applied for parametric test or mannwhitney u test was applied for non parametric test. For more than two groups Kruskal Values test was applied for non parametric test. To compare between pre-test and post-test intervention of mothers knowledge paired t-test was applied. Probability value (p value) less than 0.05 is considered for statistical significance.

Results

Section I: Description of Sample Characteristics: The data shows that all the subjects 30(100%) were mothers and most of them 20(66.7%) were in the age group of 34-41 years. With regard to the educational status of mothers 9(30%) of them were in each group of high school and graduation level of education. Regarding the source of health information 26(86.7%) of them were getting health information from the health workers. Among total subjects 17(56.7%) of the subjects expressed that they do not have history of epilepsy in
their family but 13(43.3%) of them had the history of epilepsy in their family.

Section II: Effectiveness of the Parent Education programme on Knowledge of mothers.

</table>

Table 2 show that the mothers have shown significant improvement in knowledge in all the areas. Further it shows that the area which shows maximum improvement in General Information and Misconceptions (mean difference is 6.83) followed by signs and symptoms of epilepsy with the mean difference of 2.5.

Section IV: Analysis of Comparison Pre-test Knowledge scores of Mothers with Demographic variables.

Analysis done on comparison of pre-test knowledge scores of mothers with selected demographic variables. The demographic variables included were age, education, occupation, type of family, area of residence and history of epilepsy in the family. The p-value (0.000) shows that there is significant association between the pre-test knowledge score only in the area of education and occupation of parent.

Discussion

Objective-1: Assess the effectiveness of a parent education programme on knowledge regarding the home care management of children with epilepsy.

The mean post-test knowledge score (23.26) is significantly higher than the mean pre-test knowledge score (14.50) which indicates that the mothers gained more knowledge after the administration of parent education programme on home care management of children with epilepsy.

The study is supported by a study conducted by Najimi A, Dolatabadi NK, Esmaeili AA, on the effect of educational programme on knowledge, attitude and practice of mothers regarding prevention of seizures at Iran. The study was conducted among 88 mothers attending a children’s hospital and the intervention consisted of educational sessions. The results showed that
a significant increase in knowledge (p<0.001), attitude (p<0.04) and practice (p<0.001) in the intervention group one month after the intervention compared with that of before intervention.16

Objective 2: Compare the pre-test knowledge scores of mothers of children with epilepsy and the selected demographic variables.

The comparison of pre-test knowledge scores of mothers with selected demographic variables shows that there is significant association between the pre-test knowledge score only in the area of education and occupation of the parents.

Conclusion

An epilepsy diagnosis can be a frightening, an unwelcome interruption in any family’s life. But with education, support and perseverance, parents can ensure that their child has a happy and meaningful life.

Abstract

Health care for all” has been receiving attention of multilateral forums to strategize the same as a fundamental right and duty of all sovereigns. The Health care sector comprises of composite health care functions and services by health and is a USD 250 billion market globally; as far as pharmaceutical industry alone is concerned. The pharmaceutical industry is highly regulated and is subject to tangential sectoral regulations, interfaces of Price Control Measures, Intellectual Property Law and Public Welfare element and is a sector which is largely concentrated and is prone to anticompetitive practices in manufacture, supply, distribution and sale of generic branded and generic generic drugs. Evidence globally has shown abuse of market power through dominance in the relevant market, cartelization in fixing prices and territories in generic drug segments as also prescription medicines to the detriment of general masses globally with price escalation of over 1000%. The paper examines the efficacy of Price Regulations in keeping the drug prices unabated and their appropriate calibration with incentivizing R & D to bring new innovation and the anti-competitive practices endemic to sector. It explores the relevance of enforcing Competition Law interventions to extant ecosystem of pharmaceutical industry to ensure removal of Competition bottlenecks.

Keywords: Price Regulation, Intellectual Property, Anticompetitive practices, Public Interest.

Introduction

Health Care Sector in India

The WHO Declaration on Primary Health Care at Alma Ata in 1978 advocated action to ‘protect and promote health for all’ and recognized it as a fundamental right¹ and re-endorsed in October, 2018 at Primary Health Care Global Conference, Astana. United Nations has set up 17 Sustainable Development Goals (UNSDG) with mission of ‘leaving no one behind’ for 2030 and Goal 3 relates to objective of ensuring ‘healthy lives and promote well being for all ages’. Under Article 21 of the Constitution of India, this is not an explicit fundamental right but rather a derived right; and in ND Jayal versus Union of India; it was specifically recognized to be right to life.² Government of India has set up National Health Mission to benchmark its initiatives in compliance to UNSDG. Through Directive Principles of State Policy; improvement of public health is foremost duty of Government and National Health Policy addresses the preventive health matters³.

The National Health Accounts India monitors the health care expenditure across government and private-sector ⁴. The 2018 report illustrates the Total Health Expenditure (THE) as 3.84 % of GDP at INR 5.28 trillion with per capita expenditure being INR 4116 and the Current Health Expenditure (CHE) was at INR 4.95 trillion being 93.7% of the THE (National Health Accounts Estimates for India, 2018) ⁴. The total pharmaceutical expenditure (including prescribed medicines, over the counter drugs and those provided to inpatient/OPD by the healthcare providers) contributed nearly 35% of the CHE with expenditure on traditional, complementary and alternative medicines being 12% of CHE ⁴.

As a nation which is trying to follow a model of inclusive growth targeted for those at the bottom of the pyramid of the Indian population; bulk of which do not have or have least access to the healthcare providing affordable healthcare to all becomes a daunting challenge as a public policy prescription measure ³. The Indian healthcare customers face perilous situation
Despite price controls under Drug Price Control Orders due to presence of structural deformities arising out of lack of adequate competition culture within the country which results in instances of manipulation of prices to the detriment of masses at large for innovated, branded generic and generic-generic drugs to which the current article addresses.

The ecosystem of Indian healthcare market: India occupies a unique space in the world pharmaceutical market and is estimated amongst first three in terms of volume/value created. There is competition amongst the generics as well branded generics, a phenomenon not seen in developed countries and more so the combination drugs which allow the companies to keep their prices artificially high notwithstanding that therapeutic properties in terms of health outcomes are far from satisfactory. The generics contribute 72% of the revenue, OTC drugs 19% and patented drugs 9% respectively of the revenue in country.

The Indian pharmaceutical industry today primarily thrives on manufacturing generic drugs and exports thereof with 20% of the worldwide exports being contributed by India subject to their meeting local regulatory compliances; for drugs which have come off patent list overseas. This calls for a calibrated approach to encourage companies to invest for R & D and ensuring cheaper prices to achieve the public welfare objectives.

When the High Court of Delhi takes cognizance of the public interest litigation filed in the matter of Birender Sangwan versus Union of India for intervention of the Court for inclusion of coronary stents in the NLEM List which incidentally fall under the definition of drugs under section 3 (b) (iv) of the Drugs and Cosmetics Act but ceiling prices for which were not monitored by NPPA; it being a non-scheduled drug; or when the Apex court in the matter of Union of India versus K Gopinath directs for inclusion of non-essential medicines in the list of NLEM; they need to be seen in context of the public interest involved.

Section 3 of the Essential Commodities Act empowers the Government to issue Drug Price Control Orders through notification in the Gazette of India, declaring a ceiling price for essential and life-saving medicines as indicated in the National List of Essential Medicines (NLEM) to ensure that life-saving and essential drugs are available under price control mechanism for safeguarding public interest. Section 31 of the DPCO provides for non-application of the DPCO in respect of new drugs patented under the Indian Patents Act for a period of five years from the date of commencement of the commercial production in the country. The NLEM lists 376 medicines which are scheduled drugs/formulations and nearly 30% of the domestic market in India is under price regulation through DPCO rather than effective competition. A press release points out saving of INR 12,447 crores due to price fixation of essential medicines.

The National Pharmaceutical Pricing Policy, while regulating the prices under DPCO takes into regard only the medicines listed in NLEM a market-based pricing to ensure affordability and availability and the price control to be made applicable only on drug formulations; and in respect of non-scheduled drugs the DPCO prescribes for the price not to exceed the price of said nonscheduled medicine during the last 12 months. During 2014, National Pharmaceutical Pricing Authority (NPPA), brought in conception of public interest for covering 108 drugs outside the NLEM list under price control regulation invoking extraordinary circumstances.

Despite such framework of price regulation and control, there have been persistent instances of overcharging of cases for period up till March 2019. NPPA has issued internal guidelines for dealing with ‘overcharging’ and ‘Without Price Approval (WPA)’ cases which inter alia provide for appropriate action against the drug manufacturers for selling the formulation at higher than the notified price under DPCO for which action can be initiated for overcharged amount.

It is equally pertinent to examine the emerging directions of the Indian pharmaceutical industry which on line of what has been happening globally is going in the direction of strategic alliances to remain competitive as there are compelling reasons for their being sustainable. A drug before it gets finally launched in the market takes few years for completion of ‘conception’ to ‘prescription’ phase and in process on an average USD 300 million getting spent on its trials. As patent in India last only for 20 years before products becomes generic; compels the pharmaceutical sector to foray in horizontal or vertical integration.

Anti-trust and Healthcare globally: It is not that developing countries like India alone are at the receiving end of market infringements affecting the consumer interests. An anti-trust lawsuit in the United
States highlights the menace of excessive drug pricing in generic drug segments such as tablets, capsules, ointments and prescription medicines including antibiotics, antidepressants and anti-inflammatory drugs primarily used for the treatment of opportunistic infections, diabetes, cancer and antiretrieval treatment amongst.\textsuperscript{18} Prices were escalated to extent of 1000% thus affecting the patients, taxpayers funded healthcare programs and the insurers and evidenced conspiracy in fixing prices and territories and thus cause restraints in trade through competition retardation in over hundred generic drugs which have billion-dollar strong foothold in US market by established brands.\textsuperscript{18}

With such trends continuing; huge scale anti-trust violations are not ruled out given the current trends for strategic alliances as also increasing tendency for a coordinated approach and market for pricing and territorial strategies to cause least turbulence arising out of competition.\textsuperscript{19} Vitamin Cartel; referred as the mother of all cartels, involving many countries around globe and as per a study, caused cartel damages of USD 4000 million.\textsuperscript{20}

**Market Infringements in India:** Under the Competition Act 2002\textsuperscript{21}; section 4 focuses on regulating the conduct of the market players in restricting competition exploitative conditions and inflicting supra high prices and cannibalizing the competition through predatory pricing. The competition regulator has to take into account the dominance of undertaking to charge unfair price regardless of the competitive forces and the state of competition in the relevant market and setting up such terms of trade which affect competitors, consumers and the relevant market The Competition Commission of India (CCI), the anti-trust regulator in India, in the case of *HT media Ltd versus Super Cassette Industries* has laid down what constitutes *excessive pricing* and related it to higher than the price charged by the competitor.\textsuperscript{22}

Going opposite this conception of laissez faire (allowing market to connect on own in the case of *Shamsher Kataria versus Honda*, the CCI ruling came in favour of remedial interventions for structurally modifying the market for corrections in prices as the practices infringed the provisions of section 4 (2).\textsuperscript{23}

In the case of *Biocon versus Hoffmann Roche*, CCI, held the initial higher prices being charged by Roche not as anticompetitive conduct but rather corollary of rewarding innovation and being the originator of anti-cancer drug Trastuzumab and allegation by Biocon for excessive pricing in comparison to its biosimilar was quashed; albeit Roche did introduce the cheaper versions namely Biceltis in the market later.\textsuperscript{24} In the case of *Vivek Sharma versus Max Super Specialty*, CCI while recognising the dominance of Max Super Specialty in the relevant market; held its practice of requiring its in-house patients to buy syringes at higher prices than the same available outside hospital; had directed the Director-General to cause investigation not only in respect of syringes but surgical tools as well as medicines by the other specialty hospitals as well in regard to their impugned practice of charging higher prices and forestalling the competition by not allowing buying of similar/same product from outside market.\textsuperscript{25}

**Conclusion**

The country followed a socialistic government controlled pattern and with liberalization of economy during 1990’s; a need was felt to have relook into the extant provisions of the Monopolies and the Restrictive Trade Practices Act; which was found to be wanting in enforcement of a competition culture. The Competition Act 2002\textsuperscript{21, 26} has come a long way from the yesteryears MRTP Act; in its 10 years of active enforcement; yet it is to find steam in detecting and deterring the business practices which cause adverse appreciable effect on competition.\textsuperscript{27} Such restraints through the collusive conduct of pharma companies who while are meant to compete with each other in the market; but rather enter into gentlemen agreement of collaborative approach resulting in distortions to free play of markets through manipulated market share, volume allocation, price distortions affecting the consumer sovereignty.\textsuperscript{27}

Indian pharmaceutical market faces host of issues beyond price regulation; namely role of trade associations, marketing practices and trends towards strategic alliances and competition violations which are not permitting the market to grow. Barring the OTC drugs, the end user segment is dependent upon the particular drug which may have been prescribed by the physician and choices are curtailed by nature of industry due to asymmetric information affecting the competition.

Due to inherent preference for Original Innovations and branded generics, with a concentrated market of few dominant players; they tend to usurp market power to dictate terms to adversity of Competition and Customers alike despite price control under DPCO thus warranting Competition Regulatory interventions.
Pharma Market is completely intertwined and overregulated already. Interface of Intellectual Property Law, price intervention through DPCO crisscross each other. Patents allow companies to amass market power and affect fair play of markets and competition. Anti Trust Laws and Intellectual Property Law, though complimentary, bring about divergent perspectives for consumers.

Multiplicity of supply chains and their unfair practices also raises a competition concern as also the definition of relevant market in view of original, branded generic and generic generic drugs. SSNIP test may not be helpful due to substitutability.

There are challenges with regard to what constitutes a benchmarked fair price when seen in context of the initial investments which go into research and development and any attempts on price regulation may disincentivise the motivation for future research. Whether or not the stance taken by CCI to make excessive pricing cognizable only once undertaken by a dominant form in the relevant market can be said to be a cogent approach to anti-trust regulation when the instances of higher prices are at galore. The current tendency of enforcing remedial action beyond price regulation is something which needs to be examined for a benchmarked perspective for future.

What would warrant inclusion of a drug in the NLEM; should it be guided by ‘essentiality’ and should include the ‘analogues’ and ‘close substitutes’ needs attention. An era of transparency and predictability needs to be built in achieving the outcome of National Pharmaceuticals Pricing Policy namely better healthcare by making available the essential medicines at reasonable prices based on premise of ‘essentiality’, ‘control of formulations prices only’ and ‘market-based pricing’

The public interest element therefore in addition to price regulation; in order for overall comprehensive promotion of freedom of trade, choice to consumers, manufacturers, supply chain participants and other stakeholders; warrants a move towards integration of Competition Laws for a regulatory framework beyond administered prices to control the anticompetitive practices of abuse of dominance, cartel practices and exclusionary/exploitative conduct.

An Analytical Study of Sleep Duration, BMI and Blood Pressure Reactivity among Medical College Students

Randhir Singh Bisht¹, Lily Walia², Bimal K. Agrawal³

¹Research Scholar, Department of Physiology, Mmimsr, ²Prof & Head, Department of Physiology, Mmimsr, ³Professor & Principal, Department of Medicine, MM(DU) Mullana, Ambala, India

Abstract

Introduction: Short sleep duration is a major risk factor for higher BMI and has been supported by much evidence from the past studies. Hypertension is an important risk factor for cardiovascular disease in children as well as in adults. So in this study we aim to evaluate the effect of insufficient sleep duration on BMI as well as blood pressure in medical college students of MMIMSR, Ambala.

Method: A cross-sectional study of 200 young medical college students of age 18–24 years were recruited randomly for this study. All the participants were assessed under similar laboratory conditions in the departmental research laboratory. Sleep pattern and duration were determined by using a validated Pittsburg sleep quality index (PSQI) questionnaire. Body weight and height were measured and BMI was calculated by using the Quetelet index as BMI = kg/m² where kg is a participant’s weight in kilograms and m² is their height in meters squared. Blood pressure was measured by using mercury sphygmomanometer.

Results: Shorter sleep duration was highly significantly (p<0.01) associated with higher BMI and with higher SBP. Sleep duration was also significantly (p<0.05) associated with DBP in both male and female student participants.

Conclusion: Participants with relatively shorter sleep durations (<7hrs) had higher blood pressure reactivity and were either overweight or obese. Preliminary findings are consistent with the hypothesis that sleep duration may be one mechanism through which daily social stress influences BMI and long-term cardiovascular health.

Keywords: Sleep duration, BMI, Blood pressure.

Introduction

In India, for the last few years decline in sleep duration has grown to be a hallmark of modern-day society among the children as well as in adults. Both are having shorter bedtimes with average sleep duration of 7 hours per night and one-third sleeping less than 7 hours per night [1,2]. Televisions and smartphones which came into households as remarkable source of information and entertainment has robbed sleep time and voluntary sleep restriction. Using cell phones at night is common among children and in adults as reported by them. It has become a serious barrier to health development [3]. Sleep is a critical modulator of neuroendocrine function and glucose metabolism in children and in adults. Short sleep alters metabolic as well as endocrine functions which leads to reduced glucose tolerance, decreased insulin sensitivity, increase in night time concentrations of cortisol, increased ghrelin level and decreased leptin levels [4,5,6]. All of these results in more hunger and appetite. So, short sleep duration has evolved into the dramatic growth in the prevalence of obesity [7,8]. In this modern world the relationship between short Sleep duration and Blood Pressure is also an issue. In an analysis of worldwide data it has also been observed that the prevalence of both hypertension and prehypertension are on significant rise in the recent
years\textsuperscript{[9-11]}. High blood pressure (BP) during childhood acts as an indicator for the prevalence of coronary artery disease during adulthood. In adults both hypertension and coronary artery disease have been associated with short sleep duration\textsuperscript{[12,13]}\textsuperscript{[133,145]}. However, the cause of this relationship is not completely understood and very little is known about the interrelationship between usual sleep and hypertension. In India, Hypertension exerts a significant burden on cardiovascular health status and healthcare systems\textsuperscript{[14,15]}\textsuperscript{[133,145]}. Hypertension is responsible for 57% of all stroke deaths and 24% of all coronary heart disease deaths\textsuperscript{[16]}\textsuperscript{[115,164]}. According to WHO, hypertension is one of the main cause of premature death worldwide\textsuperscript{[17]}\textsuperscript{[133,145]}. According to a worldwide data, in India 20.6% of men and 20.9% of women are suffering from hypertension in 2005 and at these rates for hypertension is expected to go up to 22.9% for men and 23.6% women, respectively by 2025\textsuperscript{[18]}\textsuperscript{[115,164]}. So, in view of significantly increasing BMI and prevalence of hypertension in relation to short sleep duration among medical college students this study was planned.

**Material and Method**

This cross-sectional study was conducted in the Department of Physiology of Maharishi Markandeshwar Institute of Medical Sciences and Research, Ambala. The study comprised of 200 healthy subjects of which 100 male student participants and 100 female student participants were taken randomly and a written informed consent was taken at the beginning of the study. The study was approved by Institutional ethical committee.

**Inclusion criteria:** For this study we have taken apparently healthy, non-alcoholic and non-smoker male and female medical students of age group 18-24 years.

**Excluding criteria:** Medical students on a long term medication or with any acute or chronic illness & any history of hypertension in parents were excluded from this study.

**Anthropometric Indices:** All the anthropometric indices were measured.

Weight was measured in minimal clothing i.e. bare feet and with light clothing. Daily calibration was made to the weighing scale.

Height was measured with the subject barefoot, the heels, hip and shoulder and head in neutral position with eye gazing forward.

Body mass index(BMI) was calculated by dividing weight in kilograms by square root of body height in meters(kg/m\(^2\)). According to body type classification for Health ministry and Diabetes Foundation of India in 2008 normal weight considered as BMI 18.5 to \(\leq 22.9\), overweight as BMI 23 to \(\leq 24.9\) and obesity as BMI \(\geq 25\) kg/m\(^2\)\textsuperscript{[19]}.

**Sleep duration determination:** Sleep duration was determined by using standardized and validated Pittsburgh sleep quality index questionnaire which was given to each student participant\textsuperscript{[20]}.

**Blood Pressure:** Blood pressure (BP) is characterized by large spontaneous variations, therefore the diagnosis of hypertension was based on taking multiple BP measurements. Standard mercury sphygmomanometer was used. Appropriate-size BP cuff was used to measure BP. The BP cuff encircle and cover two-thirds of the length of the arm. Proper maintenance and calibration of the sphygmomanometer was ensured. Student participants were asked not to drink tea/coffee or take heavy meals and exercise for at least 30 minutes before the measurement the BP. Student participants were allowed to sit for at least five minutes in a quiet room before measuring their blood pressure. Measurement was taken preferably in a sitting position. Student’s arm was fully bared and supported at the level of heart. According to the recommendation of the 4\textsuperscript{th} report of national high blood pressure in children and Adolescents blood pressure was measured\textsuperscript{[21,22]}.

**Statistical Analysis:** By using Microsoft Excel and SPSS software Statistical analysis was done. Anthropometric indices were compared with sleep duration and blood pressure. Pearson correlation was used where P value <0.05 was considered as significant and <0.01 was considered as highly significant.

**Results and Analysis:** The study included 200 medical students of MMIMSR, Ambala of which 100 were male and 100 were female student participants. Among 100 male participants, a usual sleep duration of 8 or more hours per night was reported by 23% of the male and 21% female participants including 23% male participants and 21 % female participants sleeping 9 hours or more per night respectively. A usual sleep duration of less than 7 to <8 hours per night was reported by 13% male and 18% female participants. Sleep duration of 6 to <7 hours were reported by 24% male and 32% female participants while sleep duration of < 6 hours were
reported by 17% male and 14% female participants. Hypertension was identified on the basis of measured blood pressure. We found that decreased sleep duration was highly significantly associated (p<0.01) with higher Body mass index (BMI) in both male (Table no.1) and female participants (Table no.2). Our results showed that with the decrease in sleep duration there was significant increase in weight gain among both the male [Figure 1] as well as female student participants [Figure 2]. However, when compared 8-9 hours of sleeping to sleeping less than 7 hours it was found to be significantly associated with the increased Blood pressure and risk factors for pre-hypertension and hypertension. Sleep duration was highly significantly (p<0.01) associated with increased Systolic Blood Pressure (SBP) and significantly (p<0.05) associated with Diastolic Blood Pressure (DBP) in both male (Table no.1) and female participants (Table no.1).

In our study we found that longer usual sleep duration is significantly associated with decrease in Body mass index (BMI) and also serve as an indicator of normal BP in both the participants i.e. increased sleep duration was significantly related with decreased chances of prehypertension and hypertension in both the genders (Figure 1 and Figure 2).

Discussion

In India, the ongoing prevalence of obesity in doctors and medical students, has emerged as a huge challenge. Sleep deficiency and irregularity in sleep patterns is common among doctors as well as medical students. Some risks which are documented for the prevalence of obesity are food eating patterns, consumption of sweet beverages and fried food snacks. However, sociocultural aspects like societal pressure on academic performance seriously affects their health. Moreover, the criticality of recreation, play and physical activity in almost nil in medical students and they are unable to find a way to neutralize this pressure. Obesity has become a sedentary lifestyle disease and has become a topic of concern. Prevalence is increasing at the epidemic rate. This study showed that there is a considerable overall irregularity in sleep among both male and female medical student participants. Our results support a positive relationship between higher BMI and short sleep duration. Studies conducted by Deen. W. Beebe et al found that the subjects having short sleep duration and disturbed sleep were having more BMI as compared to the control participants\[23]. Our results also correlates with the study done by Patel SR et al,\[24] Gangwisch JE et al\[25] in which a direct association was found between short sleep duration and weight gain. According to Kripke et al\[26] and Cummings et al\[27] a direct relationship between disturbed sleep duration and weight gain in adults was found.
Stressful lifestyle and busy work schedule along with altered food choices has led high blood pressure to be a major health issue among medical students as well as in public health which is growing exponentially every year in India. Our study correlates with the studies done by Meininger et al,[28] which in their study found the direct association between long sleep duration with a decrease in both the SBP as well as DBP. Archbold et al.[29] in their study found direct relationship between lack of sleep duration and an increase in BMI with increased BP. According to a study done by Kuciene R and Dulskiene[30] <8 hours of sleep was directly associated with Prehypertension and Hypertension among both children as well as in adolescents. In a recent research, one in three adults are suffering from this hazardous lifestyle disease and the prevalence of hypertension in urban areas of India is 20%-40% and 12%-17% in rural areas[31].

Conclusion

High blood pressure (BP) has turned into the most predominant chronic disease in India. What’s even horrifying is that hypertension is no longer an old age disease. Adults and even children who sleep much less are at the risk of having higher BMI and high blood pressure. Major contributing factors to this silent but deadly disease are sedentary way of living with no exercise, night time snacking, consuming more salty and fatty ingredients in diet. Since, hypertension takes time to develop, around 90% of the patients are not even aware from it until the threshold of their blood pressure increases and the symptoms start appearing. In summary, in today’s world students and even general population are too busy in achieving their goals that they don’t have time even for selfcare. Small but necessary lifestyle modification such as daily exercising, proper sleeping and healthy eating should be at the top of the priority list. Exercising regularly makes us more positive, energetic, productive and creative. It makes us more effective entrepreneur so that we can generate more revenue and create a bigger impact in the world and can go a long way in reducing the risk of hypertension and other associated health complications.

Abstract

Gingival recession is defined as apical migration of gingival margins resulting in exposure of the root surface. It can be either localized or generalized, involving one or more than 1 surfaces and thereby leading to functional & esthetic problems like hypersensitivity, cervical abrasions & root caries. Various techniques have been developed to achieve root coverage. The current case report describes treatment of multiple class I gingival recession using vestibular incision sub periosteal tunnel access (VISTA) technique and platelet rich fibrin (PRF) membrane. Position of gingiva was maintained using coronally anchored sutures during initial healing period. The use of PRF membrane along with the VISTA allows clinicians to successfully treat multiple gingival recession defects.

Keywords: VISTA, Platelet rich fibrin, gingival recession, tunnel technique, sutures, wound healing.
Nothing significant was recorded in the medical and dental history. The patient presented with Miller Class I recession i.r.t 12,13 (Figure 1). Recession Width (RW), Recession depth (RD), Clinical Attachment Level (CAL), Probing Depth (PD), Gingival Thickness (GT), Keratinized tissue height (KTH) were the clinical parameters. Scaling and root planning were performed. Once the patient was able to maintain her oral hygiene an informed consent was obtained and the surgical procedure was carried out.

Procedure: After administration of LA, root planning was done. Using a 15 C blade, a vestibular access incision of 3mm was given in the vestibule between 12 and 13(Figure 2). Sub-periosteal tunnel was created using microsurgical tunneling instruments. The tunnel was extended to one teeth beyond the teeth that required root coverage in order to allow mobilization of the flap and to facilitate its coronal advancement. Additionally, the tunnel was extended inter-proximally under each papilla as far as the embrasure space permitted without penetrating the papilla (Figure 3).

Once the gingival margin was coronally advanced, 10ml of venous blood was drawn from the patient and placed into a sterilized glass test tube of 10 ml and centrifuged at 3000 rpm for 10 min using a tabletop centrifuge (REMI R-8C Laboratory Centrifuge). Due to differential densities, centrifugation will result in the separation of three basic layers: RBC layer at the bottom, PRF clot at the center and Acellular platelet poor plasma at the top. The middle PRF layer was removed and placed in between two sterile gauze pieces to obtain a membrane of uniform thickness. 4-0 resorbable sutures were used to give support sutures on both the ends of the PRF membrane which was guided through the access incision (Figure 4). In order to position the PRF membrane into the desired site, the support sutures were pulled through the sulcus of 12 and 13. Once in position, the support sutures were used to stabilize and suture the PRF membrane with the subperiosteal tunnel (Figure 5).

The membrane and mucogingival complex were then advanced coronally using a 5-0 silk suture and adapted to the new position with coronally anchored sutures which were approximately 2 to 3 mm apical to the gingival margin. A knot was tied at the mid coronal portion of the facial aspect of each tooth, and secured with composite resin (Figure 5). Periodontal pack was placed and post-operative instructions were given. Patient was prescribed analgesics to be taken as and when required and 0.2% chlorhexidine gluconate mouthwash for plaque control. The sutures were removed after 21 days and the patient kept on maintenance therapy.

Results: The result demonstrated 100% root coverage at 6 months. Healing was satisfactory and results were stable at 6 months. (Figure 6).

Discussion: Over the past years, a number of different techniques have been used with various degree of success for the treatment of gingival recession which may be classified as: epithelialized grafts or connective tissue grafts and pedicle soft tissue grafts such as the laterally sliding flap the double papilla flap the coronally repositioned flap and its modification the semilunar coronally repositioned flap. This search for predictable esthetic outcomes has led to the development of several new and modified surgical techniques in this past decade.

Different tunnel techniques have been attempted for management of recession defects which maintain better blood supply and critical papillary integrity. However, these procedures are technique sensitive and cause tissue trauma to sulcular epithelium leading to unfavorable healing outcome. To avoid these complications, the vestibular incision sub-periosteal tunnel access (VISTA) approach was introduced. The most differentiating feature between VISTA and other tunneling approaches/other classical gingival augmentation procedures is the degree of coronal advancement obtained during the procedure (to adjacent interdental papilla rather than CEJ). The advantage of placing the access incision in the vestibule has various advantages like: i) little/no visible scarring resulting in better esthetic outcome. ii) provides access to the entire area including the underlying alveolar bone and root dehiscence iii) less likely to disrupt the blood supply iv) decreases the likelihood of traumatizing the gingiva of the teeth being treated. Advantage of using coronally anchored suturing includes: i) prevention of apical relapse of the gingiva during initial stages of healing. ii) Minimize the micro-motion of the gingiva thereby preventing scar tissue formation, whereas in conventional techniques the gingiva is subjected to displacement during facial movements. In addition to careful preparation of the sub-periosteal tunnel, addition of PRF membrane contributes to the final success of this technique.

In 1970’s platelet rich plasma was first applied as a glue. Presently, fibrin glue is prepared from platelet poor plasma and is seen to have a positive impact on repair and regeneration. However it has limited use
due to complicated and time consuming preparation.\textsuperscript{12} According to studies in 1900s & 2000s PRP was observed to be a promising reservoir for growth factors that could make wound healing and bone regeneration easier.\textsuperscript{13,14,15} However, addition of bovine thrombin posed a risk of transmission of diseases, also the key role of fibrin was neglected at this time. Anitua and coworkers\textsuperscript{16,17} in 1999 developed Platelet Rich in Growth Factors which was characterized by elimination of leukocytes to suppress their pro-inflammatory properties. With the aim to eliminate xenofactors and to simplify the PRP preparation, Choukroun et al\textsuperscript{6} developed platelet rich fibrin (PRF) which is derived from patient’s own blood and comprises of platelets, monocytes, B- and T-lymphocytes, neutrophilic granulocytes, growth factors & stem cells.\textsuperscript{33,34} It was stated that PRF could be an important source of hematopoietic stem cells (HSCs), which can potentially play a major role in tissue regenerative dentistry.\textsuperscript{18,19} Choukroun further modified PRF by reducing the centrifuge speed to produce Advanced PRF (A-PRF) and Injectable PRF (I-PRF) which are characterized by platelets, leuocytes, stem cells & endothelial cells in fibrin clot.\textsuperscript{20,21} In 2006, Sacci et al\textsuperscript{22} developed concentrated growth factor (CGF) using a centrifuge device that has a special programmed spin cycle to obtain a fibrin matrix that is larger, denser and richer in GF as compared to PRF. PRF technology draws on the following three fundamental principles and biological processes of haemostasis\textsuperscript{23} and wound healing:\textsuperscript{24} i) Presence of fibrin matrix at the site of surgery can act to provide a scaffold for recruiting and migration of cells (like fibroblasts, epithelial & endothelial cells) throughout wound healing and reparation process. ii) Within the fibrin matrix, platelets, neutrophils, leukocytes and monocytes release growth factors & chemotactic proteins that recruit fibroblasts, epithelial & endothelial cells in order to facilitate wound healing and reparation. iii) Angiogenesis depends on fibrin matrix and stimulation of endothelial cells recruitment through vascular endothelial growth factors. New blood vessels in the wound bed are essential for carrying oxygen and nutrients to sustain cell metabolism and regeneration.

Various case reports\textsuperscript{25,26} have been published wherein VISTA technique was used along with Platelet Rich Fibrin and CTG and they have concluded that VISTA technique together with platelet-rich fibrin (PRF) and CTG membrane can be successfully used as a treatment method for multiple Millers Class I and Class II defects.

Recent studies\textsuperscript{27,28} have confirmed that PRF has a sustained release of key growth factors for a period of at least 1 week and up to 28 days. It was seen that PRF could stimulate its environment for a notable period during the wound healing process. PRF contains large amount of platelets and cytokines, which have an important role in the self-regulation of inflammatory and infectious processes. PRF membrane has mechanical adhesive properties, biologic functions, maintains the flap in position and increases angiogenesis. Hence PRF membrane can be used as an alternative to other bioactive agents. Use of PRF has an added benefit of preventing additional surgical site which is associated with harvesting of CTG, thereby reducing patient morbidity. Various studies\textsuperscript{29,30} have compared PRF with CTG and have concluded that PRF is a valid alternative to CTG in the treatment of gingival recession. In the present case report access incision was given in the vestibule between 12 and 13. To the best of the author’s knowledge this is the first case report where in contrary to the usual position of the access incision (i.e. labial frenum) for VISTA procedure, the access incision was given in the vestibule between 12 and 13.

Photographs

Figure 1: Preoperative view

Figure 2: Access Incision between 12 & 13
Various treatment options exist for the treatment of gingival recession. However, treatment of multiple gingival recession is always a greater challenge compared to single recession defects. Hence, VISTA technique with PRF membrane used in this case report is aimed at overcoming the shortcoming of other treatment options and gives better results in multiple class I & II Millers gingival recessions. Clearly, long-term follow-up with clinical and histological studies will be required to obtain more information about this technique as a root coverage for multiple adjacent gingival recession.

Abstract

Background: Women augment family income by working; however, this reduces the time for childcare and may adversely influence the nutritional status of children. Objectives: A preliminary study was conducted to assess the impact of mothers’ working status on the nutritional status of their preschool children (2-5 years). Method: A cross-sectional study was conducted on 80 mother-child dyads (40 each from rural areas, and urban slum of Pune). Information on mothers’ working status, socio-demographics, socioeconomics and food consumption pattern of children were collected. The children’s anthropometric indices, namely, Z-scores of weight-for-height (WHZ), weight-for-age (WAZ), height-for-age (HAZ) were estimated. Results: The study did not find any significant difference in the nutritional status of children with respect to the working status of their mothers. It was found that children of formally educated mothers had significantly higher mean Z-scores for WAZ (p=0.050) and WHZ (p=0.035); children who received family-based childcare practice had higher mean WAZ (p=0.039) and WHZ (p=0.05), and children whose fathers were in skilled occupation had higher mean HAZ (p=0.040) scores. Children who frequently consumed chocolates and candies had lower mean HAZ (p=0.039) and WAZ (p=0.005), and used savories had significantly lower mean WAZ (p=0.045), and HAZ (p=0.019) scores. Conclusion: The present study indicates the importance of sociodemographic factors and the necessity for appropriate nutritional care for young children of working mothers.

Keywords: Working status, Preschool children, Nutrition status, India, urban slums, and rural area.
village Marunji, under Man division was selected for the study. Aganwadi centers located in the urban slums and rural areas were approached for the recruitment of the study participants. In total 80 apparently healthy preschool children aged between 2-5 years (urban slum=40 and rural area=40) were included in the study. Children suffering from any chronic illnesses, sick at the time of recruitment, children with mental illnesses were excluded from the study. Permission for the study were obtained from Women and Child Development Department of Pune. Ethical approval was obtained from the Institutional Ethics Committee, Symbiosis International University, Pune. The study purpose and protocols were explained to mothers and caretakers in local language (i.e. Marathi). Participants who met the inclusion criteria were recruited for the study after obtaining a written consent from mothers as the children were minors.

The data were collected through household surveys and personal interview of the mother were conducted. Working mothers (i.e. mothers involved in self-employment at home or outside the home to generate income) and nonworking mothers (i.e. mothers were not involved in any type of income generating activities) were recruited for the present study. The type of child care arrangement mothers sought to while they were at work were categorized as family-based care (i.e. child care performed by grandparents or closed relative or father or taking the child to their workplace) and non-family care (i.e. leaving child with neighbour or with young sibling). The mother’s occupational status was classified into two categories as skilled (i.e. nonmanual work secretarial or clerical, teaching, nursing etc.) and unskilled (i.e. domestic work or agricultural labourers).

Anthropometric data followed WHO standard protocol using Tanita digital weighing scale (Model HD 380) with accuracy of 0.1 kg and portable SECA Stadiometer (Model 213) with accuracy of 0.1 cm was used to measure the weight and height respectively. Triplicate measurements were taken and mean of three readings were taken. The measuring devices were calibrated using standard measures. WHO Anthro software version 1.0.3. was used to determine the nutrition status. Height-for-age, weight-for-age and weight-for-height were compared to the growth standards (WHO).

A qualitative food frequency questionnaire (FFQ) was used to assess the dietary patterns of children by interviewing their mothers. The food items in FFQ were grouped as cereals, pulses & legumes, poultry & meat, milk & milk products, vegetables, fruit, beverages, confectioneries & bakery products, and savory. The FFQ was designed with five food frequency categories such as daily, weekly, fortnightly, monthly, and never. For analysis of the food frequency questionnaire the above categories were grouped into dichotomous variables as frequently consumed (i.e. daily and weekly consumption of food items) and less frequently consumed (i.e. fortnightly and monthly consumption of food items).

The data were analyzed using SPSS software version 20.0. Descriptive statistics were used to summarize the characteristics the study participants and their family parameters. The Kuppuswamy’s scale was used to classify socioeconomic status of study population. Chi Square test was used to compare the significant difference of sociodemographic characteristics among rural and urban population and compare the nutritional status of preschool children of working and non-working mothers from selected rural areas and urban slums. Student t test were used to find the significant association of different factors with nutritional status of preschool children. P values of ≤ 0.05 is considered statistically significant.

**Findings**

A total of 88 children were approached for recruitment in the study, and 80 preschool children (40 Urban slums;40 Rural areas) agreed to participate giving the response rate of 90%. The mean ± SD age of preschool children were 43.8 ± 9.8 months (n=40) and 46.5 ± 7.8 months (n=40) in urban and rural areas, respectively [Table 1]. The study showed that 65%(n=52) of children belonged to lower socioeconomic status with a higher proportion of these children from urban slums than in rural areas (82.5% vs 47.5%; p=0.001). The proportion of working mothers were significantly higher in urban slums (i.e.62%(n=26) vs 40%(n=16); p=0.025) than rural areas and were primarily engaged in unskilled occupation (n=90%). The majority of fathers in the study were engaged in unskilled occupations i.e. 88.7%(n=71) and 27.5%(n=22) of mothers had no formal education [Table 1]. About 75% of children of working mothers had family-based care regardless of being located in urban slum or rural area. Among children, 77.5% were non-vegetarians and 22.5% were vegetarians [Table 1]. The proportion of non-vegetarian children were significantly higher in the urban slums than in rural areas (p=0.007).

Evaluation of the nutrition status of children of working and non-working mothers from rural areas and urban slums showed that 69.2% children were stunted, 23.1% were wasted and 50% were underweight [Table 2]. Similarly, in rural areas, 43.8% children of working mothers were stunted, 18.8% were wasted and 43.8% were underweight. The study did not find significant difference between the nutritional status of preschool children regardless of their location (i.e. urban slum vs rural areas) [Table 2].

Statistical test used: Chi Square Test. Significance at *P≤0.05

The association between nutritional status of children with age, gender, sociodemographic factors (educational status of parents, occupational status of parents) were explored. The study found significantly lower mean Z-scores of height-for-age in children whose fathers were employed in unskilled occupations (p=0.041). On the other hand, the mean Z-score of weight-for-age, and weight-for-height were found to be higher among children of educated mothers than children of mothers who had no formal education (p=0.050 and p=0.035, respectively) [Table 3]. The mean Z-score of weight-for-age (p=0.039) and weight-for-height(p=0.005) were significantly higher among children whose caregivers were family members than those whose caregivers were non-family members.
The associations of nutritional status of children with the frequency of consumption of different food groups such as vegetables, fruits, milk and products, unhealthy foods (i.e. chocolate and candies, savories and bakery items) were analyzed [Table 4]. Results showed that mean z-scores of height-for-age, weight-for-age and weight-for-height were significantly lower in children who consumed chocolates and candies frequently than those who consumed these less frequently (p=0.039, p=0.005 and p=0.034, respectively) The mean Z-score of height-for-age and weight-for-age was significantly lower among children who consumed savories frequently than who consumed these less frequently (p=0.019 and p=0.045, respectively) [Table 4].

Additionally, it was observed that the children of working mothers had significantly higher frequency of use of bakery products than children of non-working mothers (p=0.033) [Table 5]. The intake of the other food groups such as vegetables, milk, savories and sweets remained the same between both the groups.

Discussion

The present study was aimed to assess the impact of mothers’ working status on the nutritional status of their preschool children. The results showed that working status of mothers did not affect the nutritional status of their pre-school children. Additionally, sociodemographic factors such as mother’s educational status, father’s occupational status, family-based care of children and the dietary factors (i.e. the higher frequency of consumption of chocolates, savories and bakery products by the children) influenced the nutritional status of preschool children. The children of working mothers had a higher frequency of use of bakery products than that of non-working mothers.

The earlier studies from Madhya Pradesh and Nepal indicated that mothers’ working status influenced the nutritional status of their children due to the lesser time for childcare.10,11 A few previous studies from States other than Maharashtra have reported that mothers’ socioeconomic, education, and working status, and a rural family background determined the nutritional status of preschool children.12,13 However, the present study found that mothers’ working status and socioeconomic status of families did not influence the nutritional status of their children. The above contrasting results could be attributed to a smaller sample size of the present study or due to chance. Also, children in the present study received family-based care while mother was away at work which would have supported a good nutritional status of these children.14,15 In the study area it was observed that grandparents, elder siblings or neighbours provided caregiving while mother was at work. Also, we report the absence of any supportive childcare facilities such as creches or any other facility for childcare in this study area.

Additionally, the present study indicates that occupational status of father had significant impact on the nutritional status of the children. Our findings are similar to the study results of Sharma et. al. who found that fathers of underweight and thin children were employed in unskilled occupations. Further, this could have contributed to irregular income flow to the family, and thus, poverty.16,17 In addition to the other factors, some studies reported that mothers’ education status impact the nutritional status of their children.18,19 The present study showed a significant association between mothers’ education and nutritional status of their children.

Another important finding from this study was the frequent consumption of bakery products (i.e. Khari and
Biscuits) among children of working mothers compared to non-working mothers. This could be because working women in urban areas were unable to spend enough time on cooking for children and family members, which leads to an increased demand for convenience and processed foods. The study had a significantly higher number of working mothers from urban slums than in rural areas, and these working women plausibly replaced some of the meals of children with processed foods. Similar results reported by Japanese study that children of employed mothers very often skipped their meals and snacked more.

The results from the present study should be considered with caution. The results are from a preliminary study with a smaller sample size that may not be enough to establish a causal relationship between working status of the mothers and nutritional status of their children. Despite this limitation, the study provides an understanding on the existing prevalence of undernutrition among preschool children from rural areas and urban slum in selected areas of Pune with reference to working status of mothers. Additionally, the study report insights to the food pattern of preschool children, and the impact of working status of mothers on their food consumption pattern. In order to assess the causal relationship a study with larger sample size would be required.

**Conclusion**

In summary, the present study showed that mothers’ education status, father’s occupational status family based childcare support while mothers are at work and the frequent use of bakery products determined the nutritional status of their preschool children. In the context of unavailability of mothers’ care, children may develop poor dietary habits that adversely influence their health, nutritional status and development.

Weekly Iron and Folic Acid Therapy in the Treatment of Anemia in Adolescents

Sarala Premkumar¹, Padmasani Venkat Ramanan², T. Gayathri³

¹Associate Professor, Department of Pediatrics, ²Professor, Department of Pediatrics, ³Senior Lecturer in Statistics, Allied Health Sciences, Sri Ramachandra Institute of Higher Education and Research

Abstract

Objectives: To study the effectiveness of weekly iron and folic acid therapy in the treatment of nutritional anemia in adolescents as an alternative to daily therapy.

Method: A comparative study was done in 123 anemic adolescents aged 12-15 years, in Chennai, Tamil Nadu. The study was done with the approval of our Institutional Ethics Committee and permission from the school authorities. The study population was divided into two groups, one receiving weekly and the other daily iron and folic acid therapy. Hemoglobin (Hb) estimation was done at baseline, 8 weeks and 16 weeks after initiating the treatment.

Results: Overall 105 children, 56 in the weekly therapy group and 49 in daily group completed the study. Within the groups analysis was done by repeated measurements of ANOVA at 3 different points of time. The increase in Hb level from baseline at 8 and 16 weeks was found to be significant within both the groups (p value <0.001). The improvement in Hb levels in the two groups was compared by independent student t test. There was no significant difference between the groups (p value > 0.05).

Conclusions: Weekly iron and folic acid therapy is as effective as daily therapy in the treatment of nutritional anemia.

Keywords: Anemia, weekly treatment, iron and folic acid, adolescents.

Introduction

Iron deficiency anemia (IDA) is a major public health problem affecting billions worldwide. In India, the prevalence among the women in the reproductive ages and children is almost 50%.¹ IDA in adolescents can affect the growth, immunity, development, scholastic abilities and educational achievements.² The diagnosis of anemia and its treatment in adolescent girls is important because they reach the reproductive phase sooner.³ Prevention and control of anemia is one of the major components of health programs for improving adolescent health.⁴

The National Anemia Prevention and Control Program in India developed by Ministry of health and Family Welfare (MoHFW) recommends weekly supplementation of iron and folic acid (IFA) to children between 5 -19 years for the prevention of anemia.⁵ Its beneficial effect in anemia prevention is well known. However, there is no recommendation for pretreatment screening of these children for anemia. For established anemia, daily therapy is still recommended. When any medication has to be taken daily, compliance is a challenge, particularly in adolescence. Adherence to a weekly regime, especially when implemented through the school is easier and if proved effective it will be a good alternative to daily iron.

Since the prevalence of anemia in this age group is almost 50%, we studied the effect of weekly iron and
folic acid therapy through the school on improving the Hemoglobin (Hb) level in anemic adolescents.

**Material and Method**

This comparative study was done in school children in Chennai, South India, between August 2018 and January 2019. The study was done with the approval of our Institutional Ethics Committee and with the permission from the school authorities. The trial was registered with Clinical Trial Registry of India (CTRI/2018/01/011181). After obtaining informed consent from the parents and assent from the adolescents, students in classes 7 to 10 (aged 12 to 15 years), in two schools A and B were screened for anemia. After history and physical examination, Hb estimation using the Haemocue method was done by a trained lab technician. This Haemocue method is generally recommended for use in surveys. This Portable Photometer with disposable microcuvettes having reagent in a dry form, stored in a dry place at room temperature was used for analysis. The modified azidemethemoglobin reaction happens in the microcuvettes. Diagnosis of anemia and its severity was based on WHO classification. Mild - Hb : 11-11.9gm/dl, moderate – Hb : 8-10.9 gm/dl and severe (<8 gm/dl). In males at 15 years of age and above 11-12.9 gm/dl was considered mild anemia.

**Inclusion Criteria:**
2. Written consent from parents and assent from the adolescents.

The children with severe anemia (Hb<8gm/dl), suspected non nutritional anemia (palpable spleen / goiter), chronic systemic diseases and those who had been hospitalized or used any medication for two weeks in the previous 3 months were excluded from the study.

**Sample Size Calculation:** Based on the previous studies, with the observed value of 0.15, difference in Hb between baseline and after 3 weeks of weekly therapy with standard deviation of 0.08, effect size 0.63, power 90 and alpha error 5, a sample size of 44 in each group was derived. Considering 20% attrition a sample size 60 in each group was calculated. A non inferiority margin of 0.2 was taken for sample size calculation

Overall, out of 550 children in two schools (A &B) screened for anemia, 152 children (27.6%) were found to be anemic. This 27.6% prevalence of anemia is of moderate public health significance. Those willing to participate were enrolled after obtaining written consent from the parents and assent from the adolescent. Those fulfilling the inclusion criteria from school A (N = 60) were allotted to the weekly therapy group while those from school B (N= 63) were assigned to the daily therapy group. The two groups were comparable in terms of, age, sex, BMI and baseline Hb (Table 1). The children, parents and class teachers were educated regarding the possible side effects by the Principle Investigator (PI) and they were asked to report to the class teacher in the event of any side effects. If any child in the weekly therapy group had a drop in the hemoglobin by 8 weeks, change to daily therapy was planned.

Ferrous sulphate sustained release capsule 150mg (46 mg of elemental iron) and 500 mcg of folic acid was used in both the groups. For daily treatment one capsule per day was prescribed. As per the national guidelines by the MoHFW, 60 mg elemental is given daily to anemic children in the age group of 10-19 years for 3 months. Since the capsule we used was 46mg of elemental iron, we gave it for 16 weeks. The capsules were provided to the respective class teachers in both the groups. The weekly therapy group (Group A) received two capsules once a week under the direct supervision of the school teacher for 16 weeks. In the daily therapy group (Group B) the parents were called and given 14 capsules every two weeks by class teacher and asked to give one capsule daily at home and record the administration in a calendar. This was continued for 16 weeks. A self reported adherence to treatment on six out of seven days in a week was taken as adequate. Children in both the groups received Tablet Albendazole 400mg (2 doses, 2 weeks apart) before starting therapy. In both groups, first hemoglobin estimation was done at the end of 8 weeks (+ 4 days) and the second, at the end of 16 weeks (+ 4 days).

Data was analyzed using SPSS version 16. Independent t test was used to analyze the differences between the groups. Within the groups analysis was done by repeated measurements of ANOVA at 3 different points of time and by Friedman test. Chi square test was used for the baseline demographic characteristics. P values less than 0.05 was considered significant.
Findings

The total number of children enrolled initially was 123 (60 in group A and 63 in Group B). There were 14 dropouts in daily treatment group due to gastrointestinal side effects (4 children) and poor adherence (10 children) and four in the weekly therapy group, one after the first dose due to gastro intestinal side effect and other three after two doses due to withdrawal of consent for personal reasons unrelated to side effects. Hence 49 in daily treatment group and 56 in the weekly therapy group completed the study. Details of the study population are given in Table 1.

The mean Hb concentration showed significant increase from the baseline at 8 weeks and 16 weeks in both the groups (p value <0.001). (Table 2). There was no significant difference between the two groups at either 8 or 16 weeks. At the end of 16 weeks 69.6% (39/56) in weekly group and 61.2% (30/49) in daily group had normal Hb level. (Table 3).

Discussion

Overall, with weekly IFA therapy, of the 56 anemic children, 42.9% became non anemic in 8 weeks and 69.6% in 16 weeks while in the daily therapy group this was seen in 44.9% and 61.2% respectively. The mean increase in Hb from the base line was similar in the two groups. The overall incidence of significant gastrointestinal side effects was very low in both groups (weekly group 1/60 and daily group 4/63).

A lower response rate to weekly therapy (50% vs 56.7%) was observed in one previous study in adolescent girls. [10] However they had used 350 mg of ferrous sulphate (70mg elemental iron) and 1.5 mg of folic acid per dose in both the daily and weekly regimes for 100 days. Our response rate to weekly therapy was higher probably due to the higher dose (92 mg) of elemental iron.
In our study the mean increase in hemoglobin from the baseline in both the groups was only around 1 gm over 8 weeks. This is lower than that reported in other studies where in children aged 5 – 10 years received 200mg ferrous sulphate given daily or weekly for 56 days, the mean Hb increase was 2.5 gm/dL in daily group and 2 gm/dL in weekly group.\[11\]

In our study the incidence of reported Gastro intestinal side effects was very small in both groups and seen only in the first week. This could be because of the pre intervention counseling and small sample size of 123. Other studies, with larger sample size, have reported a higher incidence of side effects (25% in first week, 7% in week two and 5% in weeks three) following weekly iron and folic acid supplementation.\[12\]

The weekly supplementation strategy is based on the intestinal turnover time which is 5-6 days in human beings. This is because saturation of the iron binding protein (apoferritin) in the mucosal cells blocks further iron absorption till these cells are shed.\[13, 14\] Animal studies have shown better iron absorption when given every 3rd day than when given daily.\[15\] Weekly iron and folic acid administration is as effective as daily therapy in the treatment of nutritional anemia in adolescents.

The major limitation of our study is we enrolled only children with mild to moderate anemia. Also, we have not confirmed iron / folic acid deficiency as the cause of anemia or studied the iron status. Further studies without these limitations are needed before making guidelines.

Conclusions

Our study suggests that weekly iron and folic acid therapy is an effective alternative to daily iron therapy in the treatment of anemia in adolescents. Since the iron and folic acid therapy can be given under the direct supervision of school teacher compliance is also better.

Envisaging the Model of a Yoga Based Physical Activity Promotion in India

Satyajit Mohanty¹, Sandul Yasobant², Venkatarao Epari³

¹Scholar, ²Junior Researcher, Center for Development Research (ZEF), ³Professor, Department of Community Medicine, IMS & SUM Hospital, Siksha ‘O’ Anusandhan Deemed to be University, Bhubaneswar, Odisha, India

Abstract

Background: There are numerous yoga centers around India promoting yoga for health and spirituality. Their model of propagation of yoga addresses both community engagement and individual level treatment through yoga. On other hand, India needs a National Physical Activity Plan based on a sound model encompassing both community & individual level to combat NCDs which is economically less taxing. As promulgation of yoga sounds promising in fulfilling above said two criteria, we analyzed the model of yoga propagation of a non-governmental organization in India named Patanjali yogpeeth.

Method: Google scholar, pubmed, Cochrane data base are searched for literature on yoga by Patanjali yogpeeth. The official web site of Patanjali yogpeeth i.e. www.divyayoga.com, Video clippings from You tube are searched for yoga camps by Swami Ramdev. Swami Ramdev’s TV programs on “Aastha” channel was searched for more information.

Result: The search yielded 193 items. All of them are available for analysis. We found there is a definitive model of yoga based physical activity promotion by Patanjali yogpeeth. Further, there is a similarity between the two most recommended models of physical activity promotion and yogic yogic physical activity promotion model.

Conclusion: Government of India must take a closer look at this model and prepare a system of induction of the YPA model in to the public health care system to prevent NCDs.

Keywords: Physical activity, Exercise, yoga, Energy expenditure, Health promotion, Non-communicable disease, National physical activity plan, Patanjali yogpeeth, Swami Ramdev.

Background

As per the 2015 statistics health care costs for non communicable diseases has surpassed that of the communicable diseases¹. Although Indian government is gradually focusing more on NCDs, healthcare costs in India are very high and it’s expected to rise in near future²⁻⁴. For this proactive and cost effective measures are required to respond to the NCD threat. According to WHO, well designed national prevention & management response can avert nearly 50% of premature annual NCD deaths⁵. Preventive steps of NCDs are distinctly different from communicable diseases. And physical activity promotion takes a lead role in NCD prevention.

To prevent NCDs at individual level, WHO recommends a stipulated amount of physical activity (PA) per day⁶. India has formulated a PAG obliging to WHO recommendation⁷. But at present there is no national physical activity policy (NPAP) in India. However, to combat NCDs at population level physical activity should be promoted through a “Whole society approach”⁸. For this to happen, first there should be

Corresponding Author:
Dr. satyajit Mohanty
PhD Scholar, Department of Community Medicine, IMS & SUM Hospital, Siksha ‘O’ Anusandhan deemed to be University, Bhubaneswar, Odisha, India - 751003
a national level program to engage the community to physical activity and second there should be a comprehensive system for PA interventions at individual level. The later should aim to make PA an inclusive element of medical paradigm for prevention and treatment of NCD healthcare system. India is a country of lifestyle recommendations to the world since time immemorial. India is known to boast spiritual lifestyle recommendations by ancient philosophers. Earliest Indian health directives are embedded in it’s philosophical systems which dates back to 1500 to 500 BC. These primeval philosophical systems gave many lifestyle recommendations for then existing population. There is a renewed interest of those lifestyle recommendations in current Indian society especially of yoga. According to the definition of physical activity by caspersen et al yoga can safely be assumed to be a type of physical activity. Further recent studies on yoga indicates, for example a specific yoga style called vinyasa yoga can lead to significant energy expenditure similar to that of any other physical activity of moderate intensity.

At present, there are numerous yoga centers around India promoting yoga for health and spirituality. And yoga have found it’s way through television and similar such mass media to reach common household. The model of propagation of yoga addresses both community engagement and individual level treatment. On other hand, India needs a National Physical Activity Plan based on a cost effective yet sound PA model encompassing both community & individual level to combat NCDs. As promulgation of yoga sounds promising in fulfilling above said two criteria, we analyzed the yoga propagation of a non-governmental organization in India named Patanjali yogpeeth which is one of the most popular yoga organization in India. Though, aims of yoga and Ayurveda in this organization are similar and complimentary to each other, they are kept separate. Among the multifarious yoga activities following are note worthy:

(a) yoga classes by trained yoga teachers held as camps outside and in the institution
(b) television broadcasts of the classes
(c) printing of yoga literature through books & magazines
(d) university based yoga course

It is noteworthy that “Agita Sao Polo” started as a regional PA promotion plan in Sao Polo, Brazil in 1996 is now recommended by WHO as a PA promotion model for developing countries. Most important aim in “Agita Sao Polo” model is community engagement for physical activity. Whereas established in the year 2007 by American Medical Association and American College of Sports Medicine, the “Exercise is medicine” solution model is said to be a global model for PA promotion. “Exercise is medicine” solution model focuses on a physical activity intervention. It provides a comprehensive system for PA interventions at individual level aiming to make PA as an inclusive element of medical paradigm for prevention and treatment of NCD healthcare system.

Material and Method

Google scholar, pubmed, Cochrane data base are searched for literature on yoga by Patanjali yogpeeth. The official web site of Patanjali yogpeeth i.e. www.divyayoga.com, video clippings from You tube are searched for yoga camps by Swami Ramdev. Swami Ramdev’s TV programs on “Aastha” channel was searched for more information. The search yielded 193 items excluding the duplicates and similar content and TV commercials of Ayurvedic & home care products by Patanjali yogpeeth.

Findings

About Patanjali yogpeeth: Patanjali yogpeeth (www.divyayoga.com) is associated with a phenomenal yoga based PA promotion in India. It’s founded by two well known social activists cum yogis, including Swami Ramdev who has an astounding reach as a health advisor to one sixth of Indian population. Though, aims of yoga and Ayurveda in this organization are similar and complimentary to each other, they are kept separate. Among the multifarious yoga activities following are note worthy:

(a) yoga classes by trained yoga teachers held as camps outside and in the institution
(b) television broadcasts of the classes
(c) printing of yoga literature through books & magazines
(d) university based yoga course

In the following section we will refer yoga by Patanjali yogpeeth as yogic physical activity or the YPA. Summary of our analysis on YPA promotion by Patanjali yogpeeth is as follows:

1. The community engagement module:

   a. Platform for community engagement: Media exposure & public messaging

      Popularity of Swami Ramdev as a yoga teacher both in India and across the globe attracts

print and electronic media coverage of all of his activities including his yoga camps. Hence there is no paid media approach for spreading the message of yoga. In addition, perception of public message is “Call for physical activity is from a spiritual master of ancient yogic system on holistic health” further helps in community engagement. For those who cannot attend yoga camps most of his yoga demonstrations comes live or in recorded format in different TV channels. Similarly, to engage more participants eminent personalities such as politicians & movie stars are invited to attend the camps. Public message is also spread through yoga teachers trained by Patanjali yogpeeth conducting small group sessions in the community.

b. “One to many” intervention format at camps: Format of the yoga sessions in the camp remains the same for all the places wherever it’s held. Camps are informative, interactive and interventional in nature. Swami Ramdev teaches yoga both to healthy and suffering participants by demonstrating it himself and asking the audience to follow while trained volunteers supervise each of the participants. Following can be observed in a typical yoga camp:

- These camps address mostly NCDs. Yoga or YPA is projected both as an independent solution and as a complimentary treatment. A typical session lasting up to 30-60 min is a good mix of sequence of different yogic and non yogic exercises, yogic postures, breath control exercises (pranayama), relaxation & cool down exercises and meditation.

- Participants are given the knowledge of applications & benefits incurred by regularly performing particular yoga or pranayama technique. In few of the instances quantum of change expected due to regular performance of yoga over a certain parameter or a disease is shared with the participant. Regular yoga is emphasized to all participants to have control and amelioration of their ailments. Post-camp, group sessions organized by trained volunteers is a factor for adherence to YPA.

c. Pre-camp screening, focusing mostly on NCD related ailments by trained Ayurvedic doctors are carried out. Participants are also given detailed knowhow of precautions & contraindications for using yoga in different ailments. For example certain violent expiratory pranayama techniques are asked to be avoided by participants suffering from cardiovascular diseases.

d. Branches and franchise of Ayurvedic pharmaceutical division of Patanjali yogpeeth ensure endorsement of YPA along with Ayurvedic medications by qualified Ayurvedic physicians who are trained on yogic exercises in their professional training course. This makes YPA available at individual level.

2. Sustainable community links created by Inspirational talks: Swami Ramdev is known for his inspirational talks that include general & health economics and Indian welfare. He restarted a Swadesi (means your “own country’s”) movement. This term “Swadesi” was profusely used in pre independence era India. Freedom fighters used this term to influence Indian people to use Indian goods. Swami Ramdev’s Swadesi movement is to call all Indians to use goods produced in India and adopting an oriental lifestyle as recommended in Ayurvedic system of health care. Thus YPA being an important part of Ayurveda has become the epicenter of his camps & campaigns. Addition of “Swadesi” movement attracts sustainable community changes.

3. The education module:

a. Education & skill training: Professional and university certified Yoga teachers & Patanjali yogpeeth certified yoga trainers (of different levels) are involved in YPA specific skill development. Many non professionals among lay public are prepared as YPA volunteers by short term training on YPA.

b. Service delivery mechanism of YPA: There is system for employing & engaging YPA-skilled persons for community and individual service. Many medically lay volunteers but trained in YPA extend the community service on suo moto basis.
4. Clinical module: Individual based, self driven & based on a focused practice system: YPA has a distinct edge in preventive health care in addressing wellness as it comes from the oriental system of spiritual practice. (See the following flowchart).

Disease control through YPA
↓
Physical wellness
& Mental wellness through YPA
↓
Social wellness (YPA is firm pillar of Swadesi movement which is an example of spreading commitment towards community)
↓
Spiritual wellness

5. Research Module

a. Activities: A quality research center Patanjali yogpeeth (at Haridwar) conduct research activities in Ayurvedic system and yoga. Research team at Patanjali yogpeeth is comprised of medical researchers from both Ayurvedic and modern medicine. Research output is shared with the scientific community through publications in different journals. In addition Patanjali yogpeeth has its own publishing house for periodicals, books on yoga, Ayurveda.

b. Evidence base: While conducting camps, research evidences regarding efficacy of certain YPA technique(s) over a disease or on health is disseminated. However, Many of Swami Ramdev’s references are generally anecdotal references and case studies from his primary data sources of the research center.

6. Expenditures: YPA is self driven and cost effective. YPA consolidates the Indian health care system for NCD prevention and care without banking on government resources.

Conclusion

Physical activity promotion by Patanjali yogpeeth demonstrates a definite model. Similar to the “Agita Sao Polo” model YPA has a good public messaging mechanism and it engages the community into physical activity. On other hand, similar to “Exercise is medicine” solution model YPA has a sound physical activity intervention format. Hence YPA combines the essence of both of the models i.e. “Agita Sao Polo” Model & “Exercise is medicine” solution model. Though not scientifically tested, YPA model seems to be a replicable model for PA promotion in public health.

YPA not only cost effective but also it seems to have an edge over above discussed two models as it promotes all the components of health i.e. physical, mental, social, spiritual. Hence it can potentially be a complete PA promotional model for economies like India.

A clarion call to public health practitioners & policy makers: A precarious scenario looms over Indian public health arena. On one hand there is a rise in the NCD occurrences with parallel increase in physical inactivity where as on the other hand there is an absence of an exclusive NPAP to promote PA at population level. As reflected in the recent National Health Policy released in year 2017 there is no planning for formulation of exclusive NPAP.

Creating a sustainable system for PA promotion & delivering the service at community and individual level for prevention and treatment of NCD is a herculean ask for a population of 132 crore. Nonetheless, YPA is a genuinely functional and well publicized platform for government of India to consider regarding PA promotion. Government of India must take a closer look at it and prepare a system for induction of the YPA model in to the public health care system. The economic feasibility for the same is assuring as YPA is already serving from individual to community level in all parts of India. Hence YPA model has the potential to help Indian NCDs scenario. However YPA needs a close scrutiny by experienced public health practitioners and researchers for suitable modification to fit all socio-religio-demographic spans. And a lot of clinical and public health research on YPA is needed to show a newer way to health in this NCD age.

Shetty Memorial Institute of Dental Sciences, NITTE (Deemed to be University), Mangalore, Karnataka, India

Abstract

Dental index or indices are devices to find out the incidence, prevalence and severity of the disease, based on which preventive programs can be adopted. This current review article emphasizes and lists out the different indices that are used regularly in screening and treatment of various oral conditions. Few of the recent advances on dental indices have also been enumerated in the current article.

Keywords: Dental indices, oral hygiene, caries, Periodontitis, Tooth wear, Mobility.

Introduction

Oral diseases can be quantified more precisely than any other chronic conditions. The quantitative measures of these oral conditions most commonly rely on Indices or Indexes. Such differences can only be determined by indices¹.

According to Russel AL, an Index is defined as a numerical value describing the relative status of a population on a graduated scale with definite upper and lower limits, which is designed to permit and facilitate comparison with other populations classified by the same criteria and method². The ideal requisites of an indices are clarity, simplicity, objectivity, validity, reliability, Quantifiability, sensitivity, acceptability. The main uses of indices can be divided into three:

1. For individuals – for providing individual assessment.
2. For research – to determine baseline data.
3. For community health – to show the prevalence and incidence of a particular condition³.

Various indices are put forwarded for assessing the oral health status.

Few of the indices are described below:

Indices Used for Assessing Oral Hygiene:

There are number of indices which are used to assess the oral hygiene status. The indices those are used are: Oral hygiene index(OHI), Oral hygiene index simplified(OHI-S), Glass index for debris, Patient hygiene performance index (PHP), Modified patient hygiene performance index (PHP-M), Plaque free score, Clinical system for scoring Patient’s Oral Hygiene Performance, The university of Mississippi oral hygiene Index (UM-OHI)⁴. Out of all these we are discussing some of the indices in detail:

1. Oral Hygiene Index (OHI): It was developed by John C. Greene and Jack R. Vermillion (1960) to classify and assess oral hygiene status. This index is composed of Debris and Calculus Index. Rules for scoring are: 1) Only permanent teeth are scored, 2) Third molars or incompletely erupted teeth are not scored, 3) The buccal and lingual debris scores are both taken on the tooth in a segment having the greatest surface area covered by debris. 4) Interpretation: The minimum number of points for all segments in either debris or calculus score is 0. The maximum number of points for all segments in either debris or calculus score is 36. The higher
the score, the poorer the oral hygiene. Limitations are even though the oral hygiene index was to determined to be simple and sensitive, it was time consuming and required more decision making. So, an effort was made to develop a more simplified criterion. 

2. **Simplified Oral Hygiene Index (OHI-S):** It was developed by John C. Greene and Jack R. Vermillion (1964) to reduce both the number of decisions required on the part of examiner and time required for the inspection. It differs from the original OHI in number of tooth surfaces (6 rather than 12). Substitution of missing teeth is possible in OHI-S when compared to OHI. The criteria used for assessing scores to the tooth surfaces are same as those used for the OHI.

Rules for scoring OHI-S are at least two of the six possible tooth surfaces must have been examined. Third molars are included only included if they are functional. Natural teeth with full crown restorations and surfaces reduced in height by caries or trauma are not scored. Instruments used are no.23 explorer and mouth mirror.

**Indices Used for Assessing Plaque:** There are number of indices used for assessing the plaque inside the oral cavity. Those are: plaque index and its modifications, Quigley –Hein Index and its modifications, Turskey-Gilmore-Glickman modification of the Quigley Hein plaque index, Shick and Ash Modification of plaque criteria, Global plaque index, Navy plaque index, Gingival marginal plaque index or Harpp index (GMPI), Distal mesial plaque index (DMPI), Proximal Marginal plaque index (PMPI), New method of plaque scoring (NMPS), Plaque assessment scoring system (PASS), Topographic plaque index.

1. **Plaque Index:** It was described by Silness jand Loe H in 1964 and more fully described by Loe.H in 1967. It is unique among indices because it ignores coronal extent of plaque and assesses only the thickness of plaque at the gingival area of the tooth. it can be used as full mouth or as simplified index. The only limitation is the subjectivity in estimating plaque and if any single index tooth is missing, there is no substitution and a full mouth examination has to be done. Instruments used are mouth mirror and a dental explorer.

2. **Turskey-Gilmore-Glickman Modification of The Quigley–Hein Plaque Index:** Quigley G. and Hein J in 1962 reported a plaque measurement that focused on the gingival third of the tooth surface. They examined only the facial surfaces of anterior teeth. A numerical scoring system of 0 to 5 was used. The Quigley – Hein plaque index was modified by Turskey S, Gilmore N. D and Glickman I in 1970. Instruments used are mouth mirror and disclosing agent (Quigley and Turskey used basic fuschin). Calculation will be index score =Total score/ number of surfaces examined. Interpretation is like a score of 0 to 1 is considered low and a score of 2 or more is considered high.

**Indices Used for Assessing Gingival Disease:** Indices that are used to assess the gingival diseases have been widely used through out the dentistry. Some of them are: Papillary Marginal Attached (PMA) index, Papillary Marginal (PM) index. Gingival index,Glass index, Gingival Bleeding Index (GBI), Gingival Assessment index, Dental health care index, Gingival tissue index. We are going to discuss some of the commonly used gingival indices:

1. **Papillary Marginal Attached (PMA) Index:** This index was developed by Maury Massler and Schour in 1944. The basic philosophy used is very similar to DMF (Decayed Missing and Filled Tooth Index) i.e number of gingival units affected were counted rather than the severity of the inflammation. A gingival unit was divided into three component parts: papillary gingiva, Marginal gingiva, Attached gingiva. The number of affected papillary, Marginal and attached gingival units are counted and then totaled separately, then added together and expressed numerically as the PMA index score per person.

2. **Gingival Index (GI):** This index was developed by Loe H and Sillness J in 1963, only for the purpose of assessing the severity of gingivitis and location in the four possible areas by examining only the qualitative changes of the gingival soft tissue. Instruments used are Mouth mirror and periodontal probe. All the four surfaces are examined and divide by number of tooth examined. The interpretation will be on mild, moderate and severe gingivitis.

**Indices Used for Assessing Periodontitis:** Indices that are used for assessing periodontitis are: Periodontal index (PI), Periodontal Disease Index (PDI), Community Periodontal Index for treatment Needs (CPITN),
Gingival Periodontal Index, Gingival-Bone Count Index, Community Periodontal Index (CPI), Dutch Periodontal Screening Index, Periodontitis Severity Index etc. Here will be discussing some of the commonly used index in detail:

1. Russel’s Periodontal Index (PI): This was developed by Russel A. L. in 1956, over a trial period of 10 years. The PI was intended to find deeper periodontal disease by measuring the presence or absence of gingival inflammation and its severity, pocket formation and masticatory function. The PI is a composite index. Instruments used are Mouth mirror and Plain probe. All the teeth are examined and Russel ‘s Rule states that “When in a doubt assign lesser score”. It is calculated by sum of the individual score divided by Number of teeth present. One of the limitation is since calibrated probe is not used there might be under estimation of true level of periodontal disease.

2. Community Periodontal Index for Treatment Needs (CPITN): This index was developed by the “joint working committee” of the “World Health Organization” and “Federation Dentaire Internationale” by Jukka Ainamo, David Barmes, George Beagrie, Terry Cutress, Jean Martin, and Jeniffer sardo-Infirri in 1982. This survey was developed primarily to survey and evaluate periodontal treatment needs rather than determining past and present periodontal status. The limitations of CPITN that it doesn’t record the position of the gingival margin and doesn’t provide assessment of past periodontal breakdown. It can be calculated in two ways by: Index teeth and Sextants. Instruments used are mouth mirror and CPITN Probe. Classification of diseases are coded from Code 0 to Code X. Classification of treatment needs are coded from TN 0 to TN 3.

3. Community Periodontal Index (CPI): It is just a modification of CPITN. The modification is done by the inclusion of measurement of “Loss of attachment” and elimination of the “Treatment need” category. Instruments used are mouth mirror and CPITN-C Probe. The codes and criteria are same as that of CPITN. The scoring criteria is from 0 to 9.

Indices Used for Assessing Dental Caries: Dental caries is the most common problem faced in our community. So to assess the dental caries in a wide population we have to relay upon these indices. The indices used for assessing dental caries are:

- Decayed, Missed, Filled Teeth Index (DMFT), Decayed, Missed, filled surface Index (DMFS), Simplified Caries Index, Modified DMFT index, International caries detection and assessment system (ICDAS), Root caries index, Root surface caries severity index, Root surface Caries index etc. We will be discussing some of them in detail:

1. Decayed Missing Filled Teeth Index (DMFT): This index was developed by Henrt T. Klien, Carrole E. Palmer and Knutson J.W. in 1938 to determine the prevalence of coronal caries. The main advantages of this indices are Simple, Rapid, Versatile and Universally accepted. Instruments used are Mouth mirror and Explorer. All the 28 permanent teeth are included. The maximum score for an individual DMFT Score is 28 or 32. Total each component, i.e. D + M and F Separately, then, total DMF. There are several limitations like DMFT Values doesn’t show number of teeth at risk. DMFT index can overestimate caries experience in teeth in which preventive fillings are made. It gives only little study about root caries. DMFT equates a disease state with a healthy state by assigning the same score for a decayed tooth as well as for a filled healthy tooth. It was then modified in 1987 and 1997, in that all third molars were included and temporary restorations are considered as decay. only missing due to caries is missing component. In 1997 modification WHO Probe was made to assess the DMFT score and also for the individuals 30 years and older, M component should comprise teeth missing due to caries for any other reason.

2. International Caries Detection and Assessment System (ICDAS): Codes for coronal caries range from 0 to 6 depending upon the severity of the lesion. Criteria for the coding is described like:
   - 0=Sound teeth
   - 1=First visual change.
   - 2=Distinct visual change.
   - 3=Localized enamel break down.
   - 4=Underlying dark shadow of dentin.
   - 5=Distinct cavity with visible dentin.
   - 6=Extensive distinct cavity with visible dentin.
3. **Specific Caries Index:** This was proposed by Sashidhar Acharya in 2006. These criteria for this index is based on GV BLACK, classification of cavity preparation. The main advantages are providing information on caries prevalence, criteria are simple and easy to use. Reproducibility is fair to good. Some of the limitations are in cases of large lesions covering more than one surfaces can’t be assessed. Lack of provision of root caries and inability of this index if used alone to capture information on treatment planning.\(^{16}\)

**Indices Used for Assessing Root Caries:** Root surface caries are generally confined to exposed root surfaces and is therefore an unusual condition, because it is dependent on previous disease, resulting in loss of attachment and cementum exposure. Some of the indices used are Root caries index, Root surface caries severity index, Root caries criteria as given by Banting DE, Ellen RP and Fillery ED\(^4\).

1. **Root Caries Index (RCI):** It was developed by Ralph V Katz in 1979. Only teeth with gingival recession are examined. Method- Mesial, distal, buccal lingual are examined.

   \[
   \text{RCI Score= RD+RF 100/ RD +RF+RN}
   \]

   \(RD=\) Recession present, surface decayed

   \(RF=\) Recession present, surface filled

   \(RN=\) Recession present, Surface Normal or Sound\(^{17}\).

2. **Root Surface Severity Index:** It was developed by Billings RJ in 1986. According to these index criteria was graded. Grade I (incipient), Grade II (shallow), Grade III (cavitation), Grade IV (pulpal)\(^{18}\).

4. **Indices Used for Assessing Tooth Wear and Mobility:** Many tooth wear indices have been developed for clinical and laboratory use. Some of the common tooth wear indices are Tooth wear index, simplified tooth wear index, System for Assessing Occlusal tooth wear, Individual tooth wear index, UK Adult Health Survey Criteria, The Exact tooth wear Index\(^4\). We will be explaining some of them in detail:

1. **Tooth Wear Index (TWI):** This was introduced by B.G.N.Smith and J.K. Knightin 1984 to assess the extent severity of dental erosion, attrition, and abrasion as well as any combination of these conditions. Scores are given in four criteria from no loss of enamel to defect more than 2mm deep–pulpal exposure. Some of the limitations are the thresholds proposed were high, erring towards understatement rather than exaggerations of pathological wear. Full use of index as a research tool is not feasible without computer assistance\(^{19}\).

2. **Simplified Tooth Wear Index:** Barsdely et al pioneered a new, simplified version of TWI. Tooth wear scoring was essentially dichotomized into the presence or absence of dentine, with even cupping of dentine scoring one. Scores vary from 0 to 4 varying from No wear into dentine and exposure of pulp or secondary dentine\(^20\).

5. **Indices to Assess Tooth Mobility:** Certain indices were developed to evaluate the tooth mobility to overcome the problems with devices. Some of them are Tooth Mobility Index, Mobility Index by Ramfjord, Mobility Index by Laster et al, Tooth Mobility Index by Lindhe\(^4\).

1. **Tooth Mobility Index:** It was described by Miller SC in 1950. Tooth is held firmly between two instruments and moved back and forth. Mobility is scored from 0-3\(^{21}\).

2. **Mobility Index by Ramfjord:** It was described by RAMFJORD in 1967. Code ranges from M0 to M3. From physiologic mobility to Extreme mobility\(^22\).

3. **Mobility Index by Laster et al:** It was assessed by the application of Lateral horizontal forces based on the score from 0 to 3 i.e. from Normal to Mobility greater than 1mm\(^23\).

6. **Conclusion**

Indices are the essential tool for conducting research projects, diagnosis, making treatment plans and evaluation of prognosis and treatment outcome. It is really difficult to find all related indices at one place, so in this current article we have tried to compile the different indices regularly used in dentistry for research and clinical evaluation of various oral disease & conditions. Future studies should be conducted on all indices that the future dentists will know the importance of indices in research as well as in clinical evaluation level.

Psychology of Spirituality: Mental Health Perspectives

Shivani Bhambri¹, Mamata Mahapatra²

¹Research Scholar, Amity Institute of Psychology and Allied Sciences, ²Professor, Centre Head for Organizational Psychology, Amity Institute of Psychology and Allied Sciences, Amity University, Noida

Abstract

India is a land of spirituality with rich heritage of spiritual literature. Researchers proved that spirituality and mental health are inter related. Spirituality has a positive effect on physical as well as on mental health. Recent research reports strongly suggest that to many patients, religion and spirituality are resources that help them to cope with the stresses in life, including those of their illness. Many psychiatrists now believe that religion and spirituality are important in the life of their patients.

Align to the above present research emphasized on the importance of Spirituality and mental health. In the present paper the researchers have attempted in depth analysis of followers of four different discourses. The sample of the study consists of 311 followers of Divergent Discourses. Sample was collected in two of the States i.e Delhi and Rajasthan. The results revealed that there is relationship between mental health and spirituality of followers of four divergent discourses. Mental health was determined with the help of Mental Health Inventory developed by Dr Jagdish and Dr Srivastav. Spirituality was determined with the help of spirituality assessment scale developed by Judy. W. Howden. Research indicates that experiencing various kind of stress, anxiety increases the risk of suffering from various mental illnesses. From the perspective of positive psychology or holism, mental health may include an individual’s ability to enjoy life, and create a balance between life activities and efforts to achieve psychological resilience.

Keywords: Mental Health, Spirituality, Psychological Resilience, Discourses, Positivity.

Introduction

India is a land of spirituality with rich heritage of spiritual literature. Spiritual gurus like Swami Vivekananda, Swami Chinmayya worked relentlessly for about 40 years to bring about spiritual revival in India and abroad. Spirituality is linked to better health, less stress during difficult times, more positive feelings, greater psychological well being, and superior ability to handle stress.

Research has shown that those who are more religious or spiritual and use their spirituality to cope with life, experience many benefits to their health and well-being. Older adults use prayer more than any other alternative therapies for health, specifically to cope with stress. Thus we come to know that how spirituality plays an important role to keep our mental as well as physical health intact.

Patricia Higgins in (2011)³ found that in England people with dementia living in care homes can be enhanced by the provision of person-centered care.

Mental health is a level of psychological well-being, or an absence of a mental disorder, it is the “psychological state of someone who is functioning at a satisfactory level of emotional and behavioral adjustment”.

Océane Agli (2014)¹ talked about that how religious and spiritual issues are clearly important to the older adult population and may play a positive role in maintaining health and recovering from illness.

Spirituality may denote almost any kind of blissful experience. It denotes a process of transformation, but in a context separate from organized religious institutions,

Phone No.: 97171 50315
termed “spiritual but not religious”. In modern times the emphasis is on subjective experience.

Dorte Toudal Viftrup (2013)\(^2\) used Inclusion and exclusion criteria, and checklists from standardized assessment tools. However, clear and delimited conceptualization of spiritual and religious factors is crucial in order to be able to conclude the direct influences of spiritual or religious factors on outcomes.

In (2010)\(^4\) P. S. Fry described the psychosocial model of mental health postulates that wellbeing in late life is significantly influenced by several externally generated factors such as social resources, income and negative life events.

Robert C. Atchley (2009)\(^5\) described spiritual life, one focused on personal growth and deep human experience, is a major focus and motivator for people over the age of forty. Ellen Idler (2008)\(^6\) highlighted through a discussion of current research and related observations that many of the positive benefits that religious and spiritual practice can have on one’s health and well-being.

Researcher has chosen the followers of four divergent discourses mentioned below:

- Radha Soami Satsang Beas (RSSB)
- Nirankari
- The Art of Living
- Anandpur Kuttiya

**Review of literature:** In modern society keeping mental health intact is important in day to day life. In this study we are talking about that how spirituality has a positive or negative impact on the mental health of followers of religious discourses. Some of the related reviews are:

Océane Agli et al in 2014 talked about that how religious and spiritual issues are clearly important to the older adult population and may play a positive role in maintaining health and recovering from illness. This study systematically reviewed the literature examining the effects of religion and spirituality on health outcomes such as cognitive functioning, coping strategies, and quality of life in people with dementia.

Dorte Toudal Viftrup, et al 2013 used Inclusion and exclusion criteria, and checklists from standardized assessment tools were applied to the research literature. Qualitative and quantitative papers were included. In total, 8 articles were considered eligible for the review. Findings from the evaluation suggested that the concepts of spirituality and religiosity were poorly conceptualized and the way in which spiritual and religious factors were integrated into such group psychotherapies, which distinguished it from other types of group psychotherapies, was not fully conceptualized or understood either. However, clear and delimited conceptualization of spiritual and religious factors is crucial in order to be able to conclude the direct influences of spiritual or religious factors on outcomes.

Patricia Higgins in 2011 found that in England and Wales there are over 700,000 people living with dementia, a third of who live in care homes. Notably two thirds of residents in care homes have dementia (Department of Health 2009). A study by Cohen–Mansfield et al 2006 found that the well-being of people with dementia living in care homes can be enhanced by the provision of person-centered care based on knowledge of their unique life story and the creation of positive relationships. For people with dementia, helping to maintain a link or reconnect with their religion as part of their provision of care has the potential to increase their sense of well-being. This has been recognized in the National Service Framework for Older People (DOH 2001) and by NICE/SCIE (2006). Both documents stress the necessity of providing person-centered care that responds to the individual’s needs including those relating to spirituality and religion.

P.S. Fry in 2010 described the psychosocial model of mental health postulates that wellbeing in late life is significantly influenced by several externally generated factors such as social resources, income and negative life events. More recently, the gerontological literature is drawing attention to the increasingly influential role of existential factors such as religiosity, spirituality and personal meaning in the psychological wellbeing of older adults. This study examined the unique and combined contribution of specific dimensions of religiosity, spirituality and personal meaning in life as predictors of wellbeing in samples of community-residing and institutionalized older adults. Using hierarchical regression analyses, the results showed that personal meaning, involvement in formal religion, participation in spiritual practices, importance of religion, degree of comfort derived from religion, sense of inner peace with self, and accessibility to religious resources were significant predictors of wellbeing for
the combined sample. The findings confirmed that existential measures of personal meaning, religiosity and spirituality contributed more significantly to the variance in wellbeing than did demographic variables or other traditional measures such as social resources, physical health or negative life events. The importance of existential constructs of religiosity, spirituality and personal meaning in helping older adults to transcend old age stresses and sustain wellbeing are discussed.

Similarly in 2009 Robert C. Atchley described spiritual life, one focused on personal growth and deep human experience, is a major focus and motivator for people over the age of forty. Yet there is a marked lack of rigorous academic study of spirituality’s importance in the lives of aging people. Noted gerontologist Robert C. Atchley remedies this problem by developing complex concepts and language about spirituality. Spirituality and Aging incorporates material from two decades of interviews, observations, study, and reflection to illustrate ways of thinking about and discussing spirituality—what it is why it is important, and how it influences the experience of aging. This book provides a nuanced view of spirituality and the richness it brings to the lives of older people. Atchley next focuses on two dimensions of spirituality that is likely to manifest later in life: becoming a sage (developing the capacity to bring spiritual light to everyday issues) and serving from spirit (creating opportunities for service that are rooted in spirituality). The last section illustrates how spirituality informs other aspects of late life, such as psychological coping and the experience of dying and death.

In 2008 Ellen Idler highlighted through a discussion of current research and related observations that many of the positive benefits that religious and spiritual practice can have on one’s health and well-being. Starting at an early age, the choices one makes based on spiritual beliefs and values directly relate to the creation of certain lifestyle habits, such as diet, alcohol use, and sexual practices. The overall effect of such practices on one’s health and well-being is found to be positive throughout one’s lifetime.

Methodology

Aim of the study: The main aim of the present research work is to study the psychology of spirituality: Mental health perspectives.

Hypotheses: There will be a significant relationship between mental health and spirituality of followers of divergent discourses of metropolitan city and non metropolitan city.

There will be significant difference in mental health and spirituality of followers of divergent discourses of metropolitan and non metropolitan cities.

Divergent discourses will have significant positive effect on mental health of followers of metropolitan and non metropolitan cities.

Spirituality will be significant predictor of mental health of followers in both metropolitan and non metropolitan cities.

There will be significant gender differences in mental health and spirituality of followers of divergent discourses of metropolitan and non metropolitan cities.

Sample: The present research focuses on “psychology of spirituality: Mental health perspectives.” For this, a sample of 311 followers of Divergent Discourses was taken. The sample of the research was taken from Delhi and Rajasthan. Total sample was of 311 followers of Divergent Discourses was taken for this research.

Instruments

Mental Health Inventory: The Mental health Inventory consists of 56 questions was developed by Dr Jagdish and Dr Srivastav in the year 1983. The Mental Health Inventory has a reliability of .73 and validity of .54. It consists of a series of statements reflecting the six areas: Positive Self Evaluation, Perception of reality, Integration of personality, Autonomy, Group oriented attitudes, Environmental mastery. There are positive and negative statements. Respondents rate positive statements on a scale of 4 to 1, with 4 indicating always and 1 indicating never. And respondents rate negative statements on a scale of 1 to 4, with 1 indicating always and 4 indicating never.

Spirituality Assessment scale: The Spirituality Assessment scale consists of 28 questions was developed by Judy W. Howden in the year 1992. There are four dimensions in this scale: Personal and meaning in life, Innerness, Unifying interconnectedness, Transcendence. Respondents rate statements on a scale of 1 to 6, with 1 indicating strong disagreement and 6 indicating strong agreement.
Procedure for Data Collection: The researcher personally went to collect the sample. Sample was selected and were asked if would volunteer to participate in a study on “psychology of spirituality: Mental health perspectives.” Each of the Followers met personally and clarified their doubts if any on the questionnaire. The instructions for filling the questionnaires were given. Respondents were assured of confidentiality. Convenient time was given.

Results and discussion: In the initial step, mean and S.D., for every variable was put under measurable examination, at that point, higher statistical processes were begun in which, Correlation was taken. Results are presented in the mentioned below tables. In comparison, significant difference was found.

<table>

</table>

*The result is significant at the 0.05 level
**The result is significant at the 0.01 level

The above table is showing the Correlation between spirituality and mental health where correlation between different dimensions and their significant level that indicating a significant difference between different dimensions lying at 0.01 levels and 0.005 levels.

Table shows Correlation between innerness and personal and meaning in life is .68**. Correlation between interconnectedness and personal and meaning in life comes to .52**. Correlation between Transcendence and personal and meaning in life is .60**. Correlation between innerness and interconnectedness is .63**. Correlation between innerness and transcendence is .72**.Interconnectedness and transcendence comes to .68**.Correlation between SAS and Transcendence is .87**.

Correlation between integration of personality and personal and meaning in life comes to .13*, whereas correlation between integration of personality and innerness is .17**, correlation between integration of personality and interconnectedness is .19**, correlation between integration of personality and transcendence is .18**. Correlation between integration of personality and SAS is .20**.

Correlation between autonomy and integrity of personality is .12*, correlation between group oriented attitudes and positive self evaluation is .11*,Correlation between environmental mastery and positive self evaluation is .31**,correlation between Mental health inventory and personal and meaning in life is .13*,correlation between mental health inventory and positive self evaluation is .50**, correlation between mental health inventory and perception of reality is .32**,correlation between mental health inventory and integration of personality is .42**, correlation
between mental health inventory and autonomy is .42**, correlation between mental health inventory and group oriented attitude is .51**, correlation between mental health inventory and environmental mastery is .34**.

The obtained results show that there is relationship between Spirituality and mental health of believers of divergent discourses. From the present research we come to know that how spirituality helps us in attaining good mental health. It does not eliminate stress or erase life’s difficulties, instead, it gives people strength to tackle problems head on, overcome adversity and move on their lives. Dealing with change or loss is an inevitable part of life. At some point, everyone experiences varying degrees of setbacks, rejections of all types such as social rejection, rejection from loved ones, rejection in marriage etc. All these rejections can have negative effect on person’s well being. Some of these challenges might be relatively minor (not getting into a class you really wanted to take), while others are disastrous on a much larger scale (hurricanes, tornadoes, terrorist attacks). How we deal with these problems can play a major role in not only the outcome, but also the long-term psychological consequences. Psychologists have identified some of the factors that make someone more mentally strong, among them a positive attitude, optimism, the ability to regulate emotions, and the ability to see failure as a form of helpful feedback.

**Conclusion**

This study examines the relation between psychology of spirituality: Mental health perspectives. This study was conducted so that results would yield a better picture that how spirituality has a positive or negative relation on mental health of believers. The findings suggested that spirituality may protect person’s well being on the other hand high level of stress, worries, rejection can harm person’s mental, physical and spiritual well being. However, more research and intervention plans are needed to understand the importance of spirituality in one’s lives.

Serodagnosis and Molecular Characterization of Scrub Typhus in and around Vijayapura, North Karnataka Region

Shriharsha Hegde M.L.¹, Basavaraj V. Peerapur², Nazeer Sharif³, S.L. Hoti⁴

¹Scholar, Department of Microbiology, BLDEUs Shri B.M. Patil Medical College, Vijayapura, ²Professor & Head Department of Microbiology, Raichur Institute of Medical Sciences, Raichur, ³Research Associate, ICMR-National Institute of Traditional Medicine, Belagavi, ⁴Scientist ‘G’, Director In-charge, ICMR- National Institute of Traditional Medicine, Belagavi, Karnataka

Abstract

Background: Scrub typhus or tsutsugamushi disease, transmitted by the bites of infected immature mites (chiggers) is a most covert re-emerging febrile infection currently. The disease is unnoticed or misdiagnosed due to low manifestation and lack of specific diagnostic tests at all levels. Failure of timely diagnosis leads to significant morbidity and mortality. Geographically this disease is widely endemic in a confined area of the Asia-Pacific region. In India, Scrub typhus infection is increasing and reported from various geographical parts during the past 10-15 yrs. Serological test is widely used for the diagnosis of the disease.

Aim & Objectives: To investigate the presence of Scrub typhus infection in and around Vijayapura of North Karnataka region using serological tests and nested PCR.

Materials and Method: During the period of 2015-17, a total of 209 patients presenting with acute febrile illness with rashes, body ache were examined for Scrub typhus infections by Weil Felix agglutination test and IgM ELISA. Further all the ELISA positive samples were tested by nested PCR using the specific primers of the gene encoding the immunodominant 56 kDa protein and PCR products were sequenced.

Results: Out of 209 cases, 39 (18.5%) samples showed agglutination in Weil Felix antigen OXK test with titre 1:160 and above. In Scrub typhus IgM ELISA 13 (6.3%) samples were positive with the OD value more than 0.5. In nested PCR, two samples were amplified a 483 base pairs diagnostic segment of the gene encoding the 56 kDa antigen of Otsutsugamushi using specific primers. PCR product was sequenced bidirectionally, and nucleotide sequences queried against NCBI BLAST programme to identify the sequenced sample.

Conclusion: Findings of our study demonstrated that, though more seropositivity of Spotted Fever Group Rickettsia infection is observed by WF test, scrub typhus infection is also circulating and causing acute febrile illness in and around Vijayapura, North Karnataka region. As the routinely used Weil felix test is less sensitive, inclusion of more specific tests like ELISA and nested PCR is very useful in proper diagnosis and patient management.

Keywords: Weil Felix test, Rickettsia, Scrub typhus, ELISA, Nested PCR.

Introduction

Rickettsial diseases are the most covert re-emerging febrile infections of the current era and mostly go unnoticed or misdiagnosed due to low manifestation and lack of specific diagnostic tests at all levels. Biogroups of Rickettsiaceae includes Spotted fever group, Typhus group and Scrub typhus¹. Scrub typhus or tsutsugamushi disease is caused by the bacterium Orientia tsutsugamushi, which is transmitted by the
bites of infected, immature mites (chiggers) belonging to the family Trombiculidae. Illness typically begins after the bite of an infected chigger and lasts for 7-10 days. The most common symptoms of infected persons are consistent fever of more than 7 days, headache, myalgia, rashes, eschar and lymphadenopathy. Delay in diagnosis and treatment leads to severe complications like central nervous system problems or circulatory collapse caused by disseminated intravascular coagulation and even death of the individual\textsuperscript{2,3}. Geographically this disease is widely endemic in a confined area of the Asia-Pacific region, distributed in tsutsugamushi-triangle i.e. India and Nepal in the west; China, Japan, South Korea, and Taiwan in the north, and Australia and Indonesia in the south\textsuperscript{2,3,4}. In India, the presence of Rickettsiosis has been reported from Jammu and Kashmir, Himachal Pradesh, Delhi, Rajasthan, Uttarakhand, West Bengal, Assam, Meghalaya, Karnataka, Andra Pradesh, Maharashtra, Tamil Nadu, Puducherry and Kerala\textsuperscript{3-14}.

During the last 10 - 15 years, several researchers from different geographical parts of India have reported seropositivity of scrub typhus infections using single or combination of serology based tests like, ELISA, Weil felix and Microimmunofluorescence assay etc\textsuperscript{3-14}. Further, a few researchers have also demonstrated the PCR, a molecular test for the diagnosis of scrub typhus by detecting different genes, namely 56kDa\textsuperscript{15-20}, Groel, and 16SrRNA\textsuperscript{16} from blood samples\textsuperscript{15-19} and rodents\textsuperscript{20}.

When we reviewed the hospital medical records of last two years, we observed significantly high number of acute febrile illness cases diagnosed as Rickettsial infection on the basis of single serological test i.e. Weil felix. Though Scrub typhus infection has been increasing and reported from various geographical parts of India, no confirmatory data is available from north Karnataka region. Hence, we undertook this study during the period 2015–2017 to investigate the existence of Scrub typhus infection in and around Vijayapur, Karnataka using both serological tests and molecular test- nested PCR.

**Materials and Method**

During the period of 2015-17, a total of 209 patients presenting with acute febrile illness, rashes and body ache were screened for the presence of Scrub typhus infection. It was a prospective study and the study group comprised of patients of all age-groups and both sexes who attended and admitted to OP/IP departments Shri B.M. Patil Medical College, Hospital and Research centre, Vijayapur and District hospital, Vijayapur. The patients with acute febrile illness, and already diagnosed as other infections like malaria, enteric fever, dengue during the sample collection were excluded from the study.

After obtaining the informed consent, 5 ml of Venus blood samples were collected from patients in plain tube and serum was separated and blood clots of all the samples were stored at -20ºC.

**Serological Tests**

**Weil Felix test**: Serum samples were screened for the presence of antibodies against Scrub typhus infection by Weil felix tube agglutination test (Tulip diagnostics, Goa), in which the antibodies present in the serum reacts with antigens derived from various proteus species and exhibit agglutination. Samples with titres of 1:160 and above for OXK were considered as positive for Scrub typhus infection.

**IgM ELISA**: All the samples were screened for the serological confirmation of the presence of specific antibodies against Scrub typhus infection by IgM ELISA (Inbios International, USA), a method which is reported to be more sensitive and specific by several researchers\textsuperscript{3,4,8,10,11}. Both positive and negative controls provided with the kit were also included in the assay. Both the serological tests were performed strictly according to the manufacturer’s instructions.

**Nested PCR**: Blood clot was homogenized and the DNA was extracted from 200 μl of homogenized blood using the QIamp blood mini kit (Qiagen) as per manufacturer’s instructions. The eluted DNA was aliquoted and stored at -30ºC. Nested PCR was performed using two sets of primers to amplify a 483 base pairs segment of the gene encoding the 56 kDa antigen of *O. tsutsugamushi* as described by Furuya \textit{et al}. (1993). The primers were procured from Integrated DNA Technologies (IDT).

**Details of primers used are:**

First set (Outer primer); P34: 5’-TCA AGC TTA TTG CTA GTG CAA TGT CTGC- 3’ and P55: 5’-AGG GAT CCC TGC TGC TGT GCT TGC TGCG-3’

Second set (Inner primer); P10: 5’-GAT CAA GCT TCC TCA GCC TAC TAT AAT GCC-3’ and P11: 5’-CTA GGG ATC CCG ACA GAT GCA CTA TTA GGC-3’
Premixed ready to use green master mix (Promega, USA) was used for amplification, which consists of Taq Polymerase, dNTPs, MgCl₂ and reaction buffers at optimal concentrations for efficient amplification of DNA templates by PCR. Total volume of reaction mixture including templates was 50 µl. First PCR was performed with the template DNA using first set of primers (p34 & p55). The first PCR product was used as template for the second PCR with second set of primers (p10 & p11). Amplification protocol for both PCR was: initial denaturation of template at 95°C for 10 min, denaturation at 95°C for 30 sec, annealing at 55°C for 1 min, extension at 70°C for 1 min for 35 cycles followed by final elongation at 70°C for 10 min in a thermal cycler (Aeris, ESCO). The amplicons were electrophoresed in a 1% agarose gel containing ethidium bromide (0.5µg/ml) and visualized in Gel documentation system system (Syngene, USA). PCR products were sequenced by Sanger sequencing method to identify the species.

Results

Out of 209 samples, 39 samples showed agglutination with OXK antigen with titre of 1:160 and above, and 13 samples were positive by IgM ELISA. Interpretation was done as per the manufacturer instructions (Table 1).

Table 1: Results of comparison of two serological tests performed for the detection of Scrub typhus infection (n = 209).

</tbody>
</table>

Negatives include samples with titre 1:80 and below for OXK, and samples positive for other WF antigens except OXK. Samples non reactive with WF antigens were not evaluated.

In nested PCR, out of 13 ELISA positives, two samples amplified the gene encoding the 56 kDa antigen of O. tsutsugamushi. (Fig 1). One positive control received from Dept of Microbiology, BMCRI, Bangalore and one negative control was also tested along with the samples.

PCR product was sequenced bidirectionally using Applied Biosystems model 3730xI/ 3730XLPA-19137-017 at Eurofins genomics India Pvt. Ltd, and quality of sequences was checked with Finch TV Version 1.4 and consensus sequence was generated using Bio Edit software version 7.2. Further nucleotide sequences were queried against NCBI BLAST programme to identify the sequenced sample. NCBI BLAST program (blastn suite) showed 97 to 99% homology with the strains reported from KMC Manipal (MG283201.1), Andaman and Nicobar (MF457892.1), Pondicherry (KT970967.1) and Himalayan region (DQ286233.1), Uttar Pradesh (KR706188.1).

Discussion

Rickettsial infections are re-emerging in India and will lead to significant morbidity and mortality if failed to diagnose timely and take appropriate treatment. The diagnosis of scrub typhus is generally made by the history and clinical presentation. The vast variability and common clinical manifestations of the disease which is similar to other febrile illnesses makes the clinical diagnosis challenging. During the last decade, several researchers have reported the existence of rickettsial infection in different part of India using single or a combination of serological tests like Weil felix, ELISA and Microimmunofluorescence assay [1, 3-14] and using both Serological test and molecular test- PCR[16-19].

When we reviewed the last two years medical records of tertiary care facility Shri B.M. Patil medical college Hospital and research centre Vijayapura, we found that significant numbers of cases have been diagnosed using Weil felix test alone, and in which seropositivity for
SFG Rickettsiae or Indian Tick typhus was commonly reported than Scrub typhus. We also have observed and reported similar results in our previous serological study on R. conorii. In that study, out of 231 cases screened, 105 cases were positive for OX2 antigen by Weil felix test suggestive of R. conorii and 27 cases were confirmed serologically by IgM ELISA.

Though scrub typhus infection have been increasing and reported from various parts of India, Scrub typhus was not evaluated and no confirmatory data is available from north Karnataka region. Hence, we undertook this study to investigate the existence of Scrub typhus in Vijayapura area of Karnataka using both serological and molecular tests. All the cases included in the study were clinically suspected with fever of more than one week (100%), body ache (23%) and rashes (19%). We could not find eschar in any cases.

Out of 209 symptomatic cases screened, 39 (18.5%) were positive by Weil felix with titre of OXK >1:160 and 13 were positive by IgM ELISA suggestive of Scrub typhus infection. It is highly significant in this region even though the results obtained in our study shows considerable difference in percentage of positive cases reported by several researchers from different geographical parts of India like Karnataka, Andrapradesh, Pondicherry, Tamil Nadu, Himachal Pradesh and Delhi. We have observed more seropositivity during cooler months between August to January, and same was reported by few of the investigators.

Since both the serological tests exhibit significantly varied sensitivity and specificity according to the geographical area, the detection of causative organism directly from the patients sample would be highly important. Different PCR techniques have been reported during the last decade for detection of different genes of scrub typhus namely 56kDa, Groel and 16SrRNA from blood samples and rodents. To substantiate the seropositivity observed in the study area, we performed the nested PCR on blood clots of ELISA positive samples for the confirmation of organism using the primers encoding the 56kDa gene of O. tsutsugamushi as described by Furuya et.al. While ELISA positive samples had high OD value, we succeeded to amplify a 483 bp segment of the gene encoding the 56 kDa antigen of O. tsutsugamushi in only two samples which were positive by both the serological tests Weil Felix and IgM ELISA. Results of Nucleotide sequences queried against NCBI BLAST programme showed 97 to 99% homology with the strains reported from KMC Manipal (MG283201.1), Andaman and Nicobar (MF457892.1), Pondicherry (KT970967.1), Himalayan region (DQ286233.1) and Uttar Pradesh (KR706188.1).

**Conclusion**

Findings of our study demonstrated that though more seropositivity of SFG Rickettsial infection is observed by Weil Felix test, scrub typhus infection is also circulating and causing acute febrile illness in and around Vijayapura, North Karnataka region. As the routinely used Weil felix test is less sensitive, inclusion of specific tests like ELISA and nested PCR is very useful in proper diagnosis and patient management.

Management of Type I Talon’s Cusp Using Cone Beamed Computed Tomography as a Diagnostic Aid: A Case Report

Sree Theja Upadhyay¹, Tina Puthen Purayil², Siddharth Mehta³

¹Consultant Endodontist, Kondapur, Hyderabad, Telangana, ²Associate Professor, Department of Conservative Dentistry and Endodontics, ³Former Assistant Professor, Department of Orthodontics, Manipal College of Dental Sciences, Manipal, Manipal University, Karnataka, India

Abstract

Talon’s cusp is an uncommon developmental anomaly that frequently creates an occlusal interference resulting in occlusal trauma, premature contact or reversible apical periodontitis of the opposing tooth. Such occlusal interference is commonly encountered during orthodontic treatment while retraction of maxillary anterior teeth. Advanced diagnostic tools like CBCT is useful for exploring the details of endodontic architecture. The present case revealed bilateral existence of talon’s cusp on the palatal aspect of maxillary lateral incisors interfering with the bite during orthodontic treatment. With the use of CBCT as a diagnostic aid, this case was managed using a minimally invasive approach with greater patient comfort.

Keywords: Dental anomaly, Talon’s cusp, CBCT, accessory cusp.

Introduction

Talon’s cusps are unusual dental anomalies with an accessory cusp like projection on the cingulum area of the anterior teeth. It was first reported by Mitchell in 1892 and was termed as “Talon cusp” by Mellor and Ripa in 1970 as its shape resembles an eagle’s talon. The etiopathogenesis of talon’s cusp is multifactorial and polygenetic with influence of some environmental factors. It occurs during the morphodifferentiation stage of odontogenesis, as a consequence of outward folding of the inner enamel epithelial cells and a transient focal hyperplasia of dental papilla.¹

Maxilla shows a greater predilection for talon’s cusps, commonly affecting the maxillary lateral incisors followed by central incisors, with male to female ratio of 16:9.² It has also been seen in patients with Sturge-Weber syndrome, Mohr syndrome, Rubinstein-Taybi syndrome and incontinentia pigmenti achromians. It may also be associated with other dental anomalies like microdontia, peg lateral incisors, dens invaginatus, odontoma, impacted mesiodens, supernumerary teeth, accessory cusps of premolars, bifid cingulum, cingulum hypertrophy and prominent cusps of carabelli.¹

The talon cusp might result in clinical problems like occlusal interference, caries, attrition, displacement of the affected tooth and irritation of local soft tissues.³ As talon’s cusp frequently interferes with the orthodontic tooth movement of incisors during retraction, it demands an early and preventive intervention. In the present case report, we successfully managed a case of talon’s cusp on the palatal aspect of bilateral maxillary lateral incisors interfering with the orthodontic tooth alignment, using a minimally invasive approach.

Case report: A 19 years old female patient undergoing orthodontic treatment was referred to the department of conservative dentistry and endodontics as bilateral cuspal projections on the palatal surfaces of maxillary lateral incisors were interfering with the correction of overjet. Medical and dental history was non-contributory. On intraoral examination, talon’s cusps were seen on both the maxillary lateral incisors, extending from the cingulum to incisal edge and were
almost in contact with the mandibular anterior teeth on occlusion (Fig: 1A, 1B). Both the lateral incisors were non caries and the teeth responded normally to pulp sensibility testing.

As intraoral periapical radiograph (IOPA) shows superimposition of talon’s cusp over the tooth crown, a CBCT (i-CAT, Hatfield, Pennsylvania, USA) with limited field of view (FOV) was advised, that confirmed the extension of pulp horn into the talon’s cusp. In sagittal and coronal sections, CBCT also revealed that the pulp has extended around 2.4 mm to 3.4 mm into the talon’s cusp (Fig: 1C, 1D). So, to prevent the exposure of the pulp, a conservative treatment plan of gradual reduction of the cusp at consecutive appointments with an interval of 4-6 weeks was planned.

The patient was prescribed desensitizing toothpaste (Sensodyne, GSK Ltd, India) at the start of the treatment to prevent sensitivity. Before starting grinding of the cusp, a putty index (Aquasil soft putty, Dentsply IH Ltd, UK) was made and cut sagittally at the maximum height of talon’s cusp. In every appointment, the talon’s cusp was reduced 1mm along the side of the cusp using a flame-shaped diamond bur (Mani, Japan) using putty index as a reference. A desensitizing agent (Colgate Duraphat Varnish, UK) was applied on the reduced tooth surface after each session (Fig: 1E, 1F). The pulpal health was assessed using a cold test before each grinding session and the entire cusp was completely reduced in four appointments (Fig: 2). There was no pulpal exposure during reduction and after final reduction, a thin layer of flowable composite (Filtex Supreme Ultra, 3M ESPE, US) was placed to cover the exposed dentinal tubules.

Complete grinding of the talon’s cusp allowed adequate space for retraction of the maxillary anterior teeth and the orthodontic treatment was completed with a proper overjet. The patient was completely asymptomatic and the pulpal health of both lateral incisors were regularly assessed for period of one year.

Discussion

Maxillary lateral incisors are susceptible to develop a talon’s cusp because of the compression of its tooth germ from the adjacent central incisor and canine in the morphodifferentiation stage, which develops 7 months prior to lateral incisor.4 Though a talon’s cusp associates with other developmental abnormalities, the patient did not have any other documented developmental anomalies in the present case.

Based on the degree of cusp formation and extension, talon’s cusp is categorised into three types.5 Type I (Talon) contains a supplementary cusp that encompasses at least half of the distance from Cemento Enamel Junction (CEJ) to the incisal edge, Type II (Semitalon) covers over less than half the distance from CEJ to incisal edge and Type III (Trace talon) exhibits a prominent cingulate with variations like conical, bifid, and tuber types. The present case comes under the category of Type I as the cusp extends from from CEJ to incisal edge.

Treatment of talon’s cusp is usually not required, when the caries or advanced attrition is absent, esthetic appearance is satisfactory and the function is within normal limits.6 But in the present case, management became necessary as the cusp was interfering with occlusion for the orthodontic correction of excessive overjet.

Talon’s cusp contains enamel and dentin with variable extents of the pulp tissue.7 Treatment planning mainly depends on whether the cusp comprises or lacks a pulp horn.1 In intraoral periapical radiographs, it becomes very difficult to detect the pulpal configuration inside the talon’s cusp. This is because of the result of superimposition of the cusp over the tooth crown as these radiographs provide only two dimensional imaging.8 Hence, a CBCT with limited FOV was advised in the present case to reduce the radiation exposure to the patient and to accurately interpret the complex three dimensional anatomy of pulp.9

Type I Talon’s cusp can be managed by total reduction of the cusp in single appointment or periodic gradual reduction of the cusp at consecutive appointments.1 The total reduction of the cusp is usually accompanied by pulp therapy like root canal treatment, pulpotomy or partial pulpotomy, which is normally indicated in cases of severe occlusal interference. The gradual reduction of the cusp with an interval of 4-6 weeks stimulates reparative dentin deposition for protecting the pulp.5

The gradual reduction of the cusp was chosen because it is a minimally invasive approach with reduced risk of pulp exposure that preserves the pulp vitality. It also reduces patient’s discomfort without hindering the progress of orthodontic treatment.10 Thus, CBCT helped in understanding the pulpal configuration before opting for invasive treatment approaches that might result in pulpal exposure.
Putty index acted as a reference guide which facilitated predictable way of tracking the amount of cuspal reduction in every appointment. As most of the odontoblasts lie along the length of the cusp, the grinding was performed mainly on the side of the cusp rather than at its tip to promote reparative dentin formation. Cold test was performed in every appointment to assess the pulpal health as the electric pulp test findings are not reliable in teeth undergoing orthodontic tooth movement.

The management of talon’s cusp in the present case was performed in a stepwise calculated manner entirely based on the principles of minimal intervention dentistry. This allowed a very precise and limited removal of dental tissues for preserving the tooth vitality.

Figure 1A: Bilateral talon’s cusps on maxillary lateral incisors, Figure 1B: Talon’s cusps causing occlusal interference by touching the lower incisors, Figure 1C: In sagittal sections of CBCT, 12 revealed 3.22 mm and 22 showed 2.44 mm of pulpal extension into talon’s cusp, Figure 1D: In coronal sections of CBCT, 12 revealed 3.4 mm and 22 showed 2.6 mm extension of pulp into talon’s cusp, Figure 1E: Correction of overjet orthodontically after grinding of talon’s cusps, Figure 1F: Completed grinding of talon’s cusps in four appointments

Figure 2: Grinding of talon’s cusp in consecutive appointments, Figure 2A: First appointment, Figure 2B: Second appointment, Figure 2C: Third appointment, Figure 2D: Fourth appointment
Conclusion

A correct diagnosis with a prompt treatment is necessary for improving the oral health and quality of life of the patient. CBCT is a superior diagnostic aid for management of teeth with uncommon anatomy that may pose substantial challenge to clinicians during treatment planning. The management of talon cusp should always aim at maintaining the pulpal vitality along with re-establishing the occlusal and esthetic requirements.

Perception and Attitude Regarding Measles Rubella (MR) Vaccination

Sreejesh K.P.¹, Sheeba S.¹, Haripriya V.R.², Hima Gopinath²

¹Assistant Professor, ²4th Year B.Sc. Nursing Student, Amrita College of Nursing, AMRITA Vishwa Vidyapeetham, Kochi, Kerala

Abstract

Objectives: Objectives of the study are to assess the perception and attitude regarding Measles Rubella vaccination and find out the association between demographic variables with perception and attitude regarding Measles Rubella vaccination.

Methodology: Descriptive survey design was adopted for the study. Convenience sampling technique used to select 300 people from 1st, 14th and 16th ward of Nayarambalam Panchayath. The tool used for the study consists of structured questionnaire to identify perception regarding Measles Rubella vaccination and demographic data and five point Likert scale to assess Measles Rubella vaccination. Data was analyzed using descriptive and inferential statistics.

Results: Most of the subjects (95%) had good perception and in the case of attitude most of them (91%) had favourable attitude towards Measles Rubella vaccination. The age of the subjects had significant association with perception and attitude regarding Measles Rubella vaccination.

Conclusion: In conclusion of the study people had favourable approach to Measles Rubella vaccination.

Keywords: Perception, attitude, Measles Rubella vaccination.
MR vaccination introduced in routine immunization and replaced measles vaccine given at 9-12 months and 16-24 months of age of child. After the success of first phase of MR campaign second phase of MR campaign launched in eight states and union territories. The second phase completed in Andrapradesh, Chandigarh, Himachel Pradesh, Kerala, Telangana, Uttarakhand, Dadra and Nagar Haveli and Daman and Diu from August 2017. In Kerala Measles Rubella campaign started on October 3rd 2017. There was resistance from a group of people against measles rubella vaccination in the initial phase and lead to less coverage. A qualitative study conducted by V K Krishnendu and Lyana Susan George about drivers and barriers for Measles Rubella Campaign and the study identified that the main barriers for the MR campaign was anti vaccination propaganda in social media. A case control study conducted in Kancheepuram about trust in health information and acceptance of Measles-Rubella campaign in Tamil Nadu. The study result shows teachers have good role in Measles rubella campaign and Perception of parents regarding the benefits of measles rubella vaccination was not good. Majority of people have the confusion regarding the Measles Rubella Vaccination. Perceptions regarding Measles Rubella vaccination affect coverage of measles and rubella vaccination. The researcher interested to check the perceptions and attitudes regarding MR vaccination in people residing in selected south Indian rural village.

**Statement of the problem:** Study to assess the perception and attitude regarding Measles Rubella Vaccination among the people residing in selected south Indian rural village.

**Objective of the Study**

**Primary objective:**

1. To assess the perceptions and attitude regarding Measles Rubella (MR) Vaccination among people in selected community

**Secondary objective:** To find out the association of demographic variables with perceptions and attitudes regarding Measles Rubella (MR) vaccination among people in selected community

**Research Methodology:** The present study used a descriptive survey design to collect the data. The study conducted at 1st, 14th and 16th ward of Nayarambalam Panchayat in Ernakulum district of Kerala and data collection period from 11/12/2017 to 23/12/2017. Sample was taken by convenience sampling technique and the sample size was 300. The subjects included that study was people having the age group of 20 to 60 years and are able to read Malayalam and English. The tool used for the study included structured questionnaire and five point Likert scale. Structured questionnaire used to collect demographic data and perceptions regarding Measles Rubella vaccination. Demographic data included age, educational status, occupational status and monthly income. Five point Likert scale used to assess the attitude regarding Measles Rubella Vaccination. Data collected after approval obtained from the research committee of Amrita College of Nursing Scientific committee and ethical committee of AIMS. Permission to conduct the study collected from Nayarambalam Panchayath. Informed written consent taken from the participants before commencement of the study. Data analysed with descriptive and inferential statistics. Percentage and frequency used as descriptive statistics and chi square test used as inferential statistics. Ethical permission took from the ethical committee, AIMS before the data collection.

**Results**

Socio demographic factors such as age, sex, marital status, educational status and occupation of subjects were studied. The study finding show that nearly half of the subjects, 147 (49%) were in the age group of 31-40 years followed by 89 subjects (29.7%) in the age group of 18-30. Out of 300 majority of the subjects, 237 (79%) were females. About the marital status, most of the subjects, 289 (96.3%) were married. Regarding the educational status, 119 subjects (39.7%) were having education status of higher secondary followed by 118 subjects (39.3%) in secondary. About the occupation majority of the subjects, 185 (61.7%) were unemployed.

**Figure 1: Perception regarding measles rubella vaccination.**
Figure 1 depicts the perception regarding measles rubella vaccination. Most of the subjects (95%) had good perception regarding measles rubella vaccination and demographic variables reveals that only age of the subjects has association with perception ($\chi^2 = 6.865$, $p=0.032$).

**Discussion**

In our study most of the subjects (95%) had good perception regarding Measles Rubella vaccination and most of the subjects (91%) had favourable attitude towards Measles Rubella vaccination. In demographic variables only age of the subjects had significant association with perception and attitude regarding Measles Rubella vaccination. No other demographic variables had significant association with perception and attitude regarding Measles Rubella vaccination. A descriptive study conducted about the level of knowledge regarding Measles Rubella Vaccine Among mothers of under 15 years Children In Rural Area, Bhucho Mandi, Bathinda, Punjab\textsuperscript{13}. The result was contradictory to the present study Sample method used for the study was purposive sampling and sampling size was 150. Study result was nearly half of the subjects (53.33%) had moderately adequate knowledge, 45.33% had inadequate knowledge and 1.33% had adequate knowledge. There was association between occupation, family income, religion with the knowledge of Measles-Rubella vaccine among mothers of under 15 years of children. In our study only association present between perception and age of the subjects. Another study conducted among students of Egyptian University after the measles rubella campaign\textsuperscript{14} The descriptive study conducted to assess uptake of MR vaccine and reasons for declining the vaccine among medical and non-medical students in the campaign and to assess the knowledge about the vaccine and the diseases .The finding was students were not informed all the aspects of vaccination especially about adverse effects and contraindication and medical students informed more than other students. Overall 64.8% medical students accepted the vaccine and among the non vaccinated subjects around half of subjects (43.3) were given reason that little information about the vaccine leads to their non vaccination .In our study people had good perception regarding all aspects of Measles rubella vaccination.

**Conclusion**

In conclusion of the study people had favourable approach to Measles Rubella vaccination. The health awareness programme may helps to improve good perception and promote favourable attitude towards Measles Rubella vaccination.

Laryngospasm: Prevention Better than Cure

Sumesh T. Rao¹, Julie C.R. Misquith¹, Karl Nicholas Sa Ribeiro²

¹Associate Professor, Department of Anesthesiology, Kasturba Medical College, Mangalore, Manipal Academy of Higher Education, ²Associate Professor, Department of Anesthesiology, Father Muller Medical College, Mangalore, Rajiv Gandhi University of Health Sciences

Abstract

Laryngospasm is one of the most commonly occurring perioperative complication seen in the practice of every Anaesthesiologist. It can present with varying degrees of severity and presentation may not be the same in all individuals. There are several risk factors that can cause laryngospasm, knowledge of which can help in its prevention. Over the years, several researchers have published data on the prevention and management of the laryngospasm. This article highlights the types, mechanism of action, risk factors, prevention and treatment by reviewing literature on this long studied and frequently encountered anesthetic emergency.

Keywords: Anesthetic emergency, laryngeal muscles, glottic spasm, Larsons manoeuvre, no touch technique.

Introduction

For an anaesthesiologist, laryngospasm is one of the most common difficulties seen in the perioperative period especially during induction and extubation. It is a superior laryngeal nerve mediated reflex resulting in prolonged glottic closure. In 1937, Guedel added laryngospasm in the description of anesthetic planes, as seen as excitement, in Phase II. An incidence study that was computer aided including 1,36,929 reported that laryngospasm is said to be less than 1%. The incidence in children was twice that of adults and increases by three times in the first three months of life. In patients undergoing adenoidecтомy and tonsillectomy, incidence in the literature is as high as 25%. In adults, 40% of the airway obstructions have been reported to be a consequence of laryngospasm.

We performed an electronic search in Google Scholar, PubMed and Cochrane databases for original and review articles on laryngospasm from 1950 to 2019. The current preventive and management techniques around Laryngospasm are summarized.

Mechanism of Laryngospasm

Fink described three mechanisms of laryngospasm: ball valve obstruction which is controlled by both the extrinsic and intrinsic muscles of the larynx and the inspiratory and expiratory stridor controlled only by the intrinsic muscles. Unlike adduction of the vocal cords which gets a mixed sensory input, laryngospasm occurs with pure superior laryngeal nerve stimulation. Thermoreceptors, mechanoreceptors and chemoreceptors transmit sensory input from the larynx via the internal branch of the superior laryngeal nerve, the highest density of which lies posterior to the true vocal cords. The recurrent laryngeal nerve stimulates the motor response which supplies the three main intrinsic laryngeal muscles, the lateral cricoarytenoids, thyroarytenoids and cricoarytenoids. True vocal cord adduction, and sometimes accompanying adduction of false cords, is responsible for laryngospasm. Supraglottic soft tissues are drawn into the laryngeal inlet as they become rounded with the increased pressure in the larynx causing compression.

Risk Factors

A lighter plane of anaesthesia especially during intubation and extubation can trigger laryngospasm especially in patients who are prone to it due to other related factors. The incidence during the induction and maintenance phase was increased when a face mask or laryngeal mask airway (LMA) was used.

Volatile anaesthetics may cause laryngospasms especially in children (2.3%)\textsuperscript{15}. Desflurane has the highest incidence (50\%) of triggering a laryngospasm than any other volatile anaesthetic while there are no changes in incidence with respect to sevoflurane and halothane\textsuperscript{16}. Isoflurane can also cause laryngospasms while compared to sevoflurane and halothane\textsuperscript{17}.

Intubation per say can trigger a laryngospasm due to manipulation of the airway especially when neuromuscular blockers are not used. Repeated attempts as well as trauma to the glottic aperture can stimulate the same\textsuperscript{18}. Laryngospasms were also common after tracheal extubation\textsuperscript{19}.

Intravenous induction agent like thiopentone is said to cause higher incidence of laryngospasm in patients than with propofol because its lack of suppression of airway reflexes\textsuperscript{20-23}. The incidence of ketamine causing laryngospasm is 0.4\%\textsuperscript{22} as it may irritate the vocal cords due to its tendency to increase salivary secretions\textsuperscript{23}.

Paediatric population are more prone to laryngospasms especially the ones who had a respiratory tract infection in the past 4-6 weeks\textsuperscript{24}. Several studies have reported the higher incidence in desaturation, laryngospasm and bronchospasm in children with active or recent (< 6 weeks) upper respiratory tract infections\textsuperscript{25-28}.

Airway reactivity: Approximately a 10 times increase in risk, if patients had active asthma and 10-fold risk continued for up to 6 weeks\textsuperscript{29,30}. Even in adults who are chronic smokers the incidence is said to be higher than non-smokers\textsuperscript{31}. Passive smoking and tobacco use can trigger laryngospasms especially in children\textsuperscript{22,32}.

Patient related factors: Smoking\textsuperscript{22,32,33}, obesity, obstructive sleep apnoea, difficult airway\textsuperscript{34}, gastroesophageal reflux disease\textsuperscript{35}, ASA IV patients are conditions where incidence of laryngospasm has been shown to be higher.

Type of surgery: Among incidence in upper airway surgery, which is 21-26\%, tonsil and adenoids surgery have the highest incidence of laryngospasms\textsuperscript{35,36}. Other surgeries that can trigger laryngospasms include appendectomy, Lords dilatation and dilation of the cervix, skin transplants, bronchoscopy and mediastinoscopy and hypospadias surgery. Reports have shown that iatrogenic removal of the parathyroid glands or damage to the superior laryngeal nerve during surgery of the thyroid causes hypocalcemia that has predisposed to laryngospasm\textsuperscript{37,38}.

Prevention

The best way to treat laryngospasm is the awareness of precipitating factors and avoiding them. As Anaesthesiologists we may witness laryngospasms during three phases, induction\textsuperscript{39}, during the time of extubation and postoperatively\textsuperscript{40,41}.

A study done in 2015 found that an adequate depth with limiting the number of attempts at intubation decreased the morbidity and hence the incidence of cardiac arrest and death\textsuperscript{42-44}. The main factors responsible were repeated airway manipulations and inadequate anesthetic depth accounting about 43.4\% and 22.6\% respectively\textsuperscript{45}.

In children with history of asthma and those with hyper reactive airways, propofol has been shown to be the best drug used for induction due to its property of depressing the laryngeal reflexes. Pre-treatment with opioids also seems to decrease hyper stimulatory reflexes by 10\%\textsuperscript{45}.

Blood and secretions are irritants and reflex closure of the muscles of the larynx can prevent foreign material from entering the tracheobronchial tree.

In 2016, Qi X et al demonstrated that using intravenous (1 to 2 mg/ kg) or topical lignocaine during general anesthesia, especially in children was efficacious in preventing laryngospasm\textsuperscript{46}. Nebulised lidocaine reduces sensitivity of upper airway and may be used before tracheal intubation\textsuperscript{47}.

Magnesium sulphate at a dose of 15mg/ kg has a protective effect due to its effect on muscle relaxation and increasing depth of anaesthesia, although more studies are required. It is used to prevent laryngospasm especially after tonsillectomy and adenoidectomy\textsuperscript{48}.

During extubation, the no touch technique decreased the incidence of laryngospasm and this was shown by Tsui and colleagues\textsuperscript{36}. The patients’ secretions are aspirated, at an adequate plane of anaesthesia, and placed in left lateral position. This is followed by tracheal extubation when the patient is awake and is then ventilated with 100\% oxygen through a face mask\textsuperscript{11}. The basis of this technique is that extubation is done while the lungs are in positive pressure, which reduces the laryngeal response to adduction and thereby laryngospasm.
A survey done in the United states found that 64% anaesthesiologists performed deep extubation and it was shown in two studies by Koga et al. and Patel et al. there was no difference in airway obstruction when patients were extubated awake or in deep plane.

**Treatment**

The first step is to identify and treat the precipitating cause especially if it is an obvious one like stimulation due to surgery or pain.

Applying gentle pressure at the angle of the mouth like in jaw thrust manoeuvre has shown to overcome moderate laryngospasm. The placement of an oral airway may also be sufficient depending on the grade of laryngospasm. In cases where mouth opening can be a hindrance a nasal cannula can be carefully placed through the nose without causing trauma to the nasal cavity.

Application of continuous positive airway pressure (CPAP) with 100% oxygen via face mask, in extreme cases can be used with two hands. It should be borne in mind that air should not be insufflated into the stomach during this technique as it can cause regurgitation or vomiting which makes the situation worse especially if the patient aspirates.

**Larson's manoeuvre:** Guadagni and Larson advocated that a firm press at the 'laryngospasm notch' helps relieve spasm because anterior displacement of the mandible can prevent the tongue from falling backwards. This is justified with the explanation that the periosteal pain caused by pressing on the styloid process triggers the autonomic nervous system to relax the vocal cords.

If gentle jaw thrust is unable to relieve laryngospasm immediately, the depth of anaesthesia can be increased by administration of propofol. It has been shown that propofol breaks the laryngospasm in 77% of cases with just a small dose of 0.25 to 0.8 mg/kg. Occasionally cardiovascular depression, bradycardia, cyanosis and apnoea can occur when propofol is injected. Volatile agents such as sevoflurane has decreased airway complications compared to other agents.

**Administration of muscle relaxant:** Succinylcholine at an intravenous dose of 0.1 mg.kg\(^{-1}\) should be used especially when above described procedures fail. If the intravenous route is unavailable, intramuscular (i.m), sublingual or intraosseous routes are alternatives at doses of 3-4 mg.kg\(^{-1}\). If succinylcholine is unavailable, rocuronium which is a non-depolarizing muscle relaxant can be used at an average dose of 1.2 mg/kg intravenously.

**Superior laryngeal nerve block:** Monso et al reported that laryngospasm can be successfully treated with superior laryngeal nerve blocks. Mevorach described the mechanism of superior laryngeal nerve block stating that it interrupts the reflex arc and thus helps in dissipating the stimulus that causes laryngospasm.

**Conclusion**

Laryngospasm can be a detrimental situation if not detected and treated immediately. Knowing the risk factors and taking appropriate measures to prevent it is crucial especially in patients who are known to be susceptible. Since it’s a common occurrence, it is prudent to be vigilant and aggressive in treating this condition.

A Study on Knowledge, Attitude and Practice Regarding Sanitation and Personal Hygiene among Sanitation Workers of an Urban Local Body in Odisha, India

Tanmoy Kumar Satpathy\textsuperscript{1}, Kamala Kanta Sahoo\textsuperscript{2}, P.K. Satpathy\textsuperscript{3}

\textsuperscript{1}2nd Yr. Research Scholar (Ph.D.), KIIT University, \textsuperscript{2}Associate Professor, Statistics Community Medicine, Hi-Tech Medical college & Hospital, \textsuperscript{3}Professor, Pathology, Hi-Tech Medical College & Hospital, Bhubaneswar (Odisha)

Abstract

A study on knowledge, attitude and practice was conducted on 140 nos. of sanitation workers employed in the city of Cuttack in Odisha. Out of 140 participants, 76 (54.3\%) were female with mean age of 37.8 yrs ± 7.39 and 64 (45.7\%) were male mean age of 37.2 yrs ± 7.39.

Out of 140 participants, 107 (76\%) had adequate knowledge regarding sanitation and personal hygiene and 122 (86\%) reported good practices. This study shows adequate level of knowledge, attitude and practices among the sanitation workers.

Keywords: Sanitation, Personal hygiene, Sanitation workers, KAP.

Introduction

Maintenance of clean environment has become a challenge and many sanitation workers are working under urban local bodies to maintain sanitation in their respective towns and cities. They do variety of work like collection and transportation of garbage to cleaning of roads and toilets.\textsuperscript{1} These workers are exposed to a number of pathogens (bacteria, viruses, parasites and cysts), toxic substances and extremes of temperature.\textsuperscript{2} In low-income countries, these sanitation workers’ medical problem is often compounded by socio-economic factors such as poverty, lack of education, poor housing conditions and poor diet.\textsuperscript{3}

A worker should be aware of sanitation and personal hygiene to work in sound health and mind for which the worker must know the work hazards which may affect his/her health during working hours. If the worker remains healthy, the exposure to health hazards during work decreases and the productivity increases.

A study done in Thailand showed that most sanitation workers have low level of knowledge and alertness on occupational health risks.\textsuperscript{4} Despite the severity of occupational health hazards encounter by these sanitation workers, many studies have shown that the provision and usage of personal protective equipment (PPE) is low.\textsuperscript{5,6,7} During their work they are prone to carry dreadful pathogens through their dresses, hands, skin and hair to their houses and can be major sources to contaminate the food and water of their families for which they should be aware of sanitation and personal hygiene.

This study was done to assess the knowledge, attitude and practice among sanitation workers of Cuttack Municipal Corporation on sanitation and personal hygiene.

Objectives of the study:

1. To determine Knowledge, Attitude and Practice of the Street Cleaners regarding sanitation and personal hygiene.
2. To determine association of Knowledge, Attitude and Practice with different socio-economic factors.
Materials and Method

This cross-sectional study was conducted between January 2019 and June 2019 among the sanitation workers engaged in street cleaning of Cuttack city, Odisha. A sample of 140 nos. of street cleaners was taken out of which males were 76(54.3%) and females were 64(45.7%) in number chosen from four sweeper’s colonies of Cuttack city. A well structured and a pretested questionnaire was used which was printed in the local Odiya language to be filled up by the sanitation workers. The study population used to work from early morning 6 A.M. to 2 P.M. daily for which they were contacted only in the afternoon hours i.e. from 4 P.M. to 6.30 P.M. and they were explained lucidly regarding filling up the questionnaires.

Inclusion and Exclusion criteria: The sanitation workers who gave their consents to participate in this study irrespective of sex within the age group of 21 years to 60 years were included. If both husband and wife were having the same job, only one of them was included in the study. Part time workers were excluded from the study.

Sample size and sampling technique: A pilot study was conducted on 50 nos. of street cleaners and it was found out that 90% of such workers were having good knowledge of sanitation and hygiene basing on which a sample of 140 sanitation workers were selected from four sweeper colonies of Cuttack city with the following formula to calculate the sample size. Further samples were drawn at the rate of 35 from each sweeper colony through stratified systematic random sampling method.

\[ n = \frac{Z^2pq}{d^2} \]

where \( n \) = required sample size, \( Z = 1.96 \) (standard normal variate), \( p = \text{proportion} \), \( q = (1 - p) \) and \( d = \text{desired level of precision at 95% CI} = 5\% = 0.05 \)

\[ n = \left[\frac{(1.96)^2 \times 0.9 \times 0.1}{0.5 \times 0.5}\right] = 138.24 \text{ or say 140}, \text{Hence } n = 140 \]

Data Analysis: Data was entered in Microsoft Excel sheet. Qualitative data were presented as frequency distribution with its percentage; and for quantitative data descriptive statistics were done. Chi-square test had been calculated to relate the three KAP scores with different socio-demographic variables. A p-value of less than 0.05 was taken as the statistical level of significance.

Results

The participants (n=140) comprised of 76(54%) females and 64(46%) males. The mean age of female participant was 37.2 years while the mean age of male participants was 37.8 years. Their age profile showed majority, 59(42.2%) in the age group of 35-45 years as shown in Table No.1. Most, 56(40%) of the participants belongs to upper lower socio-economic class as per modified Kuppuswamy socio-economic classification scale. (J) of them, ninety (64.3%) possessed education up to primary level as shown in Table No.1.

Out of 140 participants, 110(76.4%) have adequate knowledge and attitude. There was no significant difference in knowledge and attitude in respect to gender, age or socio-economic status as shown in Table No. 2. But there is a significant association between educational status of the participants and knowledge and attitude. (Table No.2)

One hundred twenty-one (86%) participants reported good practice related to sanitation and hygiene. There was a significant association between educational status of the participants and good practices. However, no significant association was found between good practices and gender, age or socio-economic status as shown in Table No.3

Discussions

Out of 140 participants, 107 (76.4%) were found to have adequate knowledge about sanitation and hygiene. In a similar study done in Indore city, 85% sanitation workers were found to have adequate knowledge. In another study done in Nigeria, only 15% of sanitation workers reported adequate knowledge.

One twenty-one (86%) respondents in this study reported good practices relating to sanitation and hygiene. This result is discordant with the results from a similar study in Indore city where only 18% reported good practices and another study done in Addis Ababa, which reported only 27% good practice.

The present study shows a gap between knowledge and practice among the sanitation workers regarding sanitation and hygiene measures. All these findings suggest the absence of a proper health and safety mechanism at the place of work.

There is a need for necessary programme interventions in the colonies and community of the street cleaners to educate them on environmental sanitation, personal hygiene, hand washing and solid waste disposal as their work is responsible for a clean look of the city. At the same time proper personal protective equipment (PPE) should be provided to the sanitation workers.

Comparison of Ultrasound and Low Level Laser Therapy in the Management of Diabetic Foot Ulcer

Vahini Devi. Ch, Chiranjeevi. Jannu, Prathap Suganthirababu, Goverdhan Puchchakayala

1Research Scholar, Saveetha University, Chennai, India, 2Associate Professor, College of Allied Health Sciences, Gulf Medical University, Ajman, UAE, 3Director of Clinical Pharmacy, Vaagdevi College of Pharmacy, Ramnagar, Warangal, Telangana, India

Abstract

Introduction: Diabetic foot ulcer (DFU) is one of the complications of diabetes mellitus. It is caused due to destruction of deep tissue which is associated with neurological abnormalities and various degree of peripheral vascular disease of lower limbs. DFU and its infections cause major medical, economic and social problems and leads to morbidity and mortality in developing countries like India. Mixed bacterial infections are the major predisposing factors for foot ulceration

Method and methodology: 30 male and female patients were selected based on the inclusion criteria (according to wagner grading system). They were divided into two groups randomly and named group A as control group and group B as experimental group. Group A received ultrasound where as group B has received low level laser therapy (LLLT) Helium–Neon (He–Ne) of 660nm wavelength with a dosage of 4J/cm² for five days a week for four weeks.

Results: Both the groups were compared with pre intervention and post intervention scores by using T test. Group A results were not significant where as group B results showed significant values at p <0.05.

Keywords: Diabetic foot ulcer (DFU), Ultrasound (USD), Low level laser therapy (LLLT), Helium Neon laser (He–Ne).

Introduction

Diabetic foot ulcer (DFU) is one of the complications of diabetes mellitus. It is caused due to destruction of deep tissue which is associated with neurological abnormalities and various degree of peripheral vascular disease of lower limbs. DFU and its infections cause major medical, economic and social problems and leads to morbidity and mortality in developing countries like India. Mixed bacterial infections are the major predisposing factors for foot ulceration (1)

Based on the recent epidemiological data from world health organization, India has the largest number of diabetic patients with about 20 million and the number is predicted to reach about 57 million by the year of 2025. Foot is a complex part of the human body. Approximately 40–72% of all lower extremity amputations are related to diabetes. DFU is a common cause for hospital admission among diabetics in India. This could be attributed to several socio cultural practices such as barefoot walking, inadequate facilities for diabetes care and education and poor socio-economic conditions. Diabetes foot is thus a serious issue of great economic and social importance. Many drugs like Augmentin, Amoxycillin with potassium clavulanate were tried to reduce infections like streptococci and staphylococci at the wound site but they were not successful (2).

Many Physiotherapy modalities like infra red rays, Ultra-violet rays and electrical stimulations was used, but the recovery was very slow with these modalities. Ultrasound (USD) and low level laser therapy (LLLT) is gaining much more importance to reduce foot ulcers. It is administered safely and has no side effects. Laser is...
broadly used as an analgesic, anti-inflammatory and for tissue healing \(^3, 4\).

USD is a high frequency modality which delivers mechanical vibration and promotes healing at cellular level. It reduces pain and increases circulation and mobility of soft tissues. It helps in reducing inflammation and promotes healing process \(^5\).

LLLT is a non invasive modality and it does not involve thermal interaction. Due its photon energy it causes photochemical, photo physical and photo biological effects in cells and tissues which is useful in nerve regeneration. One of the possible mechanisms behind the therapeutic effects of LLLT is the interaction of photons from laser irradiation at optimal doses (therapeutic window) with specific receptors in the mitochondria through induction of epithelial cells and modification of capillary density, stimulation of local microcirculation at the periphery which helps in tissue healing \(^6, 7, 8\).

**Materials and methodology**

**Subjects:** thirty patients both males and females were selected for the study from MGM hospital and Vaagdevi physiotherapy centre.

**Type of study:** Simple randomized experimental study

**Duration of study:** four weeks

**Inclusion Criteria:** Patients diagnosed with diabetes mellitus and suffering with diabetic foot ulcer, according to Wagner grading score 3.

**Exclusion criteria:** Patients who are suffering with diabetic foot ulcer above Wagner grade 3, other neurological complications, orthopaedic complication, circulatory complications, renal complications and cardiac complications were excluded from the study.

**Outcome measure:** Wagner grading system is used as an outcome measure. It consists of five grades, these grades are used in the calculation of ulcer depth, presence of osteomyelitis and gangrene.

- grade 0: pre-or postulcerative lesion,
- grade 1: partial/full thickness ulcer,
- grade 2: probing to tendon or capsule,
- grade 3: deep with osteitis,
- grade 4: partial foot gangrene, and
- grade 5: whole foot gangrene \(^9\).

**Methodology:** thirty male and female patients were alienated into two groups by means of simple random sampling technique. Each group has 15 patients. They were named as group A and group B. Group A was treated with Ultrasound and group B was treated with LLLT. Group A received Ultrasound with a dosage of 1MHz with an intensity of 1W/cm\(^2\) \(^10\) for 10 mins. Ultrasound was applied around the periphery of the wound in a circular manner. This was continued for five days a week for four weeks.

Whereas group B received Helium – Neon (He – Ne) laser with a dosage of 4J/cm\(^2\) for 10 mins. Laser was applied directly onto the wound (Centre of the wound). This was continued for five days a week for four weeks. Both the groups were positioned comfortably before treatment and their pre and post treatment values were recorded according to Wagner grading system.

**Results**

Both the groups pre and post treatment values were extracted. Group A received ultrasound for four weeks, group B received laser for four weeks. The pre and post test values were calculated by using **Kruskal – Wallis** test \(^11\)

The test statistic is given by

\[
H = \frac{12}{n(n+1)} \sum_{i=1}^{5} \frac{T_i^2}{n_i} - 3(n + 1)
\]

The calculated value for group A (Pre & Post treatment values) is \(H = 22.86\), here \(n = 15\ (>10)\) so the Kruskal – Wallis test is converted into chi-square test.

Whereas the calculated value for group B (Pre & Post treatment values) is \(H = 40.99\), with their mean and standard deviation.
Table.1 Mean and Standard deviation of Group A and B (Pre and Post Values)

<table>
<thead>
<tr>
<th></th>

<td>S.D.</td>
<td>0.7</td>
<td>0.6</td>
<td>0.6</td>
<td>0.5</td>
</tr>
</tbody>
</table>

Table Value: $\chi^2_{(4)}$ d.f = 23.685

In group A the calculated H value is lesser than table value. So null hypothesis is accepted. Where as in group B the calculated H values is greater than table value, so null hypothesis is rejected.

This shows that group B has improved more when compared with group A.

Discussion

This study was performed to identify the effect of USD Vs LLLT in the management of diabetic foot ulcer. patients were assessed by using Wagner grading system. The pre and post treatment values were extracted for every week for four weeks. Later on they were calculated by using Kruskal – Wallis test. When compared with group A, Group B has improved a lot in reduction of wound size. Healing has been accelerated more in group B patients who received LLLT for four weeks than USD group.

The reduction of wound size in group B could be due to increased circulation to the wound site, release of cytokines and growth factors. These are responsible for vasodilatation and form new capillaries.

Conclusion

The study concludes that, there is marked amount of reduction of wound size and acceleration of wound by applying laser when compared with USD group. So LLLT can be incorporated in the management of DFU, which will reduce the burden and is cost - effective. For better results this study has to be performed on large group.

The Level of Stress among the Parents of Children Having CAH 21 Hydroxylase Deficiency between 6 Years and above in a Selected Tertiary Care Hospital, Bangalore

Vasantha Singarayan¹, Anita David², Vageesh Ayyar³, Saji James⁴

¹Faculty, College of Nursing, St John Medical College & Hospital, B’lore, ²Professor, Faculty of Nursing, Sri Ramachandra Medical College & Research Institution (DU), Porur, Chennai, Tamilnadu, India, ³HOD & Professor, Dept. of Endocrinology, St John Medical College & Hospital, Bangalore, ⁴Professor, Department of Pediatrics, Sri Ramachandra Medical College & Research Institution (DU), Porur, Chennai, Tamilnadu, India

Abstract

Background: CAH Congenital adrenal hyperplasia (CAH) is a genetic disorder, when confronted with the unexpected diagnosis of CAH, the parents experience severe stress. This study assess the stress among parents of children having CAH 21 hydroxylase deficiency and find the association between stress and selected baseline variables.

Method: The research design selected for this study was descriptive design. The setting selected was the OPD at Indira Gandhi Institute of Child Health Hospital, Bangalore. Parents of children affected with CAH 21 hydroxylase deficiency were selected for interview schedule to assess the level of stress by them. The collected data were analysed using descriptive and inferential statistics.

Results: The findings of the study showed that the parents had severe financial stress. The parents having low income, low educational level had significantly high stress (P<0.001). Parents having more than one child affected and birth order of child ≥ 2 showed more stress and significant at p<0.01 level of significance. The Parents who had not received counselling also elicited more stress at p<0.01 level of significance.

Conclusion: These findings of the study clearly point out that CAH 21 hydroxylase deficiency is a stressful event faced by the parents. Positive attitude towards stress is present but needs to be better handled.

Keyword: CAH 21 hydroxylase deficiency, stress, OPD.

Introduction

Congenital adrenal hyperplasia (CAH) is an autosomal recessive inherited disorder of 21 hydroxylase gene (CYP 21) defect. If left untreated, low serum cortisol and aldosterone levels result in shock in both sexes. Early diagnosis and prompt initiation of replacement therapy with glucocorticoid and mineralocorticoid is life-saving¹.

When confronted with the unexpected diagnosis of CAH, the parents experience severe stress. Parenting a child with a chronic illness increases the likelihood of mental health problems in parents. Parents with chronically ill children are more likely to experience depression and marital discord as compared to parents without a chronically ill child². ³. Generally, mothers are responsible for more day to day care of children and families, and as such, the majority of research studies have examined the effects on mothers rather than on fathers or parents in general³. While it is difficult for parents in general, fathers more than mothers responded to a change by mourning the loss of the son they thought they were going to have⁴. Parents often go through a period of grief and bereavement such as might be expected when one loses a child⁵. These parents also

e-mail: anitadavid@sriramachandra.edu.in
feel “bewilderment about the medical implications of the child’s condition”, and they may feel confused, threatened, or angry about the implication of a genetic origin to the disorder. Another study of parental response found that parents of girls with CAH and over masculinized genitalia were less likely to feel symptoms of depression than parents of male children with under masculinized genitalia. Psychological support for the care givers is therefore particularly important and is a vital part of comprehensive medical treatment. Health personnel need to inform patients and care givers on therapeutic developments, future directions, and encourage psychological support.

Since CAH 21 hydroxylase deficiency causes more stress among the parents, the researchers felt it is a strong need to study the stress of parents of children with CAH 21 hydroxylase deficiency attending OPD to plan for interventional study among them to assess the level of stress among the parents of children having CAH 21 hydroxylase deficiency between 6 years and above in a selected tertiary care hospital, Bangalore. Study also find the association between stress and selected baseline variables.

Materials and Method

A descriptive cross-sectional study was conducted from October to November 2017, comprises 100 parents of children having CAH 21 hydroxylase deficiency after obtaining the permission and approval from the Institutional committee of ethics (ICE). The study was conducted in the OPD and wards of Indira Gandhi Institute of Child Health, Bangalore which is equipped with major subspecialty departments in paediatrics, including a full-fledged neonatal and paediatric intensive care unit. The sample size for the study was determined based for a previous study using the following formula.

\[ N = \frac{z^2 \times s^2}{d^2} \]

\[ Z = Z \text{ Value corresponding to a 95% level of significance (1.96), } S = \text{Estimated sample size, } d = \text{Absolute precision (10%)} \]

Samples were selected using purposive sampling technique guided by inclusion criteria of the study. The data was collected using stress scale by a structured interview schedule method. The time take for each interview was about 15 minutes, 5-8 parents were interviewed per day. Variables were stress among the parents of children and extraneous variables were age, sex, educational status of the parent, occupation and income of parent, duration of illness of child, birth order of child, number of siblings affected, frequency of visit, family type, and place of residence, religion and previous counselling received.

Chronicity Impact Parent Questionnaire developed by Debra P. Hymorich (1984) to measure the stress. In this Section A contained the baseline variables of the parent and the child and Section B had consists of 27 items. These items are rated on a 5-point rating scale where 1-Never, 2-rarely, 3-sometimes, 4-often and 5 represents always. The lowest score is 27 and the highest score is 135. Content validity and Reliability of tool was sent for validation to 13 experts. Reliability of the tool was established by split-half method and calculated using spearman’s brown prophecy formula. The reliability of the stress scale, \( r=0.71 \) Data were analysed with with the student’s t-test, x test and F-max test as test of significance to determine the association between the baseline variables and stress.

Results

Parents belonged to the age group 20-50 years in majority and the mean age was 34.1±6.8. Children belonged to the age group 6-15 years and the mean age group was 7.7±6.6. All the children were first hospitalized between the age group of 0.08 to 5 years of age and the mean being 1.01± 1.01. Majority (46%) of the parents had completed high school education, 22% of them were graduates, 14% of them had completed higher secondary education and 9%, 6% and 3% were illiterate, primary and post graduates respectively. That 63% of the parents were semiskilled workers, 19% of them were skilled and 18% of them were unskilled workers. The income status shows that 65% of them had a monthly income between Rs.1,001-5,000; 18% of them had between Rs.5,001-10,000; 7% between Rs.10,001-15,000 and Rs.15,001-20,000 each and 3% of them had income above Rs.20,000. 35% of the children had the illness duration of 6-10 years, 34% of them were between 1-5 years and 24% between 11-15 years where as 7% of them were below 1 year of age. The ranges of illness are 0.4-14.0 and mean duration being 6.5 (SD-4.1). The majority of the children having CAH 21 Hydroxylase deficiency (57%) were males and 43% of them were females. 94% of the children affected did not have any other sibling with the same problem where as 6% of them had one sibling affected in the family.
The majority of the children (56%) were first born in the family, 34% of them were second born, and 8% third born and only 2% of them were of the fourth birth order. Distribution of parents according to the frequency of visit of the children to the hospital shows that majority (65%) of them had to visit the hospital once a month, 21% of them visited once in less than a month and 14% of them visited once in more than a month. In the data finding, 53% of the parents belonged to extended family and 47% of them belonged to the nuclear family. 55% of the population belonged to urban area and 45% of them were from rural area. Majority (75%) of the samples was from Hindu background, 21% of them were Muslims and 4% of them were Christians. The table also shows that 71% of the parents had not received any counselling and only 29% of them had received previous counselling. The data shows that 94% of the samples did not have similar illness in the family background and only 6% had similar problems within the family relations. The data presented in table 1 shows that 82% elicited financial stress, 59.60% had emotional stress, 48.60% experienced social stress and 43.75% had physical stress. Majority (77.30%) of the samples expressed moderate stress and 21% of them had mild stress. The most of the samples elicited severe financial stress (74%) and majority had moderate emotional stress (70%).

There was association between the educational status and the stress at p< 0.01 level of significance. The obtained value of ‘r’ was -0.28, which indicates that the lower the educational status, the greater the stress experienced by them. Association was also found between the income and stress of the sample. The obtained ‘r’ value was -0.40 and is highly significant at p<0.001 level. This shows that the parents having less income experienced more stress (Table 2). There was a significant relationship between the stress scores and the birth order of the child at p<0.01. This shows that higher the birth order; greater is the stress of parents. There was also a significant relationship found between the stress and the number of siblings affected at p<0.01. Parents having more than one child affected with CAH 21 Hydroxylase deficiency experienced more stress as evident in the table 3. Association was found between the stress and previous counselling received at p<0.01. The data shows that parents who did not receive previous counselling had more stress.

**Discussion**

The major stressors affecting parents were categorized into physical, emotional, social and financial. The participants mainly elicited financial stress (82% mean), 59.6% mean had emotional stress, 48.6% mean had social stress. Similar findings have been found in the study conducted at NIMHANS were caregivers concerns were regarding the future (91%), illness (80%) and finances (73%). Another study cited by Melnyk et al. reported that finance is one of the factors which contributed to the stress of parents of young children admitted in hospitals. The similar findings were obtained in a study conducted at Athens where mothers were of mean age group of 43 years (range, 30-53 years) Nineteen females were interviewed and out of them 10(52.6%) were employed and 10(52.6%) were employed and 10(52.6%) had completed nine years of education. The parents of this study mainly were from
urban (55%) background and 75% of them belonged to Hindu religion. Almost similar findings were found in a study conducted at NIMHANS were 52% of the participants were from urban background and 80% of them were Hindus. 

The stress was found to be associated with various extraneous factors which were assessed in the study. The results showed that there was an association between stress and income at p<0.001, stress and birth order of child, stress and number of siblings-affected, Previous counselling received and stress and educational status at p<0.01 level. A study conducted to assess perception of stress among mothers found that mothers education was significantly associated with the sex of the caregiver ($\chi^2 =6.02$, p=0.014). Twenty eight (76%) of women caregivers had poorer quality of life. This data contradicts to the present study findings as there was no association found between sex of parent and stress. This is supported by a study a study conducted in Israel were no significant differences was found between interaction and severity of illness by fathers and mothers, F (df-2.77) = 0.30; p>0.05. The research hypothesis is partly accepted as there was an association found between stress and baseline variables like educational status, income per month, birth order of the child, number of siblings affected and previous counselling received.

**Conclusion**

CAH 21 hydroxylase deficiency is the most common autosomal recessive disorders. The impact of CAH on families is so intense and the burden is more than what most families can bear. These findings of the study clearly point out that CAH 21 hydroxylase deficiency is a stressful event faced by the parents, which also suggests that positive attitude towards stress is present but needs to be better handled.

Introduction

A healthy and balanced diet is essential for all organisms for their harmonious growth, good health and nutrition. It protects human beings against various chronic noncommunicable diseases, such as cardiovascular diseases (CVD), type 2 diabetes, Nonalcoholic fatty liver disease (NAFLD) and cancer. A good diet or food should taste good too for consumption. There are five very well-known taste qualities such as sweet, salty, bitter, sour, and umami. The production of physiologically important incretin hormone Glucagon like peptide-1 (GLP-1) in the taste perception cells and the presence of its known receptor GLP-1R on adjacent taste nerve fibers evidently suggest that GLP-1 signaling is associated with the function of taste. In this brief review, we will provide a bird eye view on the recent advance in taste, taste receptors and GLP-1 signaling and we will discuss their pivotal role in overall taste perception and signaling.

Keywords: Taste, Sweet, Sour, Umami, GLP-1.

Mechanism of Taste Perception: The transient receptor potential (TRP) ion channels are evolutionarily conserved integral membrane protein superfamily of ion channels occurring in cell membranes that are involved in various types of sensory reception including taste. These proteins are encoded by 30 distinct genes in humans. These are cation channels that enhance the

Abstract
Balanced diet and proper healthy nutrition, avoidance of consuming high calorie or junk food or ingesting toxic substances that are harmful to the body and maintenance of physiological energy homeostasis are very crucial for all living organisms including human beings. After every food ingestion brain gets sensory signal from gustatory receptors and segregates and evaluates the stimuli based on the individual taste, leading to the personalized experience very commonly known as flavor. There are five very well-known taste qualities such as sweet, salty, bitter, sour, and umami. The production of physiologically important incretin hormone Glucagon like peptide-1 (GLP-1) in the taste perception cells and the presence of its known receptor GLP-1R on adjacent taste nerve fibers evidently suggest that GLP-1 signaling is associated with the function of taste. In this brief review, we will provide a bird eye view on the recent advance in taste, taste receptors and GLP-1 signaling and we will discuss their pivotal role in overall taste perception and signaling.

Keywords: Taste, Sweet, Sour, Umami, GLP-1.
The mechanism involves ligand binding at the taste receptors which further activates the second messenger cascades causing depolarization of the taste cells. Further, for perception of bitter taste a set of Ga subunit called Gustducin are associated having a major role in TAS2R (Taste receptor type 1 member 2). Additionally, taste receptors involve the use of TRM5 (Transient receptor potential cation channel subfamily M member 5) and phospholipase PLCβ2. Activation of PLCβ2 by Gustducin in response to external taste results in activation of IP3/ITP3 signaling. ITP3 channels in response to IP3 facilitate the movement of Calcium out of the endoplasmic reticulum. These calcium cations activate TRPM5 causing depolarization. (Figure 1).

Sweet: The taste of sugar and its broad ranges of substitutes are expressed when the molecules bind to the sweet receptors i.e., the TAS1R2+ TAS1R3 heterodimer receptors. The TAS1R3 homodimer also functions as sweet receptors in a similar manner to TAS1R2+3 but show reduced sensitivity to sweet substances. However, natural sugars are easily detected by TAS1R3 receptors compared to other sugar substituent thereby explaining the reason for different taste perception between natural sugars and artificial sweeteners.

Bitter: The taste receptors for bitter taste are the TAS2R proteins. There are 43 existing human TAS2R genes each lacking intros and coding for GPCR proteins (excluding five pseudogenes). Compared to TAS1R proteins they possess shorter domains. Some of the common bitter ligands are cycloheximide, denatonium, PROP (6-n-propyl-2-thiouracil), PTC (phenylthiocarbamide) and β-glucopyranosides.

The α subunit of Gustducin are also involved in the signal transduction of bitter stimuli by activating taste phosphodiesterases and decreasing levels of cyclic nucleotides. Its βγ subunits mediate taste by activating IP3 and DAG pathways by opening gated ion channels and releasing internal calcium. One such mechanism proposed for gustducin independent bitter tasting involves interaction with the ion channels by specific bitter ligands similar to that occurring for sour and salty stimuli.

Sour: Earlier studies on sour taste perception anticipated that only when free hydrogen ions directly depolarized the taste receptors, sour taste could be produced. However, research indicates the involvement of certain specific receptors with other modes of action for sour taste. HCN1 and HCN4 are two such proposed HCN channels, both of which are cyclic nucleotide-gated channel receptors. The other two ion channels suggested to contribute to sour taste perception are ACCN1 and TASK-1.

Salt: Salt plays major role in our diet and many times without salt and salty taste food seems tasteless. There are many numbers of salty receptors have also been proposed along with the possible taste detection of commonly known components of food such as lipids, carbohydrates and water. However, these receptors lack strong scientific evidences to prove their presence in mammals including human beings. However, they have shown the presence of ENaC receptor for the detection sodium in Drosophila. Therefore, this ENaC plays major role in salt taste (sodium) perception in Drosophila.

Savoury or Umami: The tastes for savory or umami are frequently associated with food additive monosodium glutamate (MSG) and are enhanced through the binding of inosine monophosphate (IMP) and guanosine monophosphate (GMP) molecules. The umami receptors are the TAS1R1+ TAS1R3 heterodimer receptors which respond to L-amino acid binding particularly L-glutamate. Alternative candidate umami taste receptors include splice variants of metabotropic glutamate receptors, mGluR1 and mGluR4 and NMDA type glutamate ion channel receptors.

Genetic Variation in Taste Receptors: Individual food choices (vegan and non vegan) vary on a wide number of criteria like geological, sociocultural, theological, physiological, nutritional and environmental factors. However, the sensory quality of food is critical to dietary preferences and taste in particular might be a vital determinant in food choices. Genetic polymorphism in taste receptors may contribute to the variability in taste perception between individuals, their food choices and dietary habits. This in turn affects the nutritional, physiological, physical and health status of the individual as well as their risk factors to various chronic diseases. Recent researches have highlighted that bitter taste perception is mediated by T2Rs, a family of GPCRs which are encoded by about 25 functional TAS2R genes located on chromosome 5, 7 and 12 in humans.

As evident from day to day observation, unlike bitters, sweet substances are perceived as pleasant and
are clustered separately from bitter taste in humans which reflect the evolutionary pressure to choose high energy food substances. Although T1R2/T1R3 heteromer have been associated with sweet taste detection, the number of sweet taste receptors unresolved.

The human gene encoding for T1R3, Tas1r3 are located on chromosome 1 along with the first and second members of the taste receptor family 1 TAS1R1 and TAS1R2 respectively.

The primary substance eliciting umami taste in humans is the L-glutamate and L-aspartate, abundantly found in foods that occur as monosodium glutamate (MSG). The response was increased in presence of IMP or GMP and T1R1 and T1R3 do not respond to sweet stimuli, D-amino acids, or either IMP or GMP alone.

Over the past few years strong evidences regarding two transient receptor potential ion channels (TRP) baring relation to putative sour taste has been established. In humans, the amiloride sensitivity of NaCl perception is specific to minor sour component of the taste rather than to the salty stimuli itself. The salty taste perception is however inhibited on rinsing with oral antiseptic chlorhexidine which suggests that salt sensitive ion channels in the TRCs are not selectively sensitive to amiloride.

As discussed earlier the genetic and environmental factors play a major role in the nutritional and overall health status of an individual which is a growing public health concern. Therefore, understanding the concept behind food intake and its correlation with taste perception is of prime importance since taste perception lies at the interface between the food an individual consumes and the biological predisposition to prefer certain food depending on the individual’s environment. Polymorphism in taste receptors is useful as surrogate markers of dietary exposure in the gene- disease association studies where information on dietary habits are not available.

**GLP-1 And Taste Signalling**

**Glucagon Like Peptide-1**: The pro-glucagon gene undergoes transcription to give the product which is known as Glucagon-like peptide gene (GLP-1). GLPs are obtained from expression of prepro-glucagon gene which is present on the chromosome 17 and is a member of glucagon peptide family. The intestinal ileum contains L-cells which secretes GLP-1 after the absorption of nutrients in small intestine. The pro-peptide convertase acts upon the gene product that breaks the product into at C-terminal into proprotein and pro-peptide substrate in order to create the biologically active peptides.

**Functions of GLP-1**: The glucagon like peptide effects the glucose secretion of insulin mainly in the beta cells of Langerhans in the pancreas. It also increases the expression of insulin and blocks the apoptosis of beta cells. It also helps in the regeneration of the beta cells in pancreas and decrease the secretion of glucagon (Figure 2).

In stomach GLP-1 decreases gastric emptying and motility through the nonadrenergic and non cholinergic pathways. It decreases the food transit time in colon by changing the parasympathetic neuronal input thereby increases the cholinergic stimulation and alters the colonic transit time.

In adipose tissue the GLP-1 functions to increase the thermogenesis of brown adipose tissue via sympathetic nervous system. It also increases browning of white adipose tissue by reducing the sympathetic activity and further increases energy expenditure.

In brain GLP-1 decreases the food uptake and decrease body weight due to the reduction of the peripheral nervous GLP-1 receptor. The GPCR signaling cascade initiated by sweet, bitter and umami sensitive cells cause an activation of neural signals to the brain. T1R and T2R for sweet, umami and bitter respectively and the G protein subunit α-gustducin are also expressed in the cells of the lower GI tract and are involved in the nutrient- dependent regulation of metabolism. For instance, the GLP-1 present in enteroendocrine L cells are mediated by T1R3 taste receptor subunits and α-gustducin. On observing the molecular similarity between the enteroendocrine L cells of the gut and the taste receptor cells of the oral cavity it can be suggested that the GLP-1 signaling could also play a major role in the gustatory functions.
Figure 1: A schematic representation of taste signaling for bitter, sweet, and umami

Figure 2: A schematic representation of taste-induced signaling via T2Rs and T1Rs in enteroendocrine cell activates GLP-1 signaling
Conclusion
Diet and diet induced obesity, type 2 diabetes, NAFLD, cardiovascular diseases and cancer are major health problems of 21st century. Recently, artificial GLP-1 analogues also have shown promising effect not only on the patients suffering from type 2 diabetes but also on patients with type 1 diabetes. These analogues also have shown positive role in reducing blood glucose and significantly reduces the fasting and post-prandial blood glucose. They can be exploited in the treatment of diabetes, Nonalcoholic Fatty Liver, CVD and Cancer. Therefore, these artificial tastants and GLP-1 analogues have revolutionized the modern medicine and the way we look at metabolic syndrome and associated diseases by providing us with the first anti-hyperglycemic weight-losing oral or injectable drugs.35

Impact of Work Life Balance on Employee Performance

Vinita Kumari¹, S. Vasantha²

¹Ph.D. Scholar, ²Professor, School of Management Studies, Vels Institute of Science Technology & Advanced Studies (VISTAS)

Abstract
Work life balance plays a significant role in influencing the performance and behaviour of the employee. There goes a popular saying that “All work and no play makes Jack a dull boy”. An individual needs to have activities which will help him to overcome the stress caused by his mundane activities at his workplace. The aim of this paper is to understand the effects of work life balance on the performance and behaviour of the employee. Based on the literature reviews, it was found that work life balance had a positive influence on employee performance and behaviour. It increased the levels of job satisfaction, commitment and engagement. This ultimately increases the performance of the employees. It is also helpful in reducing the stress level of employees. A conceptual framework has been proposed based on the literature reviews. It focuses on the relationship between factors that cause work family life conflict and job performance and mediating effect of work life balance.

Keywords: Employee, Stress, Resilience, Work life Balance.

Introduction
The success of a nation be it developed or developing, lies on the hands of the human resources. The natural, physical, financial and technological resources can be utilized to the fullest potential only if the nation has a strong, competent and knowledgeable workforce. The quality of the human resources play a crucial role in the development process of the developed countries. Organizations are in need of energetic and motivated individuals to achieve the organizational goals. The organization, in turn, should strive to keep the enthusiasm and energy levels high. This job is undertaken by the Human Resources Department. Management of human resources has undergone an evolution. The human resources cannot be managed in the same way as it was done during the traditional times. The employees are ensuring that they meet all the needs and demands of their family members. This is done due to the peer pressure faced by the employee and their family members in the society. This causes the employees to travel that extra mile to achieve the best for himself and the people dependent on him. This extra mile comes as a package along with erratic work schedules, extended working hours, intense competition etc. This has unfortunately increased the stress levels.

Stress impacts the health and performance of the employees. There is a pressing need for the HR managers to understand these factors to deal with the human resources efficiently. The HR managers need to have the emotional intelligence for understanding and appreciating the emotions and feelings of the employees.

The term work life balance came into existence in 1986. This term came up as an outburst of the feelings of the individuals who were overburdened and pressurized due to the ever-increasing demands at their workplace. They felt that they were being stressed to that level that they were not able to spend time with their families. There was a constant conflict between work and family life. This gave rise to terms like “Family-work conflict” or “Work-Family conflict”. Work life balance has been defined as contentment achieved at work and home in performing the duties and responsibilities without or minimum conflict in terms of roles[3]. This point could be like achieving equilibrium between work and home. A

person who has achieved work life balance is able to meet the demands of family and work. Achieving work life balance is about deriving satisfaction in three domains. The employee is happy at work, home and personal front. Spending time with oneself is also considered as a part of work life balance. Work life balance does not mean that an individual has to spend the same amount of time at home and work. It is the amount of satisfaction a person derives fulfilling his responsibilities at home and work. He/she needs to feel that they have completed a particular task within the speculated time and need not carry it when they leave that particular place. The pressure on personal and work front have created a huge amount of stress among individuals. This stress has led to health issues like depressions, anxiety attacks, heart attacks etc. It has also affected the organization’s productivity. The organization needs to devise policies which help the employees to achieve work life balance. They need to understand that the standard of living of the employees have increased due to increasing demands. The organizations have to organize trainings related to emotional intelligence and resilience. This will help in reducing the stress levels of the employees.

Objectives
• To understand the importance of work life balance
• To review the literatures which deal with the effect of work life balance on the employee performance

Research Methodology: The paper relies on the secondary data published in the journals for gaining an in-depth knowledge about work life balance and its effect on employee performance.

Literature review: Work-life balance acts as an interface between the work for which the individual is being paid by the organization and other activities which are unpaid and it is performed by the individual for the betterment of the individual, his family, society and his community. Work-life balance is about generating a constructive work culture which will help the employees to minimize the conflicts between family and work. This means that organization is supportive towards the employees. They have devised policies that benefit the employees. If the employees are benefitted by the policies, it would reflect in their behaviour. The job satisfaction, engagement levels, performance, efficiency and productivity will improve eventually. Work life balance also has a positive effect on the health of the employees.

Work life balance concept in organization should incorporate training programmes related to time management. Time management is extremely necessary to maintain a balance between professional and personal commitments. It will eventually help the employees to prioritize their work. The employees will be able to handle stressful situations in a proper manner.

Devising employee friendly work life balance policies benefit the organization as well as the employee. The work life balance policies could be providing work from home options to the employee, part time work options, child care provisions at workplace, flexible working hours etc.

The employee can resort to negative behaviours like disengagement from work, absenteeism, negligent behaviour if there is a constant conflict between his work and family. This can be rectified if the work life balance policies are in place. The policies should be framed in such a way that the productivity of the organization and individuals should get boosted. Taking initiatives with respect to work life balance can help the organization to increase the levels of job satisfaction, engagement, commitment and decrease the levels of absenteeism and negligent behaviour.

A study has been conducted on the work life balance of the public sector banking employees. They have also studied the relationship of work life balance on variables like job satisfaction, commitment, career development, target achievement, rate of absenteeism. They found that work life balance exhibited a positive relationship with job satisfaction, commitment, career development, target achievement and was negatively related with rate of absenteeism and stress. They have also proved that work life balance is negatively related with stress and rate of absenteeism.

The effect of work life balance has been studied on the engagement level of employees. They felt the employees need to be engaged with the company to perform better. The policies related to work life balance influences the behaviour of the employee towards the organization. An employee wishes to work in an organization that cares about its employees. The formulation of sound work life balance assures that the employee engagement level goes up. This increases the productivity and performance of the individual and organization.

The effect of work life balance of employees working in commercial banks of Nigeria has been
analysed. The effect of work life balance initiatives like flexible working hours, initiatives to take care of the dependents, policies related to paid leaves have been taken into account. They were found to have positive effect on work life balance. The researches have suggested that these initiatives will help the employee to support his family and reduce his intention to quit. It will also improve the levels of satisfaction and performance. They have suggested that the management should assess their work life balance policies from time to time. This will ensure that the employers understand the problems faced by the employees. The employees will also be committed towards the organization.\[11\]

**Proposed Conceptual Framework**

- Work Load
- Long Working Hours
- Peer to Peer Competition

**Work Life Balance Initiatives**

<table>
<thead>
<tr>
<th>Increase in levels of</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) Job Satisfaction</td>
</tr>
<tr>
<td>(b) Commitment</td>
</tr>
<tr>
<td>(c) Performance</td>
</tr>
</tbody>
</table>

**Discussion and Conclusion**

The current paper highlights the importance of work life balance in the life of an employee. Work life balance helps the employee maintain equilibrium between work and life. It also benefits the organization as it increases the levels of job satisfaction, commitment, engagement and productivity. These are in accordance with the findings of the study which states that the organization should work and formulate policies to help the employees to achieve work life balance. The organization should render support to the employees, which will help them to establish healthy rapport with the employees.\[2\].

Physical Fitness among the Dental Physician, Dental Undergraduates and Postgraduates Students

David¹, A. Jothi Priya², Gayatri Devi²

¹Undergraduate student, Saveetha Dental College, ²Assistant Professor, Department of Physiology, Saveetha Institute of Medical & Technical Sciences, Poonamalle, Chennai, India

Abstract

Introduction: The aim of the survey is to check the physical fitness among the dental physician and Dental students.

Dentistry is a something that provides satisfaction, but it is a very demanding job with a high degree of concentration and exactness and accuracy in work. Dentists require depth perception, psychomotor skills, manual dexterity, and ability to maintain occupational postures over long periods.

Many of the dentists are much vulnerable to work-related musculoskeletal disorders (WMSDs) of the neck and upper extremities and low back. The widespread presence, of these in dentists and students are very high. Precise manner of long working hours, inability to select the appropriate size of dental instruments and high job demand are the most significant risk factors. Back and neck pain, has been found to be a major health problem for dental physicians with musculoskeletal disorders affect the physical, psychological and social aspects of dentists. This, in turn, has an great impact on their productivity and ultimately reduces their quality of life. Musculoskeletal disorders contribute significantly to sick leave, and reduced productivity and quitting the profession. The most common regions of pain in dentists are the neck, back and shoulders and back.

Materials and method: A Study was carried out among 102 professional people 15 questions were given to each of them. A validated, online self-administered questionnaire was used to gather the data to each of them to avoid discussion among them and also to avoid false results, thereby no bias is evidence in this study. Each of them were given one hour to complete the questionnaire. The results were statistically analysed descriptive statistics were used to analyse frequency, percentage.

Result: A questionnaire was prepared and circulated among the students of Saveetha dental college. It was also circulated among few staffs. The profession of dentistry itself is a hectic and long hours of working job. They keep on working for longer periods which developed stress and strain the back. Due to their inappropriate postures during dental procedures, they develop musculoskeletal pain.

Conclusion: Important that the education in and the application of ergonomic principles should begin early on, beginning with students of dentistry, and continue throughout the life-long postgraduate education of working dentists.

Keywords: Backache, Dentists, Musculoskeletal, Neck pain, Low back pain.

Introduction

Dentists are exposed to multiple types of health hazards while doing routine professional duties, for example, are exposed to occupational health hazards that predispose them to develop a multiple of health disorders. A wide variety of injurious work, like environmental factors are proved to affect the physical health of dentists or even aggravate their pre-existing disorders [¹]
A dentist working for more than seven to eight hours a day without 15-20 min break between patients is found to increase the chance of Muscular skeletal disease. The dental physician and dental students are at very high risk of neck, back, and shoulder complaints due to the limited work area and because they do not have access to impaired vision associated with the oral mouth cavity.

Dentistry is a highly rewarding profession, but it is a very demanding job with a high degree of concentration and precision in work. Dentists require good visual acuity, hearing, depth perception, psychomotor skills, manual dexterity, and ability to maintain occupational postures over long periods [2].

Moreover, dental procedures and planning are usually long and require much more concentration during work. Back pain is one of the most common and troublesome of complaints; its exact causes are unknown, and anography diagnosis is often very difficult [3].

Even in optimal seated postures, more than one-half of the body’s muscles are contracted statically, and there is little movement of the vertebral joints. The condition may result in damaging physiological micro changes which occur that can lead to back, neck or shoulder pain or musculoskeletal disorders leading to macro changes in the body because of the overstrained and awkward postures, repetitiveness of different joint movements, use of very high frequency vibration tools, both physiological and psychological stress have been identified as high risk factors [5,6]. Studies have shown that dental physicians reported more frequent musculoskeletal pain [7,8], particularly low back and neck pain, including shoulder pain has been found to be a major health condition for dental physicians and dental students [9-10] its exact causes and diagnosis is often very difficult.

It has been stated that the most frequent sites of pain among dentists physicians and dental students are in the areas of the cervical and lumbar vertebrae involving low thoracic vertebrae [11-13]. It has been pointed out that common postural faults among dentists are craning or sometimes excessive bending and twisting of neck, bending forward from the waist, elevation of shoulders, and general bending which leads to twisting of the back and the neck [14].

As preventive measure dentists should be taught relaxation techniques and resting between each patient taught them early in clinical training, and they should be taught correct working posture at chair side.

Recently, “Ergonomics” has become a popular term. The term has been used in most professions, but increasingly in the dental profession. It is a discipline that studies workers and their relationship to their occupational environment. This includes many different concepts such as how dentists position themselves and their patients, how they utilize equipment, how work areas are designed, and how all of these impact the health of dentists.

It is very important to maintain an adequate work postures and that the instruments and furniture that the dental physicians and students is working with have adequate working characteristics [15]. Furthermore, they are exposed to biomechanical risk factors, which indicate that work forced postures, would imply more risk of soreness and presence of skeletal muscle lesions. These lesions could begin to appear at the beginning of their clinical practice as students, by acquiring inadequate postures and working habits that will harmful to them in future if they are corrected in early the postures of their professional life, acquiring an unhealthy lifestyle in their work environment [16].

Due to lack of understanding ergonomic principles may also play its role. Specially the students who is joining the dental professions in their first year curriculum, must be orientation on how to decrease musculoskeletal disorders, partially implemented even by the relatively motivated group of dental students and dental physicians [17-20]. However, there is a lack of data regarding musculoskeletal pain among the Dental physicians and dental students in south Tamil Nadu.

Hence, this study was conducted with the aim to determine the prevalence of Musculoskeletal disorders among dental physicians and dental students in south Tamil Nadu and factors associated with its ubiquity.

The objectives of this study were to know the prevalence of pain in different anatomic location and to investigate the association between Musculoskeletal disorders and demographic and clinical details.

This questionnaire study was taken to assess the prevalence, severity, and extent of lower back and neck pain and propose some preventive measures. Hence the aim of the survey is to check the physical fitness among the dental physician and dental students.
Materials and method

A Study was carried out among 102 professional people 15 questions were given to each of them. A validated, online self-administered questionnaire was used to gather the data to each of them to avoid discussion among them and also to avoid false results, thereby no bias is evidence in this study. Each of them were given 1 hour to complete the questionnaire. The results were statistically analysed descriptive statistics were used to analyse frequency, percentage

Result and discussion

A questionnaire was prepared and circulated among the students of Saveetha dental college. It was also circulated among few staff. The profession of dentistry itself is a hectic job. Working for longer periods which developed stress and strain. Due to their inappropriate postures they develop musculoskeletal pain. Hundred and twenty dentists completed and returned the questionnaires through online survey for analyses, hence a response rate of 120 dentists, 40 (33%) were male and female 60(50%) and mean age 34yrs in both sex. Years of practising dentistry 5yrs 59% and more than 7yrs 28% table 1. The practice taking breaks in between 80% said yes and 20% said No table 2. Physical activity like swimming, jogging walking and running, most of the dentist said walking more than 30km 39% table 3. Hand dominance using right hand 90% and left hand 10% table 3. Reducing work overload due to muscular skeletal pain low back pain 41%, neck pain21%, and shoulder pain 20% table 4. Preventing from practice dentistry occasionally 40%.taking sick leave from work for low back 42% and neck pain 20%.table 5.

From these results it shows many dental physicians and dental students are suffering from low back pain and ergonomic principles must be taught them in early carrier to prevent musculoskeletal disorders.

Figure 1: Years of practising dentistry 5yrs 59% and more than 7yrs 28%

Figure 2: The practice taking breaks in between 80% Yes and 20% No.

Figure 3: Physical activity like swimming, jogging walking and running, most of the dentist said walking more than 30km 39%.

Figure 4: Hand dominance using right hand 90% and left hand 10%

Figure 5: Reduction of work overload due to muscular skeletal pain low back pain 41%, neck pain 21%, shoulder pain 20%.
Conclusion

To prevent the occurrence of pain in future dentists, more emphasis must be placed on prevention strategies and proper work positioning in the undergraduate and Postgraduate curriculum. Continuing dental education programs can be conducted for practicing dentists to update their knowledge.

Anti-Depressant and Anti-Anxiety Like Effects of Cydonia Oblonga in Mice Exposed to Mild Stress

Bushra Shaida¹, Karuna Singh², Ashok Kumar Dubey³, Prashant Sharma⁴

¹Scholar, Amity Institute of Food Technology, Amity University, Noida and Assistant Professor, School of Allied Health Sciences, Sharda University, Greater Noida, ²Assistant Professor-III, Amity Institute of Food Technology, Amity University, Noida, ³Professor, Department of Pharmacology, SMS & R, Sharda University, Greater Noida, ⁴Assistant Professor, Amity Institute of Food Technology, Amity University, Noida, Department of Pharmacology, SMS, R, Sharda University, Greater Noida

Abstract

Background: Cydonia oblonga is the scientific name of Quince and it has been claimed to have antioxidant, antidiabetic, antimicrobial, antihemolytic, aphrodisiac and anti-allergic properties in previous studies.

Objectives: Anxiety and depression are linked with oxidative injury so in the present study, Cydonia oblonga was explored for its antidepressant and antianxiety potential.

Material & Method: The experiments with Cydonia oblonga seed extract were carried out in animal models of depression and anxiety (Swiss albino). Five groups of six mice each (total of 30 mice) were trained initially to consume 2% sucrose solution for three weeks. The first group was normal control, the remaining four were exposed to stress and were fed with either: 10ml water per kg p.o, imipramine (antidepressant drug) 15 mg/kg body weight, diazepam (anti-anxiety drug) 25mg/kg body weight and Cydonia oblonga seed extract in dosages of (40 mg, 60 mg, 80mg per kg body weight) for the time period of 30 days.

Results: indicated that Cydonia oblonga seed extract of 80 mg/kg body weight and imipramine groups had significantly increased sucrose consumption, decreased duration of immobility during Forced Swim Test (FST) and tail suspension test (TST) thus indicating significant antidepressant like activity of the extract. Similar results were seen for anti-anxiety effect, this effect was evaluated using photoactometer and elevated plus maze method.

Conclusion: The findings of the study indicate that Cydonia oblonga seed extract is effective in depression and anxiety and the effects are dose dependent with comparable efficacy at higher dosage to the standard approved drugs.

Keywords: Cydonia oblonga, Forced Swim test (FST), Tail Suspension Test (TST), antidepressive, anti-anxiety, photoactometer.

Introduction

Depression and anxiety are two extremely common neurotic disorders affecting different age groups and genders globally. WHO reported in 2015 that around the world an estimated 322 million populations were affected by depression¹. Several non-communicable diseases are linked to depression². Depression of moderate to severe nature becomes a disabling condition creating substantial health and socio-economic impact on people, families, the community and society at large³. Depression is generally caused by reduced secretion of monoamines, i.e. neurotransmitters like serotonin, dopamine and nor-epinephrine which play an important role in pathogenesis of depression⁴.

Anxiety is a normal human emotion. Anxiety is considered pathological once it leads to psychological,
social, occupational, biological, and alternative impairment. Women of reproductive age are more susceptible to neurotic disorders like anxiety and depression.

In recent decades, despite the advancement in pharmacotherapy for the treatment of depression and anxiety, a significant proportion of patients are still treatment resistant. Antidepressant drugs generally have more side-effects or they are lacking in desired results for the patients. Their chronic therapy is also an economic burden for the patients. Thus, explorative studies for anti-depressive or anti-anxiety like effect of natural substances is justified by the need to find new compounds that have good clinical efficacy and fewer adverse effects.

Quince scientifically known as *Cydonia oblonga* is a shrub of Rosacea family and native west Asia region. Its fruits are edible and consumed in many forms. Quince seeds presented a good phenolic profile composed of quinic acids, lucenin-2, vicenin etc and have been shown to have anti-oxidant properties. "Phenolic compounds represent a promising class of natural substances in neuropharmacology, taking into account its antioxidant and neuroprotective properties." Oxidative damage can lead to depression and anxiety; studies have shown that significant increase in serum levels of oxidative stress biomarkers in depressed patients in acute phase as compared to those of healthy subjects. Quince seeds possess antioxidant properties thus present study aimed to investigate the effects of repeated administration of *Cydonia oblonga* seed extract in modulating behavioural changes in stress induced mice.

**Material and Method**

**Plant Material:** *Cydonia oblonga* seeds were obtained from Srinagar, Jammu & Kashmir India. Seeds were washed several times with water and air dried. The dried seeds were packed under vacuum and stored at 18°C in dark till taken out for experiments.

**Preparation of extract:** The seeds as stored above were ground to fine powder and 100 g was taken in Soxhlet apparatus for solvent extraction by using ethanol as solvent at 60-80 °C for 9-10 hrs. The solvent of the extract was allowed to evaporate at room temperature and the material left was stored at 4°C for analysis.

**Standard drug:** Imipramine was referred to as the standard drug used for evaluating anti-anxiety activity in mice. Drugs were powdered and made into suspension in distilled water.

**Animals:** Proper care of animals was taken as per the guidelines of the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA) for laboratory animal facilities, and permission from the Institutional Animal Ethics Committee (Regn No. 1173/ac/po/08/CPCSEA) was obtained. Thirty Swiss albino mice of either sex weighing between 25 and 30 g were housed in a group of 6 in a polypropylene cages, exposed to standard laboratory conditions i.e. 12 hr dark-light cycle at the temperature of 22°C ± 2°C with the access of free drinking water and were fed ad libitum with standard laboratory pellet diet.

**Protocol for the Experiment:** In the beginning of the experiments, animals were trained to consume 2% sucrose solution. Relation between consumption of sucrose and bodyweight was observed for 2 weeks and then grouping was done. Total of 30 mice of either sex were subjected to the study. Evaluation of anti-depressive activity was done in five different groups (n = 6/group) of mice. The control, standard drug and three test groups were orally administered distilled water (10 ml/kg), Imipramine (20 mg/kg), and incremental doses on 40, 60 and 80 mg of *Cydonia oblonga* seed extract respectively.

Evaluation of anti-anxiety activity was done in five different groups (n = 6/group) of mice. The control, standard drug and three test group were orally administered distilled water (10 ml/kg), Diazepam (5 mg/kg), and incremental doses on 40, 60 and 80 mg of *Cydonia oblonga* seed extract respectively.

**Experimental groups:** The experimental test was performed one hour after oral (p.o) administration of vehicle/drug.

- **Group 1** – Control:(Distilled water) (10ml/kg, p.o.) – [Control]
- **Group 2** – Standard drug: Imipramine (20 mg/kg, p.o)
- **Group 3** – Standard drug: Diazepam 5 mg/kg, p.o for anti-anxiety activity
- **Group 4** – *Cydonia oblonga* seed extract (40 mg/kg, p.o.) -[QSE 40]
- **Group 5** – *Cydonia oblonga* seed extract (60 mg/kg, p.o.) - [QSE 60]
Group 6 – *Cydonia oblonga* seed extract (80 mg/kg, p.o.) - [QSE 80].

Chronic Mild Stress procedure: The mice were subjected to the chronic stress protocol as described by P. Willner\(^1\) with slight modifications. Stress was given after 2 weeks of adaptation with 2% sucrose except for the control group (Group I), all the animals were subjected to chronic mild stress. The procedure was done as follows: 16hrs of water deprivation; 5h food deprivation prior to sucrose test (2days); 17h of overnight illumination and exposure to low temperature at 0\(^\circ\)C for 5h. These stress procedures were run for 30 days.

Experimental models for depression

**Forced swim test:** The forced swim test was developed by Porssolt et.al. 1977 to verify the behavioural change in animals after giving them antidepressant substances\(^12\). Each animal was placed inside a vertical plexi glass cylinder (40 cm in height and 18 cm in diameter), containing water up to a height of 15 cm maintained at 24 – 25\(^\circ\)C. After the initial two to three minutes of vigorous struggling activity, an animal usually assumes a typical immobile posture. A mouse was considered to be immobile when it remained floating in the water without trying to struggle, making only minimum movements of its limbs, necessary to keep its head above water. During the test, each animal was placed in the water for 6 min. The duration of immobility was recorded during the last four minutes of the forced swim test. After removing the mice from water they were allowed to dry for 15 min. and then replaced back into the cage. An antidepressant effect was indicated when there was decrease in the duration of immobility.

**The tail suspension test:** Tail suspension test was used as an alternative to forced swim test for the assessment of anti-depressive potential of substances\(^13\). In this test, each mouse was suspended from the edge of a 58 cm high table top with the help of an adhesive tape placed approximately 1 cm from the tip of the tail. The duration of immobility was recorded for a period of 5 minutes. Mouse was considered immobile when it hung passively and remained completely motionless, except for the respiratory movements, for at least 1 min. The duration of immobility in the different groups was compared. A decreased duration of immobility is indicative of antidepressant effect.

Experimental models for Anxiety

**Elevated plus maze method:** Elevated plus maze (EPM) is an apparatus to measure anxiety in mice providing laboratory conditions as suggested by Guy et al.\(^14\). The apparatus consists of two open arms, two enclosed arms giving a shape of plus (+) thus both the closed and open arms are facing each other. Each animal was placed at the centre of the apparatus facing towards the open arms. Digital recording was done to measure time spent and number of entries in open and closed arms within the duration of 5 min test period. Anxiety is expressed in term of time spend in closed chamber by the mouse.

**Measurement of spontaneous locomotor activity:** Spontaneous locomotor activity was measured using photoactometer. Photoactometer is an apparatus in which continuous beams of light pass through the chamber. Mice was placed in between and by the criss-cross movement of mice light beam got interrupted and these interruptions were recorded for a period of 10 min. Spontaneous locomotor activity was expressed in terms of total photo beam interruptions.

**Statistical Analysis:** Results were analysed using one-way analysis of variance followed by Turkey post hoc tests.

Difference between groups were considered significant P<0.01.

Results

**Sucrose intake:** Sucrose intake was observed to decrease from 1.98 ml to 0.84 ml per day in mice exposed to mild stress. Normal control group maintained the sucrose intake compared to imipramine fed animals. Higher sucrose intake was observed at higher dosage of *Cydonia oblonga* seed extract i.e 80mg/kg(P<0.05), which was similar to imipramine fed animals. Results are shown in Figure 1.
Effect of Quince seed on the duration of immobility in FST and TST: Cydonia Oblonga seed extract (40, 60 and 80 mg/kg, p.o) decreased the immobility time in FST \( F(4,29) = 47.23, P<0.01 \) and TST \( F(4,29) = 684.69, P<0.01 \) as compared to control group. Imipramine, (20mg/kg, p.o.) used as a positive control, showed effects similar to Cydonia oblonga seed extract 80 mg/kg, p.o. which was statistically significant thus dose of 80 mg/kg, p.o was the most effective dose in reducing mobility time in the forced swim test and this was chosen for subsequent experiments in the model of depression.

Effect of Cydonia oblonga seed extract on anxiety level of mice: Results of the impact of different dosages of Cydonia oblonga seed extract on anxiety level of mice are presented in Fig 2,3. Maximum reduction of SMA (Spontaneous locomotor activity) count was observed using the dosage of 80 µg/ml of the extract which is statistically significant in comparison to standard drug Diazepam 5mg/kg p.o. \( F(2,45) = 345.89 \). Results revealed that the effect of Cydonia oblonga seed extract on anxiety is dose dependent.

Similar results have been observed for elevated plus maze test, dosage of 80 µg/ml increases the time spent in closed arm which is statistically significant when compared to standard drug diazepam 5mg/kg p.o. \( F(2,45) = 345.89 \). Results revealed that the effect of Cydonia oblonga seed extract on anxiety is dose dependent.

Table 1: Effect of different dosages of Cydonia oblona (QSE40, QSE60 and QSE 80 µg/ml) seed extract on duration of immobility in FST (significance at 0.01% level), mean value having different superscript letters for each element are significantly different.

**Discussion**

Depression and anxiety are the most prevalent mental disorders which widely effect world’s population. Diagnosis, treatment and recovery of these disorders become a great challenge due to the complexities of nervous system which deliberately affect the whole process. More of research is required to reduce the global impact of these disorders. For the treatment of depression and anxiety serotonin- specific reuptake inhibitors (SSRIs), antidepressants and benzodiazepines are routinely prescribed to patients\(^{15}\). These classes of drugs are effective but have unwanted side effects and are costly. Hence, there is need to develop more effective and safer alternatives, thus this study focuses on effects of *Cydonia oblonga* seed extract on depression and anxiety.

Brain functions are closely related to intake of energy from carbohydrate sources like sucrose\(^5\). A much greater sucrose intake was observed in the *Cydonia oblonga* seed extract (80\(\mu\)g/ml) and imipramine group. It has been shown that higher intake of polyphenols increases glucose intake, there by stimulating neurons for better cognitive function, indicating reduced oxidative stress\(^{16}\).

Figure 1 suggests that higher dosage of the extract can be supplemented for improved cognitive functions.

Behavioral changes were reported in animals exposed to stress\(^{17}\), animal models were used for evaluating the efficacy anti-depressive and anti-anxiety properties of different natural formulations. In the present study anti-depressive and anti-anxiety properties of quince seed extract were studied using behavioral changes in mice.

Forced Swim test and elevated plus maze method were used to produce the behavioral changes in mice. Results indicated that *Cydonia oblonga* seed extract of high dosage i.e 80 \(\mu\)g/kg p.o reduced the immobility time of mice when compared with imipramine. This effect may be due to the presence of polyphenols, as many studies have proved that natural polyphenols play important role in brain functions and modulate neurotransmitters\(^9\). Silva, et. al has suggested that *Cydonia oblonga* seed extract has significant amount of polyphenols\(^{18}\).

Spontaneous locomotor activity model was used to assess the anti-anxiety effect of *Cydonia oblonga* seed extract. Results indicate that the behavior change is dose
dependent and when compared with diazepam there is significant reduction in exploratory behavior of mice in photoactometer. Similar results were seen for elevated plus maze method, thus the extract of higher dosage, i.e 80 mg/kg body weight shows anti-depressive and anti-anxiety effect.

**Conclusion**

The findings of the study indicate that *Cydonia oblonga* seed extract is effective in depression and anxiety and the effects are dose dependent with comparable efficacy at higher dosage to the standard approved drugs. Further biochemical and molecular biological studies are needed to determine the exact mechanisms by which the *Cydonia oblonga* seed extract exhibits anti-depressant and anti-anxiety effects.

Accessibility and Barriers to Oral Health Care among Gypsy Tribes in Chennai: A Cross Sectional Study

N. Divya Lalitha¹, Prabu. D.², Rajmohan³, Sunayana Manipal³, Bharathwaj V.V.⁴

¹Postgraduate, ²Professor & Head, ³Reader, ⁴Senior Lecturer, Department of Public Health Dentistry

Abstract:

Background: Narikuravars are nomadic population who do not tend to give importance to their oral health. Many people among them consume alcohol and tobacco products which might deteriorate their oral health.

AIM: The aim of this study was to evaluate the accessibility and barriers to oral health and to evaluate the oral health status of the narikuravar population.

Methodology: The present cross-sectional descriptive study was conducted among gypsy narikuravar population in Chennai. The sample size was 102. A pre-tested questionnaire containing 15 questions was used to collect data from all sample recruited for the study. Data was collected by face to face interview in tamil. Complete oral examination was done and recorded in WHO proforma 2013.

Results: Totally 68 (66.6%) females and 34 (33.4%) males participated in the study. Majority of them 60 (58.9%) individuals use tobacco products and only 42 (41.1%) do not use it. 72.6% get their dental treatments done in private dental clinics and 21.6% only get their treatments done in government hospitals. 72.5% participants have dental caries which is in majority among other oral diseases. Periodontal problems were present in 35.3% participants. 23.5% had missing teeth. 3.9% had oral lesions. 1.9% of participants only had dental fluorosis and dental erosion.

Conclusion: The narikuravar community tend to have a negligence towards oral health. Measures to improve their access and limits to their barriers to oral health care must be taken to improve their oral health status.

Keywords: Narikuravar, oral health, barriers, accessibility.

Introduction

The word “Narikurava” is a fusion of two Tamil words “Nari” and “Kurava” meaning “fox people” or the”jackal people”.¹ They are an indigenous community from Indian states of Tamil Nadu. The main employment of this people who originally belong to the indigenous tribal group, is hunting. But since they were prohibited from entering into the forests to continue their main occupation, they were forced to sell beaded ornaments as an alternative to survive. Hence, they had to migrate from one place to another in search of a market for their beads. Children also accompany their parents wherever they go, which invariably means they dont get to attend schools or colleges.

The Narikuravars like the other tribes in other areas of Tamil Nadu speak vagriboli language. There is no written form for this vagriboli language. They also sing folk songs in this language. The narikuravars are well-versed in Tamil too.²

There are about 36 types of tribal and local communities who reside in forests and nearby areas of Tamil Nadu.³ Their entire families live together in small huts or tents, in both rural areas and cities of Tamil Nadu which are at times even made of elephant grass stems. They continue their hunting of birds, rabbits etc. The women in their community indulge themselves in the making and selling of beaded necklaces. Men as well

as women wear jewelleries made of shells, beads and coins. The women often wear ghagro which are colorful pleated skirts that are not as long as saris.

The Narikuravar community people are evenly distributed all over the South Indian states. They are a nomadic people who are often known to other people for their passionate behaviour, independent nature and unwillingness to work under others. Unlike many caste of Hindus, most Narikuravars consume country liquor, especially during a pooja or festivals.

Majority among this community, have primary level education only. Due to this they might not have much knowledge about oral health too. They do not tend to give importance to their oral health. Many people among them consume alcohol and tobacco products which might deteriorate their oral health. Hence, an attempt was made in this study to evaluate their accessibility and barriers to oral health and to evaluate their oral health status.

Materials and Method

The present cross-sectional descriptive study was conducted among gypsy narikuravar population in chennai.

The sample size was 102 based on convenience sampling among the narikuravar population living in Avadi and Thirumullaivoyal in chennai. Ethical committee approval was obtained for conducting the study.

The inclusion criteria included all the participants who gave consent to participate in this study. All the participants were informed about the purpose of the study and confidentiality was assured. Verbal consent was obtained from all the participants. The study was conducted during the period of December 2018 to January 2019.

A pre-tested questionnaire containing 15 questions was used to collect data from all sample recruited for the study. Data was collected by face to face interview in tamil. The questions were put forward on their demographic details (Name, age, and gender), their oral hygiene practices, dental issues, access to oral care and barriers.

Oral health of all the participants was accessed according to American Dental Association type 4 clinical examination with available illumination. Complete oral examination was done and recorded in WHO proforma 2013.

Descriptive statistics was done and the association was assessed using Pearson’s Chi Square test. Statistics was done using SPSS version 23.0 and the p-value was set at 0.05.

Results

This study was a cross sectional study done among narikuravars in Chennai, tamilnadu to assess their accessibility and barriers to oral health care. A total of 102 narikuravars in the age group of 12-70 years participated in the study.

Table 1: Distribution based on gender, user and non user of tobacco and alcohol

Table 3 shows the distribution based on dental checkup, last visit, reasons and interest in knowing about oral health. Majority of the participants, 70 (68.6%) have had dental checkups done by a dentist. 32 (31.1%) participants have visited a dentist 6 months to 1 year back. The reason for dental visit was dental caries in 40 (39.2%) participants followed by 36 (35.3%) for tooth pain. Inspite of having a dental problem, 34 (33.3%) participants did not get their treatments done because of no time whereas 24(23.5%) did not because of fear. 52 (50.9%) prefer a particular center because of its easy accessibility from the place they live. Majorly 88 (86.3%) participants are interested in knowing about oral health.

Figure 2: Prevalence of dental diseases among the study population

Figure 2 shows the prevalence of dental diseases among the study population. 72.5% participants have dental caries which is in majority among other oral diseases. Periodontal problems were present in 35.3% participants. 23.5% had missing teeth. 3.9% had oral lesions. 1.9% of participants only had dental fluorosis and dental erosion.

*p value significant

Table 5 shows the association between alcohol consumption and dental caries. 54 (49.3%) participants who consume alcohol had dental caries whereas 20 (24.6%) participants who do not consume alcohol had dental caries. A significant p value was obtained while assessing the association between dental caries and consumption of alcohol.

Discussion

Dental problems are generally not self-limiting in nature. If left untreated, these dental diseases may affect the one’s well-being and even their overall quality of life. [6] The world health organization acknowledges the importance of oral health care in the maintenance of general health. Various local, national, and international organizations put in lots of efforts to increase the oral health awareness among the people. Even then the oral health negligence continues to prevail among the people.[7] The nomadic gypsy population be one among them. A negative oral health care seeking behavior is seen to prevail among them due to lack of knowledge and awareness. Colonization of these indigenous people has also resulted in vast health inequalities. [8]

In the present study, use of tobacco products either in smoking or smokeless forms and use of alcohol is more among the narikuravar population. About 58.9 % of them use any form of tobacco products and 66.6% of them consume alcohol which is at a high. This might be due to the lack of awareness about the ill effects of using tobacco products and alcohol among them. This in-turn might be due to lack of education among them. [5]

Majority of the participants, 70 (68.6%) have had dental checkups done by a dentist. 32 (31.1%) participants have visited a dentist 6 months to 1 year back. The major reason for visit in the present study was decayed tooth (39.2%) which is in contrast with was in contrast with the study conducted by Bommireddy VS et al [7] where tooth pain was the main reason for visit.

Majority of the participants underwent their dental treatments in a private dental clinic with accessibility being the main reason for preferring the particular center. This was in accordance with the Bommireddy VS et al study. [7]

Dental Caries was the majorly prevalent disease among the gypsy population (72.5%) followed by missing teeth among 23.5% population.

A significant association was obtained while assessing the association of use of tobacco products either in smoked or smokeless forms and dental caries. This increase in the susceptibility to dental caries can be due to lower pH levels, a decrease in the buffering capacity of smoker’s saliva, and the higher number of lactobacilli and Streptococcus mutans counts. [9] Nicotine, being the major ingredient in tobacco, would promote the attachment of Streptococcus mutans to the dental surfaces, and further may increase the incidence and severity of dental caries in tobacco users. [10] the dental caries experience can be more due to use of sugar constituents in the chewing tobacco products. [11] A significant association was obtained while assessing the association alcohol consumption and dental caries in the present study.

In the present study, 86.3% of the narikuravar population were interested in knowing about oral health. So, initiatives to improve their oral health knowledge by regular camps and awareness programmes can benefit these people.

The limitations of the present study were that the study was a cross sectional study done only among narikuravars who reside in Chennai, so the results cannot be generalized. Further researches in other parts of Tamilnadu can be conducted to know the oral health access and barriers of the nomadic narikuravar population.

Conclusion

The narikuravar community tend to have negligence towards oral health. This has led to increase prevalence
of dental diseases among them. They do not take proper care of their oral cavity. Initiatives to improve their knowledge must be undertaken. Measures to improve their access and limit their barriers to oral health care must be taken to improve their oral health status.

Abstract

Background: Adolescence is a period of rapid growth which reaches its peak between 11 and 14 years for the girls and between 13 and 16 for the boys. Adolescence is the period of transition from childhood to adulthood with accelerated physical, mental and emotional development. To strengthen any nation, there is need of healthy mothers as they only produce healthy citizens.

Objectives: A descriptive study aimed to assess the knowledge and perception of Kishori Shakti Yojana services among adolescent girls.

Materials and Method: Convenient sampling technique was used to select the sample size of 100 adolescent girls. Data was collected using structured knowledge questionnaire with 19 items and Likert scale with 16 items.

Results: Overall grading of knowledge score and perception score revealed that one-third of the subjects (75%) had inadequate knowledge and 71 adolescent girls (71%) had unfavorable perception towards KSY Services. There was a significant association between knowledge of adolescent girls regarding KSY Services and age, annual family income, previous knowledge and source of knowledge. There was no significant association between perception scores of adolescent girls regarding KSY Services and selected demographic characteristics.

Conclusion: The adolescent girls are provided with some sort of educational interventions such as information booklets, teaching programmes, modules on KSY Services will definitely update their knowledge and develops favourable perception towards KSY Services, which in turn contribute to improve the total quality of one’s health.

Keywords: Knowledge, perception, adolescent girls, KSY.

Introduction

Adolescence is a period of rapid growth which reaches its peak between 11 and 14 years for the girls and between 13 and 16 for the boys. Several physical, biochemical and physiological changes take place with onset of puberty. The attitude towards diet is often very unhealthy during the period of adolescence because this period is accompanied with considerable stress.
due to physiological and psychological changes. On the contrary, an adolescent girl requires all nutrients in good quantities not just for the rapid growth but also to obtain optimal storage for later requirements during pregnancy.\[1\]

In India, social, economic and health factors may undermine the ability of adolescents to lead full and productive lives. This is of particular concern given the sheer number of young people in India- an estimated 31% (358 million) of national population is aged between 10 to 19 years olds (242 million). \[2\]India houses nearly 224 million adolescents within the age group of 10 to 19 years, of them 105 million are girls. Adolescent accounts to be 22% of India’s population which means every 5\textsuperscript{th} person in India is an adolescent and every 10\textsuperscript{th} person living in the country is an adolescent girl. Among adolescents, girls are more vulnerable and are most neglected group as far as their health, nutrition, education and their overall growth and development are concerned. As a result, most of the adolescent girls in India make the transition to adulthood with low health and nutritional status which increases the risk of reproductive morbidity and mortality. However, there are very few programmes implemented in the country which are meant for improving the health and nutrition status of adolescent.\[3\]

The Govt of India thus introduced a number of schemes for the welfare of the people and more specifically for the women and girls but the schemes also do not reach to the appropriate group of people because of lack of awareness and corruption along with a number of other reasons. This has motivated the investigator to assess the knowledge of adolescent girls regarding one of the Govt. Schemes i.e. KSY, so that appropriate intervention could be undertaken so that adolescent girls get the knowledge about the scheme & will get benefit of it.

**Materials and Method**

**Sample setting and sample size:** The research design selected for this study was descriptive correlative design. The study was carried out in Kumpala area of Kotekar PHC, Kotekar post, Mangaluru, Karnataka in January 2018. In the present study, convenient sampling technique was used to select the sample size of 100 adolescent girls.

**Tools and techniques:** A demographic proforma having 9 items, structured knowledge questionnaire with 19 items under 3 domains \[r=0.83\] to assess the knowledge and Likert scale with 16 items under 2 domains \[r=0.76\] to determine the perception was administered to collect the data from adolescent girls.

**Data analysis:** The data was collected after obtaining prior permission from the concerned authority to conduct the study. The participants were assured about the confidentiality of their responses. The data was analyzed in terms of objectives of the study using both descriptive and inferential statistics. The data obtained was plotted in the master sheets.

**Results**

More than half (52%) of the subjects were in the age group of 17 – 19 years. The mean age calculated was 16 years ± 0.75. Majority of the adolescent girls 89 (89%) belonged to the Hindu religion and 81 (81%) were residing in nuclear family structure. More than half (61%) of the subjects had higher secondary education. More than half (55%) of the adolescent girls had prior knowledge regarding KSY Services.

One-third of the subjects (75%) had inadequate knowledge and rest (25%) of the subjects had adequate knowledge regarding KSY Services [fig. 1]. The highest percentage of knowledge was seen in the domain of eligibility of KSY Services (54%) followed by the domain of benefits/services of KSY Services (50%). The least knowledge percentage was seen in the domain of administration of KSY Services (22%) [table 1].

Most of the adolescent girls 71 (71%) had unfavourable perception towards KSY Services and 29 adolescent girls (29%) had favourable perception towards KSY Services [fig. 2]. The highest percentage of perception was seen in the domain of perception related to benefits (74%). The least perception percentage was in the domain of perception related to benefits (67%) [table 2]. There was a positive weak correlation \(r=0.025\) between the knowledge scores and perception scores of adolescent girls regarding KSY Services.

There was a significant association between knowledge of adolescent girls regarding KSY Services and age \(\chi^2=8.30, p=0.016\), annual family income \(\chi^2=34.28, p=0.001\), previous knowledge \(\chi^2=18.43,p=0.001\) and source of knowledge \(\chi^2=43.71,p=0.001\). There was no significant association between perception scores of adolescent girls regarding KSY Services and selected demographic characteristics.

Discussion

Section I: Description of demographic characteristics of adolescent girls: The present study revealed that more than half 52 (52%) of the subjects were in the age group of 17-19 years. The mean age calculated was 16 years ±0.75 and 89% were Hindus. Most of the adolescent girls (61%) had qualification of higher secondary. More than half (55%) of the adolescent girls had prior knowledge regarding KSY Services. The study findings are supported by the studies conducted by Vishal R, et al. in Sewapuri block of Varanasi district in U.P in 2014 and Thakur A, et al. in Palampur where the results revealed that 54% of the adolescent girls were in the age group of 15–18 years and same proportion of the subjects had educational qualification of 11–12 standard and 63.3% had prior knowledge regarding KSY.[4][5]
Section II: Analysis of knowledge of adolescent girls regarding KSY Services: The mean percentage of 43.68 depicts that the subjects had inadequate knowledge regarding KSY Services. The overall grading of knowledge score showed that one-third of the subjects (75%) had inadequate knowledge and rest (25%) of the subjects had adequate knowledge regarding KSY Services. Highest percentage of knowledge was seen in the domain of eligibility of KSY (54%) and least knowledge percentage was seen in the domain of administration of KSY (22%). The study findings are opposed by a study conducted by Vishal R, et al. in Sewapuri block of Varanasi district in U.P in 2014 where the results showed that all adolescent girls were aware about the KSY Services. They also specified that appliances were made available to the beneficiaries of KSY for income generation.[4]

Section III: Analysis of perception of adolescent girls regarding KSY Services: The present study interpreted that majority (71%) of the subjects had unfavorable perception towards KSY Services. Highest percentage of perception was seen in the domain of perception related to benefits (74%). The least perception percentage was in the domain of perception related to benefits (67%).

Section IV: Association of knowledge score and perception score of adolescent girls regarding KSY Services with selected demographic characteristics: The findings of the present study revealed that there was a significant association between knowledge of adolescent girls regarding KSY Services and age ($\chi^2=8.30$, $p=0.016$), annual family income ($\chi^2=34.28$, $p=0.001$), previous knowledge ($\chi^2=18.43$, $p=0.001$) and source of knowledge ($\chi^2=43.71$, $p=0.001$). There was no significant association between perception scores of adolescent girls regarding KSY Services and selected demographic characteristics. and rest of the demographic characteristics have no significant association. The study findings are consistent to a study conducted by Thakur A, et al. in selected schools of Palampur in 2015 where the results revealed that there were significant association of

age and the source of knowledge with knowledge level of adolescent girls regarding KSY. [5]

Conclusion

The study concludes that if the adolescent girls are provided with some sort of educational interventions such as information booklets, teaching programmes, modules on KSY Services will definitely update their knowledge and develops favourable perception towards KSY Services, which in turn contribute to improve the total quality of one’s health.

Factors Affecting Immunization Coverage of Children in Rural Area in Tamil Nadu

Janani Jeevaraj1, Jahnavi Narayanan1, J. Sharon Preethi1, B. Charumathi2, Ruma Dutta3, Timsi Jain4

1Final year MBBS Students, 2Post Graduate, 3Associate Professor, 4Professor and Head, Department of Community Medicine, Saveetha Medical College Hospital, Thandalam, District Kanchipuram

Abstract

Background: Vaccine preventable diseases (VPDs) are one of the greatest causes of morbidity and mortality among children in India. They are still responsible for over 0.5 million deaths annually in the country. Worldwide, about 2.5 million deaths of under-5 children are averted annually by immunization.

Objectives: To assess the current status of immunization of children during the first year of life and analyze the factors affecting immunization coverage during the first year of life in Kuthambakkam district in Tamil Nadu.

Methodology: A descriptive cross-sectional study was conducted in Kuthambakkam village in Tamil Nadu. The Sample size of 195 was calculated. The study population was selected by simple random sampling technique. A pre-designed, pre-tested semi-structured questionnaire was used to collect data after obtaining informed consent. Data entered in MS excel and analyzed using proportion.

Results: Out of the 195 cases studied, 87% of the children were completely immunized, 12% were partially immunized and only 1% was non-immunized. 59% had adverse effects following immunization (AEFI) and 39% waited for more than 1 hour to be immunized, but 94% were satisfied with the services they received. 41% of the mothers and 37% of the fathers received education up to a secondary school level, and 57% of the respondents worked in skilled and semi-skilled professions.

Conclusion: The delivery of routine immunization services to Indian children appears to have improved. Regular systematic reviews of the immunization coverage data and expansion of vaccination services are recommended.

Keywords: Immunization, childhood vaccination trends, inequity, immunization coverage.

Introduction

Vaccine preventable disease (VPD’s) is one of the greatest causes of morbidity and mortality among children in India. Vaccines not only protect children from potentially fatal illnesses, but also prevent disease transmission in a community1.

However, in India, VPD’s are still responsible for over 0.5 million deaths annually2. In 2003, the UN Millennium Declaration had outlined the reduction of under-five mortality as one of the eight goals with proportion of 1-year-old children immunized against measles as one of the monitoring indicators (UN 2003).

The World Health Organization (WHO) launched the Expanded Immunization Programme (EPI) in 1974 to prevent nine major VPDs namely tuberculosis, diphtheria, whooping cough (pertussis), tetanus, polio, measles, mumps, rubella and hepatitis-B3. It was subsequently renamed Universal Immunization Programme (UIP) in 1985. India was one of the first countries to adopt the programme in 1978. Since its inception, considerable progress has been made in terms of reduction in disease burden2.
However, despite being operational for over 30 years, UIP has been able to fully immunize only 65% children in the first year of their life. Mission Indradhanush has been launched by the Health & Family Welfare Ministry of India, with the aim to immunize all children under the age of 2 years, as well as all pregnant women, against the nine VPDs. The Mission is to be implemented in 201 high focus districts in the first phase, where nearly 50% of all unvaccinated or partially vaccinated children reside. Mission Indradhanush aims to achieve 90% immunization of children by 2020. There are wide coverage disparities between the rich and the poor and between urban and rural children. There is wide inter-district, intra-district, urban-rural and rich-poor difference with respect to immunization coverage. This variation indicates a service coverage gap and reinforces the fact that those who need these services the most are the ones who are also neglected the most.

Despite a steady rise in overall immunization coverage, children living in rural areas sands lumsre main in completely immunized. Children who are not immunized on time are more likely to be from families of low socio-economic status and having low parental educational level. These factors suggest the need for further investigation into specific populations and the identification of barriers within different subgroups.

Assessing immunization coverage helps to evaluate progress in achieving programme objectives and in improving service delivery. Equity in immunization should not be restricted to merely creating equal opportunities for immunization of children within the country. It should also identify the groups at highest risk of remaining unvaccinated and thereby bridging these gaps and imbalances as far as possible. Hence a systematic assessment of childhood vaccination trends must be undertaken to identify inequity in childhood routine immunization in India and to explore the reasons for the same.

Material and Method

A descriptive cross-sectional study was conducted in Mappedu village in Tamil Nadu. The study was conducted by interviewing heads of household who were selected randomly after the sample size calculation. Assuming 60% prevalence of primary immunization, with allowable error of 7%, the sample size of 195 was calculated using the formula \(4pq/L^2\). Data was collected and the necessary details were sought in terms of age, sex, place of immunization, source of information, satisfaction level, parents’ education and socioeconomic status. Information regarding immunization status was obtained on the basis of documentary proof (immunization card) and if card was unavailable, status was determined by enquiring about received vaccines.

According to WHO guidelines, a fully immunized child was defined as the one who had received one dose of Bacillus Calmette Guérin (BCG), three doses of oral polio vaccine (OPV) (excluding Polio 0), three injections of diphtheria-pertussis-tetanus (DPT), and one dose of measles before first birthday and who had not received even a single dose were considered as non-immunized. Those children who had missed at least one dose were considered as partially immunized.

The collected data were entered into Microsoft Excel. Analysis was done using SPSS.21 software and the results were interpreted in terms of percentage, mean, chi-square and z-test.

Results

(a) Socio-demographic Profile: Out of 195 children, 102 (52.3%) were male and 93 (47.7%) were female. Modified Kuppuswamy scale was used to assess the socio-economic status of study population. Majority of the population belonged to lower middle class (32.81%). With regards to education status, 80 (41.0%) of the mothers received a High School level of certification. Maximum number of fathers 73 (37.4%) received a High School certification. The study found that majority of the people worked in skilled 57 (29.2%). Majority of the population are Hindu 164 (85.6%), followed by Christian 27 (13.8%) and only 4(2%) being Muslim. (Table 1).

(b) Immunization status: Out of 195 respondents who were surveyed, 171 (87.7%) of the total were fully immunized and 24 (12.3%) were partially immunized. Only 1(0.5%) was non-immunized. (Figure 1).

![Figure 1: Immunization status of children](image-url)
With respect to the place of immunization, 84 (43.1%) respondents reported availing of the services of Government hospitals, while 46 (23.6%) and 36 (18.5%) respectively reported use of public health dispensaries and private clinics respectively. Only a small minority of 13 (6.7%) of children were immunized at home by health care workers.

76 (39.0%) respondents reported waiting for more than 1 hour in order to avail of immunization services. 60 (30.8%) waited for at imeperiodranging from 30 minutes to an hour. Only 42 (21.5%) waited for less than a half hour in order to get immunized.

The cross tabulation between the socio-demographic profile of the respondents and their immunization status was done, and assessed using the chi-square test.

Table 2 shows that there is statistically significant association between the immunization status and the gender of the child with P = 0.0011 (P < 0.05) as well as between the immunization status and the socioeconomic classification of the respondents with P = 5.5919 (P > 0.05).

Source of information: An overwhelming majority of the respondents received information regarding immunization services and schedules from clinicians and health care workers 155 (79.5%). 16 (8.2%) received health information from their families, and 12 (6.2%) from their neighbors and friends.

(c) Reasons for incomplete immunization: 12 (48.2%) of the respondents reported missing the government schedule for vaccination then finding it too expensive to vaccinate elsewhere at private clinics. 5 (20.6%) of the partially immunized children reported transportation difficulties. The guardian of the non-immunized child reported that she did not believe that her child needed vaccines hence did not immunize him.

114 (58.5%) of the respondents’ children had adverse effects following immunization (AEFI). When asked to enumerate the symptoms most respondents mentioned mild fever which was immediately relieved on taking medication.

However, only 11 (5.6%) of the respondents showed any dissatisfaction with the immunization services offered to them, with 183 (93.8%) feeling that the services afforded to them were satisfactory.
Discussion

The results of the present study revealed that 87% of the children, a majority of the respondents were completely immunized. 12% were partially immunized and only 1% of the children were non-immunized. This contrasts with the results of a similar study conducted by Santosh K. Prusty et al in urban slums in Odisha\(^2\) and Rup Kumar Phukan et al in Assam\(^4\).

The disparity in the immunization status between different states can be attributed to the higher literacy levels among South Indians compared to their Northern counterparts\(^9\), as well the relative success of programs like Universal Immunization Programme and Mission Indradhanush.

59% of the respondents’ children had adverse effects following immunization, which is considerably less than the 75% reported in studies in Odisha\(^2\). 39% reported waiting for more than 1 hour in order to avail immunization. Interestingly, only 6% showed any dissatisfaction with the services offered. This could be indicative of low-level of expectation among slum-dwellers from public health delivery system and lower level of understanding about quality of services.

When asked about sources of information regarding vaccines, 79% respondents largely attributed it to clinicians and health care workers.

In terms of literacy level of respondents, 41% of the mothers received a secondary level of education 22% of them received a primary level. This correlates with the study conducted in Odisha\(^2\) but is contradicts the level of literacy among mothers in the Assam study\(^4\).

The literacy level of mother has important role for better immunization coverage of the children. With respect to the fathers, 37% and 21% respectively received secondary level and primary level of education. The close association between parental, especially maternal education has also been documented in other studies from India and other developing countries.

With respect to the occupation the respondents were employed in, a total of 57% work in skilled and semi-skilled professions, with only 27% working in well-paying professional or semiprofessional jobs. This can be attributed to the rural setting of the survey, as well as affects the overall economic status of the family and their ability to access quality health care for them and their families.

Accordingly, a majority 32% of the respondents fell into the Lower Middle class (class III) by Kuppuswamy classification, with only 25% and 22% belonging to the Upper (class I) and Upper Lower classes (class IV) respectively. In general, people with higher socioeconomic status are more educated, have higher incomes and are more likely to be aware of the importance of immunization than those of a lower class. They also have better everyday access to health care, particularly through the private sector. Such similar findings are echoed by the study conducted by Rup Kumar et al in Assam\(^4\).

Conclusion and Recommendations

Total number of children surveyed is 195, out of which 52% were male and 48% were female. 87% of the children were completely immunized, 12% were partially immunized and only 1% were non-immunized. 59% had adverse effects following immunization and 39% waited for more than 1 hour to be immunized, but 94% were
satisfied with the services they received. 41% of the mothers and 37% of the fathers received education up to a secondary school level, and 57% of the respondents worked in skilled and semi-skilled professions.

The much higher vaccination coverage in this study reflects the efforts made by the Government of India to review the pre-existing data on state- and national-level vaccination coverage systematically and dramatically improve vaccine provision and documentation at all levels. Although these results indicate there have been substantial increases in coverage, much work is still needed to reach Mission Indradhanush’s coverage goals.

Recommendations for further improving immunization coverage in this community include regular vaccine supervision, more frequent assessment of vaccine coverage and continuous education of women at health facilities and in schools. Improvement in female literacy coupled with the reduction in the dropout rate would add to achieve a higher target of immunization. To strengthen the accuracy of vaccination coverage estimates, more attention should also be paid to immunization card retention. Additionally, improvement in vaccine information dissemination by clinicians and health care workers, and dispelling of taboos and myths regarding vaccination would be an affective foothold in achieving our nations’ vaccination goals.

Awareness of Parents of Children with Congenital Heart Disease about Oral Health and Disease

Deepti Anna John¹, Jayanth Kumar Vadivel²

¹Undergraduate Student, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, Tamil Nadu, India, ²Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, Tamil Nadu, India

Abstract

Introduction: Congenital defects of the heart are considered to be one of the common malformations in new-borns but with the advancements made in medicine has improved the quality of life in these patients, still Infective endocarditis is considered to be a major complication of this disease. Transient bacteraemia induced due to dental procedures put these patients at a risk, hence proper oral health care and awareness should be provided. The aim of the article is to find out the perception parents of children with congenital heart disease towards general oral health and to assess their knowledge about the association of cardiac health and oral health.

Materials and Method: Questionnaires containing 15 questions were given to 20 parents of children with congenital heart disease at Madras Medical Mission and Frontier Lifeline Hospital, Chennai, Tamil Nadu, India.

Results: It was shown that very few parents knew about infective endocarditis and lacked the awareness of the connection between Oral disease and cardiac disease.

Conclusion: A lack of oral health education are being provided to the children with cardiovascular disease and their parents, therefore provides an opportunity to improve the treatment outcomes and oral hygiene care.

Keywords: Congenital heart disease, Oral health, infective endocarditis, oral disease, awareness.

Introduction

“Congenital heart defect” is defined by Mitchell et al. (1971) as “a gross structural abnormality of the heart or intrathoracic great vessels that is actually or potentially of functional significance” (Mitchell, Korones and Berendes 1971). Congenital heart disease(CHD) is one of the major causes for infant mortality worldwide with a birth prevalence of 4-8 per 1000¹. In India, there is no database about the incidence rate of CHD as most of the births take place at home without any medical supervision, so the birth prevalence is a low as 2.5 per 1000 births.² However, progress in cardiovascular diagnostics in the past few decades have improved the survival rates for many children with CHD Innovations in surgical and anaesthetic techniques with extensive development in paediatric care have improved treatment and care for CHD patients, but as these children reach adulthood, they form new patients with various individual needs that need constant medical surveillance.³,⁴ As the dental health of these children with CHD is compromised due to the attention given to the systemic disease, they are at a risk for many complications. CHD affects dental health either in dentition, increased of infective endocarditis or implications of treatment delivery Method.⁵
Many children with CHD have issues with nutrition with vomiting as the most common problem. In order to treat the issue, frequent meals and night feeds are given to maintain nutrition and often the medication given for heart disease contain sucrose can cause xerostomia. Systemic diseases that occur during the formation of the teeth, can lead to defective formation of the teeth such as thinner enamel because the ameloblasts that lay the enamel are extremely sensitive to metabolic changes. These findings were seen in studies done in children with lower body weights and children suffering from CHD. Hence the teeth of the children with CHD is more susceptible to dental caries and are more difficult to restore than healthy individuals, so proper planning and treatment is required.

Transient bacteraemia is a major risk factor for infective endocarditis, which occur due to dental procedures. Some recent studies have found that only one -eighth of the patients with infective endocarditis have had a dental procedure done prior to the onset of the symptoms. Hence even everyday activities such as brushing teeth or chewing food can also be a cause for transient bacteraemia. Oral Streptococcus mutans is considered as the organism responsible for infective endocarditis and accounts for two fifth of the cases in children. Infective endocarditis is caused by endothelial damage due to CHD and cause deposition of fibrin and platelets which form a non-bacterial thrombotic endocarditis which in an environment of bacteria can become infective endocarditis. Antibiotic prophylaxis before any dental procedure is mandatory for CHD patients but importance of good dental health should be instilled.

Despite all the advancements, not much importance is given to dental health due to lack awareness and understanding of the co-relation between CHD and oral health, since the key to protection is improved dental health awareness and hygiene so that the complications can be kept to a minimum. The purpose of this study is to assess the level of understanding about oral health and congenital heart disease of the parents of children with CHD.

Materials and Method

Patients: A total of 20 children with various kinds of congenital heart disease was included in the study. All the patients were in and out patients of the Department of Paediatric Cardiology at Madras Medical Mission and Frontier Lifeline, Chennai, Tamil Nadu, India. All patients with CHD were included, whereas children with cardiac dysrhythmia were excluded.

Study Design: The study was based on the null hypothesis that the parents of children with CHD were not aware of the relation of congenital heart disease and oral disease and health. The questionnaire used, is from a study done by Steffen Koerdt et al at the Department of Paediatric Cardiology and Congenital Heart Defects at the German Heart Centre, Munich of the State of Bavaria and the Technical University of Munich, Germany which was developed by paediatric cardiologist and two dentists. The study was designed according to the guidelines of the Declaration of Helsinki. The questionnaire consists of 15 close ended questions.

All parents were informed and written consent was obtained from them.

Data Collection and Analysis: The data collected was analysed using IBM SPSS 16 software (IBM Corporation, United States of America) and the frequencies and percentages for the different questions were calculated.

Results

In the study, a total of 20 parents of children with CHD participated, out of which 12 (60%) were boys and 8 (40%) were girls, all the participants were the parents of the outpatients at Madras Medical Mission and Frontier Lifeline, Chennai, Tamil Nadu, India. The mean age for the children were 11± 4 years (range 2-17 years old). The distribution in age group was 10 (50%) 2-5 years old, 6 (30%) 6-12 years old and 4 (20%) 13-17 years old.

Regarding the questions of general dental health, the following were answered as, only three (15%) of the children visit the dentist once a year, three (15%) visit the dentist less than one year and the remaining fourteen (70%) have never visited the dentist. In terms of receiving dental treatment only two (10%) have received dental treatment, where one patient had an extraction done and the other patient did a restoration done. One child (5%) received antibiotics in the context of dental
treatment and five (25%) were unsure if they were given antibiotics. Thirteen children (65%) brush their teeth once a day, six (30%) brush twice a day and only one (5%) brushes thrice a day. Fifteen parents (75%) never check the oral hygiene of their children, only four (20%) check the oral hygiene once a week and one parent (5%) checks the oral hygiene daily. Ten children (50%) use fluoride supplementation through toothpastes. None of the twenty children have undergone orthodontic treatment. Five children (25%) have more than two sweets per day and eight children (40%) have one or two sweets per day. Seven children (35%) consume sweetened beverages at least once a week.

Regarding the questions related to CHD, fourteen parents (70%) were informed about oral health by their doctors when their child was first diagnosed with CHD and seven parents (35%) gave importance to oral health due to CHD.

A study stated that two fifth of the children has untreated dental caries which increases their risk to transient bacteraemia because of the requirements and reluctance of the dentist. This surprising percentage accounts for the misinformation of the parents. In addition, regular visits to the family dentist are less frequently than in the recommended guidelines in this current study. This is in accordance with the results of Balmer and colleagues. In 1997, Das M et al reported that children with CHD had more severe gingivitis with more accumulation of plaque. Similarly, Hobson and Slattery found that one third of the 69 children examined had well established periodontal disease and half of them had untreated dental caries. Parry and Khan in 2000, sent out questionnaires to 524 dentists to get their opinion about treating medically compromised patients and found that in a five-year period most dentists come across only 2 patients with congenital malformations and one third of the practitioners felt confident in treating these patients.

A study conducted by Hallett et al, he found that children with CHD had a significantly higher prevalence...
of mesiocclusion and crowding, compared with unaffected children. Enamel hypoplasia and dental neglect was seen in a child with tetralogy of Fallot and also facial dysmorphism is also seen in many of the cases. It also possible that the enamel hypoplasia could be due to the systemic disturbances such as cardiac failure and surgical complications due to congenital heart disease during pre- neonatal and neonatal growth.

In India, very few children with CHD are properly diagnosed and reach tertiary and quaternary healthcare centres and receive proper treatment for their disease, and majority of the parents of these patients are unable to afford treatment. Therefore, oral health care is not given much importance because of limited medical and dental resources.

According to Soble et al, all medically compromised patients should be considered handicapped even if they have normal oral status but their medical condition prevents them from receiving regular dental treatment. In conclusion, the dental health should be given utmost importance as it can put the general health of the individual at risk, guidelines have been given for medically compromised patients who have a risk of getting dental caries and this risk is higher for patients who already have dental caries. Although it also, it is possible that the patients with CHD indulge more frequently in sweets and snack foods due to their chronic illness, the aetiology of Infective endocarditis and CHD is closely related, hence oral hygiene maintenance should be taken care of, especially in older individuals with CHD as it will improve the quality of life in both general and oral health. The study was done to evaluate the parents of the children with CHD about the connection of CHD and oral health and general dental health.

**Conclusion**

From the study, it is seen that the perception towards general oral health and knowledge about the connection between oral health and cardiac disease is poor. But can be improved if dentists are specifically trained to treat medically compromised patients and a system be introduced where it is mandatory for a dental appointment where immediate access to treatment is possible.

Effectiveness of Coordination Exercise on Dynamic Balance of Knee Injured Male Professional Footballers

Jibi Paul¹, M.S. Nagaraj², John Solomon³

¹Professor, Faculty of Physiotherapy, Dr M.G.R. Educational and Research Institute University, Chennai, ²Professor, Faculty of General and Adapted Physical Education and Yoga, Coimbatore, ³Associate Professor, School of Allied Health Sciences, Manipal University, Manipal

Abstract

Background of the study: Motor coordination is associated with timed movement of several limbs or parts of body to achieve a smooth and efficient action with respect to the intended goal. This research was aimed to find the effect of coordination exercise on dynamic balance of knee injured professional male footballers with specific intervention strategies.

Methodology: Total 106 professional footballers were selected on the base of inclusion and exclusion criteria. The samples were randomly divided equally in to experimental and control group for the study. The experimental group received coordination exercises and the control group received traditional stretching and strengthening exercises. Dynamic balance for right and left lower limbs were evaluated for both group.

Results: Dynamic balance significantly improved in experimental group after coordination exercise. F ratio for right and left side was 42.36 and 112.31 respectively, which are more than the table value 3.024, so they are significant at 0.05 level.

Conclusion: The study concluded that coordination exercise can improve dynamic balance of knee injured male professional footballers.

Keywords: Footballers; Knee injury; Dynamic balance; Coordination.

Introduction

Football or Soccer is a most popular sport in the world. The majority of teenagers play this sport, as a result of forces generated and mismatch in body sizes injuries to various body parts are common. Anterior Cruciate Ligament injuries are very common in footballers. Sudden change in direction of movement while running and landing from a jump may cause tears in the ACL.

Motor coordination is associated with timed movement of several limbs or parts of body to achieve a smooth and efficient action with respect to the intended goal. The integration of neural processes in the brain and spinal cord are necessary for the real proprioceptive information on position and movement of the musculoskeletal system which control, plan and relay motor commands.

Balance is defined as an ability to maintain the line of gravity of a body within the base of support and minimal postural sway. Postural sway is described as the horizontal movement of the body in the centre of gravity even when a person is standing still. Many studies have proved the effect of balance training on prevention of knee injuries and its effect on dynamic balance of lower limbs among male professional footballers.

This research was aimed to improve dynamic balance of knee injured professional male footballers with coordination training using appropriate intervention strategies. Effectiveness of specific exercise has
been assessed by intervention strategies targeted on neuromuscular and biomechanical variables for reducing injury rates.

Methodology

**Study design and setting:** This was an experimental study with randomized control trial conducted during 2013-2014. 106 samples were selected for this study based on selection criteria. The selected samples were randomly divided equally into experimental and control group. The experimental group received coordination exercises and the control group received traditional stretching and strengthening exercises. Study samples selected from football clubs of Subang Jaya, Petaling Jaya, Sungai Buloh, Selangor, Shah Alam, Sepang and Klang football association of Malaysia.

**Selection Criteria**

**Inclusion criteria:** Professional Footballers were with minimum one year of experience and males with age group between 20 and 35 years. Footballers with full range of movement (0 to 140°) at both knee joints and with previous twenty weeks history of knee injuries along with hip and ankle injuries graded one and two as per Dr. Frank Gillard., et al. were selected for this study.

**Exclusion criteria:** Footballers with knee injury associated with menisci or cartilage tears within six months and medically not fit to play football. Footballers with inflamed knee joints due to any underlying pathology were excluded from the study.

**Measurement Outcome:** All the samples of control and experimental groups were measured for dynamic balance score of both lower limbs. Dynamic balance of all the samples was measured using Star Excursion Balance test in eight directions.

**Study Materials:** Computer, ladder drill sports equipment, step board, table, marker pen, measuring tape, injury record form and colour adhesive tape.

**Procedure of intervention program:** The control and experimental group trained under the supervision of coach and physiotherapist for three days per week for 16 weeks and follow-up for 12 weeks. Any joint injury in hip, knee and ankle of lower limbs during the training period and league matches were recorded for data collection.

**Intervention for Control Group:** Control group performed stretching exercise for 15 minutes with an interval of 3 minutes rest followed by strengthening exercises for 25 minutes with an interval of 10 minutes rest.

1. **Stretching exercises:** Stretching exercise included four repetitions and holds 15 seconds for six groups of right and left side muscles (trunk flexors, hip flexors, hip adductors, quadriceps, hamstring and calf muscles). Fifteen (15) seconds of rest provided after each set of stretching exercises. Stretching exercise performed for 15 minutes including rest period. The stretching exercises were; 1. Right and left trunk side flexor stretching. 2. Right and left hip flexor stretching. 3. Right and left hip adductor muscle stretching. 4. Right and left quadriceps stretching. 5. Right and left hamstring stretching. 6. Right and left calf muscle stretching.

2. **Strengthening exercises:** Strengthening exercise included three repetitions with 30 seconds held for five groups of right and left side muscles (hip extensors, abductors, adductors, quadriceps and calf muscles). Sixty (60) seconds of rest provided after each muscle group strengthening exercises. Strengthening exercise performed for 25 minutes including rest period. The exercises were; 1. Right and Left hip extensor strengthening. 2. Right and Left hip adductor muscle strengthening. 3. Right and Left hip abductor muscle strengthening. 4. Right and Left quadriceps muscle strengthening. 5. Right and Left calf muscle strengthening.

**Intervention for Experimental Group:**

Experimental group performed eight coordination exercise program. Each program was performed for 05 minutes with adequate interval of rest. The exercises included were; 1. Single leg cross jump (X Pattern). 2. Single leg step jump. 3. Single leg forward-backward right and left jump (V Pattern). 4. Single leg jump to right and left side. 5. Double leg forward jump on marking. 6. Double leg forward-backward right and left jump (V Pattern). 7. Double leg right and left lateral jump. 8. Carioca cross over exercise.

**Results**

The demographic data for age of control group and experimental group were 25.89 ± 5.10 and 24.57 ± 4.75 respectively. Professional players experience for control group and experimental group were 6.26 ± 4.97 years and 5.60 ± 4.61 years respectively.
Dynamic balance score for right and left lower limb has been analyzed separately to find the outcome of the study. The mean of dynamic balance score has increased from 57.86 to 61.08 and from 57.63 to 61.55 respectively on pretest to post test of right and left lower limb. Standard deviation has reduced from 9.63 to 9.53 and from 9.82 to 9.55 respectively on pretest to post test of right and left dynamic balance score of experimental group.

**Table-1: One way repeated measures analysis of variance result on dynamic balance of right and left lower limb for pretest mid test and post-test of experimental group.**

Table 5 shows the obtained F ratio for dynamic balance score at right and left lower limbs are 773.302 and 677.515 respectively, which are more than the table value of 3.85 so they are significant at 0.05 level.

**Discussion**

In our study the dynamic balance of right and left lower limb has significantly increased after coordination exercise in experimental group. F ratios for right and left side were 1119.34 and 1874.01 respectively. In control group there was no significant difference in effect on improvement of dynamic balance between right and left side of lower limbs. F ratio for right and left side is 2.296 and 2.949 respectively.

Newman Keuls post hoc test for the differences between treatment means of pretest, mid test and post-test on dynamic balance score for left lower limb of coordination exercise group. The mean difference (3.217) of pretest and post-test on dynamic balance score for right lower limb of coordination exercise group is more than the critical value (0.186), so it is significant at 0.05 level.

Analysis of covariance used to compare dynamic balance between control and experimental group for right and left lower limbs found significant difference in effect in increase of dynamic balance. The table value required for significance at 0.05 level with df 845 is 3.85.

Coordination exercises improve neuro-muscular control thereby increase dynamic balance among the athletes. Many studies have found the effects of jump and balance training on knee kinematics and electromyography of athletes during a single limb drop landing. A study on balance board training has reported that, which can prevent traumatic injuries of the lower extremities in female soccer players. A study on balance board training for prevention of traumatic injuries of the lower extremities in female soccer players have shown significant improvement in their balance index standing on the non-dominant leg with extended knee.

A meta-analysis study included 270 articles matching their criteria with effect of balance training programs included were the use of tilt boards, unstable surfaces and dynamic body movements while maintaining a static stance. The study was concluded that there was significant improvement in static and dynamic balance after the prescribed balance training program.
A study on proprioceptive balance training for 6 weeks progressive wobble board balance training for 4 weeks have shown there was significant improvement in static and dynamic balance for the intervention group. Static balance was improved from base line 20.7s to 30.5s, dynamic balance from base line 2.3s to 4.0s.

**Conclusion**

The study concluded that coordination exercise can improve dynamic balance of knee injured male professional footballers, which might be due to increased neuron-receptive mechanism in knee joint and neuromuscular coordination of lower limbs.

**Ethical Approval:** There was no ethical issue from the Rama Krishna Mission Vivekanandha University, Coimbatore to conduct this study. The researchers have received no objection letter from each footballers association and informed consent from each participant to conduct this study.

**Conflict of Interest:** There was no conflict of interest for any researcher to conduct this study.

**Source of Fund:** Self managed with all the expenses towards conduct of this study.

Evaluation of Muscular Endurance among Dentists

Abigail\textsuperscript{1}, Jothi Priya\textsuperscript{2}, Gayatri Devi\textsuperscript{3}

\textsuperscript{1}Undergraduate student, Saveetha Dental College, \textsuperscript{2}Assistant Professor, Department of Physiology, \textsuperscript{3}Assistant Professor, Department of Physiology, Technical Sciences, Poonamalle, Chennai, India

Abstract

\textbf{Introduction:} Dental surgeons often cannot avoid prolonged static postures. Even in optimal seated postures, more than one-half of the muscles of the body are contracted statically. This may result in damaging physiological changes that can lead to back, neck, or shoulder pain or MSDs. The aim is to determine the muscular endurance among dentist and to compare dentists with and without occupational cervicobrachial disorders.

\textbf{Materials and Method:} This study is questionnaire based survey. The survey comprises of questions pertaining to the muscular endurance among dentists. This survey was administered to the participants through a survey planet link. 100 people responded this survey. Based on the responses the results obtained and statistically analysed.

\textbf{Results:} The study reveals that the majority of the dentist had musculoskeletal skeletal disorders which in turn affected their practice.

\textbf{Conclusion:} The physical load among dentists seems to put them at risk for the occurrence of musculoskeletal disorders. Many dentists experience the MSDs, especially in cervical region, as a consequence of occupational stresses. Therefore, detecting occupational risk factors, standards of work position, regular exercise and following ergonomic policy are intensely recommended. Prevalence of musculoskeletal symptoms among dentists represents a major occupational health issue for dentists and result revealed necessitates the need of workshops to create awareness of ergonomics as effective measures for reducing MSD among dentists.

\textbf{Keywords:} Dentists, musculoskeletal disorders, physical load.

Introduction

Muscular endurance is the ability of a muscle or a group of muscles to exert force repeatedly against resistance. It is one of the components of muscular fitness, along with muscular strength and power. Musculoskeletal Disorders or MSDs are injuries and disorders that affect the human body’s movement or musculoskeletal system (i.e. muscles, tendons, ligaments, nerves, discs, blood. Other common names for MSDs are “repetitive motion injury”, “repetitive stress injury”, “overuse injury” and many more. MSD is prevalent world over and is one of the commonest causes of long-term pain and disability affecting hundreds of millions of people. This fact has been recognized by World Health Organization (WHO) and United Nations with their endorsement of the Bone and Joint decade 2000–2010 [1]. The common risk factors which contribute to the development of health disorders can be categorized as those related to personal background variables (e.g. anthropometric characteristics, age, hereditary factors) and those related to work (e.g. repetitive motion, static posture, force, awkward position, vibration, temperature, biological factors, chemical irritating or toxic factors, radiation)\textsuperscript{[2,3]}

In the present society many groups develop several disorders related to muscular endurance. Athletes, people who work in IT companies, teachers, nurses, dentist are such groups. The reason as to why dentists were chosen for
this survey is in order to find out whether the occupation has a major influence towards such disorders. The major risk factors associated with musculoskeletal disorders in dentists are repeated unidirectional twisting of trunk (repetitive movements), working in static postures for prolonged period (prolonged static postures), awkward work postures, less flexibility and less core strength (muscle imbalances)\cite{4,5,6}. Dentistry is a demanding profession involving high degree of concentration and precision. Dentists require good visual acuity, hearing, depth perception, psychomotor skills, manual dexterity, and ability to maintain occupational postures over long periods\cite{7}. As a dentist it is the required level of control and accuracy, that requires the dental professional to maintain a rather controlled and static posture for these extended periods of time. Physiologically, a sustained tension on a muscle for extended periods of time with lack of rest cause ischemia and may lead to necrosis within the muscle\cite{8}.

It is revealed that approximately 81\% of American dentists suffer from neck, shoulder and lower back pain\cite{9}. Comparing the prevalence of upper body symptoms of pathological conditions in dentists and people who work in a different environment, such as farmers, pharmacists and office employees, the symptoms occurred more often among dentists\cite{10,11}. These are all due to the common dental posture; seated with a forward lean, lateral neck flexion with rotation and arm abducted. It is revealed that Psychological stress, when dealing with patients as well as high concentration and precision, is associated with an increased risk. Their work includes risk factors that may lead to many pathologies such as tendinitis, synovitis, tenosynovitis, and bursitis\cite{12,13}. Occupational diseases have not only physical, psychological, and social consequences, but also economic and security impacts when they reach a level of severity that directly affects work capacity, causing absences and early retirement. If regularly occurring pain or discomfort is ignored, the cumulative physiological damage can lead to an injury (macro change) or a career-ending disability\cite{14}. A thorough understanding of the underlying physiological mechanism leading to these problems is necessary to develop and implement a comprehensive approach to minimize the risk of work-related injury\cite{15}.

It is essential that clinicians must become aware of the postures and positions into which they are placing themselves on a daily basis. Pain is not just an unavoidable consequence of either the aging process or being a dental professional. Biomechanical re-
education must be introduced, taking into consideration occupational, recreational, and daily activities. Oppositional movement patterns must be created to counteract imbalances and repetitive positions, hence the aim of my study is to evaluate the musculoskeletal disorders among dentists.

**Materials and Method**

This study is questionnaire based survey. The survey comprises of questions pertaining to the muscular endurance among dentists. The questionnaire involved information on the respondent’s job history, individual characteristics, physical and psychosocial risk factors at work, general health status, and the occurrence of musculoskeletal complaints. It also included individual characteristics and work history included questions on age, anthropometry, gender, family situation, duration of employment. This survey was administered to the participants through a survey planet link. There were about 100 people who had responded this survey and the results were analysed based upon their responses and the data were statistically analysed.

**Results and Discussion**

![Figure 1: Have you at any time during the last two months had (aches, pain) in the following region?](image)

Based on the survey, above pie chart reveals that over 59\% of the surveyed dentists experienced musculoskeletal pain in the neck region. 29\% dentist experienced pain in the shoulders. The prevalence of disorders in spine was found in 18.3\% of the studied group. Pain in thoracic area was reported by 5.2\% of respondents. Dentists are also exposed to psychological stress when dealing with patients due to the need to work with high concentration and precision, which is associated with an elevated risk of developing MSDs. As is already known, stress can increase muscle tension and cause pain, especially in the trapezius muscle\cite{16}.
Musculoskeletal disorders are a diverse group of disorders with regard to pathophysiology. The study reveals knee pain 46.7% as the most common complaint of the dental surgeons under study, followed by elbow and ankle/foot pain. Long working hours is considered to be correlated with job demand, which means that dentists have to maintain static and/or awkward postures for prolonged periods contributing to musculoskeletal overload and pain. It has also been suggested that a tight work schedule has been shown to lead to an elevated risk of developing neck and upper limb WMSDs.

Dental surgeons cannot avoid prolonged static postures. Even in optimal seated postures, more than one-half of the muscles of the body are contracted statically and there is little movement of the vertebral joints. This may result in damaging physiological changes that can lead to back, neck, or shoulder pain or MSDs. 37.9% dentist feel that this is the major reason for such disorders. 22% believe that lack of rest is the cause whereas the majority 40% feel that both the causes may attribute.

An average work day by the practitioner, has a huge impact on the body, and it carries with it a high prevalence for MSD. The above diagram reveals the number of patients examine per day. 55% examine 20-50 patients. 26% examine 50-80 patients. During forward flexion and rotation, a position often assumed by dental operators, the pressure increases 400%, making the structure susceptible to injury. As MSDs are known to increase with age, if dental professionals suffer pain at this point in their lives, the problem could grow, making it difficult for them to practice in the future. Strategies need to be developed that can help them to continue clinical practice without such problem.

The most common complaint amongst dentists is how MSD is impacting their personal life, and the lack of time between working periods for recovery. MSDs affects the physical, psychological, and social aspects of practitioners. This in turn impacts on their productivity and ultimately reducing the quality of life of the practitioners. According to the responses 56% feel that such disorders decreases their work efficiency. MSD has affected the practitioners as evident from the reduction in work activity, percentage taking sick leaves, consultations with doctor and hospitalization...
Conclusion

The physical load among dentists seems to put them at risk for the occurrence of musculoskeletal disorders. Many dentists experience the MSDs, especially in cervical region, as a consequence of occupational stresses. Therefore, detecting occupational risk factors, standards of work position, regular exercise and following ergonomic policy are intensely recommended. Prevalence of musculoskeletal symptoms among dentists represents a major occupational health issue for dentists and result revealed necessitates the need of workshops to create awareness of ergonomics as effective measures for reducing MSD among dentists.

A Study of the Evolution of Medical Education in Ancient India

Joyshree Das

Assistant Professor (Contractual), Barnagar College, Sorbhog, Assam

Abstract

The story of evolution of medical education is a long one, stretching from prehistoric to modern times encompassing man through different ages and phases of evolution, culture and civilization. Study of medical history is not only to express our debt to our predecessors but is important in understanding the advances that are now taking place in theory and practice of medicine. In this regards the present study attempts to find out the history of Indian medical education, to analyze the history of Ayurvedic medicine in India and to know the evolution of Indian medicine throughout the time. The entire study is based on the secondary data such as different books, journals, magazines, internet and different research papers.

Keywords: Medical Education, Ayurvedic Medicine, India.

Introduction

The story of evolution of medical education is a long one, stretching from prehistoric to modern times encompassing man through different ages and phases of evolution, culture and civilization. Study of medical history is not only to express our debt to our predecessors but is important in understanding the advances that are now taking place in theory and practice of medicine.

Objectives:

The objectives of this paper are:

1. To find out the history of Indian medical education.
2. To analyze the history of Ayurvedic medicine in India.
3. To know the evolution of Indian medicine throughout the time.
4. To know the nature of medical science in India.

Methodology:

The research method is very important in any research activity. The selection of research method to be used is of utmost importance in research process. The proposed study is conducted under the source method. The entire study is based on the secondary data such as different books, journals, magazines, internet and different research papers.

Results and Discussion

The Prehistoric Medicine: The ‘art of healing’ began thousands of years ago with the innovations of the primitive man trying to provide relief to those close to him, in sickness and suffering, motivated by feelings of sympathy and kindness. Prehistoric and primitive medicine was characterized by seeing and believing (mystic faith and magic). These are widened and developed into thinking and knowing in later ages.

In the absence of an obvious explanation, his limited intelligence attributed disease and other calamities to the anger of God, the invasion of the body by evil spirits or the influence of stars and planets. As a logical sequence, the medicine he practiced consisted in appeasing God by prayers and rituals and sacrifices, driving out evil spirits from the human body. There is also evidence that the prehistoric man improvised stone and flint instruments with which he performed circumcisions, amputations and repining of skulls. It is thus obvious that medicine in the prehistoric era (5000 B.C) was intermingled with superstition, religion, magic and witchcraft.

Elements of prehistoric medicine are still are still present in many countries. Primitive man may be extinct, but “the supernatural theory of disease” in which he believed is not yet extinct in our modern society.

Indian Medicine: Indian medicine has a long history. Hindu medicine is as ancient as Hindu Civilisation. Ayurveda by definition implies “The Science of Life”. Ayurveda is a Sanskrit word derived from two roots: ayur, which means life, and veda, knowledge. Its origin is traced back to the Vedic times about 5000BC. Ayurveda is a part of the Atharva Veda which solely deals with
medicine. Its earliest concepts are set out in the sacred writings called the Vedas, especially in the metrical passages of the Atharvaveda, which may possibly date as far back as the 2nd millennium BCE. Atharva Veda includes eight divisions of Ayurveda:

1. Kayachikitsa (Internal Medicine)
2. Salakya Tantra (Surgery of Head & neck, Ophthalmology and Otolaryngology).
3. Shalya Tantra (Surgery)
4. Agada Tantra (Toxicology)
5. BhutaVidya (Psychiatry)
6. Kaumarabhritry (Pediatric)
7. Rasayana (Anti-aging or Gerontology or Science of Rejuvenation) and
8. Vajkarana (The Science of Fertility)

AtreyaSamhita is the oldest medical book in the world. Atreya was the son of Rishi Atri. Atri was the son of god Brahma and one of the seven immortal Rishis in Vedic literature. Rishi Atri was Acharya (Teacher) of Ayurveda. The Vedic Brahmans were priests who performed religious rites and ceremonies. They were also considered as Vaidyas (Physicians of Ayurveda). These sage physicians were the surgeons in the ancient days. It is believed that the Vaidyas received their training of Ayurveda during meditation which were later transcribed into book form.

Beginning of Medicine and Surgery in India is thought as the gifts from god Indra to Sages Bharadwaja, the patron saint of medicine and Dhanvantari, the patron saint of Surgery. These two main schools made Ayurveda a more scientifically verifiable medical system (around 1500BC). These two scholars passed their knowledge to two worthy men Atreya and Susruta. The period of Vedic medicine lasted until about 800 BCE. The Vedas are rich in magical practices for the treatment of diseases and in charms for the expulsion of the demons traditionally supposed to cause diseases. The chief conditions mentioned are fever (takman), cough, consumption, diarrhea, edema, abscesses, seizures, tumors, and skin diseases (including leprosy). The herbs recommended for treatment are numerous.

The golden age of Indian medicine, from 800 BCE until about 1000 CE, was marked especially by the production of the medical treatises known as the Charaka-samhita and Sushruta-samhita, attributed respectively to Charaka, a physician, and Sushruta, a surgeon. Estimates place the Charaka-samhita in its present form as dating from the 1st century CE, although there were earlier versions. The Sushruta-samhita probably originated in the last centuries BCE and had become fixed in its present form by the 7th century CE of somewhat lesser importance are the treatises attributed to Vagbha. All later writings on Indian medicine were based on these works. Because Hindus were prohibited by their religion from cutting the dead body, their knowledge of anatomy was limited. The Sushruta-samhita recommends that a body be placed in a basket and sunk in a river for seven days. On its removal the parts could be easily separated without cutting. As a result of these crude method, the emphasis in Hindu anatomy was given first to the bones and then to the muscles, ligaments, and joints. The nerves, blood vessels, and internal organs were very imperfectly known the Hindus believed that the body contains three elementary substances, microcosmic representatives of the three divine universal forces, which they called spirit (air), phlegm, and bile (comparable to the humours of the Greeks). Health depends on the normal balance of these three elementary substances. The seven primary constituents of the body—blood, flesh, fat, bone, marrow, chyle, and semen—are produced by the action of the elementary substances. Semen was thought to be produced from all parts of the body and not from any individual part or organ.

Both Charaka and Sushruta state the existence of a large number of diseases (Sushruta says 1,120). Rough classifications of diseases are given. In all texts, “fever,” of which numerous types are described, is regarded as important. Phthisis (wasting disease, especially pulmonary tuberculosis) was apparently prevalent, and the Hindu physicians knew the symptoms of cases likely to terminate fatally. Smallpox was common, and it is probable that smallpox inoculation was practiced. Hindu physicians employed all five senses in diagnosis. Hearing was used to distinguish the nature of the breathing, alteration in voice, and the grinding sound produced by the rubbing together of broken ends of bones. They appear to have had a good clinical sense, and their discourses on prognosis contain acute references to symptoms that have grave import. Magical beliefs still persisted, however, until late in the classical period; thus, the prognosis could be affected by such fortuitous factors as the cleanliness of the messenger sent to fetch the physician, the nature of his conveyance, or the types of persons the physician met on his journey to the patient.
Dietetic treatment was important and preceded any medicinal treatment. Fats were much used, internally and externally. The most important Method of active treatment were referred to as the “five procedures”: the administration of emetics, purgatives, water enemas, oil enemas, and sneezing powders. Inhalations were frequently administered, as were leeching, cupping, and bleeding.

The Indian materiamedica was extensive and consisted mainly of vegetable drugs, all of which were from indigenous plants. Charaka knew 500 medicinal plants, and Sushruta knew 760. But animal remedies (such as the milk of various animals, bones, gallstones) and minerals (sulfur, arsenic, lead, copper sulfate, gold) were also employed. The physicians collected and prepared their own vegetable drugs. Among those that eventually appeared in Western pharmacopoeias were cardamom and cinnamon.

As a result of the strict religious beliefs of the Hindus, hygienic measures were important in treatment. Two meals a day were decreed, with indications of the nature of the diet, the amount of water to be drunk before and after the meal, and the use of condiments. Bathing and care of the skin were carefully prescribed, as were cleansing of the teeth with twigs from named trees, anointing of the body with oil, and the use of eyewashes.

In surgery, ancient Hindu medicine reached its zenith. Operations performed by Hindu surgeons included excision of tumors, incision and draining of abscesses, punctures to release fluid in the abdomen, extraction of foreign bodies, repair of anal fistulas, splinting of fractures, amputations, cesarean sections, and stitching of wounds. A broad array of surgical instruments was used. According to Sushruta, the surgeon should be equipped with 20 sharp and 101 blunt instruments of various descriptions. The instruments were largely of steel. Alcohol seems to have been used as a narcotic during operations, and bleeding was stopped by hot oils and tar.

In two types of operations especially, the Hindus were outstanding. Stone in the bladder (vesical calculus) was common in ancient India, and the surgeons frequently removed the stones by lateral lithotomy. They also introduced plastic surgery. Amputation of the nose was one of the prescribed punishments for adultery, and repair was carried out by cutting from the patient’s cheek or forehead a piece of tissue of the required size and shape and applying it to the stump of the nose. The results appear to have been tolerably satisfactory, and the modern operation is certainly derived indirectly from this ancient source. Hindu surgeons also operated on cataracts by couching, or displacing the lens to improve vision.

**Ancient history of Pathology in India**

**Nidanasthanam:** Of the six divisions of SusrutaSamhita, second division consists of sixteen chapters devoted to Pathology, mainly of surgical diseases. Nidana developed greatly in the 7th century and was established by Madhava Kara of Bengal. His Nidana as well as Charaka and SusrutaSamhita were translated in Arabic by the order of Haran al-Rashid (786-806 AD) the Khalif of Bagdad.

According to Wilson, it is likely that it might have been translated from the translation of the book in Persian language.

**Postmortem:** In Arthasastra of Kautilya (other name of Chanakya, the greatest politician of the time), there is a mention of postmortem. Ashumritaparikshagara (examination of men who recently died). These reports of inquest were also necessary in higher courts of law (KontakaSodhana) during the reign of the Great Emperor Chandragupta. The dead bodies in cases of homicide, suicide or those who died of accidents, were kept in an examination room, which was set apart for the purpose and the cause of death had to be reported after post-mortem examination to higher authorities. To prevent decomposition dead bodies were preserved by immersion in oil.

**Conclusion**

The Golden Age of Indian Medicine was between 800BC to 600AD. Learned men from different countries such as China, Tibet, Afghanistan, the Greeks, Romans, Egyptians, Persians came to the Indian Ayurvedic Schools to learn about this World Medicine. Ayurvedic texts were translated into Arabic by the physicians like Avicenna and Razi Sempion. Both of them quoted Indian Ayurvedic texts and established Islamic medicine “Unani System”. This Indian Ayurvedic System became popular in Europe and helped to form the foundation of the European tradition of medicine. Ayurveda grew tremendously during Buddhist Kings like King Ashoka (226 BC), who patronized Ayurveda as State Medicine and established Schools of Medicine and Hospitals. Charaka (200AD), the most popular name in Ayurveda
medicine was the Court Physician to the Buddhist king Kaniskaduring Buddhist time. Due to the doctrine of “Ahinsa” (non-violence) Indian Surgery suffered a setback. With the advent of Muslims in India, Hindu Medicine eroded due to the lack of State help and support by the rulers. Unani system of medicine was introduced into India by the Muslim rulers. By the 13th Century, Unani system of medicine was firmly established mainly in Delhi, Aligarh, Lucknow and Hyderabad. During Mughal period and subsequent years Ayurveda declined due to the lack of state support. With the advent of the British in the 18th Century Ayurveda system was revived in India along with Western system of Medicine.

Effectiveness of Structured Exercise Program on Functional Capacity and Quality of Life in Grade III Chronic Obstructive Pulmonary Disease Patients

Juhi Karne¹, Poovishnudevi T.², Monisha R.³

¹Intern, ²Associate Professor, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India, ³Assistant Professor, SRM College of Physiotherapy, Chennai

Abstract

Objective: To determine the effects of structured exercise program on functional capacity and quality of life in Grade III chronic obstructive pulmonary disease.

Method: A total of 35 subjects were screened as per inclusion and exclusion criteria and they were briefed about the study and interventions. Informed consent was taken from the subjects initially through the Borg scale and chronic respiratory questionnaire each subject taken as per data collection sheet. Subjects were selected by simple random sampling, lottery method & were allocated alternatively to group A and group B, who had Grade III COPD The amount of breathlessness was noted by Borg scale and chronic respiratory questionnaire.

Conclusion: Various recent approaches are used in the treatment of subjects suffering from grade III COPD, but this study concluded that combine effect of structured exercise program was effective in decreasing the levels of dyspnea and improving quality of life.

It is proved from this study that effectiveness of structured exercise program was effective in improving functional capacity and quality of life. Thus Alternate Hypothesis H (1) states that there is significant effect of structured exercise program in grade III COPD patients.

Keywords: Stretching and strengthening exercise, functional capacity, quality life, dyspnea.

Introduction

Chronic obstructive pulmonary disease (COPD) is a major cause of chronic morbidity and mortality worldwide. The 2002 WHO world health organization report listed chronic obstructive pulmonary disease as the fifth leading cause of death in the world. In 2001, the global initiative for chronic obstructive lung disease (GOLD) issued and now updates yearly guidelines that their aim is to improve prevention and management of chronic obstructive pulmonary disease through a concerted worldwide³: chronic obstructive pulmonary disease (GOLD) defines chronic obstructive pulmonary disease as common preventable and treatable disease characterized by predominantly fixed airway obstruction as a result of air exposure to inhaled noxious environmental particles or gases.

Clinical Feature: Although chronic bronchitis and emphysema frequently co-exist, rarely features of one type may be predominantly present.

In chronic bronchitis cough only during winter months over the year the cough become continue and episode of illness increase in frequency duration and severity progresses to peripheral edema secondary to overt right ventricular failure. Patients with chronic bronchitis are over-weight and cyanotic. Because the appearance these patients are referred to as ‘blue-bloaters’ in emphysema.
The body build is asthenia with evidence of weight loss. The patient use accessory muscle of respiration, which serves to lift the sternum in an anterior superior and breathes with pursed lips, there by prolonging expiration and increases the intrabronchiolar pressure to prevent the collapse of the airway by the surrounding distended alveoli. While sitting, the patient often leans forward extending his arms to brace himself. Patients with this condition  

Prevalance of Chronic Bronchitis and Chronic Obstructive Pulmonary Disease in India: In different cities of screening New Delhi number of people screened were 2098 in which 8.1% were males and 4.6% were females. Uttar Pradesh number of people screened were 1424 in that number of males were 9.0 and female were 4.5%. north India classified into 2 groups urban and rural number of people screened were 9946 in which 4.1 are males and 2.5 are females according to above information it is said that males are more prone to chronic obstructive pulmonary disease.  

Prevalence of Chronic Obstructive Pulmonary Disease in Maharashtra: The prevalence of smoking in above 30 years age group was 40.9% among males and 3.9% amongst female in under 20 age group the prevalence was 4.5% and between 20 and 29 it was around 14% among males. Tobacco and pan masala chewing was very widely spread among both sexes especially in the hilly state and so was alcohol consumption in tribal population the rural residence lower socio economic strata,advancing age and smoking habit are likely to be major factors favoring chronic obstructive pulmonary disease. A study of 12,000 slum dwellers from Pune in Maharashtra revealed a questionnaire based chronic obstructive pulmonary disease prevalence rate of 6.5% (8.5% in males and 4.5% in females).  

Functional Capacity: It is the volume of air remaining in the lungs after normal expiration. In healthy elderly people walking percentage is more 11% and in COPD patient it is reduced to 5%. In healthy standing percentage is more 41% and in COPD patient it is less 14%, sitting percentage in healthy people is less 42% and in COPD patient it is more 52%, lying in healthy elderly is less 4% and in COPD patient it is more 12%.  

Quality of Life in Chronic Obstructive Pulmonary Disease Patient: A broad definition of quality of life includes factors that health care may not directly affect (there may be indirect effect) include financial status, housing,employment and social support.  

Interventions  

1. Pursed Lip Breathing: Pursed lip breathing it id breathing technique designed to make your breath more effective by making them slower this is done after inhaling by puckering your lips and exhaling through them slowly and deliberately often to count.  

2. Incentive Spirometry: This device will help the patient to inflate their lungs maximally and sustain that inflation .the effect of incentive spirometer chronic obstructive pulmonary disease improve oxygenation, lung function and quality of life.  

3. Shoulder and Thoracic Mobility Exercise: Trunk flexion and extension,trunk side flexion, shoulder girdle circumduction. There is significant effect on physical work capacity and there is positive effect of exercise on activities of daily living.  

4. Walking: Walking a relatively simple home program has proven beneficial to COPD patient .patient who walked at least 60min/day reduces their COPD re-hospitalization rate by 50 percent.  

5. Biceps Curls: There is frequently experienced marked dyspnea and fatigue during the performance of arm tasks important to daily leaving it is possible that arm training in people with chronic obstructive pulmonary disease have similar effect on arm exercise capacity symptom and quality of life .COPD has endurance training effect on respiratory muscles and the upper limb training program did improve upper limb endurance.  

6. Active Cycle of Breathing: Physiotherapeutic technique to aid sputum clearance my include active cycle of breathing, percussion, vibration, shaking, active cycle of breathing technique consist of breathing control, it assist bronchial clearance by enhancing mucociliary clearance ACBT is effective in the clearance of bronchial secretion and to improve lung function, without increasing hypoxaemia or airflow obstruction.  

7. Stretching of Sternocleidomastoid and Pectoralis Major: Stretching:it is sustain or intermittent external, end range stretch force, applied with over pressure and by manual contact or mechanical
device elongates a shortened muscle-tendon unit and periparticular connective tissue by moving a restricted joint is termed stretching.  

8. **Strength Training:** The art of training or strengthening muscle lies in creating the condition under which they are called upon to work to full capacity against an ever increasing resistance. 

**Method**

**Study Design:** Comparative study.

**Participants:** A total of 40 subjects, both male and female with Grade III COPD were taken in the study. Patients with Grade III chronic obstructive pulmonary function test values and lung capacities were included in the study whereas subjects receiving anti depressant drugs, symptomatic increase in cardio vascular individuals with spinal deformities and respiratory muscle dysfunction, patients with system failure were not included in the study. Written informed consent was taken from the subjects those willing to participate. The subjects were randomly allocated by simple random sampling, lottery method & were allocated alternatively to group A and group B, who had grade III chronic obstructive pulmonary disease. The functional capacity and quality of life were assessed by 6 minute walk test and chronic respiratory questionnaire. The outcome assessment was done post treatment.

**Interventions:** Two groups were formed Group A (study group) where subjects were treated with pursed lip breathing, incentive spirometry, conventional physiotherapy and Group B (control group) where subjects were treated with conventional physiotherapy + interventions stretching of sternocleidomastoid and pectoralis major and strengthening walking, bicep curls, ACBT, and shoulder and thoracic mobility exercise.

All the subjects were treated 3 times a week, for 3 months

Control group subjects were treated with conventional + intervention exercises only. This includes pursed lip breathing, incentive spirometry; walking, bicep curls, ACBT, shoulder and thoracic mobility exercise before this 20 minute walk 5 minute warm up, 10 walking, and 5 minute cooldown.

Study group was treated with all the exercises given for the control group in addition to the Grade III COPD patients.

Each patient in the study group repeated the exercise in 1st month set 1 for 10 times in 2nd month set II for 20 times in set III 30 times in 3rd month. The exercises were performed with assistance once a day, three times per week for 3 months. Bicep curls were done to improve respiratory muscles strength, ACBT done followed by cough and huff, walking for 60 min per day stretching of sternocleidomastoid and pectoralis major done 3 times hold for 15 seconds. Shoulder and thoracic mobility exercise include flexion, extension and side flexion of trunk.

**Outcome measure:** 6 minute walk test: the purpose of six minute walk test is for measuring the response to medical interventions in patient with moderate to severe heart or lung disease. In early 1960s Balked developed a simple test to evaluate the functional capacity by measuring distance walked during a defined period of time. The walking test was also adopted to assess disability in patient with chronic bronchitis. A recent review of functional walking test concluded that ‘6MWT is easy to administer and better tolerable.

Chronic respiratory questionnaire: The purpose of chronic respiratory disease questionnaire was to measure the quality of life and evaluatethe current airflow limitation of COPD patient. The questionnaire, chronic respiratory disease questionnaire examine four aspects of patient dyspnea, fatigue emotional function and mastery. In this questionnaire we described the development of questionnaire validity and responsiveness.

**Result**

**Table No. 1: Comparison of dyspnea and COPD questionnaire:**

<table>

</tbody>
</table>

**Statistics:** Statistic was done by instat graph pad. Statistic analysis revealed very significant and extremely significant in post interventions in both group. Test done by paired ‘t’ test. Group A (p =0.0204), (‘t’ =5.12) group B (p=<0.0001), (‘t’ =5.91)

**Discussion**

The study aims in finding the effect of quality of life
and functional capacity in grade III COPD patients. As patients with grade III COPD has (30% ≤ FEV1 < 50% predicted) have reduced air entry, difficulty in breathing, increased sputum, changes in posture, poor cough quality, respiratory muscle weakness which results in poor bronchial hygiene and functional capacity leading to poor quality of life.

In this study we focus not only on bronchial hygiene but also the other factors which reduces the functional capacity and quality of life. Exercises were framed accordingly focusing on aerobic, mobilization and strengthening of upper, lower limb and abdominals which remains unfocussed in many research studies. The exercise protocol is validated and the structured well enough and delivered to the interventional group.

The results of within group A and group B on functional capacity and quality of life improved statistically (t=5.12; p = 0.0204) and between group also showed statistically significant improvement (t =5.91. p = <0.001)

Jeffrey L. Alexander, et al stated that strength training for upper and lower extremities improve muscle strength and effective on functional fitness in older patient with chronic lung disease enrolled in pulmonary rehabilitation

Sarah Bernard, Francois Whitton et al proved that addition of Aerobic and strength training along with conventional therapy showed significant improvement on exercise tolerance and peripheral muscle strength in patients with chronic obstructive pulmonary disease

**Conclusion**

Various recent approaches are used in the treatment of subjects suffering from grade III COPD, but this study concluded that combine effect of structured exercise program was effective in decreasing the levels of dyspnea and improving quality of life.

It is proved from this study that effectiveness of structured exercise program was effective in improving functional capacity and quality of life. Thus Alternate Hypothesis H (1) states that there is significant effect of structured exercise program in grade III COPD patients.

**Conflict of Interest:** There were no conflicts of interest in this study.

**Funding:** This study was funded by Krishna Institute of Medical sciences Deemed to Be University, Karad.

**Ethical Clearance:** The study was approved by the institutional ethics committee of KIMSDU. The trial was registered with Clinical Registry of India with no: CTRI/2018/01/011545.

Trends in Hyperbaric Oxygen Therapy

K.T. Moly¹, Ravi Sankaran², Linette Roy³, Maya J. Nair³

¹Principal, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, ²Asst. Professor, Dept. of Physical Medicine & Rehabilitation, School of Medicine, Amrita Vishwa Vidyapeetham, Kochi, ³Fourth Year B.Sc. Nursing Students, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi

Abstract

Background: The limited interdisciplinary recognition of hyperbaric medicine and the physicians’ unfamiliarity has lead to under utilization of HBOT as adjunct therapy in defined conditions.

Objective: To explore the trends in hyperbaric oxygen therapy in relation to demographic variables, applications and indications so as to form a baseline framework for further specific research studies.

Materials and Method: A quantitative retrospective study done in 530 subjects who underwent HBOT from 2015 to 2018 in a tertiary care hospital, Kochi. Data was collected from patients’ electronic medical record using a self developed observation record. Total enumerative sampling was used.

Results: Nearly half (48.9%) of the subjects who underwent HBOT were elderly i.e. in the age group 57-70 years. Majority were males (64.9%). 88.9% were residents of Kerala and 6.2% were from abroad. 48.7% of the subjects received 6-10 cycles of therapy. Only 13% of the subjects received more than 10 cycles.

Majority 302 (57.0%) of the sample underwent HBOT for acute indications. Among the 14 universally accepted acute conditions, post anoxic encephalopathy was found to be the main indication (49.7%). Malignancy related injury was the major condition (46.0%) found among the subjects with post anoxic encephalopathy to seek HBOT, and trauma being the least (7.3%). Around one third of the patients 203 (38.3%) had chronic indications. Among the four universally accepted chronic indications, diabetic wound was the main (45.3%) followed by radiation tissue damage (29.0%). 9 subjects (1.7%) had both acute and chronic indications for taking HBOT.

Conclusion: This study has shown a wide use of HBOT as an adjunct therapy for a variety of acute and chronic conditions. However more outcome oriented research is required to prove its efficacy in specific conditions.

Keywords: Hyperbaric Oxygen Therapy, Trends, Indications.

Introduction

Over the past 40 years hyperbaric oxygen therapy (HBO) has been recommended and used in a wide variety of medical conditions, often without adequate scientific validation of efficacy or safety. Consequently a high degree of medical skepticism had developed regarding its use.[1] Gabb and Robbin in the “Chest” (1987) have highlighted the controversies relating to HBO and have documented 132 past and present indications for HBO therapy.[2]

Hyperbaric facilities now form an important part of many hospitals all over the world. In 1996 there were 259 hyperbaric facilities in USA and there has been an annual increase in the number of hyperbaric centers and increase in patients at the rate of 15 and 620 respectively. The number of patients treated annually had increased from 896 in 1971 to 12,047 in 1989.[3,4]
Hyperbaric Oxygen Therapy has now slowly started capturing the interest of doctors in India. A great lag has come to a pass in our country over the years as compared to the practice of Hyperbaric Medicine in the Western world where thousands of hyperbaric chambers are functioning.

HBOT has been described as a therapy in search of diseases [2]. The discovery of beneficial cellular and biochemical effects has strengthened the rationale for administering HBO as primary therapy or as adjunct therapy in many of the diseases, but it requires more scientific controlled studies.[5]

The primary and single most important effect of HBOT is hyperoxygenation which results in three fold increase of diffusion distance of oxygen through the tissues thus having anti ischemic effect. HBOT also improves the angiodynamics and red cell rheology [6]. This contributes to the improvement of microcirculation and reduces edema up to approximately 20% in the injured part. Local hypoxia predisposes wound to infection because the neutrophil mediated killing of bacteria by free radical is decreased [6, 7] which is restored by HBOT. In addition HBOT is bactericidal for anaerobes [8] and bacteriostatic for aerobes [9, 10, 11]. HBOT promotes the formation of collagen matrix and angiogenesis thus hasten the process of healing [12]. HBOT protects tissue from reperfusion injury[13] through increased cell re-oxygenation induced detoxifying toxic radical processes, prevention of cell membrane lipid peroxidation and reduced leucocyte tissue sequestration and leucocyte related injury. HBO at 2-3 ATA reduces the half life of carboxyhemoglobin from 4 to 5 hours in subjects breathing normal air to 20 min or less [14]. Thus it has a therapeutic effect in carbon monoxide poisoning. The HBO dissociates carbon monoxide from cytochrome ‘C’ oxidase thus preventing cellular asphyxiation [15].

Hyperbaric oxygen is administered in either a multi place or a mono place hyperbaric chamber. Normally, pressures of 2 to 2.5 ATA are used for a period of 90 minutes once or twice daily.[16] Duration of single treatment varies from 45 min for carbon monoxide poisoning to 5 hrs for severe decompression disorders. Protocols average 90 min for each of 20 to 30 treatments with HBO as an adjunct therapy of the wounds and other syndromes. De Sylva et al has used multi place hyperbaric chamber and HBOT at 2.2 ATA for 60 min daily for 12 days was administered. HBOT at pressures not exceeding 3 ATA and treatment sessions limited to 120 minute is safe.[5]

In Kerala though HBOT was first introduced in Jubilee Mission Hospital, Thrissur, the centre later closed. Next it was started in S P Fort Hospital, Thiruvananthapuram followed by Amrita Institute of Medical Sciences, Kochi in January 19, 2015. AIMS has a multi place HBOT chamber. No studies have been conducted so far to get a framework on indications, applications and outcome of HBOT in Kerala and in AIMS.

Experiences with HBO therapy in India have been published in select journals with limited circulation but there has been no inter-disciplinary recognition of hyperbaric medicine at a national level. Thus though sufficient evidence supports use of HBO in certain defined conditions, many patients go untreated because of the physicians’ unfamiliarity with recent research of HBO as adjunctive therapy [17]. Studies focused on the specific indications, outcomes, the cost effectiveness and the transparency of the procedure itself only can help patients and professionals to use HBO as an adjunct therapy.

The purpose of study was to retrospectively explore the trends in hyperbaric oxygen therapy in relation to demographic variables, indications and applications so as to form a baseline framework for further specific research studies.

**Materials and Method**

A quantitative retrospective study done in 530 subjects who had undergone HBOT from 2015 to 2018 in a tertiary care hospital, Kochi. Data was collected from patients’ electronic medical record using a self developed observation record. Total enumerative sampling was used.

The universally accepted indications supported with peer reviewed proof of efficacy as described by T Sahni, P Singh, M J John[17] was used as the standard indications for collection of data (shown below). Accordingly there are 14 acute indications and 4 chronic indications. Indications which do not come under these two were included under the category of ‘others’.

Universally accepted indications for Hyperbaric Oxygen Therapy [17]

**Acute Conditions**: include non-healing ulcers, problem wounds, compromised skin grafts and flaps, crush injury, compartment syndrome, and acute traumatic ischemias, gas gangrene/clostridial infections,
necrotizing soft tissue infections (subcutaneous tissue, muscle, fascia), thermal burns, exceptional blood loss (anaemia), intracranial abscess, post-anoxic encephalopathy, burns, sudden deafness, ocular ischemic pathology, air or gas embolism, decompression sickness, carbon monoxide poisoning and smoke inhalation and curative/primary line of treatment.

**Chronic Conditions:** Include non-healing wounds/problem wounds (diabetic/venous etc., radiation tissue damage, skin grafts and flaps (compromised) and chronic osteomyelitis (refractory).

**Ethical Consideration:** Ethical Clearance was obtained from the Institutional Ethical & Scientific Committee before data collection.

## Results

Among the subjects who had acute indications for undergoing HBOT 302 (57.0%), post anoxic encephalopathy was the commonest (49.7%) followed by the group of Crush injury, compartment syndrome and acute traumatic ischaemias.

Specific conditions in post anoxic encephalopathy

**Figure 2: Distribution of the subjects with post anoxic encephalopathy who underwent HBO therapy based on specific conditions n= 150**

Malignancy related injury was the major (46.0%) condition in this study found among the subjects with post anoxic encephalopathy to seek HBOT, and trauma being the least (7.3 %)

Among the chronic indications for HBOT 203 (38.3%), non healing wounds/problem wounds (diabetic/venous etc.) (45.3%) and radiation tissue damage (29.0%) were the major indications.

Nine (1.7 %) of the sample had both acute and chronic indications for HBOT. 16 (3.02%) of the sample had other indications for HBOT as CAD, Septic arthritis, chronic fatigue syndrome, Hypertrophic cardiomyopathy, Peripheral vascular disease, Esophagitis and Pyoderma.

**Discussion**

The present study has shown that nearly half (48.9 %) of the subjects who underwent HBOT were elderly i.e. in the age group 57-70 years. Majority were males (64.9 %). 88.9 % were residents of Kerala and 6.2 % were from abroad. 48.7 % of the subjects received 6- 10 cycles of therapy. Only 13 % of the subjects received more than 10 cycles.

Majority 302 (57.0 %) of the sample had undergone HBOT for acute indications. Among these 14 acute conditions, post anoxic encephalopathy was the main indication (49.7%), whereas the major clientele for HBOT in a study by Sourabh Bhutani, Guruswamy Viswanath (2012) was patients with non-traumatic wounds[18]. Data from an Armed Forces HBOT centre in a tertiary care hospital for the year 2008 and part of 2009 (January–September) also showed that, non-traumatic wounds formed 40% and 36% of the total HBOT workload respectively. Significant healing of wounds was seen in 87% of patients[19].

As post anoxic encephalopathy was found to be the indication for HBOT for nearly half of the subjects studied, the investigators were interested in exploring
the specific conditions under the same. Malignancy related injury was the major (46.0%) condition in this study found among the subjects with post anoxic encephalopathy to seek HBOT, and trauma being the least (7.3%).

In the present study only one third of the patients 203 (38.3 %) had chronic indications for undergoing HBOT. Among these four chronic indications, diabetic wound that comes under non healing wounds/problem wounds was the main (45.3%) followed by radiation tissue damage (29.0%). The prospective controlled trial study conducted by Doctor et al. had taken one step further to find out the outcome of the therapy. Thirty diabetics with chronic foot lesions were randomized to study and control groups were assessed for average hospital stay, control of infection and wound healing. In the study group managed with HBOT, positive cultures decreased significantly compared to the control group (most pronounced for Escherichia coli) and the need for major amputation was significantly less. However the average hospital stay was not affected. They concluded that HBOT could be safely used and would be beneficial as an adjuvant therapy in chronic diabetic foot lesions.19

It is worth noting that 9 subjects (1.7%) had both acute and chronic indications for taking HBOT of which, 5 (55.6%) had Gas gangrene/clostridia infections along with diabetic wound.

The wide use of HBOT in post anoxic encephalopathy is to be noted as it may have a great impact in not only saving the lives of patients but also in minimizing their disabilities. Thus in the long run it makes HBO Therapy cost effective. Strokes, low blood pressure, near drowning, cardiac arrest, carbon monoxide poisoning, choking, drug overdose are the seven causes of anoxic brain injury.

Conclusion: This study has shown a wide use of HBOT as an adjunct therapy for a variety of acute and chronic conditions. However more outcome oriented research is required to prove its efficacy in specific conditions.

Abstract

Background: Earlier discrepancies in the risk of cervical carcinogenesis due to $p53$ and $p21$ genes influenced us to elucidate their association with cervical cancer (CC) in the rural population of south-western Maharashtra.

Objective: The hospital based case-control study aimed to investigate association of polymorphisms in $p21$, $p53$ genes with risk of CC in Maharashtrian population.

Method: PCR-RFLP method was used to genotype polymorphisms in exon 4 and exon 7 of $p53$, exon 2 and exon 3 of $p21$ gene from 350 CC patients and 400 controls.

Results: The variant allele Ser/Ser showed association with increased risk CC as compared to Arg/Arg genotype of codon 249 of $p53$ whereas codon 72 was not associated risk of CC in rural population. Similarly when we studied C/T and T/T genotypes of exon 3 of $p21$, T/T genotypes showed significant risk of CC (OR=6.03, 95% CI: 2.63-13.81; $p<0.0001$).

Conclusion: The findings from this study showed possible association of $p53$ codon 249 and $p21$ exon3 polymorphisms with increased risk of cervical carcinogenesis in the women of rural population of Maharashtra.

Keywords: Cervical Cancer, PCR-RFLP, $p53$, Genetic Polymorphism.

Introduction

Cervical cancer (CC) is the most deadly disease in women worldwide with 570,000 new cases in 2018 conferring 6.6 % of all female cancers as per World Health Organization report. In India, CC is the second biggest reason of cancer causing mortality, accounting 1/3rd of global deaths representing almost 10% of all cancer related deaths occurring annually among women(¹, ²). Earlier reports theorized that rural women are at higher risk of developing CC when contrasted to their metropolitan counterparts (³, ⁴). The conceivable factors responsible for CC are environment and lifestyle along with other etiological factors including sexually transmitted infections like human papillomavirus (HPV) infection. It won’t guarantee that every woman exposed with said risk factors will develop CC, signifying that some other components may also responsible for cervical carcinogenesis. In such circumstances, the developing affirmation on the genetic determinants and their association with carcinogenesis has been considered, suggesting that the genetic elements may influence the development of CC.
One of such host marker is tumor suppressor gene allied with several pathways including cellular transcriptional and translational control. p53 is a crucial gene recognized to stifle the development of cancer through the enlistment of cell cycle arrest and induction of apoptosis programs in different cellular response. It is clear from earlier evidences that polymorphisms in tumor suppressor molecules may play vital role in genetic susceptibility of the society to carcinogenesis. Few studies on the polymorphisms in p21 and p53 have been studied and some of them were evidenced to be associated with cancer risk with significance. A polymorphism of p53 at codon 72 of exon 4 i.e. substitution of arginine to proline, serine to arginine substitute in p21 at codon 31 of exon 2 have been distinctively explored in different populations in relation to carcinogenesis (5, 6). Also, epidemiologic studies from India reported the influence of polymorphisms in those genes for their association with development of different types of cancer (7-9), but results are conflicting where investigations verified non-association of p53 polymorphisms to cancer development (10-15).

Involvement of p53 Arg>pro substitution at codon72 of exon 4 (16-18) and p21 polymorphism (19-21) has been investigated for their association with risk of cervical carcinogenesis. But, it’s not obvious at all the times and no significant differences in the distribution of p53 and p21 genotypes were observed, thus showed uncertainty in the findings (16, 18). Thus, there remained underlying heterogeneity between the earlier studies which still needs to be explored. Therefore, in this study we hypothesized that the polymorphism in p53 and p21 genes may contribute to the etiology of CC in rural women of Maharashtra. To judge this proposition we proposed a hospital based case-control study to investigate polymorphisms in tumor suppressor genes and their association with risk of CC in Maharashtrian population.

**Materials and Method**

The study population included 350 women with CC and 400 healthy women as controls. All cases ranged in age from 20-75 years were enlisted after being diagnosed during 2013-2018.

**Genomic DNA extraction:** Genomic DNA extraction was carried out from the peripheral blood sample using Purelink genomic DNA extraction and purification kit (Invitrogen, Life technologies) following the manufacturer’s instructions.

**Genotyping Assays:** The samples were then genotyped by PCR-RFLP. The genomic DNA was amplified using primers (p21 codon 31 exon 2: Forward Primer (FP); 5’- gtcagacgcctgctggattg-3’, Reverse primer (RP); 5’- ctcetccacactatccggg-3’, p21 exon 3: FP; 5’- cctacccaggtgtgtctgtg-3’, RP; 5’- ggctggcaggtatgtc-3’ and p53 codon 72 exon 4: FP; 5’- ttcacccatctacagtcc-3’, RP; 5’- ctcagggcaactgaccgt-3’, p53 codon 249 exon 7: FP; 5’- ggcacagagcgcaggtc-3’, p53 codon 249 exon 7: FP, 5’- ggcggccagggtatgtac-3’, RP; 5’- ggtcagcggcgagcagag-3’). The PCR conditions were optimized for amplification of 272 base pair (bp) fragment of p21- exon 2 and 300 bp fragment of p21-exon 3 were initial denaturation at 95°C for 5 minutes (min) followed by 30 cycles of 95°C- 20 seconds (sec), 58°C-20 sec, 72°C-20 sec and final extension at 72°C for 10 min. Similarly PCR conditions were optimized for amplification of codon 72 of exon 4 (309 bp) and codon 249 of exon 7 (286 bp) of p53 gene were; initial denaturation at 95°C for 5 min followed by 30 cycles of 95°C- 20 sec, 52°C-20 sec, 72°C-20 sec and final extension at 72°C for 10 min and 30 cycles of 95°C-20 sec, 60°C- 20 sec, 72°C-20 sec and final extension at 72°C for 10 min respectively. After confirmation of PCR amplification, 1µg of PCR product of each sample was subjected to restriction digestion with 10 Units of restriction enzymes. The restriction enzymes BstU1 and PstI were used for RFLP analysis of exon 2 and exon 3 of p21 respectively. Similarly RFLP analysis of p53 codon 72 exon 4 and p53 codon 249 exon 7 was carried out by BstU1 and HaeIII restriction enzymes.

**Statistical analysis**

The association between the p21 and p53 genotypes and risk of developing CC were studied by logistic regression model which was used to calculate the Odds ratio (OR) and 95% confidence intervals (CI) with adjustment of variables to determine the CC risk.

**Results**

The most of the patients in stage III well differentiated squamous cell carcinoma selected before receiving any either chemotherapy or radiation therapy. Based on clinico-pathological and demographic characteristics, it was observed that CC occurred in patients (78.90 %) who were married at younger age and pregnant soon (15-20yrs) which showed significant association when compared to the controls.

**P53 genotyping:** The DNA from patients and controls was genotyped at codon 72 at exon 4 of p53 for
Pro/Pro, Pro/Arg, Arg/Arg and codon 249 at exon 7 of p53 Arg/Arg, Arg/Ser, Ser/Ser genotypes. The genotype frequencies of p53 exon 4 and exon 7 polymorphisms are summarized in Table 1. The p53 Pro/Pro allele frequency among patients was 23.43% where in controls 23.00% whereas Arg/Arg allele frequency in patients (24.86%) and in controls (23.75%). Neither of heterozygous allele (OR=0.95; 95% CI: 0.66-1.93, p=0.79) nor proline homozygous allele (OR=1.02; 95% CI: 0.67-1.55, p=0.89) of codon 72 of p53 associated with risk of CC. When we compared the frequencies of p53 Arg/Arg, Arg/Ser and Ser/Ser genotypes of codon 249 of exon 7 among patients, we found significant difference from those among controls. Logistic regression analysis estimated the association of Ser/Ser variant allele (OR=2.47; 95% CI: 1.75-3.49; p<0.0001) with increased risk of development of CC compared to Arg/Arg genotype of codon 249 of p53 gene.

**P21 genotyping:** When we studied frequency distribution of Serine and arginine allele in codon 31 of exon 2, the Ser/Ser allele of patients (76.29 %) and controls (56.50%) where arginine allele in p21 showed negative association for the development of CC (OR=0.38, 95% CI: 0.24-0.62; p<0.0001) Table-1. When we studied C/T and T/T genotypes of exon 3 of p21, T/T genotypes showed significant risk of CC (OR=6.03, 95% CI: 2.63-13.81; p<0.0001). Thus, p21 Arg/Arg genotype did not show increase in relative risk of developing CC, whereas T/T genotypes of exon3 of p21 associated with increased risk of CC.

**Effect of confounding factors on the association of p53 and p21 polymorphisms with CC risk:** The association of p53 and p21 with risk of CC was further examined after stratification of confounding factors such as age, age at first pregnancy. The logistic regression analysis showed that none of the polymorphisms except Arg/Ser allele of p53 codon 249 associated with CC risk (OR=2.85; 95% CI: 1.82-4.47 p=0.0001) after being adjusted for earlier age at first pregnancy whereas Ser/ Arg allele of codon 31 of exon 2 of p21 showed negative association (OR=0.35; 95% CI: 0.23-0.52 p= 0.0001) with development of CC. There was an increase in the relative risk of CC associated with arginine/serine heterozygosity as compared with arginine homozygosity of p53 codon 249 between subgroups defined by age bellow 50 years (OR=3.09; 95% CI: 1.99 –4.81, p=0.0001) as compared to age above 50 years (OR=1.59; 95% CI: 0.90 –2.79, p=0.10).

Table 1: The genotype frequencies of p21 and p53 gene variants and their association with cervical cancer in untreated CC patients and healthy controls.

Discussion

In present study we used comparatively larger sample size to elucidate the interaction of p21 and p53 influencing the risk of CC in rural population of Maharashtra. Based on logistic regression analysis we found that no evident relationship of Arg 72 allele of p53 and Ser 31 allele of p21 genotype frequencies occurred to be associated with CC. But when we compared the frequencies of Arg/Arg, Arg/Ser and Ser/Ser genotypes of codon 249 of p53, we found significant association of Ser/Ser with increased risk of CC in rural women. Similarly when we studied genotype frequencies of p21 exon2 and exon 3, the frequency distribution of serine and arginine allele in codon 31 of exon 2 did not show risk to CC but we observed T/T genotypes of p21 showed significant risk of CC in rural women.

The polymorphism in p53 and p21 genes has been found to be associated with increased risk of ovarian, bladder, breast cancer (10-11, 22-24). But, in controversy no association of p53 was found with breast (10, 25) and ovarian cancer (41). Recently various studies have been carried out to review the outcome of SNPs on CC susceptibility (26, 27) however; the exact role of p53 and p21 in CC development remains controversial (28). Recent meta-analyses revealed that p53 polymorphisms are associated with increased risk of CC in Indian and other Asian population (7, 29) but in contrast, no prominent association between p53 polymorphism and CC risk was documented in patients of Africa, and eastern Asia (16, 30). Similarly, Martinez-Nava et al 2016(31) evidenced negative association of p21 polymorphism with CC risk. Thus our results revealed that the prevalence of C>T SNP of p21 and G>T polymorphism in of p53 increases the severity of CC in rural population of Maharashtra; however other studies reported negative association of codon 249 with CC risk (25). Our study also showed that p53 codon 72 polymorphism is not a significant predictor of advancement of CC in Maharashtrian population. Thus, this is preliminary information of its own kind to examine the polymorphisms in and their conceivable relationship with development of CC from a pool of unexplored rural Maharashtrian population and showed that polymorphism in exon3 of p21 and codon 249 of p53 may contribute in cervical carcinogenesis in Maharashtrian women.

Conclusion

The findings indicated possible association between codon 249 of p53 and exon3 of p21 gene polymorphisms with increased risk of cervical carcinogenesis in the women of rural Maharashtra.

An Explorative Study to Prevent the Incidence of Inpatient Falls in a Tertiary Care Hospital

Kayalvizhi Ashok¹, Khyathi G.V.²

¹Postgraduate Student, ²Assistant Professor, Department of Hospital Administration, M S Ramaiah University of Applied Sciences

Abstract

Improving patient care has become a top priority among healthcare providers, with the overall interest to achieve patient satisfaction. The quality of patient care is the adoption of a system which is patient centred or patient oriented. One such area in the hospital for improvising the quality of patient care is the prevention of patient falls. The study was carried out in the inpatient wards of a tertiary care hospital in Bangalore for a period of five months, from March 2018 to July 2018 which was cross sectional study descriptive in nature. Data on inpatient falls was collected through hospital incidence report for three years. An observational checklist was prepared to check for patient safety compliance to environmental circumstances and a self-administered questionnaire to assess the level of knowledge of nurses on fall prevention. Data analysis was done by using Quality control tools such as Pareto’s Chart, Cause and Effect Diagram and bar graphs to identify the gaps and analyse the root cause for inpatient falls in the hospital. As a result of data analysis, it was concluded that the major reasons for patient falls were due to patient related factors such as old age, weakness, loss of balance, impaired cognition and environmental factors such as wet bathroom floors, absence of patient call bells and bed rails not being raised. On the other hand evaluating the level of knowledge of nursing staffs on fall prevention revealed that 3.25% of the nurses had poor knowledge regarding the fall risk assessment, 31.33% of the nurses had less knowledge on risk factors and 15.25% were not aware of interventions for fall reduction. Overall the hospital had to improve on fall prevention strategies and conduct periodic training programs for nurses on fall prevention. An environmental safety checklist was prepared and Standard fall prevention guidelines was formulated and recommended to the hospital.

Keywords: Inpatient falls, Environmental Circumstances, Risk Factors, Patient Safety Practices.

Introduction

Patient falls has been one of the leading causes of adverse events recorded in a hospital, which constitutes around 70% of inpatient incidence. On an average the falls reported in hospitals ranges from 1.3 to 8.9 per 1000 patient bed-days¹. Inpatient fall leads to increased length of stay in hospitals, physical and emotional injury, increased healthcare costs and discharge to a long term care facility. Even when a fall doesn’t result in injury, it can cause a fear or anxiety of falling leading to depression and reduced physical activities². Patient fall results in physical injury which constitutes approximately around 30% out of which 4% to 6% relates to serious injury³. The serious fall related injuries include fractures, subdural hematomas with excessive bleeding and can even result in death of the patient⁴. It was seen that patients who had sustained injuries due to fall had an increased cost of hospital charges $4200 which was comparatively higher than patients who did not fall⁴,⁵. Since quality of care and patient safety is of prime concern, it is significant to reduce the incidence of patient fall in a hospital, thereby reducing the risk of injury and healthcare costs. Statistics in US has shown that every year more than thousands of patient’s falls have been reported in hospitals and 30%-40% are presented with injury⁶.

Epidemiology of Falls: Epidemiology of inpatient
falls has multifactorial causes and is not confined to just one factor. Patient falls related with injury in hospital is associated with several risk factors. These factors are divided into intrinsic and extrinsic factors. The intrinsic factors include gait of the patient, previous history of falling, increased age, mental status, dizziness, visual impairment, urinary frequency, specific group of diagnosis, and use of certain medications such as benzodiazepines, antipsychotics and sedatives. Extrinsic factors include environmental conditions, use of restraints, reason for hospitalization, and unit condition. Although intrinsic factors depend on the patient’s condition and mostly cannot be modified, extrinsic factors usually are related to environmental conditions which can be rectified through interventions.

**Challenges in Fall Prevention:** Prevention of falls and fall related injury has always been a challenging issue across all patient care areas. Not all patients in hospitals are prone for a fall, but a patient fall can cause a lot of distress not only to the patient but also healthcare staffs and patient members. Fall prevention comprises of multidisciplinary team in the organization which includes, nursing staffs, physicians, pharmacists, family members, physiotherapists and patients. It is important to have an effective communication of a patient’s fall risk factors, as well as specific plan care for individual patients, as each patient have their own set of risk factors which sometimes are very unique.

**Aim, Objectives & Methodology**

**Aim:** To assess the incidence of patient fall in a hospital in order to identify and analyse the causes and suggest measures to reduce the occurrence of the fall

**Objectives:**
1. To study the incidence of patient fall in the hospital
2. To identify the gaps and analyse the reasons for patient fall in the hospital
3. To assess the level of knowledge of nurses on fall prevention
4. To suggest measures for preventing patient fall

**Methodology:** A cross-sectional observational study which was descriptive in nature was conducted in a tertiary care hospital, Bangalore from March 2018 to July 2018. The following inpatient departments were considered for the study, Medical General Ward (MGW), Surgery General Ward (SGW), Paediatric General Ward (PGW), Orthopaedic General Ward (OGW), psychiatric General Ward (PSY GW), Ophthalmology General Ward (Ophal GW). Secondary data was collected from hospital incidence reports for 3 years (2015, 2016, and 2017). Secondly, an observational checklist was prepared on patient safety compliance to environmental circumstances which can trigger patient falls, based on literatures studied; observations were carried out in all the inpatient wards for a period of two weeks. Analysis was done through Cause and Effect Diagram. Finally a self-administered structured questionnaire on fall prevention was prepared based on studied literature reviews, to assess the knowledge of nursing staffs on fall prevention. The questionnaire was face validated through experts. Reliability check was done for 20 samples through Microsoft excel with Cronbach’s Alpha was 0.747899. All the nursing staffs working in the inpatient departments of General Wards were included for the study. A sample size of 107 nursing staffs was determined with a population size of 147. Confidence Level =95% and Margin of Error =5%. Out of which 98 were respondents Exclusion criteria was inpatient department of Private Wards, and nursing staffs who were on a long leave of absence.

**Results & Analysis**

**Incidence of Patient Falls:** As observed from the secondary data collected from hospital incidence reports on patient falls it was seen that, the total no: of inpatient falls in 2015, 2016 and 2017 was 14, 23 and 41 respectively. Pareto’s was plotted to analyze the area of inpatient falls. As per the data collected from hospital incidence reports, it was analyzed that the incidence of patient fall reported was high in D-block followed by Psy ward, PGW, MGW, Ophal ward, SGW and OGW.

**Patient Safety Compliance to Environmental Circumstances:** An observational checklist was used to check for compliance to environmental circumstances.

**Table: 1 Reasons for Non-Compliance to Environmental Circumstances**

<table>

<td>Absence of patient call bells and grab bars in washroom</td>
</tr>
<tr>
<td>Medical General Ward</td>
<td>Absence of patient call bells and grab bars in washroom, wet floor surfaces, slippery bathroom floors</td>
</tr>
</tbody>
</table>
Compliance to environmental circumstances in the 7 departments (MGW, SGW, Psy GW, OGW, Opthal GW, and D-block) showed that almost all departments did not have patient call bells, and even if it was present it was non-functional. Grab bars were absent in the wash room in all the wards except Psy GW and OGW. The floor surface of the bathroom was found to be wet which can increase the risk of patient for falling. The other common finding in the opthal GW and in D-block was that the bed rails were not raised, and patients could be at a risk of a fall. Presences of assistive devices were observed as obstructions in the pathway to the toilet.

Nurses Level of Knowledge on Fall Prevention:
A total of 15 items were included in the questionnaire, which covers four sections (a) Fall risk assessment, (b) Patient risk factors (c) Interventions for fall reduction, and (d) Fall prevention programs.

According to literatures a patient who is taking four or more oral medications is at risk of fall, therefore should be carefully monitored. But, as per the studies it was seen that only 37% of nursing staffs had the awareness that a patient who is on four or more oral medications is at a risk for a fall and has to be monitored closely.

Compliance to environmental circumstances in the 7 departments (MGW, SGW, Psy GW, OGW, Opthal GW, and D-block) showed that almost all departments did not have patient call bells, or if they were present it was non-functional. Presence of patient call bells in wards or in the nursing station can be adopted as a fall prevention strategy.

Another key findings in the study showed that the floors of the bathrooms were wet, where patients may slip and fall. Previous studies have shown similar highest percentage of falls have occurred in patients bathroom/toilets and suggested that bathroom is a location which can be hazardous for older adults. Studies conducted by Sebestina Anitha D’souza showed that bathing activity was rated with high risk of falling in the hospital. In order to prevent these falls, modifications in the bathrooms and toilets have found to decrease the falls such as rubber mats, and handrails have found to be useful. The study also revealed that presence of

Fig: 1 Nurses Level of Knowledge on Fall Risk Assessment and Risk Factors

From the study done to assess the nurse’s knowledge on fall risk assessment, it was analysed that the most of the nursing staffs had a good knowledge on fall risk assessment tool, and 3.25% of the total nursing staffs who were involved in the study had stated that they were not trained on using the Morse Fall Risk Assessment tool, which was adopted by the hospital recently.

Fig: 2 Nurses Level of Knowledge on Interventions for Fall Reduction and Fall Prevention Programs

Based on interventions for fall reduction, 85% of the nursing staffs were aware of individual intervention strategies.

All though most of the nurses were aware of the interventions for fall reduction, 10% of them had a negative attitude on fall prevention programs.

Discussion

The total number of inpatient falls obtained from hospital incidence reports for the three consecutive years 2015, 2016 and 2017 was 78.

The study showed that the rate of compliance to environmental circumstances was different in all the wards which were studied. Results analysed showed that most of the wards did not have patient call bells, or if they were present it was non-functional. Presence of patient call bells in wards or in the nursing station can be adopted as a fall prevention strategy.

Another key findings in the study showed that the floors of the bathrooms were wet, where patients may slip and fall. Previous studies have shown similar highest percentage of falls have occurred in patients bathroom/toilets and suggested that bathroom is a location which can be hazardous for older adults. Studies conducted by Sebestina Anitha D’souza showed that bathing activity was rated with high risk of falling in the hospital. In order to prevent these falls, modifications in the bathrooms and toilets have found to decrease the falls such as rubber mats, and handrails have found to be useful. The study also revealed that presence of
obstructive devices like wheelchairs and patient assistive devices were present in the pathway to the toilet. This can be a very hazardous environmental factor which can impact on patient safety. Another common finding in the ophthalmology department and D-Block was the bed rails were not raised for required patients.

The analysis of the results, gave many intuitions regarding the knowledge of nurse on prevention of patient fall in the hospital.

**Table: 2 Overall Score Assessed on Nurses Knowledge on Fall Prevention**

</tbody>
</table>

In relation to the data collected regarding the knowledge of nurse on fall risk assessment, it was seen that 96.75% of nursing staffs had good knowledge on using the fall risk assessment with SD ±2.64. Data analysed on the assessment of knowledge on risk factors showed a SD ±1.52 with only 68.66% of staffs aware on risk factors. Results analysed on interventions on fall prevention and fall prevention program revealed SD of ±5.47 and ±11.26 respectively, they had expressed that adequate training and education on fall prevention can overcome the huddles caused due to hazardous environment. Almost all the nurses in the study had concluded that education to patient/family members is an effective fall prevention strategy where patients can be alerted on fall risks, and can be more careful during their activities.

**Recommendations & Conclusion**

Recommendations for the prevention of inpatient falls in the hospital were suggested based on the analysis of the problem areas.

1. **Standard Guidelines on Fall Prevention**
   - Ensure environmental safety such as adequate lighting near patient bed areas, beds at appropriate height, functioning of patient call bells, floor surface clean and dry
   - Educating patients on fall risk near bed areas
   - Identify high risk patients by using unique identifiers
   - High risk patients should be kept near the nursing station for closer observation
   - Conduct fall reduction programs to all staffs
   - Regular review of medications, especially high risk patients

2. **Environment Safety Checklist**

   Prevention of patient falls and fall related injuries have been a challenging issue and also prime concern, for healthcare organizations, and for healthcare providers because providing patient safety is the highest quality of patient care. This study was conducted to analyse the root cause for patient fall in the hospital, which was carried out by obtaining the secondary data from the hospital incidence report for three years. The main gaps analysed through cause and effect diagram showed that, the environmental hazards which can trigger patient fall includes wet bathroom floors, absence of fall risk signage’s, wet floor surfaces, presence of obstructive devices in the pathway to the toilet, absence of patient call bells, insufficient bed rails, bed rails not raised and absence of grab bars in the bathroom.

   By assessing the level of knowledge of nurse on fall prevention, it was seen that most of the nurses were well aware of the fall risk assessment tool, and expressed that using a fall risk assessment tool helped them to identify patients at risk of fall. Regarding their knowledge of risk factors and intervention for fall reduction, it was seen that, only few nursing staffs were aware of risk factors like a patient who is on four or more oral medications is at a risk for a fall, while majority of them lacked the knowledge and awareness.

   Multi component interventions have been implemented across most of the hospitals to reduce patient falls, with varying success of around 30%\(^1\). New innovative technologies have been adopted by hospitals to reduce patient fall. Depth sensors were installed in inpatient units identified at high risk of falls, and events were captured through video clips. These sensors helped in analysing the nature of falls, for further developing of specific interventions for high risk fall patients\(^1\). Implementation of fall prevention programs can be made successful by identifying areas for specific interventions which includes patient and staff education, training for initial fall risk assessment, review of assessment if
required, patient-specific interventions, and an interdisciplinary team which can analyse the data on falls periodically and support the organization with updated fall prevention strategies.

Probiotics and Oral Health: A Review

Khurana Suchi1, Jodalli Praveen2, K.M. Ramya3, Arora Pallak4

1Reader and Head of Department, Department of Public Health Dentistry, PDM Dental College and Research Institute Bahadurgarh, Haryana, 2, Reader, Department of Public Health Dentistry, Yenepoya Dental College, Mangaluru, 3Assistant Professor, Department of Pedodontics, AJ Shetty Institute of Dental Sciences, Mangalore, 4Reader, Department of Oral Medicine and Radiology, DJ Dental College, Ghaziabad, U.P.

Abstract

The concept health-promoting micro-organisms and bacteriotherapy to support immune function was first introduced at the beginning of the 20th century. The development of modern dairy industry came into existence later. In milk fermentation, probiotic strains such as lactobacilli or bifidobacteria are used even today. Time has come to shift the paradigm of treatment from specific bacteria elimination to altering bacterial ecology by probiotics. Probiotics are food supplements containing beneficial bacteria. They help in stimulating health flora and also suppressing pathogens which cause and spread diseases. Various chronic diseases such as dental caries, periodontitis and recurring problems like halitosis, candidal infections, etc has been controlled in the oral cavity by use of probiotics. Probiotics may function not only by direct inhibition of, or enhanced competition with, pathogenic micro-organisms, but also by more subtle mechanisms including modulation of the mucosal immune system. This article summarizes on the potential benefits of probiotics for oral health.

Keywords: Probiotics, oral health, dental caries, periodontitis, halitosis, Candida infection.

Introduction

The term probiotic was derived from the Greek word, meaning “for life.” Every human being ingests a large number of living microorganisms, predominantly bacteria each day. Although probiotic strains are present in food and waternaturally, but can also be added in sausages, cheese, yogurt and fermented milk products during the processing of foods due to their beneficial effects for human health. As declared by the Food and Agriculture Organization and the World Health Organization, the definition of probiotics (2001), as “livemicroorganisms which when administered in adequate amounts confer health benefits on the host.” These bacteria are regarded safe as they can reside in the human body without causing any harm and, on the other hand, they are important microorganisms in milk fermentation and food preservation.

History: The Ukrainian bacteriologist and Nobel Laureate Metchnikoff (1908) after studying the flora of the human intestine concluded to a theory in the 1900s that poisoning of a body by the products of some bacteria causes senility in humans. Hence, proposed a diet containing milk fermented by lactobacilli for high amounts of lactic acid production that could increase the life span of humans. Lilley and Stillwell (1965) introduced the term probiotics. Hull (1984) identified the first probiotic species, the lactobacillus acidophilus and Holcomb (1991) identified bifidobacterium bifid.

Species of Probiotics: Probiotics can be yeast, bacteria or molds but bacterial species are predominant. Few of these species are:

(a) Lactic acid-producing bacteria (LAB):
   Lactobacillus, Bifidobacterium, Streptococcus.

(b) No lactic acid-producing bacterial species:
   Bacillus, propionibacterium.
Rationale: The concept of treatment with probiotics came from a belief that modern humans do not consume or replenish the beneficial microbes in their bodies and that they can do so by taking probiotics. Ingested probiotic strains block pathogen adhesion and growth and also give a nonspecific boost to immunity, as adhere to the gut wall. Probiotics have many other roles, like producing anti-infectives, such as bacteriocins; strengthening of host-cell mucus barriers; and prevention of virulent factors, such as toxins production. Delivery systems, such as gel matrix coatings on the bacteria themselves and center coated capsules, allow bacteria get through the stomach and hydrate the small intestine. For example, Lactobacillus strains GR-1 and RC-14 can function in the gut, survive passage and pass in faeces, and synthesize vitamins. They also ferment indigestible carbohydrates and produce beneficial short chain fatty acids.

Mechanism of action: The production of enzymes is stimulated by the lactobacillus species which further helps in digestion and metabolism of proteins and carbohydrates. Lactobacillus also aid in the synthesis of Vit B and Vit K and in the breakdown process of bile salts. More than 100 species of L. acidophilus, L. brevis, L. casei, L. rhamnose, L. salivarius has been identified. They are usually dispensed in gel, paste, powder and liquid forms. They enhanced innate and acquired immunity as well as help in inhibition of pro-inflammatory mediators. Bifidobacterium species are strictly anaerobic and predominate the large intestines. The benefits from these include metabolization of lactose, generate lactic acid and synthesize vitamins. They also ferment indigestible carbohydrates and produce beneficial short chain fatty acids.

Role of Probiotics in dental caries: Dental caries is an infectious disease that affects most of the population. This multifactorial and complex disease process occurs along the interface between the dental biofilm and enamel surface. Probiotic and molecular genetic techniques have been used to replace cariogenic organisms such as mutans streptococci and Lactobacillus species with strains of bacteria that are not cariogenic. Studies suggest that consumption of products containing probiotic lactobacilli or bifidobacteria could reduce the number of mutants streptococci in saliva. Nase et al. showed that administration of probiotic bacterium Lactobacillus reuteri ATCC55739 or Bifidobacterium DN-173010 induced significant reduction of cariogenic S. mutans in saliva. Nikawa et al. showed that bovine milk fermented with Lactobacillus reuteri was effective against S. mutans, resulting in a reduced risk for tooth decay.

Probiotics in periodontitis: Patients with various periodontal diseases; gingivitis, periodontitis and pregnancy gingivitis, were locally treated with a culture supernatant of a L. acidophilus strain. Significant recovery was reported for almost every patient. The probiotic strains used in such studies include L. reuteri strains, L. brevis (CD2), L. casei Shirota, L. salivarius WB21 and Bacillus subtilis. L. reuteri and L. brevis have improved gingival health, as measured by decreased gum bleeding. The use of probiotic chewing gum containing L. reuteri ATCC55730 and ATCCPTA 5289 also decreased levels of pro-inflammatory cytokines in GCF, and the use of L. brevis decreased MMP (collagenase) activity and other inflammatory markers in saliva. Use of tablets containing L. salivarius WB21 has been shown to decrease gingival pocket depth, particularly in high-risk groups such as smokers, and also affect the number of periodontopathogens in plaque. Twetman et al. used L. reuteri-containing chewing gum in 42 healthy patients and assessed its effects on crevicular fluid volume, cytokine (interleukin-1β, interleukin-6, interleukin-10, and TNF-α) levels and bleeding on probing. Crevicular fluid volume, as well as TNF-α, interleukin-8 levels and bleeding were significantly reduced. Due to the ability to inhibit P. gingivalis, L. salivarius TI 2711 was given for 4 or 8 weeks in a tablet to healthy volunteers at a concentration 2x107 CFU/ml. A significant reduction of black pigmented rods in saliva was observed, whereas the number of S. mutans and lactobacilli did not change. Additional finding was the convergence of pH to neutral after treatment, thus highlighting both caries and periodontal prophylactic properties. The effectiveness of the latter Lactobacillus strain was confirmed by Matsuoka et al. who demonstrated by means of real-time PCR analysis that LS1 translocates to subgingival plaque decreasing the number of P. gingivalis. This also suggests that LS1 is an effective probiotic.
**Probiotics in Halitosis:** Halitosis is not a disease but a discomfort, although some oral diseases including periodontitis may be the underlying cause. *Streptococcus salivarius* is detected most frequently among people without halitosis and is therefore considered a commensal bacterium of the oral cavity. *S. salivarius* is known to produce bacteriocins, which contribute in reducing the number of bacteria that produce Volatile Sulphur Compounds (VSC). The use of gum or lozenges containing *S. salivarius* K12 reduce levels of VSC among diagnosed with halitosis. The common organisms involved in halitosis are *Fusobacterium nucleatum, P. gingivalis, P. intermedia* and *Treponema denticola*. These organisms degrade amino acids, which are in turn transformed into volatile sulphur compounds which cause halitosis. Various strains of *Weissella cibaria* have the capacity to coaggregate with *fusobacterium nucleatum* and to adhere to epithelial cells and these bacteria produce hydrogen peroxide as well as a bacteriocin which inhibited the proliferation of *F. nucleatum*. These properties could enable *W. cibaria* to effectively colonize the oral cavity and limit the proliferation of *F. Nucleatum* and thus can prevent halitosis. In the preliminary trials of the use of a chlorhexidine rinse followed by strain K12 lozenges, the majority (8/13) of subjects with confirmed halitosis maintained reduced breath levels of volatile sulphur compounds for at least 2 weeks. The replacement of bacteria implicated in halitosis with the bacteriocin-producing commensal bacterium *S. salivarius* K12 appears to provide an alternative therapy for the long-term reduction of halitosis.

**Probiotics in orthodontic treatment:** Fixed orthodontic appliances are considered to jeopardize dental health due to accumulation of microorganisms that may cause enamel demineralization, clinically visible as white spot lesions. White spot lesion formation can be seen as an imbalance between mineral loss and mineral gain and recently have examined the possibility to prevent this side effect of orthodontic treatment. Cildir et al. in 2009 conducted a clinical study with probiotics and found out that daily consumption of fruit yogurt with *Bifidobacterium animalis* subsp. Lactis DN-173010 could reduce the salivary levels of mutans streptococci in orthodontic patients with fixed appliances.

**Probiotics in oral cancer:** Probiotics can interfere at various stages of cancer process, more significantly interfering with chromosomal and DNA damage. However, more research is required to develop specific regulations on their consumption.

**Probiotics in infections and oral diseases:** Studies have investigated the effects of probiotic bacteria on oral candida infection in humans. When a test group of elderly people consumed cheese containing *L. rhamnosus* strains GG and *Propionibacterium freudenreichii* spp. for 16 weeks, the number of high oral yeast counts decreased but no changes were observed in mucosal lesions. Hundreds of bacteria taken from saliva of volunteers were screened where it was observed that some Lactobacillus strains had produced proteins capable of binding a particular type of sugar found on HIV envelope, called mannose. The binding of the sugar enables the bacteria to stick to the mucosal lining of the mouth and digestive tract, forming colonization. One strain secreted abundant mannose binding protein particles into its surroundings, neutralizing HIV by binding to its sugar coating. The immune cells trapped by lactobacilli formed a clump. This configuration would immobilize any immune cells harbouring HIV and prevent them from infecting other cells.

**Delivery mechanisms of probiotics:** Delivery mechanisms include encapsulating probiotics, such that they rehydrate at specific sites, and encasing probiotics in nano-aggregates that protect against stomach acid and deliver their payload when the pH reaches 7.4. Potentially, such nano encapsulation will also allow delivery in foods such as biscuits, whereas targeted, water protected macrocapsules containing probiotic organisms may prove useful in animal food pellets and perhaps in liquids, which currently cannot be used because of problems with shelf stability. At the macromolecular level, it will soon be possible to coat capsules with biosensors that detect the optimal conditions for the release of probiotic contents.

**Conclusion and Recommendations:** The oral cavity with a well maintained balance of the species and species interactions may be a potential source for health-promoting probiotic bacteria. On the other hand, daily intake of probiotic supplements can control common oral diseases. Furthermore, the dosage of probiotic administration in each indication needs to be defined. Finally, safety issues are of paramount importance with any kind of bacteriotherapy. Further research is needed to understand the ability of probiotic bacteria to survive, grow, and provide therapeutic effect when added to foods to fix the doses, means and schedules of administration of probiotics.

Effectiveness of Acupressure Therapy among Patients with Low Back Pain in Selected Acupuncture Clinics at Mangaluru

Liji Sara John¹, Gireesh G.R.², Anju Ullas³, Shashikumar Jawadagi⁴

¹Post Graduate Student, ²Associate Professor, ³Lecturer, ⁴Professor, Department of MSN, YNC, Yenepoya (Deemed to be University), Mangaluru

Abstract

Aim: Acupressure is considering one of the safe alternative therapy. In low back pain acupressure is a best treatment until it is contraindicated and its natural ability helps to reduce the pain over conventional therapy and its side effects. This study evaluated the effectiveness of acupressure therapy on the level of pain among patients with low back pain.

Design: The pre-experimental one group pre-test post-test design was adopted as research design and Research approach was an evaluative approach. Non probability purposive sampling technique was used to select the study subjects (N=44, low back pain patients) from selected acupuncture clinics at Mangaluru.

Results: Acupressure therapy was found to have a substantial benefit in low back pain patients. Wilcoxon Sign Rank test was applied to analyze the effectiveness of acupressure therapy on patients with mild to moderate low back pain. The data analysis showed that the median pre-test score was 3 and while in post –test it improved to 2, < 0.05. Findings of the study revealed that the median post-test pain score was significantly lower than the median pre-test score after 10 days (9 minutes/day) of acupressure therapy. Likelihood Ratio was used to analyses the significant association. There was no association between the pre-test pain scores and the selected demographic variables.

Conclusion: The study findings showed that the acupressure therapy was effective in reducing the pain intensity among low back pain patients.

Keywords: Acupressure therapy, Effectiveness, Low back pain, Patients.

Introduction

Complementary and alternative medicine is a cluster of diverse medical & health care system and it is not a part of allopathic medicine, biomedicine, main stream medicine, orthodox medicine and western medicine. This therapy encloses with different directions including yoga, hypnosis, biofeedback, guided imagery, chiropractic therapy, aroma therapy, herbal remedies, relaxation, acupuncture and acupressure.¹

Acupressure is considering one of the safe alternative therapy which developed over 5,000 years ago in Asia, particularly in China. The aim of this therapy is to balance body, promote relaxation, healing and restoring of function. These points follow particular channels known as meridians, the same channel used in acupuncture. In LBP acupressure is a best treatment until it is contraindicated. The natural ability of this therapy helps to reduce the pain over conventional therapy and its side effects.²

It has some specific points (acu-points) on lower back. These points can be manipulated with the fingers instead of needles. Acupressure results, in positive outcome when it is applying properly. It is not only gives

Contact number: 07996814139/0824-2206000
curative effect but also helps to prevent reoccurrence of low back pain. A person who is performing the therapy must know the proper techniques because these points can harm the patient if it applies in a wrong way. These points are located near to the spine/at waist level and the lower back points are also known as sea of vitality.³

Manipulating the acupressure points are effective for serving to do diminish anxiety, stomach ache, manage nausea & vomiting, stress induced headache, tension and low back pain.⁴

Low back pain is a common condition that affecting the lower portion of the spine. Severity is depends upon the causes either it may be acute or chronic pain. Mostly variations can occur from a dull constant ache to a sudden sharp feeling. The symptoms of the pain may start suddenly after the move. Low back pain can be sub divided into three on the basis of duration of pain, such as acute, sub-chronic and chronic.⁵

In India, low back pain is one of the most common musculoskeletal disorder, prevalent from 6.2% to 92%, in both men and women equally.⁷ According to National Institute of Neurological disorders and stroke, LBP is extremely common in adults between 30-50 years. Symptoms and level of discomfort may vary according to the cause and associated risk factors.⁶

Acupressure is not an age restricted therapy, but it is contraindicated in people with HTN, cardiovascular disease, cancer, TB, venereal disease, open wounds, broken bones, ulcer, contagious skin conditions and patient with weak back, in such case do not apply any pressure to lower back points. Pregnant women should refrain from acupressure therapy, because some particular points results in miscarriage.⁷

Conventional health care practitioners are giving more importance to analgesics, muscle relaxant, opioids and NSAIDs for patients with low back pain. These medications will give quick and temporary relief with many side effects including HTN, severe GI problems, cardiovascular problems and kidney related problems. The pain will come back soon or later and in some cases will cause increased sensitivity to pain.⁸

Materials and Method

The research approach adopted for this study was an evaluative approach. The pre-experimental one group pre-test post – test design was selected as research design. Setting of the study was selected acupuncture clinics at Mangaluru. Two types of variables are used in this study. In the present study, independent variable refers to the acupressure therapy among patients with low back pain and dependent variable refers to the pain intensity among patients with LBP. Non probability purposive sampling technique was used to select 44 LBP patients with above 18 years old & who are having mild-moderate pain.

Inclusion criteria were as follows

The inclusion criteria of the present study are:

- Those who are suffering with mild to moderate low back pain.
- Patient above 18 years old are diagnosed with low back pain.
- Those who are willing to participate in this study
- Those who are able to communicate with Kannada and English

Exclusion criteria were as follows

The exclusion criteria of the present study are:

- Patient with medication
- People with weak back
- Patient diagnosed with pathological condition of the spine, cardiovascular conditions, cancer, TB and pregnant lady.
- Who are physically disabled

Demographic proforma and numerical pain scale were used to gather the data.

The reliability of the tool was obtained by Cronbach’s alpha method (r=0.81). The pre-test was conducted for 44 LBP patients. Then 9 minutes of (3 points - UB 25, UB 32, UB 54, bilaterally) acupressure therapy was administered daily from 1st – 10th day, after obtained the personal consent from the patients. The 10th day a post-test was conducted for the patients to assess the effectiveness of acupressure therapy. Analysis and interpretation of the data was done by descriptive statistics and inferential statistics. SPSS (version -23) was used for the statistical analysis.

The data presented in table-1 describes that the highest percentages 38.60 % of the subjects were in the age group of 28-37 years. Majority 59.1 % of the subjects were females. Majority 45.5 % of the subjects were graduates and 20.50% of them were teachers, 25% of the subjects were included in other category (majority sales man 6.82%, driver 4.54%, bank employee 4.50%, advocate, security, construction worker and catering worker were 2.30%). Majority 38.6% of the subjects travelling distance were 1-30 minutes. The highest percentage, 56.8 % of the subjects were having pain for the duration of 1-6 months. All are having the previous history of treatment, In that 88.6% of the subjects were undergone for allopathic treatment. Majority 61.4% of
the subjects had moderate outcome after their previous treatment.

Wilcoxon Sign Rank test (Z test) was used to analyze the effectiveness of acupressure therapy on pain among patients with LBP and the data analysis showed that the median pre-test score was 3 and while in post – test it improved to 2. Findings of the study revealed that the median post-test pain score was significantly lower than the median pre-test score. Therefore it concluded that the acupressure therapy is effective in reducing the pain intensity among patients with low back pain.

Section D: Association between the pre-test pain scores with the selected demographic variables

Likelihood Ratio was used to analyses the significant association between the pre-test pain scores and the selected demographic variables. Likelihood ratio of age was 6.469, gender - 0.437, education - 4.288 and occupation - 7.169. The obtained p value of likelihood ration was > 0.05. Hence there was no association between the pre-test pain scores and the selected demographic variables.

Discussion

Demographic variables of patients with low back pain: The present study demonstrated that acupressure therapy has large benefit on low back pain. In this study among 44 LBP patients majority 59.1 % of the subjects were females and the highest percentage 38.60 % of the subjects were in the age group of 28-37 years. Present study findings were supported with a descriptive study conducted by Deeksha Tiwai and Garima Gupta among 300 house wives between the age group of 25-70 years were selected randomly to identify the prevalence, social burden and its impacts among patients with LBP in Kanpur. Among the respondents 93% had fresh complaints of LBP. Chronic LBP was reported among 82% of the house wives and 71% were reported limited daily activity due to pain since one year. The study was concluded that prevalence of LBP was more in housewives of Kanpur city.

Effectiveness of acupressure therapy on patients with low back pain: Wilcoxon Sign Rank test (Z test) was used to analyze the effectiveness of acupressure therapy among patients with LBP and the data analysis showed that the median pre-test score was 3 and while in post – test it improved to 2. Findings of the study revealed that the median post-test pain score was significantly lower than the median pre-test score. Therefore it concluded that the acupressure therapy was effective in reducing the pain intensity among patients with low back pain. Present study findings were consistent with an another study which was conducted in university of Pittsburgh, USA to assess the effectiveness of acupressure therapy among patient with chronic low back pain. Results of the study revealed that subjects who received true auricular point acupressure experienced 75% reduction in overall pain severity, 70% of the subjects experienced with reduction in worst pain intensity and 42% reported development in disability due to low back pain than in sham auricular point acupressure group subjects. The study was concluded that true auricular point acupressure was more effective than sham auricular point acupressure among patients with low back pain.
Association between the pre-test pain scores and the selected demographic variables: Likelihood Ratio was used to analyses the significant association between the pre-test pain scores and the selected demographic variables. Likelihood ratio of age was 6.469, gender - 0.437, education - 4.288 and occupation - 7.169, (p > 0.05). There was no association between the pre-test pain scores and the selected demographic variables. Present study findings were supported with another cross-sectional study which was carried out by Anita Shankar Acharya et.al among 1,355 administrative service and medical postgraduate aspirants, from coaching institutes in Delhi, aged between 18–35 years. Majority (90.6%) of the respondents were aged between 20–29 years. Results revealed that, age, gender, posture, dietary pattern, cigarettes smoking, alcohol consumption, caffeine intake, distance and method of travelling, frequency of heavy lifting, wearing high heels, and participating in sports activities were not associated with LBP.11

Conclusion

The focus of the study was to evaluate the effectiveness of acupressure therapy on low back pain patients. One group pre-test post -test design and evaluative approach was adopted for the study. The study involves selection of 44 samples by the purposive sampling technique and collection of data done by using demographic proforma and numerical pain scale. The pain scores of subjects after the acupressure therapy suggested that the reduction in pain was occurred due to the effect of the acupressure therapy. Reduced pain intensity will also keep the people very active in their day to day activities. Therefore it concluded that the acupressure therapy was effective in reducing the pain intensity among patients with low back pain. There was no association between the pre-test pain scores and the selected demographic variables. Analysis of the obtained data was based on the objectives and hypothesis; both descriptive and inferential statistics were used for data analysis.

Awareness about Blood Donation Process and Transfusion Transmitted Malaria in a Tribal District of Odisha, India

Pallavi Mishra

Abstract

Background: Voluntary blood donation from healthy and active student populations is the safest and most ideal way to improve the quality of blood in blood banks across the country. Studies are required to be conducted at educational institutes to investigate the awareness about blood donation process among students.

Method: A total of 585 students from four colleges were interviewed with the help of structured questionnaire to collect information regarding their knowledge about blood group and blood donation process, willingness for blood donation as well as awareness towards transfusion transmitted malaria (TTM).

Results: The majority of participants (68.8%) were unaware of their blood group. Out of total 585 students 37.3% had appropriate knowledge regarding the various aspects of blood donation and only 25.3% students were aware of TTM. Although 17.7% students have donated blood once, 56.2% were willing to be blood donors in future.

Conclusion: Compared to urban dwelling general category students, the rural students belonging to socially backward category were associated with significantly inappropriate knowledge about blood group and donation process. In spite of residing in a malaria endemic region majority of students demonstrated scarce knowledge regarding TTM. There is need for regular blood donation awareness campaigns in educational institutes to provide motivation and correct information about the process of blood donation to these young and potential blood donors.

Keywords: Blood donation; Blood group; Awareness; Transfusion; Malaria.

Introduction

Blood transfusion is considered an indispensible component of health care as it saves millions of lives each year worldwide. As there is no substitute to blood, blood donation is of utmost importance for patients with bleeding disorders, accidents, child birth, surgeries, hematological diseases and malignancies.[1] The World Health Organization (WHO) recommended an increase of voluntary blood donation units and widespread awareness of blood donation, especially among young people. [2] The healthy, active and huge student populations can be a good source of quality blood as they are less commonly affected with some popular diseases like hypertension, diabetes, cardiovascular problems etc. unlike the older candidates. Further, it is easy to access this group through internet and social media through mobile applications. [3]

Transfusion transmitted malaria (TTM) poses a major threat to blood banking system. [4] Ethical concern has been raised regarding rejection of parasitaemic blood donors in malaria endemic countries where blood supplies are insufficient and rejecting such donors will exacerbate already critical blood shortage. Donor deferral based on history of exposure to malaria is not feasible in endemic countries as the exposure is universal. Malaria rapid diagnostic tests (RDTs) have been recommended by WHO for confirming malaria
diagnosis in blood donors, however, they have not been widely evaluated as a screening tool in malaria endemic settings. Therefore, awareness is required about TTM among potential blood donors in malaria-endemic regions which can improve the quality of blood collected through voluntary blood donation.

There is lack of awareness among socially underdeveloped communities about the measures needed to protect their health. Hence, studies are needed to be conducted at school and college levels to educate these students from deprived backgrounds which they can propagate at higher community level. Therefore, the objective of this study was to determine the knowledge about blood donation process as well as awareness about the blood TTM among undergraduate students in this backward malaria-endemic region of Odisha, India.

Materials and Method

Study design and Setting: This was a cross sectional study conducted in four undergraduate colleges in district Kandhamal, Odisha, India, during the period of August 2017 to March 2018. A total 585 students from four colleges were selected by doing systematic sampling from each college. After approval from the institutional ethical committee, the principal investigator explained the nature and purpose of the study to all randomly selected students and written informed consent was taken from them. Data was collected through face to face interviews using a pre-tested, close-ended questionnaire.

Data Analysis Procedure: The data so collected was analysed by Statistical Package for Social Sciences (SPSS 19.0). Descriptive statistics was used to determine mean and standard deviation for continuous variables like age while frequency and percentage for qualitative variables (gender, college, class year, caste, place of residence etc). Scoring was done for knowledge and willingness towards blood donation process and about TTM; each right response was given a score of 1 while a wrong or unsure response was scored 0. Multiple regressions were used to examine the effect of two or more independent variables on a single dependent variable to test the statistical significance at 95% confidence level. P-value of < 0.05 was considered as significant.

Results

A total of 585 interviews were performed during data collection period. The mean age of participants was 20 ± 1.58 years. Majority of respondents were males (54%), studying to Govt. College (60.3%), belonged to general category (53.3%) and resided in rural areas (57%). of the 585 students, only 31.2% (n = 183) knew their blood group. The main sources of data were the Personal Health Record (n = 83, 45.3%), verbal information from parents (n = 41, 22.4%), the results of laboratory examinations performed on a doctor’s recommendations (n = 28, 15.3%), results obtained from the blood donation campaign during blood donation (n = 22, 12%) and the results of analysis performed during college classes (n = 9, 5%).

Majority of participants (62.6%) had no proper knowledge regarding various aspect of blood donation process like frequency, exclusion criteria, minimum age, weight, haemoglobin levels and volume of blood required for donation. The sum of responses was summarized as a knowledge score and a logistic regression analysis was performed (Table 1). Male students were associated with appropriate knowledge of blood donation when compared against female gender (AOR: 0.5, 95% CI: 0.3-0.8). General category students scored much better in possessing appropriate knowledge regarding blood donation as compared to reserved backward communities (AOR: 0.2, 95% CI: 0.1-0.3). Students studying in 3rd year possess better knowledge as compared to 1st and 2nd year (AOR: 2.6, 95% CI: 2.0-3.4). Students of Urban residing students scored better than rural students in having appropriate knowledge (AOR: 0.2, 95% CI: 0.1-0.4) (Table 1).

Out of 585 study participants only 17.7% (n=104) subjects had ever donated blood. However, 56.2% (n=318) showed willingness towards blood donation in future.-The major reason for donating blood was to save lives (43.5%, n=255) while ignorance (36.2%, n=212) was the major reasons of not donating blood (Figure 1). Male students (AOR: 0.5, 95% CI: 0.3-0.7) showed more willingness towards blood donation when compared against female students (Table 2).

Knowledge about TTM was generally low among the students. Almost 21.4% students had not heard about TTM. Almost 30% of students felt that a person who has suffered from malaria should not donate blood and 32% respondents were of the opinion that screening for malaria should be performed before blood donation to prevent TTM. Urban residing students (AOR: 0.5, 95% CI: 0.3-0.8) showed better scores as compared to rural students (Table 3).

Figure 1. Reasons for no donation of blood among study participants (n=585).

Discussion

Blood donation decision making has been investigated worldwide to understand the process better which would increase donation efficiency among young subjects especially students. The present study suggests that there is deficient basic knowledge regarding blood groups (31.2%) and blood donation process (28.2%) among undergraduate students in these backward areas. Majority of the students lack basic information about universal blood donors or acceptors, rare blood group types etc. Interestingly, few first time donors took part in blood donation camps so that they can get a free analysis of their blood types. Hence, clear and concise information regarding the blood donation process should be provided in blood donation camps to the first time donors. On the contrary, other studies have specified that the students possess very high knowledge regarding blood donation.\[6\] The difference could be a reflection of the perception of practice of blood donation in different societies. Further, most of the studies were carried
among medical students who possess better fundamental knowledge about blood donation in comparison to non-medical undergraduate students as in the present study.

There are several studies that predict the attitude of non donors, first-time donors, and repeated donors and analyze the most common causes of refusing blood donation. The present survey indicates that only 17.7% of students have donated blood. This is comparable (15%) with findings from a study performed in Nigeria but very low as compared to the study results obtained from university students in Nepal (43%).

Interestingly, majority of the student blood donors confirmed that they have donated only in blood donation camps especially which were organized in the college by Red Cross Society. This aspect indicates the importance of blood donation camps in educational institutes. In our survey students were more likely to donate blood in case of increased demand (32%), because they realized that blood transfusion is a noble act and might save someone’s life. This altruistic behaviour shown by students is in agreement with other studies and needs to be cultivated for retention of blood donors. However, a great majority of respondents (33%) considered donating blood to someone closely related, as observed elsewhere. Almost 36% of students have never considered becoming a blood donor due to lack of information about when, where and whom to donate blood. This finding has been corroborated by reports from other studies.

Startlingly, it was found that despite performing the surveys among adults, some respondents (16%) do not donate blood because their parents do not agree. This was found more amongst female students. Further, it was found that compared to males students (61%), female students (46.4%) were less willing to donate blood. These findings were comparable with other survey reports. Females may not be able to donate blood because of monthly menstrual cycles. About 7.6% of respondents stated that there is nothing that could convince them to become a blood donor. The reasons for the statement were probably based on one’s belief that the collected blood is wasted or not safe in blood banks or is never available on time when needed. Other causes of refusal for blood donation amongst non donors were attributed to health reasons, fear of needles, painful experience of blood collection and fear of complications and disease transmission. It is also important to note that all the reasons provided by the students for not donating blood could be addressed through blood donation awareness campaigns by providing emphasis on benefits to be derived from blood donation. In the current study it was found that about 56.2% have never donated blood, but do not refuse that they might become a blood donor in the future. These findings are aligning with other studies elsewhere.

The risk of TTM is high in all malaria-endemic areas due to high prevalence of the infection in the blood donor community. This can create a major problem as semi-immune individuals with low level of parasitemia can remain asymptomatic and may qualify as blood donors. Donated blood is not routinely screened for malaria parasites in most malaria-endemic countries unlike that in nonmalaria-endemic regions. As a result there is a high prevalence of TTM due to blood donation from asymptomatic blood donors in malaria-endemic regions, but strategies to curtail its transmission are seldom applied. There is very little published data relating to knowledge and attitudes of blood donors to TTM. This is the first study conducted to investigate the awareness among undergraduate students about TTM in a malaria endemic district of Odisha, India.

**Conclusion**

This study indicated that the level of knowledge and awareness about blood group, blood donation process and transfusion transmitted malaria was very less among the undergraduate students especially from underprivileged backward classes residing in rural areas. Although, a major proportion of students had never donated blood, but most of them were willing to donate in future. There is need for regular blood donation awareness campaigns in educational institutes and the society at large to give these young and potential blood donors motivation and correct information on the process of safe blood donation as well as the knowledge on the value of blood as a life saver. At such social campaigns, potential donors should be encouraged to register themselves in some social networking sites so that donation reminders can be sent to them when required.

Reproductive and Sexual Health Knowledge and Utilization of Services among Adolescents: A Review Based on Available Literature

Pooja Yadav¹, Nageshwar V.², Prabhu J.³

¹M.Sc. Nsg. 2nd Year Student, ²Assistant Professor, Department of Mental Health Nursing, ³Assistant Professor, Department of Community Health Nursing, Teerthanker Mahaveer College of Nursing, TMU, Moradabad, U.P.

Abstract

Introduction: Today adolescent’s RSH is one of the essential health concern which focused as global attention. Adolescents often lack basic reproductive health (RH) information, knowledge and access to health services for RH.

Objectives: To determine the knowledge on reproductive and sexual health and utilization of services among adolescents.

Method: A comprehensive systematic session of published literature and journal articles from Pub Med and EBSCOHOST databases was done that are focusing from 2010 – 2017. Search strategy specific to each databases was used.

Result: Out of seven articles, one research study finding is showing good knowledge on RH and services. One research study found that the female adolescents had moderate knowledge regarding RSH. Two research studies revealed that lack of knowledge about RSH. Three research studies found that there was poor utilization of RSH services.

Conclusion: This review concludes that there is a need for intensified effort to increase the knowledge on RSH and utilization of services by adolescents. Hence, multiple approaches are needed to reach and meet the diverse needs of the different age group of adolescents.

Keywords: Knowledge, Reproductive and Sexual Health (RSH), Utilization, Services, Adolescents.

Introduction

Today’s generation of adolescents are the largest in history and the major source of human resource for the development of any nation. According to WHO estimates, one in every five people in the world is an adolescent.¹ Globally the adolescent is estimated to reach 1.25 billion where 85% of the adolescents are residing in the developing countries.² Adolescents are one of the heterogeneous group and that are the most vulnerable to a range of reproductive health problems, such as teenage pregnancy and childbearing, unsafe abortion and sexually transmitted infections (STI’s), including HIV.³ The reproductive and sexual health of adolescents has been recognized as an important health concern and has been focus as an important component of global attention.⁴ Globally, a number of strategies have been adopted. Universal access to sexual and reproductive health (SRH) services for adolescents as added as a target to the revise Millennium Development Goals framework in 2005. As a result, there is growing recognition of an appropriate and effective strategy to address sexual and reproductive health (SRH) needs of adolescents. Different SRH programs have been initiated at community and school levels in order to reach adolescents.⁵

A study conducted by UNICEF found that 6% of school-going children in the age group of 14 – 19 years were engaged in heterosexual intercourse and reported that around 20% of them knowing the friends who were sexually active.(4)

Young adults have insufficient access to preventive and curative services; however they have limited access to reproductive health information. The reproductive health of women in low-income countries represents a growing concern as per the rates of HIV infection among women is become higher than men. A study conducted at reproductive health (RH) clinics in Egypt reported that there was lack of knowledge on RH and also poor attendance rate of female population at the clinics.(6)

Hence, it was found necessary to design a narrative review to find the available literature for identifying the reproductive and sexual health knowledge and utilization of services among adolescents.

**Aim:** The aim of this review is to identify the knowledge on reproductive and sexual health and utilization of services among adolescents.

**Objectives:** To determine the reproductive and sexual health knowledge and utilization of services among adolescents.

**Methodology**

**Search Strategy:** An electronic search of articles published in various journals till 2017 (September) was conducted. Search was restricted to only English language. The database search done was Pub Med and EBSCOHOST. Articles containing following key search terms were retrieved.

**Types of Study:** Community based cross-sectional, comparative, survey and phenomenological study.

**Types of Participant:** Adolescents including females; School-going students and Young women.

**Settings:** Community-Town, Urban Slum, Schools and University.

**Outcome:** Knowledge of Reproductive and Sexual Health and its utilization among adolescents.

**Result**

The systematic search was conducted by framing the terms individually and in combination with all synonyms, also according to the database. In addition to this, a manual Pub Med search was undertaken using the keywords and search synonyms from already found articles. Additions of seven articles were found. Initial search retrieved 541245 articles over which 83363 articles were selected manually. Duplicates were removed and reviewed 410 articles for eligibility, 82953 articles were excluded because they didn’t match with the study criteria. 370 studies were excluded due to unavailability of full text. Hence seven articles were screened which included in qualitative synthesis.

**A detail description of study**

1. **Tegegn. Ayyalew et al.** conducted a Community-based Cross-sectional study in the year of 2008 on Reproductive Health Knowledge and Attitude among Adolescents in Jimma Town, Southwest Ethiopia. 1130 Adolescents were selected by Systematic sampling technique. Data was obtained by interview method using structured questionnaire. Findings revealed that majority of adolescents knew major health services for RH and the main health service providers of RH. The average index score of attitude for health services of RH was also moderately favourable.

2. **Heewageegana. Rajapaksa. Neelamani et al.** conducted a Survey in the year of 2015 on Sexual and reproductive knowledge, attitudes and behaviours in a school-going population of Sri Lanka. Total 2020 adolescents were selected by simple random sampling technique. Data was obtained by Self-completion Questionnaire. Findings revealed that most of them reported good parent – child relationship (88%). A minority (34%) discussed sexual issues with parents. Health professional were the preferred source of information (32%) rather than parents (12.5%) or friends (5.6%). Less than 1% demonstrated satisfactory sexual and reproductive knowledge levels.
3. **Bobhate S. Prateek et al.** conducted a Cross-sectional study in the year of 2011 on knowledge and practices about Reproductive Health among Female Adolescents in an urban slum of Mumbai. 241 Females were selected by purposive sampling. Data was obtained by face to face interview method using Semi - structured questionnaire. Findings revealed that Seventy nine (32.8%) subjects had unsatisfactory menstrual hygiene practices. Two hundred twelve (88%) women were aware about availability of ANC services. Sixty six per cent of women had correct knowledge of mode of transmission of HIV while only 18.7% knew about safe sexual practices. Education status and early adolescents age group was found to be significantly associated with the knowledge of adolescents regarding menstruation.

4. **Gelany. El Saad. et al.** conducted a Cross-sectional, community-based survey in the year of 2013 on Reproductive health awareness among educated young women in Egypt. 220 Female students were selected by purposive random sampling technique. Data was obtained by interview method by using Structured in – depth questionnaire. Findings revealed that a large proportion of the participants exhibited misunderstanding or a complete lack of knowledge about important RH issues.

5. **Bilal M. Selamawit. et al** conducted a Cross-sectional survey in the year of 2015 on Utilization of Sexual and Reproductive Health Services in Ethiopia – Does it affect sexual activity among high school students. 1042 female and male high school students were selected by multistage sampling technique. Data was obtained by self-administered questionnaire. Findings revealed that one out of five students had used the SRH services in the past year. The primary reason for visiting the SRH services was to receive information. The mean age for the first sexual intercourse was 15.7 and one - quarter of the students had multiple sexual partners. Unwanted pregnancies and abortion were reported by female students.

6. **Prasad. Shailaja M. et al.** conducted a Comparative study in the year of 2015 on Adolescent Reproductive and Sexual Health Practices (ARSH) and adolescent gynaecological problems among the girls in Sweden and India. 400 Swedish and Indian adolescents’ girls were selected by purposive sampling technique. Data was obtained by interview method using questionnaire. Findings revealed that ARSH practices were safe in Sweden in sharp contrast to India. Gynaecological problems were similar in the adolescents of both countries.

7. **Goodia. Pamela et al.** conducted a phenomenological study in the year of 2014 on Young people’s perception of sexual and reproductive health services in Kenya. 57 young boys and girls were selected by purposive sampling technique. Data was obtained by focussed group discussion and In-depth interview method using semi - structured questionnaire. Findings revealed in the following themes that are: SRH problems faced by young people, Addressing the SRH needs of young people, Perceptions of existing SRH services, Suggestion on how to improve SRH service.

**Summary and Findings:** The available literature refined to get Six quantitative and One qualitative. Out of Seven articles, one research study finding is showing good knowledge on Reproductive Health and Services. One research study found that the female adolescents had average knowledge regarding Reproductive and Sexual Health. Two research studies revealed that lack of knowledge about Reproductive and Sexual Health. Three research studies found that there was poor utilization of Reproductive and Sexual Health services.

**Importance in Education and Society:** Adolescents are too often left out of policy planning and service delivery. More focus needs to be placed on providing learning and preparation for the world of work, building healthy lifestyles that reduce non-communicable diseases and improve sexual health, and protecting adolescents from involvement in violence.

Reproductive health is not just about sex. It is part of a holistic health program starting from early age teaching values and understanding the anatomy and physiology of their body. This education continues when they are young adults to have safe and acceptable access to method of fertility regulation of their choice and the right to have access to appropriate healthcare services.

To maintain one’s sexual and reproductive health, people need access to accurate information. They must be informed and empowered to protect themselves from sexually transmitted infections. When they decide to have children, women must have access to services that can help them have a fit pregnancy, safe delivery and healthy baby.
Future Significance: The review helps to understand the knowledge on reproductive and sexual health and utilization of services among adolescents. 30% of India’s total population comprises of adolescents. Hence, it is necessary to create awareness among people, especially the adolescents, regarding various reproduction related aspects as the adolescents are the future of the country and they are most susceptible of acquiring sexually transmitted diseases.

Limitation
- Search strategy was limited to two databases.
- Search strategy was refined to knowledge on reproductive and sexual health and utilization of its services only.
- Was limited to only in Adolescents.
- Seven articles were included only.

Strength
- Article search was carried out on significant criteria.
- Review could find out the gap between knowledge on reproductive and sexual health and its service utilization among the adolescents.

Weakness
- Articles mainly focus on only knowledge.
- Only six quantitative and one qualitative articles were included for data synthesis due to limitations.

Conclusion
Knowledge on reproductive and sexual health can be increased through awareness and also by providing Reproductive and Sexual Health education among adolescents at school level. Collaboration and networking are the key strategies to improve adolescent access to reproductive and sexual health services. There is a need to network with organized and unorganized sector such as education, ICDS, NGOs working in the field of adolescent health and development to work as a team and address the multifaceted needs of the adolescents.

A Retrospective Study to Understand the Clinico-Social Profile of Neonatal Deaths in a Teaching Hospital

Soumyashree M.N., R.G. Viveki, Sunanda Halki

Postgraduate Student, Professor and Head, Statistician, Department of Community Medicine, Belagavi Institute of Medical Sciences, Belagavi, Karnataka, India

Abstract

Introduction: The first 28 days of life is the neonatal period, which represents the most vulnerable time for a child’s survival. In 2015 neonatal mortality rate was 19 and 28 per 1000 live births for world and India respectively. It is important to reduce neonatal mortality to address the major causes of neonatal deaths.

Objective: (1) To understand the clinico-social profile of the neonatal deaths. (2) To correlate the causes of neonatal deaths with age, parity and other obstetrics parameters.

Methodology: A retrospective study was conducted in Department of Pediatrics, Belagavi Institute of Medical Sciences, Belagavi from January to December 2016. 114 study cases were included, the parents of the expired neonates who were admitted in Pediatric Department, BIMS Hospital were interviewed for the information about socio-demographic details, antenatal, natal and postnatal history by using pre-designed, pre-tested and structured questionnaire after taking written informed consent. The cause of neonatal death was recorded from case sheet after taking permission from the Department of Paediatrics. Data was analysed using Ms Excel 2007 and SPSS version 22, proportion and chi square test was applied and p value < 0.05 was considered as significant.

Results: 70 (61.4%) and 44 (38.6%) of them were found to be male and female respectively. 83 (72.8%) of them resided in rural area whereas, 31 (27.2%) resided in urban area. Majority (26.3) of the mothers were illiterate. The common causes of death among the deceased neonates were prematurity (43.9%) followed by, birth asphyxia (36%). Age of the deceased neonates (early neonates, late neonates) was significantly associated with educational status of the mothers (P < 0.05) and practice of washing hands with soap water after defecation (P < 0.05).

Conclusion: Most of the neonatal mortalities can be prevented by effective implementation of MCH services and timely interventions.

Keywords: Neonate, Mortality, Hospital.

Introduction

Today’s children are tomorrow’s citizens of the country. Thus, the normal health and growth of children plays an important role in the prosperity of the country. Neonatal period (first 28 days of life) represents the most vulnerable time for a child’s survival. The children are at an increased risk of mortality and morbidity than the general population, this is more so in the first year of life. More than half the infant deaths occur in the first 28 days of life. According to WHO (2016) neonatal deaths contribute about 46% of under-five mortality. Globally, neonatal mortality rate (NMR) was 19 per 1000 live births and in India it was 28 per 1000 live births (2016). So, it is essential to reduce neonatal morbidities and mortalities, as by doing so one can reduce the infant mortality, for which the neonatal mortality is the largest

Sustainable development goal (goal three, target two) states that, by 2030, end preventable deaths of newborns and aim to reduce NMR to 12 per 1000 live births. Despite several interventions implemented for the improvement of neonatal survival, the pace of decline in NMR has been slow. Neonatal mortality is an important public health problem. Hardly there are any study conducted in Karnataka and Belagavi regarding all the determinants of neonatal mortality. The present study is an attempt to fill the knowledge gaps in understanding the socio-demographic profile of the neonates dying in a teaching hospital and to assess the etiological factors responsible for the neonatal deaths.

**Material and Method**

A retrospective study was conducted among the expired neonates in Department of Pediatrics, BIMS, Belagavi during the period of January to December 2016. Ethical Clearance was obtained from Institutional Ethical Committee (IEC). A formal permission to conduct the study was obtained from the authorities of the hospital and consent was taken from mother or the close relatives of study participants. Sample size was estimated by considering the proportion of the most common cause of neonatal deaths. According to a study by Ramdurg U Yet al. The proportion of the most common cause of neonatal deaths was found to be contributed by birth asphyxia by 34.6%. Considering 10% of allowable error, minimal sample size being 101; however, the present study included 114 study participants. All neonatal deaths occurring in Paediatric Department (NICU, PICU and ward), BIMS Hospital, Belagavi, who fulfilled selection criteria were studied till the required sample size was reached.

A structured, pre-validated, questionnaire was used to collect relevant data from the informant of the deceased neonates i.e., either mother or the close relatives through personal interviewing. The information regarding condition of the neonates before the death and cause of death of each deceased neonates was collected from the treating doctors. Neonates admitted under Paediatric Department (Neonatal intensive care unit (NICU), Paediatric intensive care unit (PICU) and ward), BIMS Hospital, Belagavi, who expired during their stay in the Hospital and all inborn / outborn deceased neonates were included. Neonate age or date of birth not known, mothers or relatives not willing to give information and mothers seriously ill and relatives not knowing the details of antenatal, intranatal and postnatal were excluded. Data was entered in Microsoft excel sheet 2007 and analyzed in SPSS version 22. Chi square test was used to test the association between different qualitative variables. At 95% Confidence interval, a probability value (p value) of ≤ 0.05 was considered as statistically significant.

**Findings:** As shown in table 1, nearly half of the mothers of deceased neonates belonged to the age group of 21 – 25 years (46.5%), followed by less or equal to 20 years (28.9%). 70 (61.4%) and 44 (38.6%) of them were found to be male and female respectively. 83 (72.8%) of them resided in rural area whereas, 31 (27.2%) resided in urban area. Majority (26.3%) of the mothers were illiterate.

In the present study, majority (50.9%) of deceased neonates were found in first birth order of the mother, followed by second birth order (29.8%). 32 (27.2%) of them were born within 1 – 2 years of birth interval, 13.2% of the study cases were found to have 3 – 4 years of birth interval. Most (85.1%) of them were born in Government health facilities, followed by private health facility (7.9%), home (5.3%). Surprisingly 2 (1.8%) cases were born in vehicle during travel to the health facility as seen in Table 2.

Table 3 shows, age of the deceased neonates (early neonates, late neonates) was significantly associated with educational status of the mothers (P < 0.05) and practice of washing hands with soap water after defecation (P < 0.05). No relationship was found with the sex of the study cases (P > 0.05). The common causes of death among the deceased neonates were prematurity (43.9%) followed by, birth asphyxia (36%), sepsis (12.3%), pneumonia (2.6%) and congenital anomalies and other (2.6%) (figure 1).

**Discussion**

82.5% of the deceased neonates were early neonates and 12.5% of them were late neonates. Similar findings were found in studies conducted in Government hospitals in Andhra Pradesh and Maharashtra, majority of the study cases were neonates followed by post neonates. Nearly half of neonatal deaths occurred among the mothers of age 21 – 25 years (47.5%). Similar results were found in a studies conducted in other countries by Kananura M R et al. In the current study majority of the deceased neonates were found to be male. Similar findings were found in studies conducted in...
et al.9, Upadhyaya S et al.10 Dube L et al.11, Manandhar S R et al.12, Titaley LC et al.13, and Weldaregaw B et al.14. This shows biological vulnerability of males to infection is more than females in their early ages. Most of the study cases resided in rural areas, similar findings were reported in a study done in India39 and also in other countries studies by Dube L et al.11, Titaley LC et al.13, and Mekonnen Y et al.16.

In this study majority (73.6%) of the mothers were literate. Most of the neonatal deaths occurred in less than secondary level of education and this association was statistically significant. Similar findings are seen in the studies conducted by Kusneniwar G N et al.17 and Mekonnen Y et al16. Maternal education is argued to improve child health through increased knowledge about the practices to improve child health and increased use of maternal care services. However studies conducted in Ethiopia and Kenya showed no association between maternal education and neonatal mortality11,54.

In this study, the common causes of death among the deceased neonates were prematurity (43.9%) followed by, birth asphyxia (36%) and sepsis (12.3%). Prematurity was the commonest cause of deaths in studies done by Patil R B et al.9 and Prasad V K et al.6. However, birth asphyxia was the commonest cause in studies done in southern India, Maharatra, Karnataka (Bagalkot) and Bangladesh10,7,4,19. As this study was hospital based, the findings cannot be generalized at the community level and a prospective follow up study of all newborns would have been ideal to know the risks associated with neonatal deaths. These were the limitations of the study.

Figure no 1: Causes of neonatal deaths

Conclusion

Most common cause of deaths was prematurity, followed by birth asphyxia. Promotion of Institutional delivery is on greater need. Mothers and their close relatives should be explained about the warning signs of labor and the need for timely referral to the health care centers for safe delivery. Proper implementation of programmes related to mother and child health care is required.

Hoarding Disorder Effects and its Management

R. Sree Raja Kumar
Associate Professor, School of Nursing Science and Research, Sharda University, Greater Noida,
School of Nursing Science and Research, Sharda University, Greater Noida

Abstract
Hoarding disorder is a persistent difficulty discarding or parting with possessions because of a perceived need to save them. A person with hoarding disorder experiences distress at the thought of getting rid of the items. Excessive accumulation of items, regardless of actual value, occurs where someone acquires an excessive number of items and stores them in a chaotic manner, usually resulting in unmanageable amounts of clutter. Hoarding disorder is also known as compulsive hoarding is a kind of behavior that is characterized by huge acquisition and not willing to discard the large quantities of objects that cover the living areas of the home that clutter and cause significant distress or impairment in areas of functioning.

Keywords: Hoarding, Cognitive behavior therapy (CBT), Compulsive hoarding, Schizophrenia, clutter.

Introduction
Hoarding disorder first defined as a mental disorder in the 5th edition of the Diagnostic and Statistical Manual (DSM) in 2013. Hoarding disorder occurs in an estimated 2 to 6 percent of the population and often leads to substantial distress and problems functioning. Some research show hoarding disorder is more common in males than females. It is also more common among older adults–three times as many adults 55 to 94 years are affected by hoarding disorder compared to adults 34 to 44 years old.1

Hoarding often creates such cramped living conditions that homes may be filled to capacity, with only narrow pathways winding through stacks of clutter. Countertops, sinks, stoves, desks, stairways and virtually all other surfaces are usually piled with stuff. And when there’s no more room inside, the clutter may spread to the garage, vehicles, yard and other storage facilities. Hoarding ranges from mild to severe. In some cases, hoarding may not have much impact on your life, while in other cases it seriously affects your functioning on a daily basis.2

The amount of clutter interferes with everyday living – for example, the person is unable to use their kitchen or bathroom and cannot access rooms the clutter is causing significant distress or negatively affecting the quality of life of the person or their family – for example, they become upset if someone tries to clear the clutter and their relationship suffers.2

Definition: Hoarding is a disorder characterized by an ongoing resistance to discarding unnecessary items like junk mail, old newspapers, and materials that most people would consider to be garbage. People with hoarding disorder also hold on to personal possessions that are no longer needed, either because they feel personally attached to the items or because they believe they will need them in the future. The accumulation of clutter and lack of order and cleanliness can cause health and safety risks within the home and create social, professional, and functional problems for a person with hoarding disorder. The disorder also affects the people around the hoarder.3

Causes: The exact cause of hoarding is disorder is not known. It can be a symptom of another condition. But there are certain known risk factors of hoarding disorder.

- Family history
- Brain injuries
- A stressful life event, such as the death of a loved one,
- Abnormalities of brain function and neuropsychological performance.3

Mental health problems associated with hoarding includes:
- Severe depression
- Schizophrenia
 Obsessive compulsive disorder (OCD).
 Attention-deficit/hyperactivity disorder (ADHD)
 Anxiety disorders.

Difference between hoarding and collecting:
Many people have the habit of collecting various objects which is being considered as a hobby such as collecting the stamps, Old currency, books which may not be considered s a problem. The major difference between hoard and collection is only how the items are being organized. A collection is usually well ordered, and the items are easily accessible. A hoard is usually much disorganized, takes up a lot of room and the items are largely inaccessible.

Fig. 1: Depicts the person with hoarding disorder

Fig. 2: Depicts that the difference between collection and hoarding

Types of items which may hoard are:
 News Papers
 Books
 Clothes
 Leaflets, Letters and Junk mail.
 Bills, Receipts
 Containers including plastic bags and card boards.
 Household supplies.
 Animals hoarding.

Signs and symptoms:
 Excessively acquiring items that are not needed or for which there’s no space.
 Persistent difficulty throwing out or parting with your things, regardless of actual value.
 Feeling a need to save these items, and being upset by the thought of discarding them.
 Building up of clutter to the point where rooms become unusable.
 Having a tendency toward indecisiveness, perfectionism, avoidance, procrastination, and problems with planning and organizing.
 Disorganized piles or stacks of items, such as newspapers, clothes, paperwork, books or sentimental items.
 Possessions that crowd and clutter your walking spaces and living areas and make the space unusable for the intended purpose, such as not being able to cook in the kitchen or use the bathroom to bathe.
 Buildup of food or trash to unusually excessive, unsanitary levels.
 Significant distress or problems functioning or keeping yourself and others safe in your home.
 Conflict with others who try to reduce or remove clutter from your home.
 Difficulty organizing items, sometimes losing important items in the clutter.

Complications
There are many complications which may leads due to hoarding are:
 Increased risk of falls.
 Injury or being trapped by shifting or falling items.
 Family conflicts.
 Loneliness and social isolation.
 Unsanitary conditions that pose a risk to health.
 A fire hazard.
 Poor work performance.
 Legal issues, such as eviction.
Diagnosis

There are specific symptoms for a hoarding diagnosis includes:

- Lasting problems with throwing out or giving away possessions regardless of their actual value.
- The problems are due to a perceived need to save the items and to distress linked to parting with them.
- Items fill, block and clutter active living spaces so they cannot be used, or use is hampered by the large amount of items.4

Treatment

**Cognitive Behavior therapy:** CBT is a type of therapy that aims to help you manage the problems by changing how they think (cognitive) and act (behavior). The goal is to improve the person’s decision-making and organizational skills, help them to overcome urges to save and, ultimately, clear the clutter, room by room.5

**Antidepressants:** Antidepressant medication (selective serotonin reuptake inhibitors or SSRIs) are the primary treatments used to relieve symptoms of hoarding disorder. One or the other, or both, may be employed.5

Conclusion

It is most important for all medical and Nursing professionals to be aware about newly arising mental ill disorders and to develop comprehensive assessment of the people with peculiar behaviors and to find out the association hoarding disorder with other mental ill problems, its early detection and prompt treatment and its prevention.

Analysis of Trunk Muscle Activity in Hemiplegia During Sitting on Two Different Unstable Surfaces

Indira Sharma¹, Radhika C.M.², Sivakumar R.³, N. Venkatesh⁴

¹Post Graduate, ²Asst. Professor, ³Principal, ⁴Course Chairman, Faculty of Physiotherapy, SRMC & RI

Abstract

Background: Following stroke, the abdominal muscles demonstrate a remarkable loss of activity. This is characterized by asymmetry in performance of rotation and side bending activities. Paralysis of the core muscles increases the tendency to fall towards the paralyzed side causing asymmetry. Trunk function along with balance and walking ability has been a valid predictor of stroke rehabilitation outcome. The aim of the study is to analyze the trunk muscle recruitment in hemiplegic stroke subjects sitting on two different unstable surfaces.

Method: 30 subjects who fulfilled the inclusion criteria were considered for the study. Out of which 15 subjects were normal individuals and 15 were hemiparetic stroke subjects. Subjects in both the groups were tested for external oblique and erector spinae muscle recruitment during set of activities like flexion, extension and lateral flexion of trunk. They were made to sit on Swiss ball and wobble board, and the muscle activity was recorded in paretic side and non-paretic side in stroke patients, right and left side in normal individuals. Average EMG value was recorded in (micro-volt), Un-paired t test and Mann-Whitney U test was used for significance difference.

Result: Data was analyzed using SPSS version 16. In normal Individuals both external oblique and erector spinae muscle activity on the two unstable surfaces was similar and did not show any significant difference. Muscle recruitment on paretic and non-paretic side showed significant difference for both Erector Spinae and external oblique muscle. Result reveals that there was no significant difference between Swiss ball and wobble board both in external oblique and Erector Spinae muscle recruitment.

Conclusion: Trunk muscle recruitment during activity on wobble board had similar effect as Swiss ball. Hence we concluded that wobble board can be used as adjunct to Swiss ball for balance training in Stroke patients.

Keywords: Trunk muscle activity, unstable surfaces, EMG, Swiss ball, wobble board, stroke patients.

Introduction

The WHO (World Health Organization) defines stroke as the rapid development of clinical signs and symptoms of focal neurological disturbances lasting more than 24 hours or leading to death with no apparent cause other than vascular origin. It is also one of the largest causes for disability and half of all stroke survivors have disability and over one-third are dependent on care givers.¹

Trunk muscles play an important role in the support of our body in antigravity postures such as sitting and standing and in the stabilization of proximal body parts during voluntary limb movements.² After the onset of stroke, the abdominal muscles demonstrate a remarkable loss of activity and tone and it is characterized by asymmetry in performance of rotation and side bending activity. The function of trunk muscles in patients with stroke is compromised, and this is reflected in many aspects, such as decreased muscle strength, poor postural control and impaired functional activities. The common
problem in hemiplegics is decrease in core muscle function, leading to paralysis and increased tendency to fall towards the paralyzed side causing asymmetry.³

The stability of the trunk on an unstable surface depends upon the ability to align the projection of the center of mass with the center of rotation of the support surface; added to this there is the need to control inertial forces generated by trunk movements⁴. Unstable environment stress sensory and motor feedback loops resulting in increased body sway and muscle activity⁵. Unstable surface increases the external swing which more effectively encourages postural orientation by forcing faster modification of sensory system and motor system and also insist in postural strategy of self–postural control.⁶

Many studies have shown the effectiveness of using Swiss ball as an unstable surface for training the trunk muscle in stroke patients . Trunk exercises performed on physio ball (unstable surfaces) are more effective than those on plinth (stable surface) for improving lateral flexion and rotation of the trunk.⁷ As such there are also few studies that has focused on effectiveness of using wobble board as a balance training in stroke patients, and they have analyzed that balance training on unstable surface is very effective in improving static and dynamic balance.⁸

Trunk control has been shown to be a valid predictor of stroke rehabilitation outcome. Many Studies in stroke patients on trunk muscle activation in different unstable surfaces has been reported but there is lack of studies that has compared two different unstable surfaces to see the motor recruitment of trunk in hemi paretic side and studies on how the support surface affects trunk muscle activation in stroke patients. Therefore, we investigate to analyze the trunk muscle activity in hemi paretic side sitting on two different unstable surfaces.

**Methodology:** An observational study approved by Instiuitional Ethical Committee Sri Ramachandra Medical and Research Institute (Deemed to be University) Porur, Chennai on 31/08/2017 (REF: CSP/17/AUG/60/250). Stroke In–patients who were admitted in Sri Ramachandra Medical Center under Neuromedicine unit were recruited. The duration of the study was six months. The sample design was purposive sampling.

**Subjects and Method:** First time stroke patients who were able to comprehend orally were screened for inclusion in the study. The Inclusion criteria includes (1) able to sit without support. (2) Able to sit on the Swiss ball with the guidance of the therapist. (3) Able to sit on the wobble board with the guidance of the therapist. Exclusion criteria: (1) congenital deformities, (2) severe balance impairment, (3) associated cardiovascular problems limiting the testing, (4) patients who are apprehensive to sit on Swiss ball and wobble board, (5) participants with severe orthopedic problems, (6) and visual problems that might interfere during the activities.

Based on the inclusion criteria after obtaining informed consent from the participants, 30 individual were recruited for the study. Stroke group included 15 patients, and 15 healthy aged matched control group (35 years and older). Subjects included acute (1 week) having (ischemic or hemorrhage) Cerebral vascular accident with left or right sided hemiplegic stroke, without any other neurological diseases that might affect their balance.

**Procedure:** Stroke subjects receiving conventional physiotherapy were included in the study. Participants both normal and hemi paretic stroke subjects were given the same sets of activities. Participants were made to sit on, multidirectional wobble board measuring 17cm (height), 17.5cm (breath), and Swiss ball (blue isokinetic anti burst exercise ball of 75cm 30”) and they were asked to sit keeping their feet completely resting on the ground with hip and knee flexed at 90degree on two surfaces .Preparation of EMG electrodes site were cleaned with scrubbing 70 percent of alcohol (ethanol) to reduce skin resistance .The participants were asked to perform trunk activities like forward flexion, extension, side flexion (right and left) and, one activity lasted for 10 second, rest period was given in between the activities. Average EMG recording was taken both from hemiparetic side (affected side) and normal side (non-affected) for stroke patients and right and left side from the normal individuals.

**Apparatus:** Surface EMG was recorded using wireless Neurotrac software 4.0 of VM (Verity Medical Ltd, United Kingdom). Surface bipolar electrodes were used to measure the EMG activity of external oblique and erector spinae muscle. Two active electrodes and one reference electrode was placed on hemiparetic side (affected) and normal side (non-affected) in stroke patients and right and left in normal individuals. For Erector Spinae electrodes were placed vertically at a distance of 30mm from the spinous process at both sides of ES(T6), ES(T10), ES(L3) muscle. Electrodes
for External Oblique muscle was placed approximately 3cm anterior to and midway along a line drawn from the lateral pelvic crest to the lateral lower ribcage parallel to muscle fiber orientation. Reference electrode was positioned over the manubrium bone of the sternum. For EMG measurement, the SENIAM recommendation (www.seniam.org) was followed. Normalization of EMG data was collected from each muscle determined by calculating the RMS (Root mean square), duration of 10sec maximum voluntary contraction of trunk activity was recorded on two unstable surfaces. Average EMG recording was taken for data analysis.

Results

Statistical Analysis: Statistical analysis was done using IBM SPSS statistics software. Descriptive statistical analysis for normal individuals and stroke patients was done. Age of the patients and age- matched healthy individuals were tested using un-paired t-test for base line similarity. Comparison between Swiss ball and wobble board on the paretic side was done using unpaired t-test and Mann Whitney U test was used to see the significant level between the two surfaces.

Discussion

This study was conducted to analyse the recruitment of trunk muscles (external oblique and erector spinae) in hemiparetic (stroke patients) and age-matched normal individuals on two different unstable surfaces. Muscle activity during sitting was compared to analyse if there was any difference in the recruitment pattern during sitting in Swiss ball and wobble board.

The right and the left side of external oblique and erector spinae muscle activities were recorded in the normal individuals on two unstable surfaces and were statistically analysed. And results showed that there was no significant mean difference between the recruitment patterns of both the muscles on both the side. The muscle activity was similar on right and left and over the two unstable surfaces. There is lack of studies which has directly compared between the two unstable surfaces but there are studies which have showed both Swiss ball and wobble board are effective in balance training.

EMG analysis on comparing the muscle activity between paretic side and non-paretic side, the results showed that there was a significant mean difference and the muscle recruitment was greater over the non-paretic side of the trunk. The recruitment was greater during flexion of the trunk on both the unstable surfaces. Task on Swiss ball lead to greater activation of external oblique, transverse abdominis, internal oblique, erector spinae and rectus abdominis level when compared with stable surface\(^9\). Thus, proving the study that the recruitment of the muscles are greater on the unstable than over the stable surface.

Our Analysis showed even though the muscle activity was not significant, there was moderate level of muscle recruitment on the paretic side also. Thus, showing that when a hemiparetic patient is made to sit on an unstable surface and made to perform the movements it increases activation of erector spinae and external oblique muscle on the paretic side. Thus, supporting the study which showed that trunk exercises performed on an unstable surface on trunk muscle activation showed activation of external and internal oblique muscles\(^10\).

There was no significant mean difference between the Swiss ball and wobble in paretic side of stroke patients. However, muscle recruitment on comparison with wobble board and Swiss ball, it was slightly higher in Swiss ball with external oblique muscle, while the activity in Erector spinae muscle during flexion, extension, and lateral flexion, mean difference was higher in wobble board. There are many studies that have used wobble board as a balance training method in Sports and rehabilitation for balance training but there fewer studies that has used wobble board in stroke patients for rehabilitation purposes. To our knowledge previous studies has only compared stable versus unstable surface in stroke patients.

This was the first study which has compared two different unstable surfaces to see whether both surfaces has similar effect in trunk muscle recruitment in hemiparetic stroke patients when sitting on wobble board and Swiss ball.

Therefore our study concluded saying that wobble board had similar effect as Swiss ball in trunk muscle recruitment in hemiparetic stroke patients. So instead of Swiss ball, wobble board can be used for balance training as it is more easy, portable to carry to the beside of patients for rehabilitation and balance training. Further to conclude the muscle activity was also significant when the stroke subjects were made to sit on the unstable surfaces which can be utilized for trunk muscle training.

Limitation

1. This study was done with single time testing in stroke patients, in a smaller sample.
2. Patients were apprehensive sitting on the wobble board instead of taking precautions so a larger diameter of wobble board can be utilized for the study.
Conclusion

Therefore, this study concluded that Swiss ball and wobble board showed almost similar recruitment pattern in hemiparetic stroke patient as well as in normal individuals so it is inconclusive to make any remark on the use of wobble board and Swiss ball for muscle recruitment on balance training for treating hemiparetic stroke patient.

Future Studies: Should be performed in larger population in hemiparetic stroke patients.

Physical and Psychological Health Issues among the Night Shift Workers

M. Sripriya¹, S.N. Sugumar²

¹Research Scholar; ²Prof. and Head, Department of Economics, VISTAS, Chennai

Abstract

In this modern century shift work, particularly night shift can be an irresistible option for many employees due to the high wages and allowances. Though financial growth is mandatory to meet our requirements, night shift may lead to some serious risks to health. Shift work can have a negative impact on both physical health and well-being of workers. Shift work may cause disturbances in normal circadian rhythms and in maintaining both relationships at family and social level. Night work effects women’s health on both hormonal and reproductive function, and their family responsibility.

Keywords: Night shift, Health, Employees, Organization, Biological clock, Circadian rhythms, Physical and Psychological health.

Introduction

We need job to acquire an honest living and job is essential for survival. Apart from these reasons we started working for various other aspects like prosperity, keeping societal growth in motion and to pretend that we are efficient of something that we are lacking than anyone around. Our society and community measure people’s success, dignity and quality by their wealth. Hence, we are forced to take any position beyond the nature including jobs with night shifts which is also called as “graveyard shift”. One of the primary reason to prefer such shift is, urge for finance and monetary and for theshift differential paid by many organization to their employees for the work which is done outside the regular hours. Night shift employee’s working hour will stand outside the regular time, nine p.m. to five a.m. The graveyard shift is a suggestive term for the night shift, between middle of the night and eight in the morning. An employee who constantly works in night shifts faces a significant increase in overall risks to their both physical and mental health¹.

Statement of the Problem: Health illness is a major challenge faced by many countries which lead to Health care costs. People started working in night shifts for higher pay and allowance, but night shifts may lead to health risks and create severe impact on both health and economic conditions of the people which lead to huge medical expenses. This study throws light on the impact of night shift on both physical and psychological health illness.

Objective of the study: To examine and analyse the physical and psychological health issues among the night shift professionals.

Review of Literature: D’Ettorre G, Pellicani V, Greco M, Mazzotta M, Vullo A², stated about the enhancement of safety among workplace and about the action need to be taken to improve medical disorder in Organizations on both scheduling shifts and consequently to ensure workers wellness. Eiriksgöt, Reykjavík³, discusses about the “association between the disruption of the circadian cycle caused by shift work and adverse health effects.”

Nea FM, Kearney J, Livingstone MB, Pourshahidi LK, Corish CA⁴ in their works on,”Dietary and
lifestyle habits and the associated health risks in shift workers” summarized the data on the effects of shift work on the diet, lifestyle and health of employees.

Angerer P, Schmook R, Elfantel I, Li J, in their works on “Night Work and the Risk of Depression”, stated that in addition to the direct effects of disrupted chrono - biological rhythm on sleep, hormone regulation, and many other biological functions, psycho-social working conditions with adverse effects on health, which are qualitatively and quantitatively different for shift workers and those who work during the day.

Giovanni Costa, in his work “Shift Work and Health: Current Problems and Preventive Actions”, tells about the overview of the issue to be tackled by occupational health due to shift work and the guidelines at both the levels, organizations and medicines on how to protect worker’s health and well-being.

Types of Organization working later hours: Professions most likely to hire night shift workers include:

- Emergency services
- Military services
- Food services
- Public transportation
- Shipping
- Hospital especially Nurses
- Law enforcement
- Software and IT
- BPO

In modern times, service industries started influencing the world’s financial resources, hence a tremendous number of workers started working in night shifts. Hence, health illness correlated with later hours has become a serious issue.

Symptoms of later hour shifts: Signs and symptoms of night shift health concerns include

- Constant feelings of fatigue and sickness
- Problems attuning to the circumstances
- Depression
- Downheartedness
- Increase in sensitivity to cold and fever.

Disorders related to digestion like nausea, diarrhea and other matters of improper functioning of the bowels or digestive tract can emerge. Disruption of the Sleeping patterns of the night shift worker may become problematic as the individual worker may find it more complex to sleep even when time is available for sleep. This will lead to the effect of sleep deprivation.

Physical and psychological issues and risks associated with night shifts: Why health is getting affected for the workers working in night shift is that a very serious issue? of course, Yes. The foremost thing which leads to all types of diseases due to non-standard shift is lack of sleep. Let’s discuss this in detail. One of the foremost reasons for the disruption of circadian rhythms is night shift which causes significant alterations of sleep and biological functions that can affect physical and psychological well-being. Three mechanisms which promotes health, performance, and safety issues correlated with night-shift work are as follows

Physical Health: Shift work such as night shift is linked with certain chronic diseases and health illness. Employees working in night shift for prolonged period could suffer from certain cancers and lead to many health issues like metabolic problems, heart diseases, ulcers, gastrointestinal problems and obesity. Insufficient or lack of sleepleads to changes in metabolism and appetite. Added to these biological factors, night shift workers have poor and irregular eating habits which will increase their risk of metabolic problems. Employees usually have irregular and unhealthy food habits. They usually skip meals and find hard to fit in exercise. The unfortunate fact is that shift workers are more at risk of weight gain and heart disease than those who work set daily hours.

Mental Health: Night shift work can increase the risk of mental health problems like depression, because of the disruption of the circadian system. It also causes certain social issues which will decrease the wellbeing and happiness. If we work in irregular hours, we might eventually feel “out of step” with the people in our family and social network.

Performance: Shift workers sleep less than the required amount, and which lead to “sleep debt” over time. Night shift workers work at night; hence they are going against the nature and biological clock. Our concentration may be decreased, and it can become harder to stay focused on any task and we will lose our productivity.
Safety: There are many reasons shift work can be dangerous. Lack of sleep leads to slower reactions and make harder in decision making. Employees working at night go against the nature, hence even if a shift worker sleeps enough, a dip in alertness can come at night. Supervision is sometimes reduced on night shifts. Driving to and from work with lack of sleep could result in accident. Employees who work in night shifts prone to commit mistakes frequently.

Circadian Rhythm: Circadian Rhythm is both physical and mental behavioral changes that follow daily cycle that lasts up to 24 hours and it is approximately 24-hour cycle in the physiological processes of humans. Sleep-wake cycle is one of the circadian rhythm. A disruption of thus rhythm is known as circadian rhythm sleep disorder. One of the gland called pineal gland produces a hormone called melatonin, which helps in maintaining circadian rhythm and regulate reproductive hormones.

CRSD - Circadian rhythm sleep disorder: Circadian rhythm sleep disorders refer to the disorder of sleep pattern. Some disorders lead to interruption in normal, physical, mental, social and emotional functioning.

“Misalignment between the internal clock and life activities, Chronic partial sleep deprivation and Melatonin suppression by light at night”.

Circadian syndrome rhythms of sleep can cause different disorders. Shift work sleep syndrome develops insomnia or excess sleepiness. Alternate night shifts and rotating shifts disturb sleep cycle and affect the performance. Both the psychological and physical health of an employee can be affected by extended night shift work. Fatigue and overtiredness due to lack of sleep may also lead to the risk of serious diseases like Cancer and heart attack. According to the research by Violanti, Vila and colleagues, “Night work and fatigue may also contribute to the risk of heart disease and cancer”.

Employees who work frequently in shift between 8 p.m. to 4 a.m. will have the highest chances of metabolic syndrome symptoms and those who frequently worked and averaged lesser than six hours of sleep were four times more likely to have metabolic syndrome. Further, another report from the year 2004, identified that employees who worked night shifts for 12-hours, were more likely to experience fatigue, and abuse to smoke and alcohol than their day-shift colleagues. Workers who work in night shift for long period are likely to get in to the risk of specific type of cancers, metabolic problems, gastrointestinal problems, obesity and heart diseases. In addition to these biotic factors, employees who work in night shift at times will have unstable eating habits and unhealthy diet which will increase their risk of metabolic problems. Workers who work in night shifts and rotating shifts won’t sleep enough, which will lead to long-term sleep deprivation. Shift work disorder can increase the risk of psychological problems like melancholy because of the disruption of the body clock and cause certain social issues which will decrease the prosperousness, wellbeing and happiness. Possibilities for the development of heart diseases increase by thirty-five to forty-five percent and the rate of risk for stroke increases for those workers who works night shifts for a period of ten to twenty years or longer. Correlated physiological risks incorporate increase in probability of high blood pressure, high cholesterol, high blood sugar, weight gain.

The graveyard shift theory at long last proves correct because the hormone melatonin, which prevents the tumor development, is produced only at night hence millions of people across the countries working in night shifts could be affected. In 1987 Richard Stevens, professor at the University of Connecticut Health Center and a cancer epidemiologist spot the connection between night shift and cancer. In recent years, many research found that women working in night shifts for a long period were prone to breast cancer and men working at night may have a higher rate of prostate cancer.

Things needed to be taken care by employees to reduce the health effects

- Need to concentrate more on healthy things such as healthy diet and exercise.
- Need to keep same schedule for sleep even when we sleep during daytime
- Need to keep the room dark and calm where we sleep.
- Calls and messages can disturb or sleep, hence try to switch off the mobile or keep it in silent mode. Continuous sleep is more important.

Conclusion

Obviously, several workers can’t quit their job though they’re in night shift because of varied reasons. However, we can attempt to keep ourselves healthy.
Foremost concern is “how will night shift workers adapt to their schedules?” per discoverer theory, “we will shift the body’s time unit clock in order that it tolerates engaging ourselves at night and sleeping throughout the day”. Earlier analysis has found that we could detain the mechanism by one or 2 hours per day. If we tend to work nights, it’s necessary that we tend to implement a schedule that is simple to follow and healthy. Obtaining enough sleep and intake of healthy foods will create operating shifts easier and might improve overall health. Sleeping in dark space, Usage of sunglasses during to and from workplace will facilitate in orientating mechanism. Healthiness isn’t the thing that we can purchase with money. Choosing right job at right time, avoiding night shifts, regular exercises and healthy food habit is crucial to keep our body healthy.

Discussion

In a process of globalization and the development of Multi National Corporations shift work becomes order of the day among the countries in the world. The nature and pattern of work culture changes due to change in the world economic system and technologies. Night shift is mandatory among the MNCs. Change in the work culture such as night shift changes shift worker’s food habits, sleeping system and life style which in turn change the physical and psychological aspects among the night shift professionals. This creates biological contradictions in human metabolism which results in so many human ailments such as insomnia, sleep disorder, frustration, poor digestion, abnormal behavior etc.

Insomnia—Some Issues and Remedical Measures

G. Raguram¹, S.N. Sugumar²

¹Research Scholar, ²Prof. and Head, Department of Economics, VISTAS, Chennai

Abstract

Sleep disorder, now-a-days is a common health issue among the people including rich and poor. This may be due to various reasons such as socio-economic, physical and psychological issues. Sleep deprivation is one of the most common causes of many human ailments. In modern times, people have less sleeping hours than their ancestors. Sleeping disorder is a condition characterized by abnormal sleep or inadequate sleep or cannot sleep due to emotional, mental and physical dysfunction. Due to sleep disorders in humans, the metabolic activity of the brain decreases significantly and result in tiredness, feel lazy, no energy, strange appetite and resulted in gain weight or lose weight, affects focus and concentration that slows down our reaction time and committing numerous mistakes. Continuous practice of a few hand mudras, yogasanas and meditations may be useful to overcome the problem of sleep disorder.

Keywords: Insomnia, Physical and mental health, hand mudras, asanas. Cognitive behavioral therapy, REM and NREM and Acupressure.

Introduction

Sleep disorder, now-a-days is a common health issue among the people including rich and poor. This may be due to various reasons such as socio-economic, physical and psychological issues. Sleep deprivation is one of the most common causes of many human ailments. In modern times, people have less sleeping hours than their ancestors. Sleeping disorder is a condition characterized by abnormal sleep or inadequate sleep or cannot sleep due to emotional, mental and physical dysfunction.

The word insomnia came from Latin and it means “without sleep”. The available literature reveals that one in three adults suffers from insomnia and 1 in 10 adults suffer from chronic insomnia. Insomnia affects women more often than men. However, aged people are more likely to get insomnia than the younger generations as the former have more chances of having pain and disturbances due to physical deterioration, stress, and too much responsibility.¹

Statement of the problem: Insomnia is a kind of ill health that is a major challenging health hazard prevails among the people throughout the world. It requires a special attention as it leads to human ailments. This is usually very common among the depressed or who have social and economic problems such as divorce or death of a spouse, having low incomes, working at night or have frequent changes in their work hours, traveling long distances with time changes, having certain medical conditions or sleep disorders that can disrupt sleep and an inactive lifestyle are the major reasons for this illness.

Objectives of this article: This article throws light on the causes and consequences of insomnia on both physical and psychological health and suggests a few remedies to overcome it.

Review of literature: A survey conducted in the United States with a sample of 1.1 million residents reveals that those who sleep about 7 hours per night had the lowest rates of mortality, whereas those who sleep less than 6 hours or more than 8 hours had higher mortality rates. Getting 8.5 or more hours of sleep per night was associated with a 15% higher mortality rate.
Severe insomnia was found those who sleep less than 3.5 hours in women and 4.5 hours in men which is associated with a 15% increase in mortality. 2

T. Roth hassaid that they may have difficulty in falling asleep, or staying asleep as long as desired.3 Insomnia is resulted daytime sleepiness, low energy, irritability, and a depressed mood. It may also result in an increased risk of motor vehicle collisions, as well as problems infocusing and learning. Insomnia can be short term, lasting for days or weeks, and long term, lasting more than a month.

Tosman and others (2015)in their research article analyzed that between 10% and 30% of adults suffer from insomnia at any given point in time and it is found among 50% of people in a given year.4A study by Wilson J.F (2008) revealed that people over the age of 65 are affected more often than younger people and females are more often affected than males5. Jiang X and others concluded in their studies that the victims of insomnia is more among university students than the general population.6

According to WHO Insomnia can occur independently or as a result of any physical, mental ailments suchas psychological stress, chronic pain, heartfailure, hyperthyroidism, heartburn, restless leg syndrome, menopause, certain medications, and drugs such as caffeine, nicotine, and alcohol and people who indulge in night shift work. Where as Taylor and Mallory concluded that it may also be due to previous thoracic surgery and Heart disease7 and Lave and others stated that insomnia may be due to deviated nasal septum and nocturnal breathing disorders.8

The National Heart Lung Institute examined that periodic limb movement disorder (PLMD), may cause insomnia. Ramakrishnan in his article said that pain due to injury and inability to find comfortable position to sleep may also cause insomnia.9 On the other hand, Santoro in his research pointed out that hormone imbalance, menstrual disorder may also lead to insomnia.10

**Significance of sleep:** Sleep is a natural state of rest for both the mind and the body and it is occurred by closing the eyes and the loss of consciousness partially or completely. Further, during sleep there is less physical movements, less external stimuli but more internal stimuli. No one knows and understands the significance of sleep, but sleep has an impotent restorative function which is indispensable for the survival of man and animals. Sleep helps the body to recover from all the works it did. Good sleep in the night is essential for the normal healthy functioning of the human body as well as mental health, including the immune system which is must to fight against diseases. Body takes rest and restores its energy levels during sleep. Sleep is often helping us to come out from stress and frustration and also to recover from illness.

According to National Sleep Foundation (NSF) sleep is considered as a complicated physiological phenomenon that scientists still not able to understand fully. Neurotransmitters are chemicals involved in nerve signaling which controls whether one sleeps or awakes. Neurons located in the brainstem induce sleep by inhibiting other parts of the brain that keeps one awake. Sleep must for a person’s physical and mental health and over all well-being. However, millions of people do not get enough sleep due to various reasons..

There are two basic forms of sleep: rapid eye movement (REM) sleep and non-rapid eye movement (NREM) sleep. Experiments have shown that if people are deprived of NREM may experience physical tiredness and if they are deprived of REM sleep then they suffer from anxious and irritable state. REM sleep has also been considering as important for memory and learning.

**Classification of insomnia:** Insomnia can be classified as transient, acute and chronic.

**Transient insomnia** lasts for less than a week. It can be caused by another disorder namely changes in the sleep environment and the timing of sleep, severe depression, or stress. It leads to sleepiness and impaired psychomotor performance.

**Acute insomnia** is inability to consistently sleep well for a period of less than a month. Insomnia is present when there is difficulty in initiating or maintaining sleep. These problems occur despite adequate opportunity and circumstances for sleep and they must result in problems with daytime function. Acute insomnia is also known as short term insomnia or stress related insomnia.

**Chronic insomnia** lasts for longer than a month. It can be caused by another disorder, or it can be a primary disorder. People with high levels of stress and hormone imbalance will have chronic insomnia. It leads to muscular weariness, hallucinations, mental fatigue and double vision.
Causes of Insomnia: The causes of insomnia may be classified into primary and secondary insomnia.

Primary insomnia is not a symptom or side effect of another medical condition. This type of insomnia usually occurs for periods of at least one month. Lifestyle disorder can trigger primary insomnia. It may be due to major or long-lasting stress or emotional upset, long travel or other factors, such as work schedules that disrupt routine sleep can also trigger primary insomnia.

Secondary insomnia is the symptom or side effect of another problem. It is a symptom of an emotional, neurological, or other medical or sleep disorder. Emotional disorders that can cause insomnia that include depression, anxiety, and post-traumatic stress disorder. Alzheimer’s disease and Parkinson’s disease are examples of common neurological disorders that can cause insomnia. Also conditions that cause chronic pain, such as arthritis and headache disorders, conditions that make it hard to breathe, such as asthma and heart failure, an overactive thyroid, gastrointestinal disorders, such as heartburn, stroke, restless legs syndrome and sleep-related breathing problems and Menopause and hot flashes.

In addition, psychological problems like fear, stress, anxiety, emotional or mental tension, work problems, financial stress, and unsatisfactory sex life, disturbances of the circadian rhythm, such as shift work and jet lag, can cause an inability to sleep at some times of the day and excessive sleepiness at other times of the day.

Consequences of insomnia: Sleep deprivation is affecting human’s brainpower, creativity and their psychological behaviors. In humans, the metabolic activity of the brain decreases significantly after 24 hours of continuous wakefulness and result in tiredness, feel lazy, no energy, strange appetite and resulted in gain weight or lose weight, affects focus and concentration of mind. This in turn leads to inability to handle stress and impossible to solve the problem with unnecessary anger even for minor mistakes and resulted in inability to judge and interact with other people in an acceptable manner. In addition, it causes a drastic change in body such as decrease in body temperature and immune system function.

Remedial measures: In recent days Cognitive behavioral therapy (CBT) is taught to improve sleeping habits among insomnia patients along with relaxation therapies and, of late, Meta cognition behavior therapy. For primary sleep disorder, as per the alternative medical practices, a few yoga asana such as savasana, sukhasana may be practiced. Savasana can be practiced by any person at any age. It is just lying down by back and completely relax the whole body with the relaxation techniques.

I. Relaxation Technique: For instance, we can relax our body while in savasana telling that “my toes are relaxed, my feet are relaxed, my ankles are relaxed, my keens are relaxed, my hip is relaxed, my abdominal muscles such as kidney and urinary bladder are relaxed, my liver and gall bladder are relaxed, my small intestine and large intestine are relaxed, my stomach and spleen are relaxed, my pancreas is relaxed, my diaphragm is relaxed, my lungs are relaxed, my heart is relaxed, my pericardium is relaxed, my triple warmer is relaxed, my central nerve system is relaxed, my chest is relaxed, my shoulders are relaxed, my hands are relaxed, my neck and throat are relaxed, my head is relaxed, my brain is relaxed, my eyes are relaxed, my nose and mouth are relaxed and my ears are relaxed. My body and all its organs, bones, muscles, nerves, tissues and cells are relaxed. This technique may also be practiced while we sit in sukhasana. sukkasana means comfortable way of sitting on the ground or chair.

II. Hand Mudras: A few hand mudras such as Gnana mudra and Prana mudra may also be practiced to induce sleep in humans.Gnana mudra can be done by sitting in a comfortable position by joining the tips of thumb and index fingers and stretching out the rest of the fingers. Prana mudra can be practiced by sitting in a comfortable position by joining the tips of thumb, little finger and ring finger and stretching out other fingers. In addition, one can give affirmative statement while we go to sleep like “All cells in my body feel sleepy” and this may be repeated with cent percent concentration, i.e., the concentration on the intention to sleep until we get sleep.

III. Acupressure and Acupuncture Points

a. Gentle stimulation or mild massage around the hand web – joining point of thumb and index point for few seconds. (LI 4 in acupuncture).

b. Gentle massage around outer crease of the elbow. (LI 11 in acupuncture)
c. Gentle massage around the heel and the ankle bones on both sides of the legs (K6 and B62 in acupuncture)

d. Gently stretching arms and legs side to side and ups and downs.

e. Gentle eye rotation with closed eyes.

IV. Energy Medicines: Law of mind is one of the immutable universal law. As per the law of mentalism mind creates everything and everything is mind. The whole world is the projection made by human mind and it is the most powerful energy in the universe. By using the power or energy of mind we can overcome all physical and mental illness. Energy medicine is a practice in which we use the power of the mind to cure any ailments. Mind power may be enhanced and realized through the practice of be in the present i.e. think what you do and do what you think, true love towards the universe (love for sake of love without any expectation). These practices will improve the concentration of mind and that is the secret of energy medicines. With the enhanced mind power if we talk to ourselves like “I go to sleep…. I sleep……” repeatedly very soon we get into sleep automatically.

V. Sleep-Friendly habits: Generally, the practice of early to bed and early to raise, keeping a regular time schedule, for sleep including weekends, taking dinner before 7 p.m., being and becoming polite and feeling happiness while go to bed, feeling happiness in every cells of the body, listening to melodious and devotional songs and music, avoid taking alcohol, tea or coffee, keeping proper ventilation for the bed room, and so on.

Conclusion

Good sleep at night naturally indicates healthy body and mind. Body needs good sleep at night to equip and rebuild energy to work next day. It is a natural energy and booster for the growth and expansion of cells in the human body. By nature, we take rest in night and we become active during the day time. Insomnia drains out the energy in the body and weakens the cell and the organ of the human body. It is indispensable to have a good sleep at night either through the conventional medical practices or through alternative medical practices. It is true that the deep sleep is possible when the mind is polite, calm, and pure and in harmony and let us practice this for good sleep and healthy life.

Discussion

Sleep is a natural state of rest for both the mind and the body, proper sleep at night makes the mind and body healthy and active in the day time. Loss of sleep means loss of health. Good sleep at night is essential for improved immune system. Of late, life style disorder is the main reason for most of the non-communicable disease such as diabetic, obesity, cardio vascular disease including sleep disorders. In the era of globalization, shift work, less physical exercises, erratic food and sleep habit, too much of dependency on machines, cause sleep disorder among the people throughout the world. At this juncture, it is pertinent that the natural way of life and being content with what we possess may lead us to healthy and wealthy life.

Socio–Economic Conditions of Industrial Workers in Theni District of Tamil Nadu

S. Saravanan, M. Ramesh, S.N. Sugumar, S. Chandrachud

Abstract

Labour is the most dynamic agency in the processes of production. The productivity of the labour force of the country is therefore vital for rapid economic growth. The social aspects of minimum wage and job security regulations are necessary to promote the welfare of the workers. Rapid growth of employment and real wages should be of primary interest to workers in any country. Employment and real earnings per employee in the manufacturing sector have risen very slowly in India while the performance of the East Asian countries has been the most outstanding in this respect. The rapid growth of employment and real earnings per employee in East Asia is the combined result of labour policies along with a whole range of successfully implemented export orientated industrialization policies which yielded rapid GDP growth.

Keywords: Dynamic agency, Minimum wage, Human capital, Workforce, Job training, Migration.

Introduction

Labour is the most dynamic agency in the processes of production. Productivity of the labour force of the country is therefore crucial for rapid economic growth. Labour markets play a major role in determining the success of the economic restructuring policies. The social aspects of minimum wage and job security regulations are necessary to promote the welfare of the workers.

World Bank has emphasized the efficiency aspect of labour markets and the interventions such as the minimum wage and job security provisions may reduce employment, and increase productivity and growth thus improving the living conditions of workers in the long run. The rapid growth of employment and real earnings per employee in East Asia is the combined result of labour policies along with a whole range of successfully implemented export orientated industrialization policies which yielded rapid GDP growth.

Importance of Labour: Labour is not homogenous in that there are vast differences in skill formation, dexterity, innate talents, productivity and earning profits. Labour is of two types viz. skilled and unskilled labourers. Human capital is formed by way of formal education, on the job training, job market information, health and nutrition and migration. When the average worker produces more in an hour i.e. when there is an increase in labour productivity, then the total output of the economy grows.

Review of Literature: Manickam. S. (2010) highlighted that the instance of conducive works relations is critical for promoting economic development in general and industrial development in particular. A perusal of data on number of strikes and lock outs in India reveals a declining trend. The number of man days lost because of lockouts has continuously been on the decline.

Deepita Chakaravarthy (2010): In her article argues that the increasing importance of unorganized manufacturing is not so much the results of weak trade unionism and the vulnerable workforce as it is of an implicit understanding between the trade unions and the management. Perpetuating in formalization is likely to
benefit the management, especially in the context of low-productivity, low-wage manufacturing in West Bengal.

Dipak Mazumdar and Sandip Sarkar (2009) in their paper that an important aspect of the recent growth pattern of the Indian economy has been apparent sluggishness in the output and employment growth in the manufacturing sector in spite of a period of relatively high growth rate of GDP.

Gala, S. and Breathy S. (2009) in their paper that An oligopolistic market, fluctuating market conditions, inadequate modernization and the subordinate status of hired workers have contributed to the poor living conditions of workers in Sircilla, a power loom centre of Andhra Pradesh.

Kannan, K. P, Raveendran, G (2009) in their papers stated that there have been considerable debates in India about the organized manufacturing sector for different periods since the early 1980’s. Good part of the resultant increase is with proportion to output growth. The workers as a class thus lost in terms of both additional employment and real wages in organized manufacturing sector.

Objectives of the Study:
1. To study the socio-economic conditions of industrial workers in the study area.
2. To examine the factors influencing wage of the industrial workers.
3. To offer practical suggestions for improving the welfare of the workers and
4. To suggest suitable policy options to ensure and enhance the holistic development of quality of life of the workers.

Limitations of the Study: Since majority of the factory owners did not have sufficient educational background, they hesitated and even some refused to grant permission to interview the workers. Hence it took long time to explain the purpose of the study to some factory employers.

Research Methodology: The study is a cross-section analysis pertaining to Industrial workers in Theni district of Tamilnadu with special reference to income, standard of living, employment and economic entitlement. Therefore, Theni district is selected as a sample district in the state of Tamilnadu. Out of 306 registered plants with Inspector of Factories,only 206 industries are presently functioning.A total of 5573 workers are working in the sample industries. Out of 5573 workers, 360 sample workers were randomly selected for the study.

Sources of Data: Primary data were collected through well-structured interview schedule, which covers details regarding their Employment, wage and, saving pattern, and debt position. Besides, secondary data pertaining to the study have been collected from the concerned Government Offices studies, books and journals.

Tools of Analysis: The study is primarily analytical in nature. Apart from the conventional statistical tools like Percentage Analysis, Garret’s Ranking Techniques, are employed to bring out scientific results.

Data Analysis:

Table 1. Age–wise distribution of Industrial Workers (in years)

<table>
<thead>

<td>36 (10.00)</td>
<td>360 (100.00)</td>
</tr>
</tbody>
</table>

Source: Survey Data, Note: Figures in parentheses are percentages to respective totals.

It is clear from table 1 that among the 360 workers in all the three categories of industries, 32.22 per cent of workers belong to the age group of 21-30 years followed by 25.56 per cent workers in the age group of 31-40 years. It could be inferred that the age category of (32.22%) 21-30 years workers are larger in numbers among the sample industries.
Table 2. Gender–wise Distribution of Industrial Workers

<table>
<thead>
<tr>
<th>SL No.</th>
<th>Sample Industries</th>
<th>Male</th>

<td>Total</td>
<td></td>
<td>224 (62.22)</td>
<td>136 (37.78)</td>
<td>360 (100.00)</td>
</tr>
</tbody>
</table>

Source: Survey Data, Note: Figures in parentheses are percentages to respective totals.

It is observed from Table 2 that out of 360 sample workers, female workers constitute only a small proportion (37.78%) to the total workers. Majority of the workers i.e., 62.22 per cent are men.

As per the investigation, most of the industrial workers belong to agriculture based families and they own their traditional family houses. It is evident that 302 industrial workers (83.89%) live in rented and leased houses.

Table 3. Family Type of Industrial Workers

<tr>
<td>Total</td>
<td>188 (52.22)</td>
<td>158 (43.89)</td>
<td>14 (3.89)</td>
<td>360 (100.00)</td>
</tr>
</tbody>
</table>

Source: Survey Data, Note: Figures in parentheses are percentages to respective total.

The details of family type of the industrial workers are presented in Table 3. There are three types of family, namely, nuclear, extended and independent in the study area. Among the three categories of sample industries, nuclear family is found to be larger (52.22 per cent) followed by extended family which accounts for 43.89 per cent. Therefore, it is seen that nuclear family concept is strongly practiced by cotton spinning, cotton weaving and processing and power loom industrial workers in the study area.

Table 4. Details of Income Received by the Sample workers (per month- in Rs.)

<table>
<thead>
<tr>
<th>Sample Industries</th>
<th>Below 2000</th>

</tr>
<tr>
<td>Power loom</td>
<td>17 (14.17)</td>
<td>23 (19.17)</td>
</tr>
<tr>
<td>Total</td>
<td>35 (9.72)</td>
<td>45 (12.50)</td>
</tr>
</tbody>
</table>

Source: Survey Data, Note: Figures in parentheses are percentages to respective totals.
It is found from table 5 that out of 360 workers, 144 of them incur monthly expenditure of Rs.3501–4500 followed by 95 workers who spend Rs.5501 and above. 41 workers spend Rs.4501–5500 per month.

The survey states that out of 360 sample workers, 271 are non-savers and 89 are savers. It is noticed that 24.72 per cent workers have the habit of saving knowing that saving is a virtue.

The study reveals that the industrial workers possess both movable and immovable properties. The movable property includes gold, cash and vessels and the immovable property consist of land and buildings. Out of 360 workers only 58 and 52 workers have house and land respectively as immovable properties. It reflects that most of the workers do not have immovable properties like house buildings and land. The simple reason is the inadequate flow of income.

**Indebtedness Analysis:** Industrial workers borrow loan from various sources to meet out their expenses. Five sources are accessed by the workers for obtaining loans. It is observed that out of 197 workers, 33 workers (16.75%) who have borrowed loan from various banks for meeting their expenses, 92 workers get the help of money lenders for availing loan. 41 of them borrow loan from their relatives and friends. 11 of them get loan from co-operative societies. 20 workers get loan from their employers. The amount of debt distribution ranges from Rs.10000 and below to Rs.40001 and above. It is observed that maximum number of workers (92) depend on money lenders for their unforeseen expenditure.

**Garrett’s Ranking Table:** Garrett ranking table is used to find out the influencing factors of wage determination according to the rank basis. The Factors are classified into eight categories. The industrial workers were asked about the factorial influence on wage determination according to their preferences. The following formula used to convert the order of the factors in to ranks.

\[
\text{Per cent position} = \frac{100(Rij - 0.5)}{N_j}
\]

\(Rij = \text{Rank given by the } i^{th} \text{ factor and } N_j = \text{Number of factors ranked by the } j^{th} \text{ individual}\)

The per cent position is obtained and it is converted into scores using Garrett’s rank table. After that, the scores of the individual workers for each of the factors are added and then divided by the total number of workers who had responded. The mean score is the rank in descending order of magnitude.

The Garrett’s ranking table reveals that, wages mostly influenced by labour cost, cost of living, labour unions and employers decision and so on.

**Findings:**

1. The analysis Age-wise distribution of workers revealed that 57.78 per cent of the workers fell in the age group of 21 to 40 years in all the three category of industries.
2. The gender-study of Industrial workers explores that 224 (62.22%) are male and 136 (37.78%) are female workers. It is also to pin point that out of 360 industrial workers 31 are male children workers and 14 are female children workers. This reflects employment of child labour is seen in the industries.
3. The analysis on housing characteristics showed that only 58 workers possess own house and remaining workers are leading their life in either rented or leased houses. The sewage facility is found only with 187 workers dwellings.
4. The analysis of economic status and family type is reveals the information that nuclear type of family is found with 52.22 per cent of industrial workers in the study area.
5. The actual income pattern of the workers reflect that the category of Rs.3001-4000 and Rs.2001-3000 is earned by the 33.05 per cent and 26.39 industrial workers respectively. Only 6.67 per cent of workers are earning Rs.5000 and above per month.
6. The expenditure pattern shows that the food expenditure is ranked as number one followed by housing, loan repayment, clothing and health care.
7. The saving position of the workers indicated that 24.72 per cent are savers and 75.28 per cent are non-savers. LIC and Post Offices are preferred by 52 workers for saving their money.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Performance appraisal</td>
</tr>
</tbody>
</table>

The Garrett’s ranking table reveals that, wages mostly influenced by labour cost, cost of living, labour unions and employers decision and so on.
8. The analysis of asset structure of industrial workers has brought out the fact that only 110 are holding movable assets which are in the form of house and land. The movable property particularly cash-holding is practiced is done by only 84 workers.

9. It is found that out of 360 industrial workers 197 get trapped in indebtedness. The loan amount is borrowed mostly for health care needs and educational needs and followed by the need to celebrate festivities.

10. The Garatt’s mean score value in cotton spinning industrial workers is 91.67 whereas under cotton weaving and processing industry and power loom the mean scores are 84.56 and 91.13 respectively. The society’s sector Garatt’s mean score value is the lowest i.e., 28.46 with cotton spinning workers. It is found that labour cost and cost of living sectors are the vital factors which determine the wage rate.

Suggestions:

1. The wage dispersal system requires systematic and rational revision with Government taking up the role of facilitators and regulators.

2. The payment of wages can be streamlined and connected with productivity of workers to ensure reasonable payment of wages to workers.

3. The practice of social security measures must be applied to the ground so as to elicit employee motivation and involvement and the consequent gratification. Nothing strokes employee motivation like assured social security measures.

4. Industrial workers clamoring for more wages and bonus payment produce the unpleasant effect of disturbing industrial peace and harmony. They must be brought to the mainstream through nurturing a shared vision where intellect and acumen reign supreme along with brawn power.

5. All industrial workers need to own themselves with full freedom to join trade unions to create the competing values framework of collaboration creation competition and control. Employers and Employees should not prey upon one another.

Conclusion

Labour is the most dynamic agency in the process of production. The inestimable importance of labour in terms of its productivity has been emphasized with the appearance of the Robinson Scarcity approach to theory of economics. It is incumbent on industrial establishment governments and industrial workers to create and promote the right atmosphere through intelligent and daring co-ordination to spell self-efficacy industrial peace and economic development. The study reiterates the obvious fact that business organizations must learn to adapt to the greater prevalence of human values at the center of their thinking in the context of ever-changing dynamics of support networks to ensure and sustain flourishing and progressive strategic agility.

Discussion

The results of the study highlighted some important socio-economic aspects of industrial workers such as age wise and gender wise distribution, family type, income and expenditure distribution. The research work also explained the significance and the determinants of the productivity of labour in the total output. In addition, the research work also analyzed the factors which determine the level of wage rate among the sample industrial workers.

The Pattern of Rural Employment in India

S. Sudha¹, S. Jansi Rani²

¹Research Scholar; ²Associate Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies (Deemed to be University), Pallavaram Chennai

Abstract

The experience of countries that succeeded in reducing poverty significantly indicates the importance of high rates of economic growth in achieving this. Every section of the Indian economy is now linked with the world outside, either through its direct involvement in international trade or through its indirect linkages with the export or import transactions of other sectors of the economy. The new policy regime is as much important, and relevant, to farmers, industrialists, traders and sundry service providers as to scientists, writers and singers. The present study is to attempts into some of the crucial dimensions of the changing employment scenario in rural India at the national as well as the state level. The present paper mainly focus on the agricultural sector is also heavily dependent on migrant, temporary and seasonal workers; the precarious conditions in which these workers labour often rob them and their families of food security. Low pay, however, is not the only problem facing agricultural workers. Agriculture is one of the most dangerous industries to work in, alongside construction and mining. Indeed, it is the sector with the most fatal accidents. Agricultural workers face many hazards: dangerous machinery, livestock, extremes of temperature and inclement weather, dehydration due to lack of access to potable water, and exposure to biological hazards arising from pesticides and other agro-chemicals. In doing so, the paper attempts to figure out the challenges and threats, as well as the potential for employment expansion that lies ahead.

Keywords: Rural Employment, Wages and agricultural occupation.

Introduction

The experience of countries that succeeded in reducing poverty significantly indicates the importance of high rates of economic growth in achieving this. High growth, however, is not a sufficient condition for poverty reduction; the pattern and sources of growth as well as the manner in which its benefits are distributed are equally important from the point of view of achieving the goal of poverty reduction. And employment plays a key role in that context. Indeed, countries which attained high rates of employment growth alongside high rates of economic growth are also the ones who succeeded in reducing poverty significantly.¹ Every section of the Indian economy is now linked with the world outside, either through its direct involvement in international trade or through its indirect linkages with the export or import transactions of other sectors of the economy. The new policy regime is as much important, and relevant, to farmers, industrialists, traders and sundry service providers as to scientists, writers and singers. It needs hardly to be emphasized that all categories of economic functionaries engaged in production and services sectors have to adjust to the changing technology-intensive investment, production, labour management and marketing requirements, dictated partly by compulsions of internal competitions and partly by international commercial pressures. Production and marketing management now needs new visions, initiatives and networking, both at home and abroad. Concerns for environment, labour standards and product acceptability, etc. have acquired added significance. Human element becomes the kingpin, from the beginning to the end; the era of captive domestic market is over and with that, quality consciousness and price competitiveness become prime considerations, for staying on in the market.²

The present study is to attempts into some of the crucial dimensions of the changing employment scenario in rural India at the national as well as the state level. The present paper mainly focus on the agricultural sector is also heavily dependent on migrant, temporary and seasonal workers; the precarious conditions in which these workers labour often rob them and their families of food security. Low pay, however, is not the only problem facing agricultural workers. Agriculture is one
of the most dangerous industries to work in, alongside construction and mining. Indeed, it is the sector with the most fatal accidents. Agricultural workers face many hazards: dangerous machinery, livestock, extremes of temperature and inclement weather, dehydration due to lack of access to potable water, and exposure to biological hazards arising from pesticides and other agro-chemicals. In doing so, the paper attempts to figure out the challenges and threats, as well as the potential for employment expansion that lies ahead.³

**Main Objectives of the Study:**

1. To understand the shifting pattern of women employment in the rural areas in the total context of the Indian economy.
2. To analyze the state-wise picture on women Employment in MGNREGA and SSI in India.

**Data and Methodology:** To study the rural women employment in different sectors and the economic development, various sectors employment have been used. To analyze the present position of economic growth, time series data for a period of 20 years, from 1990-91 to 2009-10 have been used. Although we draw upon more than one source of data, yet, in the main, we base our analysis on National Sample Survey (NSS) data, gathered over different rounds.

**Rural Women Employment Shifting Scenario in India:** Lack of employment and lack of rights are the daily reality for millions of agricultural workers in India. In 2005 the Indian parliament passed historic legislation, the National Rural Employment Guarantee Act (NREGA), which guarantees 100 days of employment for rural households across the country. Initially focused on 200 districts, it was extended to 330 districts the following year and, from 1 April 2008, it has covered all rural districts in the country.

The potential benefits of the NREGA are significant: its employment guarantee goes some way towards securing livelihoods for the most marginalised section of the workforce and contributes to a reduction in extreme levels of hunger and poverty; it can help to sustain livelihoods in the countryside and thus to reduce urbanisation; it can deliver greater employment opportunities to women; it can develop necessary basic infrastructure in rural areas, including education, health and environmental sustainability; it can deliver social justice in areas of significant inequality. The NREGA guarantees payment of the legal minimum daily wage and is specifically geared towards unskilled labourers working in water conservation, drought proofing, irrigation, repair (for example, de-silting), land development, flood control and road works. During employment, workers are entitled to drinking water, access to shade, medical kits and childcare. If workers are unable to obtain employment through the scheme, they are entitled to unemployment benefit. The act also specifies that records of funds received and projects carried out through the NREGA are publicly available at district level and can also be obtained through Right to Information legislation. Following implementation during 2006–7, the average number of days worked per household was 17. This covered a very significant range across different states, however: from 77 days in Rajasthan to 3 days in Kerala. In the initial stages of the NREGA schemes, concerns were raised about the take-up rate and problems of corruption. By organizing workers, trade unions have managed to achieve much greater adherence to the payment of the minimum wage and to get more workers participating in the scheme. For example, members of the IUF-affiliated Andhra Pradesh Vyavasaya Vruthidarula Union (APVVU) in the south of India were able to achieve three times as many workdays than the state average. In addition, while in 2006–7 40 per cent of workers in the scheme at a national level were women, in those schemes where APVVU members participated, women’s participation reached 52 per cent. While the average wages earned by agricultural workers before the introduction of NREGA in Andhra Pradesh ranged from Rs. 30 to a maximum of Rs. 60 per day, after the introduction of NREGA, the average wages earned have been between Rs. 81 and Rs. 93 per day. Similarly, the rate of distress migration of agricultural workers has fallen by 70 per cent in several districts of Andhra Pradesh. In Bihar, in the north of India, where the state-wide average work per household in 2006-7 was 8 days, members of the IUF-affiliated Hind Khet Mazdoor Panchayat (HKMP) were able to obtain 60–70 days’ employment. In the North Bengal district of West Bengal, in eastern India, following interventions from IUF affiliate Paschim Banga Khet Majoar Samity (PBKMS), rural workers in one area were able to get 45 days’ work per household in 2006, while the district average was 12.7 days per household. The NREGA is a major improvement in social protection for agricultural workers. It shows that by intervening actively trade unions can monitor and fight corruption and ensure that social justice is delivered to rural workers.⁵

**Annual Growth of Participation of Women (In Employment) Under Mgnrega: Comparison of Different State:** The annual growth of participation of women in employment under MGNREGA has increased only in sixteen states and only in two union territories. These eight states are: Andhara Pradesh, Bihar, Haryana, Himachal Pradesh, Jammu and Kashmir, Kerala, Maharashtra, Punjab, Rajasthan, Sikkim, West Bengal, Chhattisgarh, Uttarkhand, Meghalaya, Odisha, Dadra & Nagar Haveli Puducherry, and Andaman & Nicobar is the two Union Territories where the annual growth of participation of women (in employment) under MGNREGA has increased. Since the implementation of MGNREGA, the annual growth of participation of women (in employment) has been reduced in 11 states and in only one union territory. These states are: Andhra Pradesh, Arunachal Pradesh, Assam, Gujarat, Karnataka, Madhya Pradesh, Tripura, Uttar Pradesh, Manipur, Mizoram, and Nagaland. The only one union territory is Goa. Another important point to be noticed here is that the annual growth of women employment participation in MGNREGA has most positive states.
is Tamil Nadu, it’s contribution of MGNREGA is very high. This means that the contribution of agriculture is declining year by year in the state and the agricultural sector is not able to develop and it is not in a position to retain even its earlier positions. 

**Conclusion**

Occupational distribution of workforce shows that labour absorption in self cultivation is saturated and declining. But the increase in the size of agricultural labourers is more than the size decline in cultivators indicating farmers those who are leaving farming activity and those who enter newly in to agriculture are becoming agricultural labourers. The decelerating but a high rate of growth in workforce engaged non-agriculture compared to that of agriculture could not bring any drastic change in the structure of workforce a small change in workforce shifting towards non-agriculture. This is contrast with the highest ever growth of non-agricultural GDP of India that is registered during the last decade. Within the non-agriculture, growth of workforce engaged in household industry is decelerating. Moreover, the rate of growth in marginal workers engaged in non-agricultural activities is found to be higher than those of main workers increasing share of marginal workers in the total workforce of non-agriculture sectors is a cause of concern. Moreover, relatively high growth of female workforce engaged in nonagricultural appears to be a welcome feature but one needs to be prudent in interpreting it so, especially in the context of increasing informalisation of labour market.

Clinical Spectrum of Idiopathic Inflammatory Demyelinating Disorders in a Tertiary Care Centre in North–West India

Soumya Darshan Nayak, C.M. Sharma, B.L. Kumawat, D. Khandelwal, R. Yadav, Samir Sahu, Soumya Nanda

Abstract

Background: Idiopathic inflammatory demyelinating disorders of the central nervous system (IIDCDs) represent a broad spectrum of disorders whose varied clinical profile has important implications for diagnosis, management and identifying grey areas in categorization.

Objective: To study clinical, imaging & laboratory profile of IIDCDs pts. and categorize them into specific groups.

Method: Retrospective case series of 81 pts. Cases effectively categorized into 4 groups: MS, NMOSDs, CIS & ADEM and their subgroups. Cases with diagnostic difficulty later sorted out into 3 groups: Atypical, crossovers & converters.

Results: 32% categorized as NMOSDs, 28.4% as MS, 25.9% as CIS & 13.6% as ADEM. Monophasic (64.2%) course and polysymptomatic presentation were most common. 23.46% had optico-spinal presentation; LETM seen in 44% cases. Aquaporin-4 positivity seen in 31.25% NMOSDs.

Discussion: NMOSDs had higher relapse rate & disability, while longer duration of disease & frequent relapses seen in MS group. 30% CIS had abnormal brain MRI. Gray matter involvement commoner in MS & ADEM groups. Low Aquaporin-4 seropositivity in tested IIDCDs. No significant difference between seropositive & negative pts. in terms of relapses, cord length & disability.

Conclusion: Clinical features, course & severity play a dominant role in categorization. IIDCDs considered a spectrum because of common & overlapping clinical presentation.

Keywords: IIDCDs, MS, NMO spectrum disorders, ADEM, CIS, ON, LETM, ATM, EDSS, Aquaporin-4 antibody, annual relapse rate, monophasic, multiphasic, relapsing remitting, BON, RION, visual acuity, disability, clinical spectrum.
confusion seems to be in part due to the pronounced variation in the frequency of the syndromes in different ethnic groups. We cannot ignore conditions faced in our own clinical experience which provide important clues in the classification of IIDCDs.

Understanding the spectrum of IIDCDs is important for accurate diagnosis & advancing research on pathogenesis as well as treatment strategies. It is also important to acknowledge problems in the categorization of cases. The study of IIDCDs in India has been limited by various factors, including lack of facilities & financial constraints preventing use of radiological & other paraclinical tests on a wide scale in diagnosis. Also record keeping & long-term follow up of patients have serious limitations, hindering data collection and analysis. The objective of the present study was to study the clinical profile of patients presenting with IIDCDs & categorize them into specific groups according to current definitions & internationally fixed criteria.

**Materials and Method**

This was a retrospective case series to evaluate clinical, laboratory & radiologic data obtained from 81 cases of IIDCDs admitted to the Department of Neurology of SMS Medical College, a tertiary-care facility in Jaipur, Rajasthan in north-west India over a period of 31 months from October 2010 to April 2013. Included were cases of Primary IIDCDs within the 2nd-6th decade & excluded were cases with suspected infectious etiology, vasculitis, systemic autoimmune diseases with CNS manifestations, sarcoidosis, leukodystrophies & mitochondrial disorders (Fig 1-3).

Of the 81 cases taken up for evaluation, clinical data, lab parameters & imaging were obtained from the medical & discharge records. Lab parameters included routine hematologic & biochemical investigations, vasculitis profile, B12 levels, & electrophysiologic tests (VEP, BAER, NCS), CSF profile including oligoclonal bands, Aquaporin-4 antibody status, MRI brain & spinal cord imaging. The data was entered into a Microsoft excel spreadsheet and analyzed.

**Results**

Of the 81 cases 28.4% (n=23) were MS, 32.1% (n=26) NMOSD, 25.9% (n=21) CIS & 13.6% (n=11) ADEM. Males constituted 53.1% & females 46.9% giving a M:F ratio of 1.1:1. Mean age of the study population was 32.23 ± 11.15 (Range: 10-55 yrs). The maximum no. of cases (n=46) were in the age group 20-39 yrs (56.8%) while 16.1% (n=13) were under 20 yrs of age. The course of disease was monophasic in 64.2% (n=52), multiphasic in 29.6% (n=24) & progressive in 6.2% (n=5). In the MS group (RRMS=17, SPMS=1, PRMS=2, PPMS=3), 78.3% (n=18) had a relapsing course while 21.7% (n=5) had a progressive course (Table 1).

In the NMOSD group (n=26), 34.6% (n=9) fulfilled Wingerchuk's 2006 criteria for NMO although only 3 tested positive for Aquaporin-4 antibody. The rest were categorized as LETM (42.3%;n=11) or BON/RION (23.1%; n=6) as per predefined criteria.In the CIS group (n=21), 61.9% (n=13) were ON, 23.8% (n=5) were ATM & 14.3% (n=3) had a multifocal presentation. In the ADEM group (n=11), 90.9% were monophasic & 9.1% (n=1) were multiphasic. The mean no. of attacks/pt. in the MS group was 3.39±2.43 which was significantly higher (p=0.000) than the NMO spectrum group (1.62±1.75). However the annual relapse rate (ARR) was higher in the NMO spectrum group (3.91±2.75) than the MS group (2.01±2.50).

65.4% (n=53) of our cases were polysymptomatic at presentation, while pyramidal features (61.7%, n=50) were the most common clinical findings, followed by optic nerve involvement (59.3%, n=48), sensory (58%, n=47), urinary (49.4%, n=40), cerebellar (21%, n=17), brainstem (16.1%, n=13) & ophthalmoplegia (8.6%, n=7). In the ADEM group, 63.6% had history of a febrile illness. Mean visual acuity was lowest in the NMOSD group. Of the 59.26% (n=48) cases with a history of optic neuritis, it was an isolated (primary) event in 37.5% (n=18) while it was associated with other disorders in 62.5% (n=30) cases (secondary). 23.46% (n=19) cases had both optic neuritis & myelitis at presentation.

MRI brain was abnormal in 66.7% (n=50) & MRI spinal cord was abnormal in 83.6% (n=51). Compared to the MS & ADEM groups where all brain MRI were abnormal, only 43.5% (n=10) were abnormal in the NMOSD group which was statistically significant. Similarly cord imaging revealed abnormality in 90.9% (n=20/22) of NMOSDs. In the spinal cord MRI group, LETM was observed in 44.3% (n=27) of the cases & the average length of LETM was 9.43 segments. 79.5% of the VEP recordings were abnormal & subclinical ON was detected in 17.24% additional cases. VEP abnormality was significantly more in the MS & NMOSD. Only 22.86% of BAER records available were
abnormal (87.5% MS). CSF-OCB was negative in all noted records. Aquaporin-4 antibody had been tested in 30 cases belonging to the NMOSD. Only 5 cases had been positive (NMO=3, LETM=1, BON/RION=1) giving a positivity rate of 16.7% overall. 91.36% (n=74) cases had received steroids at some time during their disease course while interferons (β1A) were the most commonly used disease modifying agents with 52.2% of our MS cases on interferons. Azathioprine (14.8%, n=12), Glatiramer, methotrexate & cyclophosphamide were other agents used. Plasmapheresis was done in 3.7% cases (Table 2).

The mean EDSS & MRS at discharge was significantly higher in the NMO spectrum group (4.67±2.50, 2.85±1.41) compared to the MS & CIS groups. Also the mean EDSS, MRS & visual disability was higher in cases with a multiphasic/relapsing course (EDSS=3.65±1.97, MRS=2.34±1.19, VA (logMAR)=0.53±0.49) compared to monophasic course (EDSS=3.45±2.52, MRS=2.01±1.53, VA (logMAR)=0.44± 0.46). At least 32.1% (n=26) of our cases had an EDSS≥4 indicating moderate to severe disability of which 57.14% were NMOSD while 42.86% were MS (Table 3).

Within the NMO spectrum group we compared the Aquaporin 4 antibody positive & negative groups in terms of sex ratio, no. of attacks, course, presentation, length of cord lesion & disability and found female preponderance, higher no. of attacks, greater relapsing course, higher no. of cases with ON, longer cord lesions & greater disability (EDSS & MRS) in the antibody positive group. We also correlated VA & length of cord lesion with disability indices in various groups and found a positive correlation with both in only the NMO group (r=0.015, 0.312). of the 15 cases (atypical=11, cross-over=3, convertor=1) which posed a diagnostic dilemma, 5 were categorized in the MS group, 4 as NMOSD, 4 CIS & 2 ADEM (Table 4).

Discussion

In this study IIDCDs constituted 2.37% of all neurologic admissions. Hospital-based studies in India showed increase in MS-related admissions from 1.58% to 2.54%.

The mean age of our study population (32.23±11.15) was higher than most series on MS & lower than mean age for NMO & ADEM. Most of our cases presented in the 3rd-4th decade & the F:M ratio was 1:1.1 which was unusual for demyelinating series the world over which show a female preponderance. However several Indian studies have reported a male preponderance. Disease course was monophasic in 2/3rd of our study population while the rest had a multiphasic/progressive course. NMOSD were the most common IIDCDs constituting around 1/3rd of the total cases followed by MS, CIS & ADEM. However NMO per se constituted only 11.1% of our total IIDCDs admissions. This is in concordance with data compiled by Wingerchuk et al from India where NMO constituted 9-24% of all demyelinating disorders. This figure was higher than those in Western countries but remarkably lower than some South Asian countries (33.1%-39.3%).

In our MS patients a relapsing-remitting course was most common, occurring in 78.3% of cases. Surprisingly around 25% of our NMOSD had a relapsing course which increased to 44% in the NMO subgroup. This was much lower than seen in other series. In the CIS group isolated optic neuritis followed by ATM was the most common presentation. No isolated brainstem syndrome was noted. Review of large database of CIS pts. showed 21% presented with ON, 46% with long tract signs, 10% as a brainstem syndrome & 23% with multifocal abnormalities. Almost 2/3rd of our cases were polssymptomatic at presentation with pyramidal features & optic nerve involvement being the most common. Although single series data on spectrum of IIDCDs was lacking, our data was corroborating with similar series from India & the world.

MRI revealed a high incidence of gray matter involvement (56.3%) in the MS group similar to other series (59%). 44% of our NMO spectrum cases had an abnormal brain MRI at presentation compared to 50-85% reported in various series. MS-like demyelinating lesions on brain MRI, was the most common of the 5 types of presentation described. Disease severity had a positive correlation with both visual acuity & length of cord lesion only in the NMOSD.

The Aquaporin-4 seropositivity was only 16.7% of all tested case of IIDCDs which increased to 32% in the NMO group. This was comparatively lower than reported by Lennon et al in their NMOSD (61.3%). However other Indian studies also reported a low seropositivity (4%-11.4%). Wingerchuk et al tried to explain this discrepancy by 3 possible causes:
(a) Inadequate clinical diagnostic criteria, (b) suboptimal assay sensitivity & c) closely related autoimmune disorder with a different target autoantigen. \(^{16}\) Comparison between our Aquaporin-4 positive & negative cases within the NMOSD showed higher female preponderance, more & frequent relapses, higher incidence of ON, longer cord lesions & higher disability (EDSS) in the positive group, as seen in some other studies\(^{17,18}\).

**Limitations of our study:** Retrospective study & not all suspected cases of NMOSD had Aquaporin-4 antibody testing done & OCB data was available in only a few cases.

Factors Associated with Fear of Falls in Indian Elderly: A Systematic Review

Sampada Dhavale¹, Sonia Singh², Raju K. Parasher³

¹PhD Scholar, Physiotherapy Department, Punjabi University, Patiala, Punjab; Assistant Professor, Amar Jyoti Institute of Physiotherapy, University of Delhi, ²Assistant Professor, Physiotherapy Department, Punjabi University, Patiala, ³Director/Principal, Amar Jyoti Institute of Physiotherapy, University of Delhi

Abstract

Background: Fear of falls (FOF) is a risk for falls and collateral morbidity as it imposes self-limitations on activity. Given the increasing population of elderly in India, its unique unstructured physical environment, cultural practices and paucity of research, it was important to have a strong understanding of FOF and the factors associated with it.

Objective: Determination of prevalence and factors associated with fear of falls in the Indian elderly from review of literature.

Methodology: A systematic review based on PRISMA guidelines was used to synthesize and analyse existing literature.

Results: Six Indian studies met the inclusion criteria and were utilized for synthesis. The prevalence of FOF ranged from 33.2% to 44.2%, and various biological, psychological and social factors were found to be associated with FOF.

Conclusion: There is high prevalence of FOF in India. Inspite of its serious impact on health and quality of life of elderly, this construct is inadequately studied within the Indian context.

Keywords: Fear of Fall, Indian, Elderly, Factors associated, Falls.

Introduction

Worldwide, elderly population is estimated to reach 2 billion by the year 2050. This increased life expectancy is associated with physical, social and psychological challenges that hamper quality of longer life.

‘Falls’, a common problem in the elderly, are a deterrent to “active ageing” and are experienced by approximately one-third of community-dwelling older adults each year. They result in physical injuries, sometimes serious enough to require hospital admission incurring high financial costs, and are also the second leading cause of accidental deaths especially among frail elderly. Regardless of physical injury, the mere fear of falling can lead to a loss of self-confidence and may lead to reduction in physical activities, setting up vicious cycle of fear-reduced confidence-decreased activity.

Fear-of-fall (FOF), first identified in 1982 by Murphy and Isaacs, is defined as a perceived fear of falling that limits an individual’s ability to participate in physical activity that he/she is capable of performing. It is protective when the older adult is being more careful to avoid risk of a fall; however, it becomes a risk in itself when it imposes self-limitations on activity. FOF is an umbrella term encompassing balance confidence, fall related fear and self-efficacy. It becomes a risk factor for falls, functional decline, social isolation. This may lead to depression, anxiety and an impaired quality of life.

Initially, FOF was believed to be a key symptom of ‘post-fall syndrome’, but recent studies have reported a
high prevalence (30% to 90%) of FOF in older population regardless of history of fall\textsuperscript{9,15}. The symptoms of FOF are associated with the type of fall rather than with the fall itself\textsuperscript{9,14}.

Factors associated with FOF that have been reported in literature are previous falls, age, female gender, poor physical function, use of walking aid, poor self-rated health, poor balance, frailty, dizziness, functional decline and reduced quality of life\textsuperscript{9,10,11,16,17}. Conflicting results are presented for association with depression, anxiety and use of drugs\textsuperscript{10}. Stereotypically, older people are often offered aid when none is required, this reduces their self-efficacy and increases FOF\textsuperscript{16}. These factors can be explained according to the biopsychosocial model proposed by a German psychiatrist George Engel\textsuperscript{18}. It integrates psychosocial dimension with biological aspects of the disease\textsuperscript{19,20}.

India is changing demographically and socially due to increasing population of elderly, urbanization, migration, more women entering work force, smaller families and loss of traditional support structures\textsuperscript{21,22}. The Indian lifestyle and environment are also more demanding than many other countries because of high density living in architecturally constrained areas, cultural activities that necessitate sitting on the floor, daily activities that require visiting unorganized markets and congested places of worship\textsuperscript{23}. Given this uniqueness of the lifestyle, this systematic review is aimed to synthesize the existing literature to determine the prevalence and factors associated with fear of falls in India.

**Method**

**Identification and selection of trials**

**Data sources and search strategy:** This systematic review was conducted in accordance with the PRISMA statement. Research articles from India were electronically searched on Pubmed, Medline, Google Scholar, Embase and Cochrane Library. The keywords used for the search were, ‘fear of falls’, ‘elderly’, ‘India’, and ‘factors associated’.

**Study selection and eligibility criteria:** Studies were included if they investigated the factors associated with fear of falls in elderly living in India. Studies were excluded if they discussed falls in relation to any condition other than normal physiological ageing e.g. Parkinsonism, Stroke.

The title and abstracts of included articles were reviewed and full texts were retrieved.

**Data extraction and analysis**

**Quality:** Selected studies were assessed for methodological quality. Qualitative studies were assessed using Critical Appraisal Skills Programme (CASP) checklist and quantitative studies were assessed using Methodological Quality Appraisal Tool (MQAT). If more than 60% of the criteria on the checklist were met, the study was rated as strong quality, if 40%-60% were met, the study was rated as moderate quality and if less than 40% were met, then the study was rated as poor-quality evidence.

**Study characteristics:** The characteristics extracted from the studies were study population in terms of age range and mean age of study subjects, their gender ratio, whether they were institutionalized or non-institutionalized, place of study, percentage prevalence of fear of falls and factors that were found to be associated with fear of falls.

**Outcome data:** Data was analysed for prevalence of fear of falls and factors associated with it. Factors associated with FOF were categorized as biological, psychological or social in nature using George Engel’s biopsychosocial model.

**Results**

**Flow of studies through the review:** Following the search and removal of duplicates, 63 articles were retrieved in full text, out of which, 52 were excluded as they were not related to fear of falls in elderly. 11 full texts were assessed for eligibility, out of which 5 were excluded as they were related to falls rather than fear of falls, discussed specific medical condition or balance intervention. Theremaining 6 studies were analysed and utilized for synthesis.

**Characteristics of included studies:** The systematic search resulted in 6 articles\textsuperscript{12,14,24-27} published between 2008 to 2017. The participants in all studies were non-institutionalized elderly who belonged to age range of 60-96 years of age except one study\textsuperscript{25} that had lower age limit as 40 years (one study did not mention the age range). There was equal representation of males and females in all studies except two\textsuperscript{26,27} which did not report the gender ratio. The recruitment was done using non-probability sampling method. Most of the studies were
cross-sectional and relied on correlation statistics to infer the association of various factors with fear of fall. These studies were undertaken in Puducherry, Raichur, Manipal and Udupi, Kanpur, Dehradun and Surat.

**Prevalence of Fear of Fall:** The prevalence of fear of fall was reported to be between 33.2% to 44.2%.

**Factors associated with Fear of Fall:** The various factors that have been associated with FOF were age, presence of more than one disease, education, low socio-economic status, previous experience of fall, activity restriction, balance ability, low back pain and disability associated with it, muscle mass, strength, physical performance, depression and quality of life. These factors are further categorized as per the George Engel’s Biopsychosocial Model.

**Quality:** Two out of six studies were qualitative but had strong evidence. Four studies were quantitative, of which three were rated as moderate quality of evidence and one as strong evidence.

**Discussion**

A significant outcome of the systematic review was that there is a severe paucity of studies that have addressed this very important problem, which is increasingly afflicting the quality of life of the Indian elderly population. In this review, the evidence from studies was rated as moderate to strong, however the studies lacked proper sampling, details on the non-responders, and measures to control non-response bias.

The studies reviewed reported moderately high (33.2 – 44.2%) prevalence rate of FOF in community living Indian elderly, and interestingly, only 34.6 – 45.7% of the subjects sampled had fallen previously. Thus, the current data highlights the magnitude of the problem (FOFs) in community living Indian elderly and also importantly, that the fear of falling is independent of a history of fall. In a study conducted by Verma and Pal in 2015, that included subjects aged 40 -75 years, surprisingly a significant prevalence of FOF was also found in the young elderly, suggesting that people transitioning into old age developed a fear of falls much before an actual biological decline.

The biopsychosocial model has emphasized the significant contribution of psychosocial variables, in addition to biological pathologies to sickness and health. The model explicitly describes how deficits within each of the sub-dimensions of biology, psychology and sociology impacts disease, disability and health. Using Engel’s Biopsychosocial model factors associated with FOF found in this systematic review were categorized under the three sub-domains of biological, psychological and social. The few Indian studies reviewed identified biological factors as age, presence of more than one disease, balance ability, decreased muscle strength, physical performance and low back pain. Factors classified as psychological were also previous falls and depression, while social factors identified were activity restriction, disability, education, low socio-economic status, and poor quality of life. Similar findings have been reported in several studies conducted internationally.

**Quality:** Two out of six studies were qualitative but had strong evidence. Four studies were quantitative, of which three were rated as moderate quality of evidence and one as strong evidence.

**Discussion**

A significant outcome of the systematic review was that there is a severe paucity of studies that have addressed this very important problem, which is increasingly afflicting the quality of life of the Indian elderly population. In this review, the evidence from studies was rated as moderate to strong, however the studies lacked proper sampling, details on the non-responders, and measures to control non-response bias.

The biopsychosocial model has emphasized the significant contribution of psychosocial variables, in addition to biological pathologies to sickness and health.
be directed towards studying the fear of falling within the environmental and cultural context of the Indian elderly. This will help in development of inter-sectoral policies and programmes for enhancement of health, participation and security of older citizens in order to enact “active ageing”\(^2\).

Green Marketing in Food Industry and Impact on Health Issues

Sayeeda Jabeen S.1, M. Kavitha2

1Research Scholar, 2Professor & Research Supervisor, Department of Commerce, VISTAS Pallavaram, Chennai

Abstract

The main aim of this study is to analyze the green marketing in food industry and its impact on health issues of consumers. The researcher used one way anova to find the result. There is a negative relationship between green foods and health issues. The consumers used green foods feel there is no health issues and vice-versa. Finally, it concludes that most of the consumers are using organic/green foods for avoid the health issues.

Keywords: Health issues, Organic foods, Food Industry.

Introduction

Green marketing refers to an organization’s effort at designing, distributing, pricing, and promoting the final products that do not harm the consumer, production resources and the environment. Green products should be compatible to the Indian consumers in terms of price, promotion and delivery system. Green marketing is as one of the major trends in modern business as revealed in a number of studies (Kassaye, 2001; Pujari and Wright, 1996). Getting environment conscious not only responds to the social, legal and political pressures, it also ensures business sustainability on the market front. Greener market strategies may exert leverage in taking full advantage of consumer preferences and to some extent cost efficiencies.

The food processing industry, which is globally referred to as the sunrise sector, has gained importance in India in the recent years. It contributes immensely to economic development of the country, provides employment opportunities and assists in income generation. This sector has the capacity to provide jobs to our rural poor and thus reduce the burden on Indian agriculture for their livelihood (Rais M et al., 2013). India is counted among the world’s largest consumer of processed food products. India is only next to China in Food production and has the potential to be the biggest with food and agriculture (ASA & A, 2013).

Marketers these days are trying to capitalize on the fact that, now people are more concerned for a safe and healthier environment and prefer environment-friendly products for consumption. Consumers are offered a wide range of competitively priced products. As a result, quality control is getting essential in the food industry, and efficient quality assurance has become increasingly important to this industry. One of the major concerns is the ability to trace and authenticate each and every ingredient of a food product. As the consumer awareness increases for organic foods and sustainable products, the trade and industry is bound to meet their expectations. Increased marketing efforts and publicity are needed to communicate the advantages of a ‘green’ image to consumers (Ottman, 1993).

The catalysts and pressure groups world over have made the leading firms in the corporate sector conscious of the need of becoming eco-friendly. But the business and the industry as a whole in India will acknowledge its significance only on the popular demand of consumers and marketing intermediaries. In the Western world green movement has reached to majority of consumers and their huge percentage shows a strong interest in eco-products (Ghose, 2008).

Review of Literature: Joyce I. Boye (2013) Current Trends in Green Technologies in Food Production and Processing. This review summarizes key highlights from the recently published book entitled Green Technologies in Food Production and Processing which provides a comprehensive summary of the current status of the agriculture and agri-food sectors in regard to environmental sustainability and material and energy stewardship and further provides strategies that can be used by industries to enhance the...
use of environmentally friendly technologies for food production and processing.

Chinkala (2013) Green marketing in food industry, Commerce and Management. This study was conducted in Coimbatore city. Most the people preferring green products often read the nutritional and ingredients section of food labels before buying the new food products. Most of the Respondents agreed that the green foods are safe for human consumption. They also opined that by implementing green marketing strategy the companies are able to gain competitive advantage over others. It was observed that more than half of the respondents surveyed were willing to buy green foods even if they were costly.

Khan and S Ahmad (2014) The initiatives are needed by the government to upgrade the standards and enforce them through designated agencies. The standards should save the wastages of material and energy and hence not add extra costs to the food for the consumers. Green products should be compatible to the Indian consumers in terms of price, promotion and delivery system. Green claims must also be supported by authentication and certification to differentiate them from products with false claims. Comparative advantages should be publicised to convince the customers. Retail chains should also obtain and guarantee certification by the designated 126 F M Khan and S Ahmad authority, compliance of safety laws and procedures and should be under scrutiny by them. This paper aims at designing the marketing mix strategies and outlining the managerial initiatives necessary for achieving green marketing in the food processing industry.

Heiyantuduge Lakmal (2015) Green Marketing Practices and Customer Satisfaction: A Study of Hotels Industry in Wennappuwa Divisional Secretariat. In the last decade, consumers have become more open-minded on ecological issues. Green marketing is rising quickly and consumers are willing to pay a lot for green product. There has been little analysis of the impact of this new market on the consumers and the environment so far. Green marketing affects all areas of our economy, Companies that are green stewards stand a chance of gaining many satisfied and loyal customers. Hotel company managers increasingly have to take environmental issues into account.

Farheen Khan (2015) A Study of Green Marketing Practices in the Food Processing Industry of India. This article analyses the green marketing process and practices prevalent in the food industry of India. With the conscious-consumer at the helm, green marketing is increasingly viewed as a relevant marketing strategy in India towards sustainable development of the food industry. A questionnaire-based survey method was used for the data collection from food companies in India. In the long-term, both the consumers and the food processing industry stand to benefit greatly from such green marketing initiatives and awareness but the policies and strategies need to be formulated and implemented accordingly. This article recommends that the Government of India and various business organizations work together to adjust and promote the marketing elements to Indian consumers so as to increase the acceptance, accessibility and affordability of the green products.

Cesare Zanasi (2017) An Assessment of the Food Companies Sustainability Policies through a Greenwashing Indicator. The goal of this paper is to provide a monitoring tool able to support the food companies definition of effective green marketing strategies, avoiding the risk of greenwashing; moreover supporting the other food system stakeholders’ critical analysis of the sustainability communication coming from the food companies. The results showed that the sustainability actions related to possible greenwashing represent a relatively low share of the total action implemented by Barilla. Most interesting is the capacity of this analytical tool to encompass a broad range of dimensions related to the companies green marketing strategies evaluation; this allows also other stakeholders to more clearly analyse the capacity of a company to provide a clear honest and complete report on their sustainability activities.

Yaty Sulaiman (2017) A study of consumption patterns on green food among students in University Utara Malaysia. Journal of advances research in social and behavioural sciences. Volume 7. Issue 1. This aim of this study is to identify the green food consumption pattern on under graduate students. It finds to environmental consciousness, perceived consumer effectiveness and health consciousness is related to use the green foods by under graduate students in Malaysia.

**Objectives of the Study:**

1. To find the factors causing usage of green marketing foods
2. To know the relationship between green marketing foods and health issues of customers
Hypotheses of the Study:
1. There is no significant difference among the factors causing usage of green marketing foods
2. There is no significant relationship between green marketing foods and health issues

Influence of Age on the Customer Perceptions Towards Green Marketing Food Products and Customer Satisfaction: The perceptual difference between age of the customers towards Green Marketing food products and customer satisfaction is presented in the following anova table.

</table>

It was observed in the above table No side effects (F=182.432, P=.000) Long live (F=213.739 P=.000), Stay healthy (F=269.409, P=.000), No Pesticides (F=224.648, P=.000), No Artificial flavours (F=218.014, P=.000), Customer satisfaction (F=356.937, P=.000) are statistically significant at 5% level. This established to the mean comparison of age Below 22 -35 years, 35 -45 years and 45 - 60 years of customer perception. It is found that Below 25 – 35 years of customers strongly agree for the existence of No side effects (Mean=33.31) Long live (Mean=33.23) Stay healthy (Mean=44.78) No Pesticides (Mean=42.32) No Artificial flavours (Mean=57.31) Customer Satisfaction (Mean=31.80) in the Green Marketing food products.

It illustrates that below 25-35 years of age customers are impressed by feel happy while using green products, feel healthy and confident. It admires many customers for the reason of no health issues.

**Findings and Conclusions**

Green Marketing in food Industry attracts many customers. In the heavy competitive markets the companies are using many artificial ingredients to attract and admire the customer and stay back in the marketing field long. So the customers are preferring Green Marketing foods to avoid many health issues.

Green Marketing foods and health issues are negatively correlated. Customers are using Green marketing they have no health issues. They prefer the products for the reason of avoid artificial colouring and flavours in the food products, pesticides using in the food products, stay healthy and no side effects by the green marketing foods.

To maintain the customer’s long and getting long lasting customer relationship the companies are preferred the Green products in the marketing. This will give good profit and high equity to the firm.

Burnout: “Lived Experience” of Working Mothers: A Phenomenological Study

Sejal K. Darbar1, Kalpana Sawane2

1PG Scholar, 2Assistant Professor, Department of Nursing, Symbiosis College of Nursing, SIDU, Pune, India

Abstract

Burnout is a stress related outcome that occurs due to prolonged exposure to chronic stressors. There are various causes of burnout; research has determined that aspects of the work-family interface, particularly in the work to family direction could be important contributors to burnout. Working mothers may be at greater risk of burnout compared with other working populations because of greater home demands, and demand on time and energy.

Purpose: The purpose of the study was to obtain a lived experience of working mothers regarding burnout.

Method: A Qualitative, Phenomenological research design was used in this study. Ten working mothers were taken as a sample and data was collected by interview method. The interviews were audio recorded lasting from 25 to 30 minutes and all recordings were transcribed into word file. Analysis was done by Colaizzi’s Strategy.

Result and Discussion: By using phenomenological method several themes and sub themes emerged which provided a description of the experience of working mothers regarding burnout. Six themes such as Burnout, Affect, Time, Demand, Complaints, Strategies and several sub themes emerged from the data. This work explores the reasons of the burnout among working mothers and provides recommendations for further study. Interview results show that participants are going through the same level of burnout at the certain stage.

Summary & Conclusion: In summary, this research study used a qualitative, phenomenological method by which to gain a greater understanding of the lived experience of burnout among the working mothers. The various themes and sub themes were identified from the collected data. The specific circumstances associated with pivotal moment were different for each participant, but the clarity of the moment was universal. Although not exhaustive in their scope, the identified themes were reported to be a part of the burnout.

Keywords: Burnout, Lived Experience, Working mothers.

Introduction

Burnout is a stress related outcome that occurs due to prolonged exposure to chronic stressors. There are three types of burnout such as personal burnout, work burnout and client-related burnout. Various studies indicate that burnout affects the physical and psychological health of employees, impairs the productivity and also related to lower job satisfaction.1

In 1974, Herbert Freudenberger coined the term burnout for the first time. He has characterized burnout as a set of symptoms which includes exhaustion resulting from work’s excessive demands as well as physical symptoms such as headaches and sleeplessness, “quickness to anger”, and closed thinking. He also observed that the burned out worker “looks, acts and seems depressed”. 1

Burnout is a state of chronic continuous stress. There are three dimensions of burnout such as; a) Physical and emotional exhaustion b) Cynicism and detachment c) Feelings of ineffectiveness and lack of accomplishment.2

According to Leiter, Jackson, & Shaughnessy, 2009; job burnout is a form of job stress in which workers...
become physically, mentally and emotionally depleted or exhausted. It is a result of steady and prolonged exposure of chronic job stress (Schaufeli & Enzmann, 1998). Characteristics of job burnout are like decrease in energy, Lack of motivation, negative feelings about self, cynical or detachment from work and interpersonal interactions (Maslach, Schaufeli, & Leiter, 2001; Maslach & Jackson, 1996).3

Bischoff, De Tienne, and Quick’s (1999) study main focus were to find out the factors which affect the mental health of female staff in both private and public sectors. It was clearly understood from the studies that office politics and task clashes were major stressors which increased job burnout rate. The gaps of the researchers in these years were found that they only focused on a single profession of female employees such as teachers, doctors and industry workers rather than conducting a survey to find out the main stress factors faced by female employees regardless of their fields. 4

In these modernize eras, due to increasing demand; it gets tremendous for women to work without being stressed. In this research main focus was on burnout among working mothers in private and public sector. The word stress generally represents the feeling when one is attached with a problem that is unable to handle. Various stress factors such as inter role distance, role overload, role ambiguity, role expectation conflict, role isolation, personal inadequacy and resource inadequacy. The employee feels suffocated and starts feeling pressured by that problem. So, stress can be defined as a threat or a challenge to one’s well-being. 5

Job stress causes job burnout. Job burnout refers that when one is unclear of one’s ability to perform in their job, keeping in view the value of their job hopelessly. Research findings reveal that the jobholders at senior level face more workloads and more role-overload. Working mothers have a higher risk of having a burnout compared to other working populations. Higher burnout not only negatively affects individuals and organizations, but also family functioning and child welfare.

D.K. Creedy, M. Sidebotham, J. Gamble, Julie Pallant, J. Fenwick conducted a study to assess the prevalence of burnout, depression, anxiety, & stress in Australian midwives. The identified burnout prevalence was 64.9% reported personal burnout; 43.8% reported work-related burnout; and 10.4% reported client-related burnout6.

Yashika Negi, Rajni Bagga, conducted a study on Burnout among Nursing Professionals in Tertiary Care Hospitals of Delhi, India. Burnout prevalence rate was declared in three dimensions of burnout such as emotional exhaustion (14.39 ± 6.87) and depersonalization (4.84 ± 3.34), and an average score (34.72 ± 6.33) for personal accomplishment7.

Innstrand, S. T, Melbye Langbelle, E., Arild Espnes, G. and Gjerlow Aasland, O., identified the Positive and negative work-family interaction and burnout among working mothers. Researcher identified that Working mothers may be at greater risk of burnout compared with other working populations because of greater home demands, and demand on time and energy. Higher burnout not only negatively affects individuals and organizations, but also family functioning and child welfare8.

Materials and Method

➢ Research approach: Qualitative Research
➢ Research design: Phenomenological research design
   Interpretative phenomenological research design
➢ Inclusion Criteria:
   a. Mothers who are working in public or private hospitals.
   b. Mothers who having at least two children.
   c. Mothers who can speak Hindi or English.
   d. Mothers who are living in nuclear family or separated.
➢ Exclusion Criteria:
   a. Mothers who are not willing to participate.
   b. Mothers who are not available at the time of data collection.
   c. Mothers who have working experienced more than five years.
➢ Research Setting: Selected private hospital of Pune.
➢ Population: Primary source (staff nurse)
➢ Sample: Staff Nurse
➢ Sample Size: 10
➢ Sampling Method: Non probability sampling
   Purposive Sampling Method
Tools For Data Collection: Open Ended Questionnaire

Techniques of Data Collection: Interview Method (semi structured & in depth interview)

Data analysis: After collecting data,
- Creating a meaning/theme from collected information.
- Formulating meaning into several themes and sub themes.
- Description given regarding the particular theme.

Burnout Characteristics by Semi-Structured Questionnaire of working mother’s among selected organisation (N=10)
- Most of the working mother reported that they having difficulty in managing time between work and home. From ten working mothers only two mothers have reported that they can manage it due to supportive family and caring, understanding husband. Mostly mothers have reported that they having some physical complaints such as sleep disturbances, headache, backache, mood swings etc. from that only 1 mother reported that she have chest pain when she stressed out. Most of the working mother uses some coping strategies to manage stress and burnout such as Yoga, Meditation, Deep Breathing Exercise and Physical exercise, sharing(talk it out), maintain silence but they were not doing regularly.

Themes and Subthemes According To Interview Questionnaire (N=10)
- Researcher has identified six themes such as Burnout, Affect, Time, Demand, Complaints and Strategies and also identified various subthemes.

Burnout: Circumstances which create burnout among working mothers were overwork, inspection, sick baby, long working hours, family responsibility and working environment. Below I have mentioned some participants’ comments related to it:

I have to do daily routine work and after that NABH work also because hospital is going to be NABH so too much work load creates stress or burnout in me.

During time of inspection I have to do extra work and managing everything creates stress in me.

When my kids are sick that time I feel stressed out because they were under 5 and more prone to get infection.

Affect: Almost all participants said that burnout affect them by physically such as headache, fatigue, vomiting and emotionally such as anxiety, frustration and irritation. Below I have mentioned some participants comments related to it:

When I get frustrated or tiered I shout on the person  
I usually get frustrated due to hectic routine at work as well as home.

Yes, I use to have headache and when it is severe then I take pain killer.
Time: All participants mentioned that they have difficulty in managing time between work and home. Only 2 participants stated that;

They are able to manage time between work and home (family) due to supportive family.

Other all participants stated that,

Yes, facing difficulty to manage time between work and home.

Demand: Most of the participants said that they have difficulty in fulfilling occupational demand to work with client/employees. Most of the participants mentioned that during audit work or too much workload and due to miscommunication they experience stress and burnout. Below I have mentioned some participants comments related to it:

During inspection due to too much work arguing with co-workers affect me a lot.

Due to miscommunication between employees created delay in work and get scolding from superiors affect me.

Complaints: Almost all participants mentioned that due to stress and burnout having physical complaints such as headache, sleep disturbances, backache etc. All participants stated that,

Yes, I use to have headache and backache.

Yes, I do not sleep properly because my younger son is ten month old so he teases a lot like he wakeup in the midnight and cry for milk.

Strategies: Most of the participants mentioned about strategies which used by them were yoga, deep breathing exercise, physical exercise and maintain silence but they were not doing it regularly. Below I have mentioned some participants comments related to it:

Not daily but sometime I use to do deep breathing exercise and after that I feel so good so now my planning is to do deep breathing exercise daily.

I use to maintain silence. I do not talk to any person till my anger comes down. Mostly I maintain silence up to 4-5 hours.

Discussion

The finding of the study shows that working mothers was experiencing stress and burnout due to different circumstances or factors such as work overload, family responsibility, working environment in either public or private sector. To explain this study finding in the light of some previous studies, the researcher found it was partially related to the study of Kumar S. which found that Occupational stress is a problem of great concern for working women. The main sources of stress which were identified were sex determination, household responsibilities, and lack of funding, resources and support services, lack of knowledge and experience, task overload, job insecurity, lack of promotion, reward and recognition.

Present studies also found that working mothers was facing difficulty in managing time between home and work. Researcher was found that due to work overload, long working hours mothers not able to give spend time with their family. In addition, Maryam Zarra-Nezhad, Ali Moazami-Goodarzi, suggest that Balancing work and family roles has become a key personal and family issue for women. Employers and family studies specialists find that the changing family structure is a major source of stress and role strain in both the workplace and the home. Women usually have a feeling of guilt for sparing less time for their maternal responsibilities and family. This dual responsibility proves the double burden on her and that makes her to fight concurrently on two fronts. Sources of work stress, including role ambiguity, relationships, tools and equipment, lack of autonomy, career advancement, job security, workload and work/home interface have been implicated in affecting family functioning.

Study findings also found that due to long working hours they face difficulties in managing time between work, home and family. The study of Sirpa Weckström, it can be concluded that, besides time spent at work, strain related to work may also prevent mothers from giving time to family members. Due to long working hours, working conditions Finland mothers feels that they cannot spend time with their family and family was fed up with these work-time interferences.

Conclusion

The results obtained from this study indicated that there are various factors influencing burnout among working mothers in Pune, India. Findings also revealed that working mothers were physically and emotionally affect due to burnout and also having some physical complaints. In addition study result shows that most of the working mothers having under five years of age
children, so due to role overload, family responsibility, working responsibility, working hours are major influencing factors of burnout.

Abstract

Introduction: Cognitive impairment is the decline of intellectual abilities that leads to inability of an individual to manage his/her social or occupational activities. Elderly people are at high risk for cognitive impairment. The study was aimed to assess the prevalence and level of cognitive impairment among elderly.

Methodology: The study was conducted among 200 elderly attending Geriatric outpatient department in Kerala who were selected by convenience sampling. This descriptive study used Rowland’s Universal Dementia Assessment Scale and Mini Mental Status Examination Scale to collect the data which were analyzed using descriptive statistics involving frequency and percentage.

Result: Cognitive impairment was prevalent in 132(66%) of the elderly with predominantly mild level of cognitive impairment (CI) 61(46.2%) followed by moderate (58, 43.9%). Cognitive impairment increased with advancing age (46.6% in young old versus 88.24% in old). Widows/widowers and single individuals had higher prevalence than married people. Parkinsonism, anemia, stroke, asthma and alcoholism increased the risk for cognitive impairment.

Conclusion: The study finding indicated that elderly are at high risk for cognitive impairment. An in depth study of the contributing factors and its impact on the overall quality of life is needed. Health care should focus on early detection of the underlying disease to prevent the occurrence of further complications.

Keywords: Cognitive impairment, elderly, prevalence, geriatrics.

Introduction

Ageing is a series of processes that begin with life and continue throughout the life cycle.¹ Once beyond 65 years, men and women pass into the final stage of existence; they have become bureaucratically defined as geriatrics and senior citizens.² Ageing is a physiological process and all the body systems undergo age-related changes. The brain shrinks with advancing age and there are changes at all levels from molecules to morphology. The most widely seen cognitive change associated with ageing is that of memory. Memory decline occurs with ageing and brain activation becomes more bilateral for memory tasks.³ According to the census of India, the Indian population has nearly tripled in last 50 years and the number of older persons has increased more than fourfold. Cognitive impairment is the symptomatic pre-dementia stage on the continuum of cognitive decline, characterized by objective impairment in cognition. Studies report that the prevalence of cognitive impairment in adults aged 65 years and older to be 10-20%.⁴

During aging, the size, efficiency and complexity of arborization decreases, making communication between cells less effective. Damage to white matter tracts with aging contributes to decreased brain size. These and other structural brain changes associated with aging correspond to age related differences in performance across cognitive tasks.⁵ The brain begins to structurally deteriorate as early as 30 years of age. Maintaining youthful cognitive function is a crucial challenge of aging. Declining memory function may also begin as early as age 30 and is often evident after 50 years of age.⁶

Cognitive impairment varies from mild to severe form. Mild cognitive impairment (MCI) causes a slight but noticeable and measurable decline in cognitive abilities, including memory and thinking skills. A person with MCI is at increased risk for Alzheimer’s or another dementia. With mild impairment, people may begin to notice changes in cognitive functions but still be able to do their everyday activities. Severe levels of impairment can lead to losing the ability to understand the meaning or importance of something and the ability to talk or write, resulting in the inability to live independently. A descriptive cross-sectional study carried out in urban and rural areas of Shimla, among 400 elderly people between 60 and 90 years of age reported that cognitive impairment in both are as increased steeply with age.

As per the Alzheimer’s Disease International Delphi consensus study, of all the people with dementia, 71% will be living in developing countries by 2040. In the next four decades, the number of people suffering from dementia in India, i.e., 1.5 million is going to increase by almost 300%. In India, the prevalence of cognitive impairment in the elderly vary from 3.5% in Himachal Pradesh to 5.1% in Uttar Pradesh and 6.5% in Kashmir. Dementia is emerging as an important health problem in Kerala. Studies in Kerala report a prevalence of cognitive impairment to be 11.5% in those aged >65 years.

Early recognition of cognitive impairment is important for diagnosis of potentially reversible medical conditions, and initiation of treatment interventions. Patients and care givers will have time to prepare for lifestyle changes and plan for the future. Nurse practitioners who work in a variety of practice settings commonly provide care to the older adults with varying levels of cognitive ability. The failure to evaluate memory or cognitive complaints is likely to hinder treatment of underlying disease and co-morbid conditions, and may present safety issues for the patient and others.

**Material and Method**

The study was conducted among 200 elderly attending the Geriatric outpatient department of a hospital in Kerala. Descriptive survey design and convenience sampling was used for the study. Elderly above 65 years were included while mentally and physically handicapped were excluded. Obtained ethical clearance from the Institutional Ethics Committee and informed consent from the subjects. Data collected using Rowland’s Universal Dementia Assessment Scale (RUDAS) and Mini Mental Status Examination Scale were analyzed using frequency and percentage distribution.

Data presented in table 5 indicate that on the whole, cognitive impairment is higher among the middle age (75-84 years) with 76 (57.6%) followed by young old (65-74 years) with 41 (31.1%). Among the cognitively impaired elderly (n= 332), old old (> 85 years) had higher prevalence with 15 (88.2%) out of 17. There is a steady increase as the age advances (i.e., 76 (80%) out of 95 middle old and 46 (66%) out of 88 young old). Both male and female had almost equal chance of cognitive impairment i.e., 65 (49.2%) males vs. 67 (50.8%) females. Marital status seemed to be a significant factor among the elderly for cognitive impairment as depicted in the given data where widowed [46 out of 65 (70%)] and single [3 out of 4 (75%)] had higher prevalence than married [83 (63.4%) out of 131]. Prevalence of CI was lesser among those elderly who lived with their family members than their counterparts who lived with their friends/paid care giver/ who lived alone.

</table>
Disease conditions like diabetes (66.02% of the total diabetics (n=103)), hypertension (n=114; 76.67%), cardiac diseases (n=31; 25(80.65%), asthma (n=29; 24(82.8%) had higher prevalence of cognitive impairment (Table 6). In addition to this, all the elderly with Parkinsonism, anaemia, and stroke developed cognitive impairment.

### Discussion

Cognitive impairment was prevalent in 132 (66%) subjects; with mild level of cognitive impairment in 61(46.2%) and moderate level in 58(43.9%). Advancing age seemed to contribute to cognitive impairment where 41(46.6%) out of 88 young old, 76 (80%) out of 95 middle old and 15 (88.2%) out of 17 old old developed cognitive impairment. Prevalence was higher among males. A cross-sectional survey among 2943 older adults reported that for every one year increase in age, there was a 5% increase in the likelihood of having cognitive impairment (OR 1.05, 95% CI 1.04, 1.06). More than one fifth of the older adults had mild and more than one tenth (11.0%, n= 307) had severe impairment. In the present study, males 65 (74.7%) had a higher prevalence than females 67 (59.3%). Study among 538 Chinese people to explore the prevalence of cognitive impairment and depression among elderly ≥60 years recorded a prevalence of CI as 12.6%; female had a higher prevalence which increased with age. In the present study, males 65 (74.7%) had a higher prevalence than females 67 (59.3%). A study conducted in the Emergency Department reported that age was significantly associated with cognitive impairment (75-84 years: RR= 1.35, p<0.001; 85+ years: RR 1.69, p<0.001). The findings suggested that a higher proportion of elders are either admitted to the hospital from the ED or are being discharged from the hospital with cognitive deficits. A community based cross-sectional study reported that prevalence of cognitive impairment was significantly associated with the age (p<0.001) and was found to be highest in the age group of 80 years and above, followed by 70-79 years. Another study reported that 124 (22%) out of 554 subjects included had MCI. Clinical studies reported a prevalence of MCI in adults aged 65 years and above is 10-20%; risk increased with age. Results highlights that cognitive impairment is a threatening problem among the elderly. The prevalence of cognitive impairment among the study population was considerably high. This difference could be due to the nature of the setting i.e., a tertiary care hospital where many attend due to some or other health related issues or due to different language and versions of tools used for the different studies. Hence the study can be generalized only to the study population and future studies can be conducted in a community or natural setting for a better generalization.

A camp based study conducted among 728 elderly >60 years to determine the prevalence of cognitive decline and dementia and its various risk factors in the elderly population of Uttar Pradesh using Hindi version of Mini Mental Status Examination reported a low cognitive scoring among 43% of the elderly. Prevalence of dementia was 2.7%. In the present study, elderly with any form of co-morbidities had a higher rate of cognitive impairment than their counterparts without co-morbidities i.e., 68(66.02%) of those with diabetes, 76(66.7%) of those with hypertension, 25(80.6%) of those with cardiac diseases and 24(82.8%) of the elderly with asthma had cognitive impairment. Invariably, all those with Parkinson’s disease, stroke and anemia had cognitive impairment. History of alcoholism also contributed to cognitive impairment (10, 71% of the alcoholics; n = 14). Literature support the role of co-morbidities as contributing factor of cognitive impairment. Hence, it is evident that co-morbidity of any type could be a contributing risk factor for cognitive impairment. People with MCI are three to four times more likely to develop Alzheimer’s Dementia (AD) than those without and the risk of progressing to dementia in 6% to 25% approximately. The present study did not include patients with Alzheimer’s disease as the focus was only to determine the prevalence of cognitive impairment. Further study must be conducted to study the contributing factors of cognitive impairment.

### Conclusion

Findings provide evidence that advancing age is a risk factor for cognitive impairment. Owing to the fact that mild cognitive impairment is a precursor of many diseases including Alzheimer’s disease, attention must be given for screening the elderly for the early identification and treatment. Health care members, especially nurses play an important role in the assessment of cognitive impairment and to provide appropriate need based care.

Prevalence of Shoulder Girdle Dysfunction in Computer Users with Non-specific Neck Pain

Singh Neeraj¹, Kumar Pragya², Parasher K. Raju³

¹PhD Scholar, ²PhD; Amity Institute of Physiotherapy, Amity University, ³PhD, Amar Jyoti Institute of Physiotherapy, University of Delhi

Abstract

Aims: Prolonged improper postures while using computers/laptops/smartphones result in many health problems such as neck pain, shoulder girdle pain, forearm and wrist pain etc. High prevalence of non-specific neck pain was reported in office workers who use computers compared to the general population. The purpose of the present study was to determine the prevalence of neck pain, shoulder girdle dysfunction and the physical factors associated with computer users.

Settings and Design: A Cross sectional, observational study that was carried out at a call center that used computers terminals.

Method and Material: One hundred and eleven (111) male computer users with mean age of 34.3±9.13 years, that worked more than 8 hours a day on computers, were included in the study. They were evaluated for the following physical factors–Pectoralis minor tightness, scapular asymmetry, scapular kinematics, Forward Shoulder Posture, cervical range of motion and Posterior Capsular Tightness. The data were analyzed using descriptive statistics.

Results and Conclusions: There was a high prevalence (n = 72; 64.8%) of non-specific neck pain in our sample. Computer users with neck pain demonstrated increased deficits of cervical flexion-extension ROM (88.2%) followed by cervical side flexion (96.3%) and cervical rotation (79.2%). Shoulder girdle examination revealed a higher frequency of inferomedial scapular border prominences with neck pain, along with a high prevalence of posterior capsular tightness (75%), tight pectoralis minor muscle length (26.3%), abnormal lateral scapular slide test values with arms abducted (84.7%) and protracted shoulders (37.5%), observed in computer users with non-specific neck pain

Keywords: Non-specific neck pain, Computer users, scapular asymmetries, shoulder girdle dysfunction.

Introduction

Prolonged improper postures when using computer/laptops/smartphones and long hours in front of visual display terminals result in a whole host of musculoskeletal disorders (MSDs), such as neck and upper back pain[1]. Moreover, continuous use of these devices result in repetitive movements, awkward postures of the neck and the upper limbs leads to muscle weakness and joint dysfunction.[2] Several studies have reported postural and/or mechanical problems such as forward head posture, rounded shoulders, kyphotic posture etc. among computer users[3, 4, 5, 6, 7] which could leads to “nonspecific neck pain”. Neck pain is a great personal discomfort, results in disability, reduction in work productivity, poor quality of life, and economic losses due to inefficiency and lost days at work.[8, 9, 10, 11] Clinically, it is observed that patients with non-specific neck pain exhibit scapular deviations, similar to those with shoulder disorders.[12, 13] Sustained bad postures such as forward head postures, rounded shoulder etc. result in the asymmetrical shortening of the anterior

structures and lengthening of the posterior structures of the shoulder complex, leading to muscle weakness and biomechanical deficits.\textsuperscript{[14,15]} A vicious cycle of neck pain–sustained aberrant postures-biomechanical deficits of the neck and shoulder girdle complex develops in patients with non-specific neck pain. To the best of our knowledge the prevalence of scapular asymmetries and factors associated with it have not been investigated in computer users with nonspecific neck pain. Thus, the purpose of this study was firstly, to determine the prevalence of shoulder girdle dysfunction in computer users with non-specific neck pain and secondly to identify physical factors associated with scapular dysfunction in computer users with non-specific neck pain.

**Method and Materials**

One hundred and eleven (111) male computer users, between the ages of 20-50 years working at an academic institution and a government technology facility volunteered for this study. Computer users involved in field work, having congenital spinal abnormalities, undergone neck/shoulder surgery and with a BMI≥30 kg/m\textsuperscript{2} were excluded from the study. Following written informed consent, participants were asked to fill out a questionnaire that included relevant demographic data, such as information regarding workplace, lifestyle, ergonomics, neck pain etc. Each subject was then tested for cervical and shoulder girdle deficits using the following standardized tests protocols: Cervical Range of Motion\textsuperscript{[16]} Scapularasymmetries\textsuperscript{[17]}, Lateral Scapular Slide Test\textsuperscript{[18]}, Pectoralis Minor Index (PMI)\textsuperscript{[19]}, Forward Shoulder Posture\textsuperscript{[20]}, and Posterior Capsule Tightness\textsuperscript{[21]}

**Subject Characteristics:** The study participants were all males in the age ranging from 20-50 years (mean = 34.3±9.1 years) and mean BMI of 23.7± 2.9 kg/m\textsuperscript{2}. Sixty six percent (n=73; 66%) of the subject used their computers for more than 6 hours a day. Most computer users (60%) have work experience more than 5 years and 62% prefer using laptop against desktop (38%). Surprisingly (n=61;55%) computer users took less than one hour break during their working hours and only 28% of the computer users participated in physical activity on a regular basis.

**Prevalence:** As seen in Table 1, 64.8% of computer users reported having nonspecific neck pain, while 35.1% reported no neck pain. The mean age and body mass index (BMI) for individuals with neck pain was 34.6±9.42 years and 23.9±3.05 kg/m\textsuperscript{2}, while for individuals without pain it was 34.5±7.90 years and 23.7±3.15 kg/m\textsuperscript{2} respectively.

On visual examination as reported in Table 2, it was observed that out of the computer users that suffered from neck pain 38.8% had inferior scapular prominence, 51.3% had medial scapular prominence and 54.1% had Inferomedial scapular prominence deficits.

**Table 2: Frequency of Observed Scapular Prominence deficits regardless of side.**

As seen in Table 3, the cervical range of motion deficits were greater in computer users that reported neck pain. 88.2% of users that reported neck pain had flexion/extension deficits, 96.3% had side-to-side flexion deficits and 79.2% had deficits in rotation towards the right and/or left.

Overall, regardless of the dominance as reported in Table 4 computer users with neck pain had higher percentages of tight Pectoralis Minor deficits (47.2%) compared to users who did not have neck pain (33.3%). Also, individuals with neck pain had greater PMI deficits on the dominant side (26.3%) compared to the non-dominant side (20.8%)

As seen in Table 5, individuals with neck pain demonstrated a higher percentage of protracted shoulder deficits (69.4%) compared to individuals with no pain (58.9%) and furthermore the deficits on the dominant side were greater (37.5%) than the nondominant side (31.0%). On the other side it was surprising that computer users with no neck pain had a higher percentage of posterior capsule tightness deficits (82.0%) than individuals with neck pain (77.7%).

The Lateral Scapular Slide Test (LSST) was used to measure scapular position and/or asymmetry in three positions. As seen in Table 6, It was observed that regardless of the presence of neck pain the incidence deficits increased from position I (5.1%, 6.9%) to position II (30.7%, 18%) to position III (84.6%, 84.7%). Interestingly, there were greater deficits in position II in individuals with no pain (30.7%) compared to computer users with neck pain.

Discussion

The prolonged use of computers has been purported to lead to neck pain and/or disorders of the neck and shoulder girdle region. In this pilot study a total of one hundred and eleven (111) young males between the ages of (34.04±8.50), a representative sample of young adults working predominantly on computers in academic institutions and tech companies, were assessed for the presence of neck pain, scapular asymmetries and the factors associated with it. Not surprisingly, it was observed that almost three-fourths of the sample reported constant, non-specific neck pain and more than 75% experienced neck movement deficits. Neuroanatomical evidence in the literature provides evidence of a strong link between the neck and scapula. Cagnie B et al. reported that a mobile scapula shares common muscle attachments with the neck, and hence abnormal position of the scapula during rest or movement, in addition to other musculoskeletal factors may alter cervico-scapular muscle activity, and its mechanics. These alterations become significant contributory factors to non-specific neck pain in computer users.

Clinical evidence suggests that an altered alignment of the shoulder girdle has the potential to create mechanical dysfunction in the cervical spine causing non-specific neck pain. In the present study, a large proportion of computer users had Inferomedial border and inferior border prominence of the scapular. In addition, 47% had a shortened pectoralis minor length. Evidence suggests that continuous anterior pull due to a shortened pectoralis minor, and other anterior muscles abnormally tilts the scapula. Furthermore 51% computer users demonstrated a medial border prominence, which may be due to the tightness and over activity of the levator scapulae and rhomboid muscles. Almost three fourths of computer users demonstrated a protracted shoulder
work in prolonged static position for long periods of time. This may result in shortening and tightness of the anterior shoulder muscles and lengthening of the posterior structures, causing more forward or rounded shoulder. This imbalance in muscle dynamics causes pain, tenderness \cite{29} along with compressive, rotational, and shear forces in the cervical and the upper thoracic spine leading to non-specific neck pain in computer users. \cite{12, 13, 25, 30} Almost 80% of the computer users sampled had posterior capsular tightness as tightness and alteration in the flexibility of the posterior capsule, leads to an anterosuperior positioning of the humeral head in the glenoid cavity along with a reduction in scapular posterior tilt. This abnormal shortening of the posterior structures over a period of time will alter shoulder girdle movements, in computer users. When performing the lateral scapular slide test (LSST), the different test positions place the scapula and glenohumeral joint in various degrees of medial/lateral rotation/abduction, which requires the synchronized activity of the shoulder girdle musculature to stabilize the scapula on the chest wall. Improper muscle activation alters the scapulohumeral rhythm and force production thereby modify scapular kinematics. \cite{18} In this study, almost 85% of computer users with non-specific neck pain showed scapular asymmetries, when the arms were held in abduction (at 90 degrees), suggesting an imbalance in scapular stabilization.

**Conclusion**

It is noteworthy, that a large percentage of computer users with non-specific neck pain sampled in this study exhibited scapular asymmetries, which was objectively corroborated by specific tests. It is suggested that given the significant biomechanical linkages between the neck and scapula, a muscular imbalance triggered by chronic pain and/or movement dysfunction leads to reciprocal instability and consequently the observed deficits. Thus, clinically it is imperative that clinicians evaluate and address problems of scapular asymmetries in patients suffering from non-specific neck pain in computer users.

Finally, it is important to note and acknowledge the limitations of this study. Most importantly, there is limited internal and external validity, given the small sample size, lack of gender representation and the inclusion of work environment diversity. In addition, and importantly, the study design is descriptive and did not explicitly test the proposals. Future studies should address these limitations, so that future clinical interventions can be based on stronger evidence regarding this close linkage between neck pain and scapular dysfunction that is observed in long-term computer users.

Abstract

Objective: Chlorhexidine is considered to be the “gold-standard” among the chemotherapeutic agents. Essential oils are ideal for use in oral care products because they are both antibacterial and nontoxic—a rare combination. Lemongrass oil and neem oil have a potent antibacterial and antifungal activity. Hence, the aim of this study was to compare the antimicrobial efficacy of chlorhexidine mouthwash, lemongrass oil and neem oil against oral microflora.

Materials and Method: It was an in vitro study. The organisms used were Streptococcus mutans, Lactobacillus and Candida albicans. These bacteria were inoculated in their respective medium and incubated overnight. A suspension was made in saline and was inoculated in the respective solid media by swab method. The concentrations used for lemongrass and neem oil were 1:1, 1:2, and 1:4 dilution. A standard concentration of 0.2% Chlorhexidine mouthwash was used. Sterile discs (5 discs/concentration/micro-organism) were incorporated with equal amount of the chemicals using sterile micropipette and then were incubated overnight at 37°C aerobically. The diameters of the zones of inhibited growth were measured.

Results: The mean zone of inhibition was found to be the maximum for lemongrass oil against all the three micro-organisms as compared with neem oil and chlorhexidine mouthwash. Zone of inhibited growth was maximum against C. albicans at 1:1 dilution which means lemongrass oil highly effective against resistant C. albicans strains. The mean zone of inhibition for neem oil and chlorhexidine mouthwash was maximum against S. mutans strains.

Conclusion: Results from this study have shown that herbal oils were more effective in controlling the oral microflora compared to commercially available mouthwash. Thus turning to nature can be as good as the latest advances.

Keywords: Antimicrobial efficacy, Chlorhexidine, Lemongrass oil, Neem oil, Oral Microflora.

Introduction

Plaque leads to gingival and periodontal diseases, which affects patient’s oral health as well as overall health[¹]. Many studies have shown that tooth brushing alone removes 50% of dental plaque, hence additional mechanical and chemical measures are required to further reduce the bacterial load. Mouthwashes are nonsterile aqueous solutions. They are used for reducing oral bacteria, cleaning food remnants, and decreasing oral malodour[²,³].
Among the chemotherapeutic agents used in mouthwashes, chlorhexidine is considered to be the “gold-standard”\[4,5\]. Chlorhexidine has a wide spectrum of antimicrobial activity and is also capable of inhibiting the candidal adhesion to biological and inert surfaces \[6\]. The predominant microorganisms found in dental plaque associated with a caries lesion are Streptococcus mutans, Lactobacilli, and Candida albicans\[7\]. Even though it is effective, it has certain side effects like brown discoloration of the teeth, oral mucosal erosion, and bitter taste. Therefore natural or Ayurvedic remedies have been put forward.

Essentials oils are known to possess antimicrobial activity\[8\]. Essential oils can inhibit the growth of microorganisms by making their cell membrane permeable which leads to leakage of vital contents\[9\]. Impairment of bacterial enzyme systems may also be a potential mechanism of action \[10\].

Lemongrass (Cymbopogon) belongs to the family Germineae; and from it the lemongrass oil is extracted. It has many medicinal uses; antibacterial, antifungal, antioxidant, antiseptic, astringent, anti-inflammatory, analgesic, antipyretic and carminative property \[11\], and its antibacterial and antifungal properties can be compared to that of penicillin in its effectiveness \[12\]. Lemonene and citral present in lemongrass is the reason for its antibacterial and antifungal property.

Neem (Azadirachtaindica) is a tree of the Meliaceae family. Neem has become a wonder tree of modern medicine and is been used extensively in Ayurveda, unani and homeopathic medicine\[13\]. Neem oil is extracted from the seed. Quercetin and Beta-sitosterol present in the leaves are the reason for antibacterial property of neem.

Herbal products have antimicrobial properties which could therefore be an added advantage over the commercial products in maintaining oral hygiene\[14\]. They are also relatively safe and economical.

Many studies have been conducted to assess the antimicrobial efficacy of chlorhexidine mouthwash, lemongrass oil and neem oil separately. But no study has been conducted to compare the antimicrobial activity of the above mouthwash and oils. Hence, the aim of this study was to compare the antimicrobial efficacy of chlorhexidine mouthwash, lemongrass oil and neem oil against oral microflora.

### Materials and Method

#### Study Design, Study Location and Study Organisms:
An in-vitro study was conducted in the month of January 2019 in the Department of Public Health Dentistry and the Department of Microbiology, Saveetha Dental College, Chennai. The organisms used in this study were Streptococcus mutans, Lactobacillus and Candida albicans.

#### Table 1: Composition of the tested products

#### Ethical Clearance:
Prior to the start of the study ethical clearance was obtained from the Institutional Review Board, Saveetha Dental College, Saveetha Institute of Medical And Technical Sciences.

#### Anti-Microbial Assays:
Standard strains of Streptococcus mutans, Lactobacillus and Candida albicans were isolated. The media used was Nutrient Agar media for Streptococcus mutans and Lactobacillus acidophilus. Sabouraud Dextrose Agar media was used for Candida albicans. These bacteria were inoculated in their respective medium and incubated overnight. A suspension was made in saline(0.5 Mc Farland standard) and 50 microliters of the suspension was inoculated in the respective solid media by swab method.

#### Agar Disc Diffusion Method:
The concentrations used for lemongrass and neem oil were 1:1,1:2, and 1:4 dilution. A standard concentration of 0.2% Chlorhexidine mouthwash was used. Sterile discs (5 discs/concentration/micro-organism) were incorporated with equal amount of the chemicals using sterile micropipette. So in total 105 sterile discs were used. The discs were then placed in hot air oven for 30 minutes for drying. 20 microliters of the chemicals was used for 1:1 dilution,10 microliters for 1:2 dilution and 5 microliters for 1:4 dilution. Then these discs were placed equidistant to each other in the plates containing solid media and were incubated overnight at 37°C aerobically.
**Measurement of Zone of Inhibition:** The test plates were held in front of a desk lamp, and the zones were measured with a ruler held against the back of the petri plate. The diameters of the zones of inhibited growth were measured to the nearest whole millimeter.

**Statistical Analysis:** Data was entered in Microsoft Excel spreadsheet and analysed using Statistical Packages for Social Sciences (SPSS) software version 20. Descriptive statistics were used. Comparison between the groups was done using One-way Anova. A p value of <0.05 was considered to be statistically significant.

Discussion

The organisms used in this study were Streptococcus mutans, Lactobacillus acidophilus, and Candida albicans. The association of Streptococcus species and Lactobacillus species with dental caries is well documented. S.mutans plays an important role in caries initiation while L.acidophilus causes caries progression.

Streptococcus mutans, a gram positive coccus (round bacterium) is a significant contributor to tooth decay. Lactobacillus acidophilus is a species of gram positive bacteria which ferments sugar into acid and grows readily at rather low pH values (below 5.0). Curd like white patches (oral thrush) is formed inside the mouth, on the tongue, palate and around the lips due to Candida albicans.

Various chemical antimicrobial agents are used as antiplaque agents but due to resistance, toxic and harmful side effects of few agents, there is a need for alternate agents, which are easily affordable, non-toxic and effective. Natural plant extracts or herbal agents could be used as effective antiplaque agents.

Out of the various chemical antiplaque agents, chlorhexidine (CHX) is considered the gold standard for tooth decay.
agent for its antimicrobial efficacy. Lemongrass oil and neem oil are promising new herbal agents which have antibacterial and antifungal properties. Hence a comparison was done between gold standard-chlorhexidine mouthwash, lemongrass oil and neem oil.

The present study confirms that all three agents have a potent antibacterial and antifungal activity. Lemongrass oil showed an excellent antimicrobial activity which was in accordance with studies conducted by Bhoj R Singh et al [15] and Silva Cde B et al [16]. Zone of inhibition against S. mutans was found to be much higher than the study conducted by BringelRegoCamilla et al [17].

The findings of the antimicrobial efficacy of Neem oil was similar to the studies conducted by Gayathri R Menonet al [18] and SistlaDatta Prasad et al [19]. The results for chlorhexidine mouthwash was in accordance with study conducted by Ann Thomas [20].

The mean zone of inhibition was found to be the maximum for lemongrass oil against all the three micro-organisms as compared to neem oil and chlorhexidine mouthwash. The reason could be that lemongrass is composed of citral(65-85% w/w) and l-limonene(96-100%) which have strong antibacterial and antifungal properties.

The mean zone of inhibition for lemongrass oil was maximum against C. albicans at 1:1 dilution which means lemongrass oil highly effective against resistant C. albicansstrains. The mean zone of inhibition for neem oil and chlorhexidine mouthwash was maximum against S. mutans strains which means they are most effective against S. mutans as compared to other micro-organisms.

Thus we can say that essential oils do possess antibacterial and antifungal activity and can be used as an ideal treatment against oral microflora who prefer herbal products.

**Limitations:** The test was conducted *in vitro*, so it cannot be assumed that the results of antimicrobial efficacy could be translated into clinical effectiveness. In further studies, *in vivo* studies are recommended with persons' acceptance as well.

**Conclusion**

The present study was based on In vitro experiments. Results of this study indicated that herbal oils were more effective in controlling the oral microflora compared as to commercially available mouthwash. Thus turning to nature could be a good option. These traditional method have numerous other claims which are also of great benefit for health.

Assessment of Microhardness of Enamel Carious Like Lesions After Treatment with Nova Min, Bio Min and Remin Pro Containing Toothpastes: An in Vitro Study

Subhashree Mohapatra¹, R. Pradeep Kumar², I. Meignana Arumugham³, D. Sri Sakthi⁴, P. Jayashri⁵

¹Post-Graduate Student, ²Professor, ³Professor and Head, ⁴Reader, ⁵Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha Institute of Medical And Technical Sciences, Chennai, India

Abstract

Introduction: The initial stage of dental caries is known as incipient lesions and if the process is not interrupted here, they might progress from demineralisation to non caviatated lesions and finally to cavitated lesions. Nova Min is reactive when exposed to body fluids release calcium, sodium and phosphate ions. Bio Min contains calcium and phosphate but also has fluoride within the glass rather than assoluble addition; this allows longer term delivery of fluoride. Remin Pro contains calcium and phosphate in the hydroxyapatite form and also includes fluoride and xylitol. These agents help in remineralisation of enamel.

Materials and Method: A sample of 21 non-carious premolar teeth extracted for orthodontic reasons were used for the study. Surface microhardness value was obtained at baseline, post demineralisation and post treatment using Vickers hardness test. All the teeth were first demineralised and then the test agents were applied for 3 minutes daily for 15 days. The samples were then placed in demineralising and remineralising agents for 1 week followed by assessing the increase in surface microhardness.

Results: The mean difference in Vickers hardness value at baseline and post treatment was found to be highest for Remin Pro group-59.5, followed by Bio Min group-32.5 and the least increment was found in Nova Min group-26.5.

Conclusion: The microhardness of artificial carious like lesions increased significantly with Nova Min, Bio Min and Remin Pro containing toothpastes. However, Remin Pro group was found to be more effective as compared to Bio Min and Nova Min.

Keywords: Nova Min, Bio Min, Remin Pro, Microhardness, Carious lesions.

Introduction

Dental caries is defined as an irreversible microbial disease of the calcified tissues of the teeth, characterised by demineralisation of the inorganic portion and destruction of the organic portion of the tooth, which often leads to cavitation.[¹] In the initial stage the disease is known as incipient carious lesions which is characterised by white, chalky appearance.[²] If the process is not interrupted here, they might progress from demineralisation to non caviatated lesions and finally to cavitated lesions.[³] It is a reversible disease at an early stage but becomes irreversible and destructive after cavitation.[¹]

Demineralisation is the process by which there is loss of mineral from tooth structure.[¹] Remineralisation is the gain of mineral in the tooth structure in the form of hydroxyapatite.[¹] Remineralising agents force calcium and phosphate ions into the demineralised areas thus maintaining a supersaturated state and preventing mineral loss.[⁴]
The most common treatment for enamel caries is fluoride application in various modalities and improving oral hygiene by following proper brushing technique. Fluoride converts hydroxyapatite to the more acid resistant fluorapatite which is effective in enamel remineralisation. Nova Min (Calcium Sodium Phosphosilicate) is a bioactive glass which was originally developed as bone regenerative materials. These materials are reactive when exposed to body fluids release calcium, sodium and phosphate ions. There is a localised transient increase in pH due to release of sodium. This increase in pH helps the calcium and phosphate to form Nova Min particles, followed by calcium and phosphorus found in saliva to form a calcium phosphate layer. As the deposition of calcium phosphate complex takes place, this layer crystallizes into a calcium Hydroxylapatite, also known as hydroxyl carbonate apatite thus contributing to remineralisation process. An addition of soluble fluoride in the formulation process of the toothpaste is required.

Bio Min contains calcium and phosphate but also has fluoride (600 ppm) within the glass rather than assolute addition; this allows longer term delivery of fluoride. The ratio of these three ions reflects the molecular stoichiometry of Fluoroapatite and also the phosphate concentration is three times that of Nova Min. The particle size of BioMin is also smaller than Nova Min which allows greater physical occlusion of open dentin tubules.

Remin Pro (VOCO, Germany) is a water based remineralising cream which contains calcium and phosphate in the hydroxyapatite form and also includes fluoride and xylitol. The hydroxyapatite fills the eroded enamel, fluoride seals the dentinal tubules and xylitol acts as an antibacterial agent. The high fluoride content in Remin Pro (1450 ppm) helps in remineralising the tooth.

Several studies have been conducted to test the efficacy of Nova Min, Bio Min and Remin Pro toothpastes on the surface microhardness of demineralised enamel lesions but no attempt has been made to compare all these modalities.

Hence, the aim of the present study was to test the efficacy of Nova Min, Bio Min and Remin Pro toothpastes on the surface microhardness of enamel carious like lesions.

Materials and Method

Study Design: This was an experimental, randomized in-vitro study.

Inclusion Criteria and Exclusion Criteria: Sound maxillary premolars were included in the study. Endodontically treated teeth, teeth affected with fluorosis, teeth with enamel defects, teeth affected with wasting diseases such as attrition, abrasion, erosion and fractured teeth were excluded from the study.

Ethical Clearance: Prior to the start of the study ethical clearance was obtained from the Scientific Review Board, Saveetha Dental College, Chennai, India.

Pre Study Procedures

Collection and preservation of teeth: In this in vitro study, 21 fully erupted sound human maxillary premolars were used. Teeth extracted for orthodontic reasons were collected from the Department of Oral Surgery, Saveetha Dental College, Chennai. The specimens that were not fulfilling the inclusion criteria were rejected while those fulfilling the criteria were stored in distilled water until further use.

Specimen preparation and Enamel window formation: The roots of the teeth were cut using a water cooled Diamond saw. Then enamel blocks of 4mm (length) x 2mm (breadth) x 4mm (width) were cut from each tooth.

All the 21 enamel blocks were subjected to enamel window formation. This was done to limit the area of demineralization followed by remineralization only in the window area. This would help in surface microhardness measurement compared to unaffected area covered by nail varnish. The teeth were then placed in distilled water until further use.

Mounting the enamel specimen: The enamel blocks were subjected to mounting. The enamel blocks were mounted using blacklite powder in a casting machine.

The mounted 21 enamel blocks were analysed using Vickers hardness testing machine to record the surface microhardness of the sound enamel surface. All examinations were performed at the centre of each block. The Vickers hardness number values were noted and tabulated.
Preparation of solution: The buffered de/re mineralising solutions were prepared using analytical grade chemicals and deionized water.

(a) Demineralizing solution:

It was prepared using following chemicals:
2.2mM calcium chloride, 2.2mM sodium phosphate and 0.05M acetic acid and 1 M potassium hydroxide to adjust the pH to 4.4. 1050ml of distilled water was taken in a beaker and 2.2gm of calcium chloride was added to it. To this, 2.2gm potassium hydrogen orthophosphate, 3gm of acetic acid and 56gm of potassium hydroxide was added.

(b) Remineralizing solution:

It was prepared using the following chemicals:
1.5mM calcium chloride, 0.9mM sodium phosphate and 0.15mM potassium chloride which had a pH of 7.15. 2 ml of distilled water was taken and 0.1665gm of calcium chloride, 0.108 gm of sodium hydrogen phosphate and 11.25gm of potassium chloride was added to it.

Study Procedure

Lesion Formation: The 21 enamel blocks were subjected to demineralizing solution. The enamel blocks were kept in demineralizing solution, 10ml solution per specimen for a period of 96hours. This was done to create artificial carious lesions of approximately 200 to 250 micrometres deep among the selected teeth.

Allocation to experimental groups: After 96hours, these 21 enamel blocks were then randomly allocated into three groups, with 7 enamel blocks in each group (Group A-Sensodyne Repair and Protect toothpaste; containing Nova Min, Group B-Elsenz Anti cavity and Anti sensitivity toothpaste; containing Bio Min, Group C- Voco Remin Pro toothpaste). After demineralization, the enamel blocks were subjected to alternate remineralization and demineralization (pH cycling) to simulate the changes occurring in the oral cavity.

Treatment procedure: The mounted enamel blocks were stored in distilled water. Teeth specimens were cleaned and dried and then subjected to the application of the three toothpastes. The toothpastes were applied for 3 minutes twice daily for 15 days with a cotton applicator and then rinsed with water.

pH cycling model: The specimen were placed in the pH cycling system for 7 days. All solutions (demineralizing, remineralizing) were freshly prepared for each cycle and separate containers were used for each group throughout the experimental period. The pH of the demineralizing and remineralizing solutions was measured before every cycle. The process of pH cycling is described as below:

The specimens were first immersed in demineralising solution (10ml/section) for 3 hrs followed by immersion in remineralising solution (10ml/section) for 2 hrs. Second immersion was done in demineralising solution for 3 hrs followed by immersion in remineralising solution overnight.

The treated enamel blocks were then analysed using Vickers Hardness testing machine to quantitatively analyse the surface microhardness. These values were noted and tabulated and then compared with evaluated sound and demineralised zones of the same specimen. This was done for all the three groups.

Evaluation Technique

Vickers hardness test: Vickers hardness testing was done at Omega Inspection and Analytical Laboratory, Guindy, Chennai to measure the surface microhardness. The test specimens were placed on the stage of the tester and stabilised. Then area to indent was selected by focusing with 10 x objective lens. After this, the test was carried out where the pyramid shaped indentations were made with a rate of 100g load for 30 seconds, never close to any edge of the specimen(Figure 1). The indentation formed was viewed and measured on the display monitor with 10 x objective lens(Figure 2). The average microhardness of the specimen was determined from two indentations to avoid any discrepancy since the enamel surface has a curvature. The test provides the Vickers hardness number of the specimens.

Statistical Analysis: Data was entered into Microsoft excel spreadsheet and analysed using Statistical Package for the Social Sciences (SPSS) software version 20. Kruskal Wallis test and Wilcoxon signed ranks test to estimate differences between the surface microhardness of sound enamel, Demineralized enamel and Treated enamel within and between the three groups. For test, a p value of <0.05 is to be considered statistically significant.

Table 2 depicts the difference in Mean Vickers Hardness Value between post demineralisation and treatment among various groups. The difference in the surface microhardness between post demineralisation and post treatment for NovaMin, BioMin and Remin Pro groups were 23.5, 38.5 and 69.5 respectively. The mean difference among various groups was found to be significant.
Table 3 depicts the difference in Mean Vickers Hardness Value between baseline and post treatment among various groups. The difference in the surface microhardness between baseline and post treatment for NovaMin, BioMin and Remin Pro groups were 26.5, 32.5 and 59.5 respectively. The mean difference among various groups was found to be significant.

### Discussion

Clinical evidence suggests that fluoride is effective in preventing caries onset and arresting or possibly reversing the process of demineralization. Although the demineralizing efficacy of fluoride is substantially justified, the material is not able to surpass the high caries challenge posed in few individuals, and this highlights the need to find newer method to enhance remineralization process. The key requisite in the remineralization of enamel and dentin is the availability of calcium in the oral environment. This has led to the development of various calcium based systems that enhance the availability of calcium and phosphate.[17]

The NovaMin technology was developed by Dr. Len Litkowski and Dr. Gary Hack.[18] Originally it was used to treat hypersensitivity of dentin. Recently, it is also tried as a remineralizing agent.[19] BioMin contains calcium and phosphate but also has fluoride within the glass rather than assoluble addition; this allows longer term delivery of fluoride. It is considered as a breakthrough in remineralization because current systems are dependent on adequate saliva as a source of calcium and phosphate, but bioactive glasses are enriched with these ions.[20] The fluoride content in Remin Pro is 1450ppm which helps in remineralising. It also contains xylitol which has cariostatic property.

Vickers method was chosen in the present study because the pyramid shaped indent obtained is accurate to measure and detect visually and digitally.[21]

The mean difference in Vickers hardness value at baseline and Post treatment was found to be highest for Remin Pro group-59.5, followed by BioMin group-32.5 and the least increment was found in NovaMin group-26.5. This could be due to the presence of high fluoride content in Remin Pro toothpaste.

Farzin Heravi et al[22] conducted a study to compare the effectiveness of MI Paste Plus and Remin Pro on remineralisation of white spot lesions. The mineral content increase for MI Plus and Remin Pro was 16% and 22% respectively. Saranya Mony et al[23] conducted a study to compare the remineralising efficacy of calcium sodium phosphosilicate agent and fluoride. Fluoride achieved better hardness as compared to NovaMin. However, Vahid et al[8] found superior surface hardness with NovaMin as compared to fluoride. However, the outcome was not statistically significant.

There were a few limitations to this study. The sample size was small. The lesions were artificially induced and were not natural carious lesions. Similar studies can be conducted by storing the tooth samples in artificial saliva which would mimic the oral environment and improve the validity of the study.

**Public Health Significance:** Since the fluoride content in Remin Pro containing toothpaste is very high, it can be recommended for elderly people whose enamel layer has been lost due to acid erosion or abrasion. Since NovaMin has no fluoride content, toothpastes containing NovaMin can be prescribed for children below 6 years and special children.

**Conclusion**

Within the limitations and based on the findings of this study, it can be concluded that the microhardness of artificial carious like lesions increased significantly with NovaMin, BioMin and Remin Pro containing toothpastes. However, Remin Pro group was found to be more effective as compared to BioMin and NovaMin.

Effect of Present Day Video Games on Adolescent Cognitive Abilities

Sujatha Bhat¹, Liegelin Kavitha Bernhardt², Ashmitha Thinakaran³, Leevyadhashiny Ganasan³, Pirativ Rao Jagathesa Rao³

¹Associate Professor, Department of Microbiology, ²Associate Professor, Department of Physiology, ³MBBS Students, Melaka Manipal Medical College, Manipal Campus, Manipal Academy of Higher Education, Manipal, India

Abstract

Background: In recent days, video games have become a popular mode of entertainment; especially among adolescents and children. Proficient video gaming demands fast reflexes, good visual-motor coordination, and fast decision making abilities to cope with its tricky challenges. Earlier studies have revealed that video games influence several cognitive processes, by stimulating some of the important brain areas associated with cognition, especially the grey matter in the hippo campus. Thus regular involvement in video games improves one’s performance in terms of sensory, perceptual, attentional tasks and reflex action. There is also a common belief that video gaming has negative impact on one’s mental wellness and therefore playing video game is being restricted in young population.

Objectives: In this study we aimed at evaluating the impact of video gaming on cognitive abilities such as reaction time, memory, visual, verbal, numerical and abstract reasoning skills in adolescent population.

Method: Reaction time was measured using a phone application. A questionnaire designed to test the cognitive abilities with respect to visual, verbal, numerical and abstract reasoning were distributed to 195 volunteers, which included gamers and non-gamers. Following this, the volunteers participated in a memory test for assessing the short term/active memory. The scores were evaluated and results were analyzed using SPSS software version 16.

Results: We found that video-game players outperformed non-gamers on several cognitive measures. Habitual gamers were found to have a lower reaction time, better active memory, and higher numerical, abstract and verbal reasoning skills.

Conclusion: From the present study we can conclude that, habitual video gaming may have beneficial role on the cognitive functions among young minds.

Keywords: Video games, adolescent, cognitive abilities.

Introduction

In present days, playing video games (VG) has become a major medium of entertainment, and is increasing among children and adolescents. It has been estimated that more than 97% of the children in US play VG for at least one hour in a day¹. Wide variety of games is available in the market such as shooting, action, adventure, role-playing, simulation, strategy, sports etc. Proficient video gaming demands fast reflexes, good visual-motor coordination, and fast decision making abilities to cope with its tricky challenges. Although the outcomes of playing VGs depend on factors like nature of the VG, hours of play, age of onset, etc., both positive and negative impact of long term exposure to
VG have been documented. While sedentary life style with prolonged immobilization during VG has proven to cause negative outcomes like obesity, cardio-metabolic deficiencies, etc.\textsuperscript{3,4}, regular habitual VG playing has been reported to improve the cognitive abilities of gamers\textsuperscript{5}. Video-gamers have shown to outperform non-gamers on visual tasks\textsuperscript{6-9}, sensory, perceptual, attentional tasks and reflex action\textsuperscript{10,11}. Very recently, adventure VGs have been considered as a Psychotherapeutic tool to treat the adolescents with problems of depression\textsuperscript{12}. Good VGs designed to mimic real-world problems, positively influence players by helping them design and employ various levels of strategies and find solutions to overcome such problems\textsuperscript{13}. Improvement of cognitive aspects like reasoning skills, attention processes, visual perception, spatial skills, memory, visuomotor coordination, RT (reaction time) and executive functions in VG players can be attributed to favorable alterations in specific brain areas. In a systemic study, Palaus and his colleagues\textsuperscript{14} analyzed results from 116 scientific publications that examined the neural and cognitive outcomes of video gaming and reported that, improvement in visuospatial skills in VG players is a result of increase in size and efficiency of hippocampus and entorhinal cortex of the brain. This may positively contribute to good performances in VG players. Individuals who were trained to play VG regularly were also found to have benefited wherein, an increased hippocampal gray matter, which is crucial for working memory, spatial navigation and strategic planning, was identified\textsuperscript{6}. Contrary to the above reports, recently, few studies have presented differing views that VGs cause negative impact on one’s mental health. Also in the present days many parents consider video gaming as detrimental to one’s mental wellness and therefore children are restricted from playing video games. These conflicting views led us to examine the cognitive implications of video games with respect to RT, memory, visual, verbal, numerical and abstract reasoning abilities using cognitive tasks in a group of students in medical college.

Material and Method

195 undergraduate medical students (64 male gamers, 14 male non-gamers, 32 female gamers and 85 female non-gamers) of mean age 21 years took part in the study. A minimum of 5 hour a week of video-game usage at least for the previous one year were considered as VGPs in our study group. Those who play video games rarely (less than one hour/week) or have no/very little interest with any of games were considered as non-gamers. Students who declared themselves as addicted to video games were excluded from our study. We chose this age group of volunteers for the study because of the fact that, cognitive abilities are at a maximal level during adolescence, and later begin to decline with advancing age\textsuperscript{15}. RT was recorded using a phone application. Basic information viz. age, gender, race, type of video games preferred and duration of play were also collected via pre-test questionnaire. Following this, they completed a questionnaire containing assessment tests to measure the different cognitive abilities like visual, verbal, numerical and abstract reasoning. Memory test was performed by displaying images of 20 items on power point slides for 20 seconds, following which the students were asked to write them down on a paper. The answers were evaluated and the results were analyzed using SPSS software version 16. Informed consent was taken before they were asked to respond to the questionnaire. Institutional Research Committee (IRC-MMMC) approved this study.

Results

The minimum time duration of game played by VGPs was estimated to be 10 hours/week. We observed that, majority of them liked to play adventure type of games (30%) followed by action (26%), shoot (24%) and sports (20%). The sample number versus RT plot of gamers and non-gamers is shown in Figure 1. Regardless of participant’s gender differences, the RTs of all gamers were found to be significantly (p<0.05) lower i.e. in the range of 4.5 to 6/sec. (average RT: 5.22/sec), than that of non-gamers (with average RT of 5.99). This difference clearly indicates that gamers would require lower RT than non-gamers to visual processing stimulus.

![Figure 1: Reaction time in gamers and non-gamers](image)

Figure 2 shows the performance in memory test among gamers and non-gamers. It is clear from the figure that, VG players scored significantly better (p<0.05) in memory test than the non-gamers. This result indicates...
that regular habitual video game playing enhances short term memory.

Figure 2: Mean of memory test scoring in gamers and non-gamers. Data are expressed as mean ± SEM. Gamers Vs Non-gamers *p < 0.05

Figure 3 shows the scoring in tests performed to evaluate cognitive abilities like numerical, verbal, abstract and visual reasoning skills. Abstract reasoning, numerical and verbal skills were significantly (p<0.05) better among gamers when compared to non-gamers. The visual reasoning skill was also higher among gamers but the difference was not statistically significant. We did not find any significant gender based variation in any of the cognitive abilities tested.

Figure 3: Mean scoring of various cognitive abilities in gamers and non-gamers. Data are expressed as mean ± SEM. Gamers Vs Non-gamers *p < 0.05

**Discussion**

The present study evaluated the impact of video games on enhancement of cognitive abilities in a population of healthy young adults. Our results indicated that the speed of reaction was significantly higher in VGP when compared to non-gamers. RT is a measure of one’s ability to detect, process, and respond to a stimulus. This has an important role to play in one’s life due to its great practical implications. Previous studies in this area have shown that video gaming improves vision and increases speed of processing, increases visual selection attention by decreasing the attentional blink, enhances attentional control to task related distractors and reduces the Simon’s effect in goal directed actions. Together, these factors may facilitate to improve RT.

Although the exact mechanism by which VG improves speed of reaction remains unclear, development of specific brain areas that are stimulated during regular video gaming is thought to play a major role. fMRI studies have been able to prove this fact to a certain extent, wherein activation of prefrontal cortex, an area of the brain in front of the occipital lobe was found to be associated with reduction in RT.

In the present work, we also assessed student’s cognitive abilities, in terms of numerical, verbal, visual and abstract reasoning abilities. The numerical reasoning test measures one’s ability to logically interpret and analyze a numerical data presented in the form of a graph/table. Verbal reasoning test was used to assess verbal logic in terms of one’s ability to understand and extract the correct meaning from complex written information. Abstract reasoning is a conceptual reasoning test, which measures person’s ability to detect patterns and relationships and to solve problems in a complex level. This needs logical problem solving capacity, creative thinking and proper judgment. Visual reasoning is a nonverbal intelligence which measures one’s ability to understand, interpret and analyze visual data and solve problems using visual reasoning. Together, both visual and abstract reasoning questions measure the ability of a person to solve general problems using his reasoning skills and thereby indicate fluid intelligence. In our study we observed that, VGP outperform non-gamers in numerical, abstract and verbal reasoning skills. This finding directs us to an understanding that regular and habitual VG playing improves these reasoning abilities that are, to a certain extent important for a student in his/her career. More importantly, improvement of these cognitive domains is thought to potentially improve the mental health and well-being in adolescent population who are consistently exposed to a competitive environment as compared to earlier decades. The available research in the perceptual and cognitive domain indicates that VG play improves spatial skills such as spatial visualization, mental rotation, and the ability to mentally work in three dimensions. Neuroimaging studies in VG players have revealed significant increase in gray matter volume in the right hippocampus, right prefrontal cortex, and bilateral cerebellum. To assess
the effect of VG on short term memory, we performed a memory test, wherein we found that short term memory was significantly higher among the gamers when compared to non-gamers; a finding which indicates that modern day VGs enhance short term memory in habitual players. Earlier studies have also reported that action VG playing enhances visual short term memory. Hippocampus is a very important area of the brain which is generally thought to exhibit neuroplasticity so as to adapt to various environmental stimulations. Video gaming is believed to improve hippocampal function and performance and thus to enhance hippocampal mediated memory tasks. These reports offer evidence that video gaming meaningfully stimulates the development of those brain areas that are maximally activated during the course of playing.

Conclusion

As the above discussed cognitive domains are seen to be better among the video game players, these young minds could be smarter and better performers amongst their peers. Thus in present generation of competence based life, these individuals can fare much better in their social life as well. From the present study we can conclude that video gaming has beneficial role on cognitive functions of the brain with a note of caution that long term effects of video gaming needs to be studied in larger population before recommending this game to children and young adults.

Ethical Clearance was obtained by Institutional Research Committee (IRC-MMMC).

Development of Frame Work to Minimize Waste in the Surgical Unit of a Tertiary Care Hospital

Suvenitha D.¹, Shalini D.²

¹Post-graduate Student, Department of Hospital Administration, ²Assistant Professor, Department of Hospital Administration, Faculty of Management and Commerce, Ramaiah University of Applied Sciences, Bengaluru

Abstract

Introduction: Bio medical waste is generated from the treatment or immunization of human beings and other animals which is contaminated with body fluids, used syringes, needles, dressings, disposables, plastics and micro biological wastes. Operating rooms (ORs) have a large environmental impact; from hospital information statistics, the standard quantity of hospital waste generated is estimated to range from 0.5 to 2.0 Kg/bed/day, they account for 20% to 30% of total hospital supply costs, Waste management initiatives offers tremendous opportunity for healthcare facilities, especially ORs, to reduce disposal costs and their environmental footprint.

Method: A cross-sectional study using convenient sampling was conducted from May-July 2018 at a tertiary care hospital in Bangalore. A self-designed questionnaire and checklist as per BMW Rules, 2016 was used for data collection where sample size was 45.

Results: It was observed that wastes generated by OR department in which highest wastes segregated into infectious waste in the month of May whereas contaminated recyclable waste in June. In addition, 20.63% of glassware wastes generated in Feb whereas 16.67% sharp waste in May. From the correlation test, it was observed that the value is -0.225 which represents negative correlation between surgeon’s experience and waste generated at OR. Cronbach alpha table revealed that 0.822, which indicated high level of internal consistency for BMW management.

Conclusion: A frame work was developed based on the results and analysis of the data which can be taken into consideration for promotion of recyclable and reusable items in the surgical unit. The goal of waste minimization is to reduce, to the greatest extent possible, the waste that is destined for ultimate disposal by means of reuse, recycling and other programs. The potential benefits of waste minimization are: environmental protection enhanced occupational safety and health, cost reductions, reduced liability, regulatory compliance, and improved community relations.

Keywords: Biomedical waste, Recycle and Reuse, Waste minimization, environmentally preferable purchasing.

Introduction

Biomedical hospital waste management refers to the wastes that is generated through diagnosis, treatment or immunization of human beings and is contaminated with patient’s body fluids, syringes, needles, dressings, disposables, plastics and microbiological wastes. Health care sector is primarily meant for human care. But the latest process creates risks with unhealthy practices in the hospitals; one of this is exactly bio medical waste which is generated in treatment of human beings and other species. From hospital information statistics, the standard quantity of hospital waste generated is estimated to range from 0.5 to 2.0Kg/bed/day. Entire bio-medical waste productions in our nation is normally 484 tons per day with 1, 68, 869 from health care services, out of which 447 tons per day wastes are treated. But it is estimated that exact quantity of wastes generated by the healthcare in India is more because many of the clinics do not maintain any records pertaining to the generation
associated with wastes. The quantity of the hospital waste generated differs from one place to other or varies from one surgeon to another with regards to the ratio of waste generated affects the individuals.2

The trouble in waste management has arisen lately in developing nations where there is little history of functioning of official and unofficial community on environmental education, awareness program. The data from developing nations specify that the biomedical waste production ranges from 1-2 kg/day/bed.2

The main issue is to decrease waste generation, segregation, collection and storage of waste so that it controls contamination and provides protection for employees working in operation theatre.3

**Literature Review**

Healthcare waste is a possible health risk to the hospital employee’s, public and environment. It was found that the minor hospitals were not capable of carrying out usual training/education which had a negative impact on separation of waste. The local government institute’s training programs for healthcare employee at taluk level or District level was given to make sure an optimal level of awareness about biomedical waste management practices is useful in minor hospitals.

Hospital acquired infections in patients is due to poor infections control practices and poor waste management. Inappropriate management of waste generated from hospitals causes a direct impact on the society. The pollution which is caused due to biomedical wastes affects the air, soil and water. The micro-organism of Human Immunodeficiency Virus, Hepatitis B Virus, Hepatitis C Virus which leads to Acquired Immunodeficiency Syndrome and Hepatitis B,C and other viral and bacterial infections.4

There were certain regulations and awareness created by government which imposes how important is it to manage bio medical waste management. Though varied techniques were available, it has some threats for Health care sector. There were some challenges identified like Lack of proper operational strategy, poor regulative measures, waste picking and reusing, lack of top management commitment, institutional arrangements, reluctant to change and adoption of the rules laid by the government.5

Wastes generated from the medical hospital became a threat to the nature as well as human world. The study has focused on disposal, reduction, recycle, treatment, segregation and modification. Based on various authors, it was revealed that it was possible for generation of plastic wastes at hospitals which can be eliminated with the help of implementation of policies at health care.6

Minimization of waste materials in OR has included the wastes to recyclable materials. The author has stated in their study that comparing the daily weight of solid waste with regulated and recyclable waste for a period of two weeks. Then the weight reduced to 12% and bags to 6% in operating room/day. Regulated medical waste has reduced to 19% and 45%/day. The importance of waste segregation in operating room is due to the fact that practice reduces the disposal cost which in turn decreases the environmental foot print of the hospitals.7

**Methodology**

**Aim:** The study has aimed to formulate a frame work in minimizing waste by promoting the use of recyclable and reusable items in surgical unit of a tertiary care hospital

**Objectives:**

1. To quantify the different categories of biomedical waste
2. To assess the current practice and knowledge among different health care professionals on biomedical waste management in the surgical unit
3. To analyze the correlation between surgeon’s experience and the amount of waste generated per patient
4. To conduct an audit on reusable and recyclable items in surgical unit
5. To formulate the framework to minimize the waste and promote recycling and reuse of items in the surgical unit

**Method:** A cross-sectional study using convenient sampling was conducted from May-July 2018 at a tertiary care hospital in Bangalore. The study quantified the waste generated by the surgical unit with the help of retrospective data from Jan-Jun 2017. The primary data was collected by direct observation of waste generated from each department in the surgical unit, knowledge and practice based questionnaire was designed by use of BMW Rules, 2016 and amendment 2018; it was validated by the expert. The study had 45 respondents which represented the Nurses, OT technicians, Anesthesia
technician and Housekeeping from the surgical unit. The knowledge based questionnaire comprised of (a) Demographic profile of the respondents which includes age, designation, work experience and department (b) Knowledge on Biomedical waste management in regards to segregation, collection, handling, storage, personal protective equipments and (c) Practice on Biomedical waste. Surgeon’s experience and the waste generated per patient were the two variables used for Pearson’s correlation; audit checklist was prepared for few items from the literature review for checking the usage of reuse and recyclable items in the surgical unit. The respondents were explained about the data collection. They were assured of maintaining their privilege and anonymity. The study has used percentage method for the quantification of waste from the retrospective study, wilcoxon signed rank test and fried man test for the amount of waste generated from each department in the surgical unit. Cronbach’s alpha test was done for knowledge based questionnaire to check the reliability of the answers, observational study for the practice checklist; wilcoxon signed rank test was used to check the difference in items which are reused and recycled from two OT complex of the same hospital.

**Results**

The outcome of the study is given as per the above mentioned objectives.

From the retrospective study it was found that 22.25% and 16.5% of infectious waste and contaminated recyclable waste was generated in the month of June, 20.63% and 22.22% of glassware and sharp waste was generated in the month of Feb and June (Figure 1).

From the primary data collection it was found that orthopedics and gynecology generates the highest waste compared to other department and then next in line is urology and general surgery (Table 1).

The frame works for waste minimization was drawn on the basis of the segregation, reuse; recycle, source control method for the items used in the surgical unit, the waste can be segregated based on infectious and non-infectious waste based on the knowledge and practice level of the staffs which requires periodic training and pictogram near the place of segregation, reuse and recycle also requires periodic training for the staffs with advantages to the organization which can be done by segregating the recyclable waste separately and giving to recycling centers which is converted to by products and given away to multiple buyers which would be cost saving to the organization. The other method is source reduction which is achieved by controlling the outgoing of the items through operational control and changes in technology which can lead to invention and innovation of the products which also could be cost saving to the organization. By this we can achieve waste minimization which would benefit the environment from the pollution.

Discussions

The study revealed that the huge amount of waste was generated by the operating room and anesthesia services. The nurses showed inadequate knowledge on the BMW which was due to gender, poor education and socio-economic was too low. [8]

It was found that the minor hospitals were incapable to carry out education which had a negative impact in separation of waste. A charge involved in treatment of BMW management is an important part of healthcare costs. Investment costs and the functioning expenses were analyzed and it was found that functioning expenses had a higher impact on the hospital’s end result. The expenses were found to be higher in the minor healthcare centre. The major healthcare would be purchasing items in large volumes, which would allow them to negotiate for a lower price.9

The study conducted considered surgeon experience and how much waste did the surgeon produced per patient at operating room. Based on correlation, it was identified that there were negative correlation between these two factors.

The study showed that medical personnel had awareness and proper practice of BMW at hospital.10 Likewise, in Tertiary care Hospital, personnel had awareness about the biomedical waste and segregated the waste at the time of generation in the operating room. Hospitals generated 31.4% of medical wastes in each department.11 Further it was revealed from the fried man test that mean value for orthopedics and gynecology was 7.50 which generated more amount of waste than compared to the other department and following is the department of urology and general surgery. 100% of medical personnel in operating rooms are utilizing the personal protective equipment (gloves, mask) as safety measures but the staff in surgical unit, didn’t not use the eye glasses and aprons while cleaning likewise in their study that 93% of glove usage observed.4-1

The highest number of patients admitted monthly in Emergency rooms, hence average number of generation of wastes increased rapidly.9-1 likewise in the study, highest number of surgeries i.e. 1312 within three months which accelerated the wastes in operating rooms.
Conclusion

From the study it concludes that the OR waste minimization is a helpful method for reduction of the cost in the surgical units. The hospital can promote the reuse and recycling of the items which would be cost effective method for the organization and the profit which is gained from the reusable and recyclable items can be used for other operational expenses in the healthcare settings.

The waste products were segregated into recyclable and non-recyclable items, during the intra operative procedure the amount of waste generated was weighed using weighing scale. Almost 23.1% of total waste is produced from peri-operative procedures and 89% of the wastes are recyclable so executing recyclable policies will be the simplest intervention to minimize the environmental footprint the surgical unit.

The positive results from the study became an initiate and encouraged the employee’s to work towards the recycling program which will benefit towards the waste management and the resource distribution. It shows that the surgeons have the strategies and capacity to minimize the waste produced in the health care setting.

Recycling can have a considerable financial impact on the hospital waste. Recycling has becoming a growing trend in the United States, with 34.7% of all the waste successfully recycled in 2011 which represents an increase from 16% in 1990s and 28.5% in 2000. As per university of Minnesota medical centre USA, blue wrap is estimated to account for 19% of OR waste and 5% of all hospital waste. It is not biodegradable and also not widely recycled. The comparisons of reusable and single use in the peri-operative have made transformation in technology which has helped the medical professionals and patient protection.

Limitations: Infectious waste and contaminated recyclable waste was considered for the study, fluid waste was excluded from the study, The study took place from 9am to 5pm, waste generated in the night must be checked as there are no supervisor in the night they would tend to make mistake.

Antifungal Sensitivity of Candida Sp. Isolated from Skin Infections at a Tertiary Care Teaching Hospital

Chandan Das¹, Shrikant Kumar Dhar¹, Debasmita Behera²

¹Associate Professor, Department of Medicine, ²Assistant Professor, Department of Skin and VD, IMS and SUM Hospital, Siksha “O” Anusandhan, K8, Kalinganagar; Bhubaneswar; Odisha, India

Abstract

Objective: In this study, we have found the prevalence Candidal Sp. in skin infections of the patients attending at the department of medicine and Skin and VD. We have also evaluated the drug sensitivity patterns of identified Candida sp.

Method: This prospective, cross-sectional study was conducted at the IMS and SUM hospital from January 2016 to February 2017, and comprised the causative organisms for skin infections. Species differentiation was confirmed by specific culture medium method. Antifungal susceptibility of isolated Candida species were evaluated with disc diffusion method.

Results: of the 219 Candida isolates, majority of them were isolated from the department of skin and VD 78(35.6%) and Medicine department 59(26.9%). Moreover, 144(65.8%) samples were of females and 75(34.2%) were of males. Candida albicans 128(58.45%) was the most predominant species followed by Candida glabrata 30(13.69%), Candida tropicalis 26(11.87%), Candida krusei 17(7.76%), Candida parapsilosis 12(5.41%), Candida dubliniensis 3(1.37%) and Candida lusitaniae 3(1.37). All isolates were least susceptible to amphotericin B with a susceptibility rate of 213(97.26%). The highest resistance was found for voriconazole 40(18.26%) compared to fluconazole 32(14.61%).

Conclusion: Candida species were resistant to many antifungals and in this study it is revealed that Amphotericin B is the most sensitive antifungal for skin infections.

Keywords: Candida albicans, Non-albicans (NAC), Antifungal sensitivity test, CHROMagar Candida.

Introductions

Fungal infections, a serious clinical condition causes substantial morbidity and mortality amongst the patients globally.¹ Candida species are the normal commensal of the oral cavity, GIT and the mucosal surfaces in the body as well as the pathogens leading to colonization and infection. In the recent times incidence of fungal infections has increased with the increased incidence of immunocompromised patients.² Candida species are frequently isolated from such patients as well as those who are diabetic³, on immune-suppressants or neutropenic⁴ with malignancy undergoing chemotherapy/radiotherapy⁵, long term steroid therapy, long term antibiotic therapy etc.⁶. It has been implicated as a cause of UTI, respiratory infections, septicaemia as well as cutaneous and mucocutaneous infections. The invasive fungal infections often lead to sepsis, severe sepsis and septic shock in critically ill patients in ICU with Candida species being the most common cause of fungal sepsis, especially in the hospital acquired infections⁷.

More than 17 different Candida species are known to be aetiological agents of human infections. Though Candida albicans is the most commonly isolated fungal pathogen from clinical samples, gradually non-albicans Candida species are becoming predominant pathogens⁸. Moreover, the increased use of anti-fungal agents for treatment and also for prophylaxis especially in ICU
patients has lead to development of resistance against commonly used anti-fungal agents in the treatment like various azoles\textsuperscript{2, 4, 6}. However the *Candida species* have variable resistance towards various antifungal agents. Thus this study was carried out to identify different *Candida species* from specimens of clinically diagnosed sepsis patients and their antifungal susceptibility pattern which can be utilized for better management of sepsis patients in our set up. The objectives of this study were to isolate and identify the species of *Candida* from skin infection samples and to determine the susceptibility pattern of the *Candida species* isolates.

### Materials and Method

In this prospective study all the patients attending at the department of medicine and the department of skin and VD were participated for a period of 1 year. Thus the specimens whose Gram stained smears showed presence of any yeast cells or yeast-like cells with budding and with or without pseudohyphae were processed for fungal culture and inoculated on Sabourad’s Dextrose Agar (SDA). Plates were incubated aerobically at 37°C for 24 hours. The colonies of *Candida species* were obtained after overnight incubation. The colonies were identified by colony morphology on SDA, colony colour on Candidal differential agar Media, germ tube test and chlamydospore formation as follows. The colonies were identified according to colour. In addition to the colour of the colonies on HiCrome, a germ tube test and observation of chlamydospore formation on cornmeal agar were carried out for identification of *Candida albicans*. For germ tube test, a well isolated colony from SDA was emulsified in 0.5 ml of human serum using sterile straight wire. The test tubes were incubated at 35°C and no longer than 2 hours. A drop of serum sample was placed on a clean, grease free slide and a coverslip was placed over it. This slide was then observed first under 10X and then under 40X objective lens of microscope for the presence of germ tubes. Germ tube is a filamentous extension from yeast cell without constriction at the neck (true germ tube) and is seen in *C. albicans*. Antifungal Susceptibility test was carried out for *Candida species* according to CLSI guidelines for testing anti-fungal agents for yeasts.

### Results

Of all, 219(7.28%) samples were positive for candida infections, including 78(35.62%) from the Skin and VD department, and rest from the department of Medicine. All these positive samples produced cream to white, smooth and glossy colonies - characteristic of *Candida species* on the SDA. These Candida-positive colonies were gram stained and only those which were round to oval with purple-coloured budding yeast cells were further processed for germ tube (GT) test. A total of 131(59.82%) strains produced germ tubes, hence were categorised as either *C. albicans* or *C. dubliniensis*, while 88(40.18%) strains which were GT negative and were designated as *Candida* species. Species level identification was performed by using CHROM agar Candida and corn meal agar. On the basis of growth on both the media, out of all the positive isolates *C. albicans* 128(58.45%) was the most predominant species followed by *C. glabrata* 30(13.69%), *C. tropicalis* 26(11.87%), *C. krusei* 17(7.76%), *C. parapsilosis* 12(5.47%), *C. dubliniensis* 3(1.37%) and *C. lusitaniae* 3(1.37). Among NACs, *C. glabrata* was the most abundant species. The *Candida* species were also identified through various biochemical tests and the results confirmed microscopic and morphological observations. Moreover, 139(63.5%) of the infections were acquired in hospitals compared to 80(36.5%) community-acquired infections. *C. albicans* was the most abundant species in both the OPD and IPD, followed by *C. glabrata*, *C. tropicalis*, *C. krusei* and *C. parapsilosis*. *C. krusei* was more prevalent in OPD, while other species were abundant in IPD. Highest prevalence of *Candida species* was in skin and VD (Table-1). It was observed that the number of *C. albicans* and all the NAC species was high in females as compared to males. Among the NACs, *C. tropicalis*, *C. glabrata* and *C. krusei* were the predominant species in females. In case of males, *C. tropicalis*, *C. glabrata* were high in number after *C. albicans* (Table-2). Patients were divided into six age groups. The highest rate of *Candida* species was obtained from the patients aged above 60 years with highest prevalence of *C. albicans* followed by *C. glabrata*, *C. tropicalis* and *C. krusei*. In the age group 26-40 and 41-60 years, *C. glabrata* and *C. tropicalis* were prevalent. *C. krusei* was most abundant within the middle-aged group, i.e. 41-60 years (Table-3). In our study, amphotericin B was the most effective antifungal against all the *Candida* species with a susceptibility rate of 213(97.26%). Resistance towards amphotericin B was noted for 3(2.34%) *C. albicans*, 1(3.33%) *C. glabrata* and 1(5.88%) *C. krusei* species. Interestingly, the highest resistance was found for voriconazole 40(18.26%) compared to fluconazole 32(14.61%). *C. krusei* 4(23.5%) were the most resistant *Candida species* to fluconazole followed by *C. albicans*.
24(18.75%), C. glabrata 3(10%) and C. parapsilosis 1(8.3%). However, C. parapsilosis was the most resistant to voriconazole 4(33.3%), followed by C. krusei 4(23.5%), C. albicans 26(20.3%), C. glabrata 4(13.3%) and C. tropicalis 2(7.7%). A 100% susceptibility rate was noted in C. dubliniensis and C. lusitaniae for both the azole antifungals (Table-4). According to the antifungal resistance data of this study, cross-resistance between fluconazole and voriconazole was found among 18(8.2%) of the isolates. of them, 16(88.9%) were C. albicans while 2(11.1%) were C. glabrata. Both the C. glabrata isolates were cross-resistant to fluconazole and voriconazole. Among C. albicans, 14(87.5%) isolates were cross-resistant to fluconazole and voriconazole, 1(6.25%) isolate was resistant against amphotericin B and voriconazole while 1(6.25%) C. albicans isolate was resistant to all the three antifungals i.e., amphotericin B, fluconazole and voriconazole.

Fig 1: Colony of Candida Species on SDA

Fig 2: Antifungal susceptible of Candida species
Discussion

The virulence factors and antifungal susceptibility profile of C. albicans and NACs vary which has necessitated correct and rapid species identification as this has a direct impact on the choice of treatment. In our study, C. albicans (58.4%) was the leading pathogen as compared to NACs similar to earlier reports. Nucci et al. also reported C. albicans (37.6%) as major contributor of Candida infection followed by C. parapsilosis and C. tropicalis. The order of prevalence of NACs in our study was C. glabrata (13.7%), C. tropicalis (11.9%), C. krusei (7.8%), C. parapsilosis (5.5%), C. dubliniensis (1.4%) and C. usitaniae (1.4%). A significant finding of our study is that Candida infection was more common in ICU and Skin and VD wards. However, other studies reported that Candida infection was more common in ICU and surgical ward. Amphotericin B was found to be highly effective against all tested species except for C. albicans, C. glabrata and C. krusei, which is similar to report of De Almeida et al. Antifungal susceptibility data of this study also observed marked rise in azole resistance in NACs as compared to C. albicans. C. krusei was the most resistant species among all the isolates followed by C. albicans, C. glabrata and C. parapsilosis. Oberoi et al. reported high fluconazole sensitivity in C. tropicalis, high resistance in C. glabrata and less resistance in C. parapsilosis. All tested C. tropicalis local isolates were fluconazole sensitive in contrast to C. parapsilosis and C. glabrata. Badiee and Alborzi report 89.5% susceptibility of C. albicans to fluconazole; which is quite similar to our results. Fluconazole resistance was 18.8% similar to the Sojakova et al. which reported 13% fluconazole resistance in 227 Candida isolates. Kaya et al. reported an alarming increased fluconazole resistance in C. albicans (68.7%) and NACs (63.2%).

Effectiveness of Emotional Freedom Techniques: A Pilot Study

Deepak Krishnamurthy¹, Anil Sharma²

¹Assistant Professor, ²Associate Professor, Manikaka Topawala Institute of Nursing, Charotar University of Science and Technology, Gujarat

Abstract

Objective: To determine Effectiveness of add on Emotional freedom technique (EFT) on reduction of depression among depressive patients.

Design: Quasi Experimental study

Setting: Selected Mental Hospital

Participants: Ten patients who are aged above 18 years and diagnosed with depression and who were scored 21-40 for depression on the beck depression Inventory. Participants were randomly assigned to Experimental (EFT) (n=05) and Control (treatment as usual) (n=05) groups.

Intervention: This research is a pretest–post‐test; single-blind randomized experimental study. An Emotional Freedom Technique group (EFT) and a Treatment as usual (TAUG) were formed, each consisting of 05 depression patients in each group determined by beck depression inventory (with moderate to severe level of depression). 40 min Emotional freedom technique was administered to the depressive patients along with routine treatment and TAUG group received the routine treatment. 3 days EFT session was planned and on 3rd day beck depression inventory is administered to determine the depression level in both groups. Data were compelled using descriptive and inferential statistics.

Results: EFT participants (n=5; M=11.80, SD= 2.59) depicts significant reduction in level of depression compared with treatment as usual group (n=5; M= 4.20, SD= 2.95) (p = 0.05, d = 1.75, 95% CI [-3.55-11.65]). In the pre-test no substantial difference was found between the two arms before the intervention in terms of the mean depression level score. After the administration of Emotional freedom technique, it was determined that the mean frequency of level of depression statistically significantly lower compare to treatment as usual.

Conclusion: Emotional freedom technique is a simple non invasive tool, which helps to reduce the depression level.

Keywords: Energy psychology, EFT, Acupressure, Meridians, Tapping Depression, Emotional Freedom Techniques.

Introduction

Depression is the most common Psychological disorder, characterized by hopelessness, helplessness worthlessness and aloofness in activities that we usually relish, followed by lack of ability to perform daily activities, for at least two weeks. Additionally individuals suffering from depression usually have many of the following: decrease in appetite; loss of energy, impaired sleeping; decreased concentration; anxiety indecision; restlessness, guilt and ideas of self-harm or suicide.¹

Depression is a commonest mental health issue, with an approximately Three hundred and fifty million people suffering from depression. Depression is completely different from usual mood swings and temporary emotional reactions to challenges in daily life.²
According to the National Mental Health Survey (NMHS) 2016, conducted by National Institute of Mental Health and Neuro Sciences and other agencies, experts estimated 1.24% of adults in Gujarat are depressed. The National Crime Records Bureau (NCRB) data on depression and suicide shows that in 2014, Gujarat had a suicide rate (suicides per one lakh people) of 11.7, which went to 11.6 in 2015. However, in both these years, the national average suicide rate was 10.6. The suicide rate for women in Gujarat was 9.06 against a national average of 7.24 in 2014.

Especially on long-term living with moderate or severe intensity, depression could lead to significant health issue. Even World Health Organization declared the theme Depression: Let’s Talk’ on occasion of World Health Day observed on 7th April 2017.

The main medical treatment for depression is antidepressant drugs. Antidepressants are the medicine offered on doctor’s written prescription. Drugs can treat moderate to severe depression, however don’t seem to be counselled for kids, and can be administered solely with caution for adolescents. The drug of choice includes selective serotonin reuptake inhibitors (SSRIs),tricyclic antidepressants,atypical antidepressants, monoamine oxidase inhibitors (MAOIs), selective serotonin and nor epinephrine reuptake inhibitors (SNRI), every category of antidepressant acts on a unique neurotransmitter. Prophylactic dose to be maintained even after symptoms have improved, to prevent relapse. Food and Drug Administration (FDA) warns medications like mood elevators could enhance dangerous ideas or actions in some kids, teenagers, and youngsters during initial treatment.”

Complementary and various treatments for depression includes nutrition and, acupuncture, herbal supplements shiatsu and relaxation techniques, like attentiveness, yoga, meditation or t’ai chi.

Emotional freedom technique (EFT) has demonstrated some Progress in reducing symptoms of stress, tension, depression and concern in a very type of settings.

Need for the Study: Person affected with Depression suffer a lot and functions poorly at school, at work and in the family. Even it can lead to suicide. Approximately 80 Lakhs people commit suicide every year. It accounts for the second leading cause of death in age group between 15-29-year-olds.

It was found that an article published in the journal Review of General Psychology of American Psychological Association’s (APA), investigators found that EFT “demonstrated consistently strong effect sizes and other positive statistical results that exceed chance after relatively few treatment sessions.” Other recent study shows how EFT can accomplish progress in a short duration for people with a history of trauma.

In 2009 a study was conducted in which sixteen institutionalized adolescent boys with the history of psychological or physical abuse evidenced considerably reduced intensity of traumatic memories just after onesession of EFT.

A study was conducted among college students which involve thirty moderately to severely depressed students. 90-minutes, four EFT sessions were given to the depressed students. When students were evaluated after three weeks, students who undergone EFT demonstrated significantly less depression compare to control group.

The researcher assumes that based on review of literature EFT is a non-invasive technique which can be tested on the depression patients to reduce the depression.

Objectives:
1. To assess the depression level among depressive patients of EFT and Treatment as usual group.
2. To assess the Emotional freedom technique effectiveness on depression level.

Research hypothesis:

H0: There will be no significant difference between mean Pre and post intervention scores of depression level among EFT group at 0.05 level of significance

Methodology

Research approach: Quantitative research approach was considered the best to assess the level of depression among adults attending selected OPD of Mental Hospital, Gujarat.

Research design: Quasi experimental design with pre and posttest control group is used to assess the Emotional freedom technique effectiveness on reduction of Depression among patients attending selected OPD of Mental Hospital of Central Gujarat.

Sample size: 10 patients who are meeting the Beck Depression Inventory (BDI) standards with moderate to
severe level of depression were assigned randomly, 05 samples in EFT & 05 samples in TAU (Treatment–as–usual) Group

**Setting:** Selected Mental Hospital, Gujarat.

**Independent variable:** Emotional freedom technique.

**Dependent variable:** Depression

**Sample technique:** Simple random sampling

**Inclusive criteria:**
- Willing to participate in the study.
- Patient who are identified with moderate to severe level of depression on Beck Depression Inventory criteria.
- Patients who are undergoing antidepressant treatment or any other psychological therapies

**Exclusive criteria:**
- Patients with extreme depression according to Beck Depression Inventory
- Patient with other psychological disorder other then depression.

**Description of Tool:** Tool consist of 2 sections, First section consist of demographic variables and Second section consist of Beck Depression Inventory, consisting of 21 items, rating from 0-3, interpreted as Considered normal (1-10), Mild mood disturbance (11-16), Borderline clinical depression (17-20), Moderate depression (21-30), Severe depression (31-40).

</table>

Depression level among Patient is different in EFT group in both the condition. The Mean depression level in EFT group before intervention is 29 while in after intervention it became 17. While mean depression level in Treatment as usual in pre-test is 29.6 and reduced to 25.4 in treatment as usual. In comparing both the group statistically it is observed significant reduction in depression level in EFT group. Which means the depression level is difference in both the situation and it is statistically significant. Hence null hypothesis is rejected at 0.05 level of significance.

Discussion

After three session of EFT it is observed significant change in depression level in EFT group who are receiving 40-45 Minutes EFT sessions along with treatment as usual and routine treatment, The Treatment as usual group received standard protocol of drugs and other routine therapies. Beck depression inventory is administered for both the groups on 1st and 3rd day by independent assessor; EFT groups experienced statistically significant decrease in depression level in this study. Results depicts that EFT is an efficacious add on intervention in Hospital settings, also it is an handy tool for nurses who can administer EFT technique after undergoing appropriate training for reducing depression within a few sessions along with routine treatment. EFT is non invasive, evidence-based techniques which can be easily practiced by depression patient along with treatment as usual for better outcome and to prevent the relapse of depression, well it also facilitate reduction in anxiety, stress, PTSD, craving for drugs like alcohol, tobacco.

Recommendation: Results of this pilot study recommends the following to assess effectiveness of EFT (1) Sample size to be enhanced for generalization (2) Treatment sessions frequency can be enhanced, (3) Follow-up sessions need to be planned at different intervals of 1 month, 3 months, 6 months to observe the treatment efficacy for long term. EFT sessions can be monitored with EEG changes, EFT efficiency can be observed from vitals like heart rate, BP, Pulse, breathing. Hormonal changes can be observed in EFT and TAU group for advanced results.

Conclusion

From the above pilot study it is observed EFT group has significant changes in depression level comparing to treatment as usual, also it is found that methodology of the study is found feasible and intervention can be administered for 3 days of 40-45 minutes each to observe clinically significant changes in depression level.

Conflict-of-Interest Statement: The manuscript is original, it has not been published elsewhere and that it has not been submitted simultaneously for publication elsewhere. No part of the manuscript has been published before, nor is any part of it under consideration for publication at another journal, there are no conflicts of interest to disclose.

Effectiveness of Warm Footbath on Quality of Sleep among Elderly

Linju Prasad¹, Gireesh G.R.², Hezil Reema Barboza³, Shashikumar Jawadagi⁴

¹Post Graduate Student, ²Associate Professor, ³Lecturer, ⁴Professor, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Mangalore

Abstract
Sleep disturbance is one among the biggest worldwide health threats. Regardless of the age groups, people are affected with symptoms of insomnia one or the other way. To mention, the geriatrics. The objectives of the study are to assess the effectiveness of warm foot bath on quality of sleep among experimental group. Evaluative approach and quasi experimental, nonrandomized control group design were adopted for the study. Sixty subjects were selected by non-probability purposive sampling technique. The quality of sleep was assessed by Pittsburgh sleep quality index. Independent sample t test was used to compare the quality of sleep between experimental and control group. In the experimental group, the mean post test score of quality of sleep among elderly (11.73±3.9) was much less than of control group, (15.16±4.24). In experimental group the mean difference was (4.16) and it was more than the difference of control group (-2.26), indicate that warm footbath is effective in improving quality of sleep among elderly people. There was no association between pretest sleep quality scores and selected demographic variables.

Keywords: Elderly, insomnia, quality of sleep, warm footbath.

Introduction
Sleep is defined as a period of rest for the body and mind, during which volition and consciousness is in partial or complete abeyance and the bodily functions partially suspended.¹

There are mainly three important theories which clarify about the essentiality, purposes and functions of sleep. The first one, Evolutionary theory explains that wakefulness during the bedtime is found to be most unhealthy episodes in one’s life. Secondly, the information consolidation theory suggests that, sleep is an interval for the body to rest and support the mind to process the message that has been collected during the last day and also prepares the brain for the next day to come. According to the Repair and Restoration theory, sleep is a fundamental plan for body to preserve health and maintain entire physiological process.²

Sleep is very important for a healthy life. However, sleeplessness happens due to various reasons. It is either due to physical, mental or environmental causes. Sleep disturbances varies with type of causes, acute insomnia happens due to life stresses whereas, chronic insomnia occur because of depression, chronic stress or discomfort at night. Other agents include genetics, adults above 65 years of age, dependency on drugs, working at night shift, are results in wakefulness. It contributes the increased risk of chronic health problems like high blood pressure, diabetics, heart disease, stroke etc. According to a survey, around 90% of human suffers above causes.³

According to the statistics, 93% of people are sleep-deprived in India ⁴. Treating insomnia with medications can improve the overall sleep-health among elderly, but chronic use of sedatives can cause drug-withdrawal effects and daytime drowsiness that affects the normal sleep-wake functioning.⁵

However, complementary and alternative therapies are preferred and may results in durable benefits. Warm foot bath is an alternative and powerful medicine for
sleep disorders, by immersing the feet in warm water at 35°C till 40°C for about 10-30 minutes. It helps to circulate more blood throughout the body, boosts the immunity, induce relaxation improves lymph flow, relieves fatigue and insomnia.6

Researches revealed that administration of warm footbath can do wonders for the mood, energy level, sleeping habits, pain and any aches. Reflexology says, the entire body is connected to the feet, by caring and nurturing that part of the body provides health and wellbeing to limbs and organs. When the body temperature increases with footbath relieves stress, muscle and mental tension, and increases white blood cells activity. Thereby, boosts the immune system, prevents sickness. Warm footbath flush out the harmful toxins from the body with the help of bentonite clay prepositive and negative ions act as cleanser to detox the body. Warm footbath relaxes both mentally and physically. This reduces cognitive impairment, increases creativity and work habits, aids in good sleep and decreases mood fluctuation.7

Materials and Method

An evaluative approach and quasi experimental, nonrandomized control group design were adopted to assess the effectiveness of warm foot bath on quality of sleep among elderly. Selection of sampling was done by non-probability purposive sampling technique. Sample consists of 60 elderly people, 30 samples were assigned to experimental group and rest was assigned to control group based on inclusion and exclusion criteria.

Inclusion criteria

- Conscious and well oriented.
- Willing to participate in the study.
- Elderly between the age group of 60 to 89 years

Exclusion criteria:

- Any lesions at the foot.
- Acutely ill
- With psychiatric disorders.
- With diabetes foot ulcer.
- Insulin dependent Diabetics
- Peripheral vascular disease.
- Peripheral neuropathy.
- Swelling in the feet/legs,
- Buerger’s disease
- Frostbite
- Atherosclerosis

The ethical clearance was obtained from Yenepoya Ethics committee. Data was collected by demographic variables and Pittsburgh sleep quality index using interview method. The reliability of the tool was obtained by Cronbach’s alpha (r = 0.8), which indicates tool was reliable. The purpose of study was explained and written consent was obtained from the study participants. Warm foot bath was administered for 3 consecutive weeks in the evening 6:50 to 7pm for 10 minutes. Warm water at 40°C-37°C was measured by lotion thermometer.

Results

The results of the study data was analyzed based on the objectives and hypothesis using descriptive and inferential statistics.

Hypothesis: Hypothesis tested at 0.05 level of significance,

\[H_1\]: The mean post-test level of quality of sleep will be significantly higher than that of the mean pre-test level among elderly in experimental group.

\[H_2\]: The mean post-test level of quality of sleep among elderly in experimental group will be significantly higher than that of the control group.

\[H_3\]: There will be significant association between pretest scores of quality of sleep and selected demographic variables.

As shown in the table 5, in pretest, the experimental group, (6.7%) had good quality of sleep, (40%) of the subjects had average quality of sleep and (53.3%) of the subjects had poor quality of sleep. In control group, (16.7%) of the subjects had good quality of sleep, (50%) of the subjects had average quality of sleep, (33.3%) of them had poor quality of sleep.

In posttest, the experimental group (16.7%) of the subjects had good quality of sleep,(63.3%) of the subjects had average quality of sleep, (20%) of them had poor sleep quality. In control group (16.7%) of the subjects had good quality of sleep, (46.7%) of subjects had average quality of sleep and (36.7%) of them had poor quality of sleep.

Section 2: Comparison of pretest and posttest quality of sleep in experimental and control groups.

Figure 1: Bar diagram showing the duration of stay in old age home according to the groups

The data in figure. 3 reveals that, among the 60 subjects, 33(55%) were staying 1 to 5 years in old age home.

Section 3: Effectiveness on warm footbath on quality of sleep on pretest and posttest level of each group

H₀₁: The mean post-test level of quality of sleep will be no significantly higher than that of the mean pretest level among elderly in experimental group.

Paired “t” test was used to assess effectiveness of warm footbath on quality of sleep on pretest and posttest level of each group.

The above table shows, in the experimental group, the mean post test score of quality of sleep among elderly (11.73±3.9) was much less than of control group, (15.16±4.24). In experimental group the mean difference was (4.16) and it was more than the difference of control group (-2.26). Also in experimental group, the calculated ‘t’ value (t(29)=18.08) was found to be greater than the table value (t(29)=2.09) at <0.05 level of significance. Therefore H₀₁ was rejected and H₁ was accepted, indicate that warm footbath is effective in improving quality of sleep among elderly people.

Section 4: Effectiveness of warm footbath on quality of sleep between experimental and control group.

H₀₂: The mean post-test level of quality of sleep among elderly in experimental group will be no significantly higher than that of the control group.

Independent sample “t” test was used to compare the quality of sleep between experimental and control group.

The obtained p value were <0.05 for both pretest and posttest quality of sleep between experimental group and control group. It indicates that between the groups there was a difference in mean quality of sleep Hence H₀₁ was rejected and H₁ was accepted.

Section 5: Association between pretest scores of quality of sleep and selected demographic variables

H₀₃: There will be no significant association between pre-test scores of quality of sleep and selected demographic variables.

(p>0.05)

The Likelihood Ratio and Chi-square test was used to find the association between pretest scores of quality of sleep and selected demographic variables.

The obtained p values of Chi square and Likelihood Ratio test were >0.05. Hence there was no association between pretest sleep quality scores and selected demographic variables. Hence H3 was rejected and H03 was accepted.

Discussion

Major findings of the study:

Section 1: Description of demographic characteristics: The frequency and percentage distribution of demographic variables of elderly showed that, among the 60 subjects, 29(48.33%) belonged to the age group of 60-69 years.

- The present findings of the study supported by an another studies conducted by,

Prakash Dharam et al-regarding the prevalence and nature of insomnia among elderly population over 66 years of age. The results of the study showed that (32%) had insomnia, (89.45%) subjects were with chronic insomnia. The data suggested that insomnia was more prevalent among elderly people over 60 years of age.

Section 2: Effectiveness of warm foot bath on quality of sleep: In the experimental group, the mean post test score of quality of sleep among elderly (11.73±3.9) was much less than of control group, (15.16±4.24). In experimental group the mean difference was (4.16) and it was more than the difference of control group (-2.26).

Also in experimental group, the calculated’t’ value ($t_{29}$=18.08) was found to be greater than the table value ($t_{29}$=2.09) at <0.05 level of significance, indicate that warm footbath is effective in improving quality of sleep.

Philip Anju (2018)–supported study conducted a quasi experimental study among patients with cancer to assess the effect of warm foot bath on quality of sleep. Results showed that, mean value of quality of sleep in experimental and control group was 3.96±1.7 and 8.07±1.70 respectively, with the mean difference of 4.11. t value is 10.02 and p<0.001 level of significance. The study found that warm foot bath was an effective intervention to improve the quality of sleep.

Section 3: Association between pretest scores of quality of sleep and selected demographic variables: The obtained values of Chi square and Likelihood Ratio test were p>0.05. H03 was accepted and H3 was rejected. Hence there was no association between pretest quality of sleep scores and selected demographic variables.

- The present findings of the study supported by an another study conducted by,

R Timalsina et al-(2017) conducted an analytical cross-sectional study to identify the factors associated with insomnia among elderly, there was no significant association of age, gender, marital status, educational status, current working status, financial dependency, disease and medicine use at present with insomnia. (p>0.05).

Conclusion

The aim of the study was to assess the effectiveness of warm foot bath on quality of sleep among elderly.
Evaluative approach and quasi experimental, nonrandomized control group design were adopted for the study. Sixty subjects were selected by Non-probability purposive sampling technique. With my study i was able to improve the health and quality of sleep in elderly. So in conclusion we can say that the warm footbath is an effective treatment for sleeplessness in elderly population and it also helps to improve the quality of life without causing any side effects in comparison to medication.

Selfie Taking Behavior among College Students: A Cross Sectional Study

Arijit Kundu¹, Lipilekha Patnaik², Sumitra Pattnaik², Trilochan Sahu³

¹PG Student, ²Professor, ³Professor & Head, Department of Community Medicine, Siksha ‘O’ Anusandhan Deemed to be University, Bhubaneswar, Dist.: Khordha State: Odisha

Abstract

Background: Clicking selfie and sharing in social media is increasing day by day as an obsessive compulsive desire, which needs urgent attention.

Objectives: To know the pattern of selfie taking and sharing of selfie in social networking sites and to correlate of selfie taking with self-esteem.

Method:

Study area: Colleges of one university in India.

A predesigned and pretested online questionnaire consisting of demographic characteristics, selfie related questions and Rosenberg self-esteem scale was used to collect data. Data were analyzed by using SPSS v20.

Results: Among 595 participants, 23.1% of the students clicked selfies daily. The places where selfies clicked were public places (47.1%) followed by home (23.4%) and college (19.5%). Boredom (24.4%) was the main reason to click selfies. Negative mental health issues were seen among 56% of the participants like unhappiness, sadness, feeling worthless, depressed etc, when they didn’t receive enough likes or comments in shared selfies. Among the students, 17.6% had selfitis and 20% had low self-esteem. No relation was seen between selfitis and low self-esteem.

Conclusion: Counselling emphasizing on self-motivation and self-control on unnecessary use of social media, giving quality time to family and friends may be initiated as intervention method.

Keywords: Selfitis, social media, mental health, self-esteem, selfie addiction.

Introduction

A selfie is a photograph that one has taken of oneself, typically with a smartphone or webcam and shared via social media (Oxford Dictionary, 2013). Oxford Dictionary named ‘selfie’ as its word of the year 2013. According to language research, the use of ‘selfie’ increased by a colossal 17,000% between 2012 and 2013, which marks a huge upward trend. Selfie is a self-objectification practice of promoting the self. Selfie addiction is new disorder of modern age. But no unique name was given to this disorder yet, and it has been not included in ICD 10. Many of the researcher called it selfitis, some researcher called it as selfie syndrome or selfie addiction etc. Selfitis is an obsessive compulsive desire to take photos of oneself and post them on social media as a way to make up for the lack of self-esteem and to fill a gap in intimacy,¹ and has categorized it into three levels: borderline (up to three selfies per day, but not sharing on social media), acute (three selfies per day, and sharing them on social media), and chronic (at least six selfies per day and sharing every selfie on social media)².
According to American Psychiatric Association, selfitis is not included in DSM-5, but there are plenty of real mental disorders that need and deserve treatment. Whatever the term will be coined in future but it’s really a matter of concern for us to prevent students of being addicted to selfie. Selfie taking can be dangerous, it can cause a person injured physically or mentally.

Recent studies found that individuals with lower self-esteem were more prone to have Selfitis. This may be due to the fact that individuals with low self-esteem use social networking sites to develop social relationships with others with-out having face to face interactions.

Clicking selfie and sharing in social media is increasing day by day as an obsessive compulsive desire, which needs attention. So this study was conducted to know the pattern of selfie taking and sharing of selfie in social networking sites and to correlate of selfie taking with self-esteem.

**Method**

A cross sectional study was conducted from September to December 2017 by adapting convenient sampling method. The study strictly maintained anonymity and purely observational, so ethical permission was not required. An informed written consent was taken from students and those who gave consent for the research were included in this study. A google form was created which consisted of 2 parts. Part 1 includes the demographic characteristics and selfie related questions and part 2 consist of Rosenberg self-esteem scale. The link of the questionnaire was mailed to all the students of different colleges of the university. One person one response option was selected. A timeline was given for a month to send responses. A total of 595 responses were collected. Analysis was done by using SPSS version 20.0 licensed to the institution.

**Results**

A total of 595 students have participated in this study. Students from different colleges of the University had participated in this study consisting of medical undergraduates (49%), engineering (12%), pharmacy (10%), arts (9%), medical postgraduate students (9%), law (7%) etc. Mean age was 21.28 ± 2.46 years (range-17 to 29 years). Among the participants, 48.1% were male and 51.9% were female.

It was observed that 23.1% of the students clicked selfies daily, 12.6% participants clicked three or more selfies per day. Among them, 22% liked to click group selfie, 17.3% liked to click own selfie & 60.7% liked to click both. Only 23.4% students don’t like to share selfies. 66% share selfies in social networking sites and 44.7% share selfies by messenger applications. 9 students share 3 or more selfies per day.

![Figure 1: Places where selfies clicked](image)

Most commonly selfies were clicked in public places (47.1%), home (23.4%), college (19.5%), others like get-together, parties (10%). (Fig. 1)

It was seen that boredom (24.4%) was the main reason followed by to share lifestyle (22.6%), to keep memories (15%), to share in social media (14.9%), send to friends (12.5%), to get attention (5.1%), to see themselves (4.5%) were the reasons to click selfies.

![Figure 2: Feelings after sharing selfies](image)
A total of 44.7% said that they get some sort of satisfaction after sharing selfies in social networking sites. Mixed feelings were seen among the study participants after sharing selfies in SNSs the findings. These were happiness (35.4%), excited (11%), comfortable (7.1%), cheerful (7%), satisfaction (5.2%), feeling confident (5.1%), anxiety (5.1%), depression (5%), appreciation (4%), insecurity (3.1%). 11% of them don’t feel anything after sharing selfies and only 1% don’t share selfies. (Fig. 2)

Figure 3: Feelings if did not receive enough likes/comments

Negative feelings were seen among 56% on the participants which consists of unhappiness (19%), sadness (12%), worthless (7%), depression (5.7%), angry (4.7%), ashamed (4.6%), rejection (3%) and 44% felt nothing when they didn’t receive enough likes or comments in shared selfies. 8% of the participants said they would like to remove selfies from SNSs if didn’t get enough likes or comments. (Fig. 3)

Figure 4: Types of Selfitis among participants

Among the students, 105 (17.6%) had Selfitis. Among them 7.7% had acute selfitis, 82.7% had borderline selfitis, 9.6% had chronic selfitis. (Fig. 4)

In our study population 20% (n=59) had low self-esteem and no relation was found between selfitis and self-esteem.

Discussion

In our study we have found that near one fourth (23.1%) of the study population clicked selfies daily and near one fifth (17.6%) of the students had Selfitis. Similar kind of result was seen in a study done by Era Dutta et al⁴ in Mumbai found that 13% of students very often felt addicted to selfie taking. Though exact prevalence of Selfitis among students is not known yet. Further studies are needed to find out the exact prevalence of Selfitis.

12.6% participants clicked three or more selfies per day. This result is similar to the study done by Era Dutta et al⁴ in Mumbai where it was seen that 16.5% of the students took four or more selfies per day.

We have found that 13.2% of the students had negative experience {anxiety (5.1%), depression (5%), insecurity (3.1%)} with posting selfies on social media. Similar kind of results were observed in the study done by Satish Sarosheet al⁵ in Indore, where 16% of people under study had a negative experience with posting selfies on social media.

Among the participants, 44.7% got some sort of satisfaction after sharing selfies in SNSs which indicates narcissism among people. Narcissism leads to increased aggression in retaliation for wounded pride. Similar finding was also seen in the study done by Satish Sarosheet al⁵ in Indore where it was found that, 34% of people under study agreed to the point that they get some satisfaction from posting selfies on the social network.
Low self-esteem may contribute to externalizing behavior and delinquency, although some studies have found that there was positive correlation of low self-esteem with selfie addiction. In our study we didn’t find any association between those two variables.

Among the study population, 8% said they would like to remove selfies from SNSs if didn’t get enough likes or comments in those posted selfies. Similar finding was seen in the study done by Satish Sarosheet al in Indore, where it was seen 21% of people delete selfies if it does not get any likes. This indicates the self-endorsement people seek in the form of likes on their selfies.

**Conclusion**

Proper counselling on unnecessary use of social media and mobile phones, giving quality time to family and friends, academic guidance and career counselling may be helpful for students to prevent selfie addiction. Behavioural counselling emphasizing on self-motivation and self-control is essential.

The study was limited to students of only one university. The response from the students was very less. This was the limitation of this study. A broad multicenter study will help to find out the exact burden of the selfie addiction among students.

A Study on Human Resource Development Climate Survey in Selected Public Sector Banks in Special Reference to Thiruvannamalai District

K. Indira¹, M. Vetrivel¹, P. Jagatheesan²

¹Assistant Professor, ²Head, Department of Commerce, School of Management Studies & Commerce, VELS University, Chennai

Abstract

In the present scenario of globalization and liberalization of the economy, there is an need for efficient management of the human resources, particularly in the banking sector. The study depends mainly on primary data collected through a well-framed and structured questionnaire to obtain the well-considered opinions of the respondents. If the HRD climate is good, then the employees will contribute their maximum for the achievement of the organizational goals. The results of the present study show that the HRD climate in the public sector banks is at average level and there are lot of scopes for improvement in the HRD climate. The result also shows that there is no difference in the perception of the employees on the basis of their gender, qualification and designation but the perception of the employees differs on the basis of their age. The researcher has taken four Public Sector Banks from two taluks located in Thiruvannamalai District.

Keywords: Human Resources, Human Resource Development Climate, HRD Mechanisms.

Introduction

Management is concerned with the execution of organizational objectives by utilizing physical and monetary resources through the efforts of human resources.¹ The Human Resource Development (HRD) Departments have to play a more important role in shaping the workforce to face the challenges.² Human Resource Development (HRD) is concerned with the provision of learning and developing opportunities that support the success of business strategies and improvement of organizational, team and individual performance (Armstrong and Baron, 2002). Climate is an overall feeling that is conveyed by the physical layout, the way the human employees interact and the way members of the organization conduct themselves with outsiders.³

Objectives of the Study

- To study the type of HRD climate prevailing in some selected Public Sector Banks.
- To study the relationship between the HRD climate and work performance.
- To suggest ways and means of improving the HRD climate in Banks.

Hypotheses

- HRD Climate in Public Sector Banks is positive and optimistic.
- Factors of HRD Climate do not differ significantly.

Methodology: The methodology of the study is based on both primary as well as secondary data. The study depends mainly on primary data collected through a well-framed and structured questionnaire to obtain the well-considered opinions of the respondents. Principal Component Analysis, KMO and Bartlett’s test and Chi-Square test is adopted to analyse the responses from supervising staff and clerical staff of select Public Sector Banks in Cheyyar and Vandavasi taluks in Thiruvannamalai District.

Study Area: The study is confined to a few selected Public Sector Banks and for this purpose, the following 4 Public Sector Banks in Cheyyar and Vandavasi Taluks in Thiruvannamalai District were considered as the sample domain:
Table 1: Sample Domain

Source: Secondary data

The researcher has taken four Public Sector Banks from two taluks located in Thiruvannamalai District. Out of 134 questionnaires distributed, only 106 responses were received. Out of which 6 incomplete questionnaires were rejected. 100 questionnaires were used for the present study.

Analysis of Data: The primary data collected from the managers of select PSBs are analyzed by using the following statistical tools (Statistical Package for Social Sciences – SPSS) to obtain torrent of results regarding the objectives of the study:

1. Percentage Analysis.
2. KMO and Bartlett's test.
3. Factor Analysis by Principal Component Method will be used to identify the factors of HRD climate.

Limitations of the Study

- The study is limited to only Public Sector Banks. Private Sector Banks were not considered because HRD Climate in these banks may not be the same.
- The study was conducted in selected Public Sector Banks, which may not give the global picture of the situation.
- The study covers only two taluks located in Thiruvannamalai District. Due to time constraint, the study is restricted only to two taluks

Source: Primary data

From the table 2, State Bank of India employees are almost covered for the data collection. Four branches of the State Bank have been taken for the study which ensures that the largest player of the country is utilized sufficiently for the study. Almost 43% of the respondents are working in State Bank of India. The next important player is Indian Bank, the respondents participated in the data collection form one percent greater than the State Bank employees’ i.e. 44%.

Source: Primary data

From the table 3, it is very clear that the Wilks’ Lambda values are very near to 1, it means insignificant, therefore it is clear that the grouped means are appropriate with all other components. A 0 cells (0%) have expected frequencies less than 5. The minimum expected cell frequency is 16.2.
H₀: The psychological climate in the organization is not conducive.

H₁: The psychological climate in the organization is conducive.

Based on the name of the bank, hypothesis is tested to know the Psychological Climate among the various banks, and it is revealed that there is conducive psychological climate in the organization. The minimum expected cell frequency is 16.2, but the expected frequency is less than 5, i.e. 0.000, therefore the null hypothesis is rejected.

Source: Primary data

After allotting the weight age to the factors it was cross tabulated with the weights as shown in the table 4, and it reveals that the employees enjoy their work. Based on the cross table hypothesis is framed below to test the significance level.

H₂: Employees do not enjoy their work in public sector banks.

H₂: Employees enjoy their work in public sector banks.

From the table 5 below of the chi-square tests, it is found that only 38.3% have less than 5, the expected count is .11 and the observed is .000, therefore the null hypothesis is rejected with the conclusion that the employees working in the public sector banks enjoy their work.

From the table 6 exhibited that the different opinions of employees for the different statements. Early identification of human resource potential and development of their skill represent two major tasks of human resource development. This can only be achieved when conducive HRD Climate prevails. Thus on the whole, the researcher finds the existence of good HRD Climate in the organization according to the perceptions of employees sought through the scale constructed for measuring the same. The managers in general showed a favourable attitude towards HRD Policies and practices of the organization. They were satisfied with the developmental policies of the top management as well as contented with their work and the organization as a whole i.e. level of job satisfaction was also good.

Suggestions

• The management may take steps to bridge the communication gap among the employees.
• The employees may be encouraged to express their feelings without any fear.
• The management is to motivate the employees to know their strength and weakness with enthusiasm.
• Proper authority may be given to the employees to take suitable decisions within the notified banking policy.
• HR policies of the organization can be designed suitably to encourage the employees to contribute their best.
• Grievance Redressal measures may be taken to satisfy the employees in order to minimize their problems.
• Attention may be given to meet the basic requirements of the employees, so that the employees will concentrate on their work.

Conclusion

HRD climate plays a very important role in the success of any organization, because directly or indirectly it affects the performance of the employees. If the HRD climate is good, then the employees will contribute their maximum for the achievement of the organizational goals. The results of the present study show that the HRD climate in the public sector banks is at average level and there are lot of scopes for improvement in the HRD climate. The result also shows that there is no difference in the perception of the employees on the basis of their gender, qualification and designation but the perception of the employees differs on the basis of their age. The management can improve the HRD climate by introducing suitable changes in the HR policies and practices.

Background: Hearing is a sense that enables man to establish contact with his fellows via speech to experience life more fully. The present study was conducted to compare tympanoplasty with temporalis fascia and tragal perichondrium.

Materials and Method: The present study was conducted on 56 patients of chronic suppurative Otitis Media. Patients were divided into 2 groups. In group I, 28 patients were subjected to tympanoplasty with temporalis fascia while the in group II, 28 patients underwent with tragal perichondrium. In all patients, otomicroscopy was performed. Pure tone audiometry was done as per American speech and hearing association (ASHA).

Results: In group I, 28 patients were subjected to tympanoplasty with temporalis fascia while the in group II, 28 patients underwent with tragal perichondrium. 18 patients in group I and 17 in group II had <20 dB air bone gap, 10 in group I and 11 in group II had 21-40 dB air bone gap. The difference was non-significant (P>0.05). 22 patients in group I and 20 in group II had <20 dB air bone gap, 6 in group I and 8 in group II had 21-40 dB air bone gap. The difference was non-significant (P>0.05).

Conclusion: Both temporalis fascia and tragal perichondrium are excellent graft materials for closure of perforation of tympanic membrane and hearing improvement.

Keywords: Hearing, Tragal perichondrium, temporalis fascia.

Introduction

Hearing is a sense that enables man to establish contact with his fellows via speech to experience life more fully. Deafness in varying degrees of severity is a big impediment to the integration of a person into the social structure. The otologist in the past had not much to offer to hearing handicapped people with chronic middle ear disease. With recent times the advent of the antibiotic era, the operating microscope and modern anesthetics techniques aimed at producing a dry, magnified operating field, have radically altered the outlook.

The surgical repair of permanent perforations of the tympanic membrane was first described as a “myringoplasty” by Berthold in 1878. He placed a plaster against the tympanic membrane for three days to remove the epithelium, and then applied a thick skin graft. The concept of onlay myringoplasty was introduced by Berthold in 1878 using a skin graft while underlay myringoplast was introduced by John J. Shea and Tabb H.G in 1960 using a vein graft. Permanent perforation of the tympanic membrane resulting as sequelae of chronic suppurative otitis media is a major cause of deafness. Stalwarts from past as far back as Hippocrates have asserted the same.
Various autografts have been used for repair of the tympanic membrane perforation like full thickness skin graft, Pedicled skin grafts, split skin graft, vein graft, Fascia grafts and Perichondrium. The present study was conducted to compare tympanoplasty with temporalis fascia and tragal perichondrium.

Materials and Method

The present study was conducted in the department of Otorhinolaryngology, Krishna Institute of Medical sciences deemed to be university, Karad. It comprised of 56 patients of chronic suppurative Otitis Media. All were informed regarding the study and written consent was obtained. Ethical Clearance was obtained prior to the study.

General information such as name, age, gender etc. was recorded. Patients were divided into 2 groups. In group I, 28 patients were subjected to tympanoplasty with temporalis fascia while the in group II, 28 patients underwent with tragal perichondrium. In all patients, otomicroscopy was performed. Pure tone audiometry was done as per American speech and hearing association (ASHA). For all patients X-ray mastoid were taken. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

Discussion

Permanent perforation of the tympanic membrane resulting as sequelae of chronic suppurative otitis media is a major cause of deafness. Controversies range about every step of the operation from the incision to the material used for packing. A great deal of experimental work is being done often with contradictory results. The first known attempt to close a perforation of tympanic membrane to improve hearing was made by Marcus Banzer in 1640 using prosthesis made of pig’s bladder. Since then various graft materials like pig’s bladder, Thiersch skin graft, Split-skin graft, Pedicle graft from ear canal skin, temporalis fascia graft, Vein graft, Sclera, Corneal graft, tympanic membrane homograft and perichondrium have been used for closure of the perforated tympanic membrane. Controversies range about every step of the operation from the incision to the material used for packing. A great deal of experimental work is being done often with contradictory results. The present study was conducted to compare tympanoplasty with temporalis fascia and tragal perichondrium.

In this study, in group I, 28 patients were subjected to tympanoplasty with temporalis fascia while the in group II, 28 patients underwent with tragal perichondrium. Jyoti et al found that majority of the patients shows mild to moderate hearing loss. 47.5% of them had air-one gap up to 20 dB. 52.5% of them had air-bone gap 21-40 dB. None of them had air-bone gap above 40 dB. In the postoperative hearing analysis, 77.5% of the patients showed air- bone gap upto 20dB. 22.5% of the patients showed air- bone gap in the range of 21-40 dB. 80% of the patients operated with temporalis fascia
showed air bone gap up to 20dB. 75% of the patients operated with tragal perichondrium showed air-bone gap up to 20dB. Mean improvement in hearing temporalis fascia is 09.5 dB. Mean improvement in hearing using tragal perichondrium is 09.0 dB. Mean improvement in hearing using tragal perichondrium is 09.0 dB. 

We found that 18 patients in group I and 17 in group II had <20 dB air bone gap, 10 in group I and 11 in group II had 21- 40 dB air bone gap. Wullestein\textsuperscript{11} included 60 patients out of which 30 were subjected to myringoplasty with temporalis fascia and remaining 30 to myringoplasty with tragal perichondrium. The comparative study was done on following parameters- graft uptake, audiological outcome, donor site complications and any late complications such as reperforation, retraction, worsening of hearing and adhesions. The youngest patient in our group was 13 years while the oldest was 56 years old. The overall male: female ratio was 27:22. The patients who underwent temporalis fascia grafting, 86.73% had a gain of 15dB while 13.7% had a gain of > 15 dB. of the patients underwent tragal perichondrium grafting 50% had a gain of 15 dB while 10% had a gain of >15dB. The graft uptake rate was 85.7% for both temporalis fascia as well as tragal perichondrium.4% of the patients of the temporalis fascia group had seroma and 4% had persistent pain. Residual perforation was seen in 3 patients of temporalis fascia group and 4 patients of tragal perichondrium group. 1 case of each group showed canal stenosis.

We found that 22 patients in group I and 20 in group II had <20 dB air bone gap, 6 in group I and 8 in group II had 21- 40 dB air bone gap. Agazzi\textsuperscript{12} in their study of long term result of myringoplasty in adult and children and found the state of middle ear at the time of operation influences surgical outcome; wet ear have higher rate of reperforation.

**Conclusion**

Both temporalis fascia and tragal perichondrium are excellent graft materials for closure of perforation of tympanic membrane and hearing improvement.

Reducing Fertility Rate: A Threat Leader States

Meenakshi¹, Tushinder Preet Kaur²

¹Research Scholar, ²Professor, Mittal School of Business, Lovely Professional University, Phagwara

Abstract

The aim of the study is to analyze the situation of fertility rate in the districts of Punjab. The state is passing through the stage of demographic transition with which the major socio-economic and demographic variables are leaving a strong impact on the demographic dividend. The change in age structure along with the change in literacy, per capita income, female work participation and urbanization, the fertility rate has fallen in leader districts. The laggard districts in the state are still the evidence to high fertility rate. The rural-urban differentials are further widening this gap and changing the total composition of demographic dividend for the years to come. Keeping these factual situations in mind, the study concentrates on analyzing the differentials in the fertility rate in districts of the state, collectively effecting the working segment—the demographic dividend, which could ultimately form a sound platform for the policy makers of the state.

Keywords: Economic Development, Demographic transition, Population, fertility rate, Demographic dividend.

Introduction

Punjab is going through the stage of demographic transition which further is leading to a crucial change in the age structure and demographic dividend of the state. As fertility declines, the proportion of children in proportion to the population of working age decreases, resulting in a lower dependency ratio. This further leads to increase in living standards and the material needs which starts the wave of consumerism to the extent that even a child becomes a source of happiness like many consumer goods. With the rise in per capita capital investments in infrastructure and basic social overhead and the creation of jobs for the available increasing population of working age group, a state or a country can reap the benefits of increased production associated with the decreasing proportion of dependents till the window of the demographic dividend is open. This “demographic bonus” can thus contribute significantly to economic growth and poverty reduction and further will decrease to the proportion to a major fall in the labor force for the years to come. Fertility rate, on the other hand, if stands very low gives a challenge to development programs with very less replacement of the population ultimately leading to decrease in labor force.

The Study Area: Punjab, a name given to the state from Persian dialect means “Five Rivers”, a land of five rivers with the Education Index (0.265) Health Index (0.780063), Income index (0.678) and overall Human Development Index (0.140154) stands on the 6th rank in India. Enjoyed the Green Revolution which brought economic prosperity for the state in the decade of seventies, Punjab shows poor ranking on demographic variable especially gender variable. This is one of the major cause of an adverse environment regarding demographic variables. A very considerable regional diversity in terms of social, economic and demographic characteristics prevails in the state. All the three regions of Punjab had a long history of economic and political happenings. Not only that, there is a striking variations in level of education especially female education, female work participation, dependency ratio, fertility rate, mortality rate, level of employment, per capita income etc. among the various parts of the state, effecting the livelihood of the people. All these indicators have a tendency to further shift the major variables like migration, employment, production, urbanization patterns and overall economic development of the state.

Literature review: The size of the family and the number of children per woman has fallen substantially in many countries over the period, especially after 1960. This trend is broadly favorable for sustainable development. High fertility is associated with increased risk of poor maternal health and mortality. In most of
the cases, women who have several children find it more difficult to work outside the home, thus having fewer opportunities to improve their economic and social status and that of their families \(^{(1)}\). With advances in the field of medicine and public health, there would be a further decline in the mortality rate. The higher the income, the higher the age at marriage. Higher age at marriage shortens the reproductive span which in turn, reduces the fertility rate\(^{(2)}\). Duza and Baldwin also found that the fertility decline in Tunisia, Sri Lanka and Malaysia could be attributed to rising age at marriage as the result of enhanced educational and occupational opportunities\(^{(3)}\).

William Sander studied the fertility behavior in United Nations for four periods and confirmed that economic factors, particularly the earning ability of women affect fertility, an increase in the earning ability of women results in an increase on the price of children thereby reducing fertility\(^{(4)}\). Becker in his ‘demand model’ of fertility behavior viewed children as ‘consumer goods’ and as with other goods an increase in income resulted in an increase in the ‘quality’ and ‘quantity’ of children\(^{(5)}\). Demographic factors like age at marriage, present family size, gender preference and socioeconomic factors like education, occupation, contraceptive practice, etc. were reported the determinants of desired family size\(^{(6)}\). Bogue studied the reasons of fertility decline in Western Europe and explained that education had the powerful impact in explaining the fertility differentials. Female education shows a negative relation with fertility\(^{(7)}\). Cleland and Rodriguez also found that the wife’s education had a slightly stronger influence on fertility than husband’s education. They also noted that in countries with low levels of development the impact of primary schooling was initially positive and only became negative among women who had completed a certain level of schooling. Only when primary school was completed did greater fertility control suppressed the loss of traditional birth spacing behavior associated with exposure to modern education\(^{(8)}\). Bongaarts has taken these socioeconomic factors as indirect determinants though one or more of the proximate determinants\(^{(9)}\). Income and education, being major players among the socio-economic factors. These studies contributed to variations in the level of fertility were essential for initiating planned efforts to control fertility\(^{(10)}\).

**Objectives:**

1. To examine the variations in fertility rate in the districts of Punjab
2. To examine the relation of fertility rate with other variables like literacy rate, per capita income, urbanization etc.
3. To analyze the differentials in fertility rate leading to the formation of demographic dividend of Punjab.

**Database and Methodology:** The study is based on secondary data. It is confined to all the districts of the state. It is a comparative analysis conducted on the fertility levels of the districts of Punjab. The statistical tables, techniques like correlation is used. The disparity pattern in fertility is also explained through diagrams. The source of data collection is the Census of Punjab 2001 & 2011, Economic Survey of Government of India and Reports on Gender profile 2011 by National Women Commission, India.

**Fertility rate in Punjab:** Fertility rate has fallen below the level of replacement fertility rate in Punjab. The concept that is widely associated with TFR is replacement level fertility. A TFR of 2.1 replacement fertility since an average of two births is needed to “replace” a mother and father but only if the births survive to reproductive age. An extra 0.1 birth is added to offset the effects of premature death. Higher fertility in developing countries occurs for a number of reasons all of which work synergistically and to varying degrees depending on the country, religion, culture, and social norms. These reasons include but are not limited as lack of availability to affordable family planning, religious restrictions on the use of family planning, a desire for more children as labor supply and for security in old age, a desire for one or more children of a particular gender, female literacy, and female participation in the workforce.

The change in the fertility rate of Punjab from 1971-2010 taking into consideration two major economically active phases of Punjab; the post green revolution era and the post reform era. The urban areas of Punjab had achieved the level of replacement fertility rate of 2.1 in 1998 while the state had reached into that phase in 2005. The rural urban gap of Punjab was 1.1 in 1971 and this gap has reduced to 0.1 in 2011. Many of the districts in Punjab had practiced positively towards gender statistics so as to make the land more comfortable for women.
The state has observed a sharp fall in the fertility rate after reform period with changing age structure, increasing working force including women, per capita productive investments, rising standard of living with changing life styles and higher per capita incomes, urbanization and positively responding gender variables.

Punjab is not only the ‘Basket of India’ but also the supplier of labor force to foreign lands, working on all types of manual projects outside which had led to the increase in the level of income of an average family. The fertility rate is less in SAS Nagar, Jalandhar, Kapurthala and Ludhiana and high in Ferozepur, Amritsar, Muktsarand Tarn Taran. On the contrary the unequal difference in rural to urban gap lies maximum in Amritsar, Ferozepur, Rupnagar and Patiala which shows that the rural areas of these districts have more fertility rate. Table -1 shows a percentage change in rural and urban literacy from 2001-11. The urban literacy is more than the rural literacy due to the basic infrastructural facilities available in the towns and cities. The leaders in urban and urban female literacy are Hoshiarpur, Sahibzada Ajit Singh Nagar, Gurdaspur and laggards are Mansa, Muktsar, Ferozepur and Sangrur.

TarnTaran, Moga, Ferozepur and Mansa observed a high fertility rate while Jalandhar, Hoshiarpur and Ludhiana have the low rate. The districts with the lower fertility rate and urbanization index have a strong impact on family structures and family health.

Figure 1: District wise rural-urban fertility rate in Punjab

Data source: Census of India-2001, 2011

The leaders in urbanization with less developed rural areas are still having higher fertility rate and on the opposite the districts leaders in overall growth of the rural and urban areas are Hoshiarpur, Kapurthalaand Shaheed Bhagat Singh Nagar.

Data source Census of India-2001and 2011

**Correlation with other variables:** If we look at table no 2 we find five variables, linked to fertility rate. The very first variable is literacy rate which is strongly and inversely related to fertility rate. The other variable is per capita level of income which somehow not so strongly but inversely related to fertility rate. The fertility rate is higher in low as well as high income groups as Punjab is the land based economy with a preference to a baby boy who the social structure accepts as the real owner of land.

The third variable is urbanization which is leading to increase in bearing a child further leading to fall in fertility rate. The percentage of increasing young population and falling support ratio has a negative correlation with fertility rate.

**Correlation with gender variables:** The table 3 representing the gender variables especially the female literacy rate and the economically active rate of women has an inverse relation with fertility rate.

Table 3: District wise analysis of fertility rate and other variables-2011

</tbody>
</table>
The differentials of gender gap are also less in leader districts with a strong positive linkage while rural urban differential have negative correlation with fertility rate, it is because the low differential of rural and urban can lead to even growth.

**Conclusion**

The fertility rate is one of the key variables which acts as a driving force in a developing economy. It has an impact on the growth rate of population leading drastic fall in labor supply further leading to inter and intra-regional migrations. The district wise study clearly deducts a negative correlation of literacy rate, urbanization, gender gap in literacy rate, female work participation and young population on fertility rate and the growth of an economy. Jalandhar, Sahibzada Ajit Singh Nagar and Hoshiarpur, are the front liners in declining fertility rate esp. the urban line of the districts. On the other hand, Mansa, Muktsar and Tarn Taran lag behind in urbanization, literacy rate, female work participation, female education and ultimately facing a higher fertility rate. The regional imbalance in the state is observed among different districts which makes an unequal regional zone. The state is marching ahead in production and infrastructural sectors but needs to concentrate on the wave of the demographic dividend and enjoy the window of opportunity before it closes down. To conclude with the district analysis of Punjab in fertility rate, the differentials in leaders and laggard districts should be taken into consideration so as to evenly grow with this demographic wave.

A Correlational Study on Knowledge and Practice of Fluid and Electrolyte Administration among Staff Nurses of Selected Hospitals at Mangaluru

Melvin Jacob¹, Shashikumar², Jobin³, Hezil Reema Barboza⁴

¹MSc. Nursing, ²HOD, ³Asst. Prof., ⁴Lecturer, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, Karnataka, India

Abstract

Fluid balance monitoring is an essential part of caring critically ill patients. Human body cannot function properly when there is inadequate electrolyte and water in their cells. Increase or decrease of electrolyte which is present in the human body can lead to various disease conditions. Electrolyte balance is helpful to the human being to maintain their blood chemistry and muscle function.

Objective: Assessment on knowledge and practice of fluid and electrolyte administration among staff nurses.

Materials and Method: Knowledge questionnaire and observation checklist regarding fluid and electrolyte administration.

Result: The mean percentage of the knowledge scores and practice scores among staff nurses were 50.41% and 63% respectively. There was weak positive uphill correlation between knowledge and practice among staff nurses (r=.194).

Keywords: Fluid, electrolytes, staff nurse.

Body fluids, mainly water has to carry out several functions in human body. Without water human beings are not able to survive for a longer time. Both, fluids and electrolytes are playing a vital role for preserve good health. During disease conditions an average adult require about 2.5-3 litters of fluid to maintain the lose occur through different parts of the body. In severe case, oral rehydration is not much possible, in order to overcome fluids have to be replaced through intravenous route, it is called as infusion.¹

Introduction

Fluid is critical component recommended for a living creature. Without water human beings are not able to survive for a longer time. Both, fluids and electrolytes are playing a vital role for preserve good health. During disease conditions an average adult require about 2.5-3 litters of fluid to maintain the lose occur through different parts of the body. In severe case, oral rehydration is not much possible, in order to overcome fluids have to be replaced through intravenous route, it is called as infusion.¹

Body fluids, mainly water has to carry out several functions in human body. Transportation of oxygen, electrolyte and nutrients to the cells and control of body temperature are the vital activities executed by the water. Fluid balance monitoring is fundamental element of caring the critically ill patients. Ultimately, it is the process to maintaining balanced intake and output in order to continue the metabolic proceedings of the body. Fluid accumulation can deteriorate the patient condition, especially in critically ill conditions. Appropriate nursing intervention is necessary to avoid complications while administration of fluids.²

In critical care units, many of the procedures greatly influence the fluid and electrolyte status. A nurse working in intensive care unit must have thorough knowledge regarding the type of fluid, amount of fluid and the timings of fluids to be administered. Inadequate awareness about fluid administration accelerate poor patient outcome. It is estimated that 20 percentage of patients had poor documentation of fluid balance or unrecognized fluid imbalance which can be avoided by the proper intervention of nurses.³
Materials and Method:

Study setting and sample size: The research design selected for this study was descriptive correlational design. The study was carried out in Derlakatte and Kodiyelbail, Mangaluru, Karnataka. In the present study, samples consist of 60 staff nurses who were selected by purposive sampling technique, based on inclusion criteria.

Tools and techniques: Questionnaire was used to assess the knowledge \([r=0.70]\) and observation checklist with 12 items \([r=0.80]\) are used for the study.

Data analysis: The data was collected after obtaining prior permission from the concerned authority to conduct the study. The participants were assured about the confidentiality of their responses. The data was analyzed in terms of objectives of the study using both descriptive and inferential statistics. The data obtained was plotted in the master sheet.

Results

Majority of the subjects (83.30%) were in the age group of 21-30 years, most of the subjects were (86.70%) females. 60% had BSc nursing qualification and 80% of the subjects had 1-5 years experience.

Majority of the subjects (55%) had average knowledge level and 73.3% are practicing good fluid and electrolyte administration [fig 1].

Area wise analyses of knowledge score show that majority (48.3%) of the subjects had average knowledge in the area of components of fluid. Regarding the area of electrolyte most of the subjects (58.3%) had average and Major portion of the subjects (53.3%) had average knowledge regarding complications of fluid and electrolyte imbalance.

Area wise analysis of practice shows that majority of the subjects (53.8%) had good practice regarding the area of before fluid administration. In the second area, during the administration of fluid most of the subjects (86.7%) had average practice. In case of third area, half of the samples (50.0%) had excellent practice.

There was no significant association between selected demographic variables with the knowledge and practice. There is a positive\([r=0.194]\) correlation between the knowledge score and practice score.

Discussion

Distribution of subjects according to their knowledge score: The present study many of the subjects (55%) had average knowledge and followed by 41.7% had good knowledge. The mean percentage of overall level of knowledge score was 50.41. The study findings are supported by the study conducted by Aswathy, result showed that 50% of samples have 76-100%, 47.5% of samples have 51-75% and 2.5% have <50% knowledge score respectively.\(^4\)

Distribution of the subjects according to their practice score: The present study revealed that majority
(73.3%) of the subjects had good practice, followed by 18.3% had average practice of fluid and electrolyte administration. The mean percentage of overall level of practice was 63%. The study findings are supported by the study conducted by Kanakalakshmi, result shows that majority of the nurses (62%) had moderately adequate and 23% had inadequate knowledge. Regarding the practice 42% followed moderately safe and 37% followed safe practice.  

**Correlation between the knowledge and practice:** The present study reveals that there is a positive \( r=0.194 \) correlation between knowledge and practice. As the knowledge increases practice also increase. The study findings are supported by the study conducted by Aysegul Gunes et al. result revealed that the mean knowledge score of intravenous potassium administration was found 9.48±3.21, while the mean practice score was 10.85±2.04. Statistically positive relationship was found (\( r: 0.595; p< 0.05 \)) between the knowledge and practice scores of staff nurses.  

**Conclusion**

Present study findings showed that most of the staff nurses had average knowledge and good practice in fluid and electrolyte administration. Educations and training can make the knowledge and practice excellent.

**Financial support and sponsorship:** Nil.

**Conflict of Interest:** There are no conflicts of interest.

**Ethical Clearance:** Ethical Clearance obtained from ethics committee of Yenepoya (deemed to be university) protocol number 2017/078.

Analysis of Pattern and Extent of Substance Abuse/Dependence: An Institutional Study

Suman Deshwal1, Minakshi Vashist2, Rajiv Gupta3

1Research Scholar, 2Professor, Deptt. of Genetics, M.D. University, 3Sr. Professor and Head, Deptt. of Psychiatry, Pt.B.D.S. University of Health, Sciences, Rohtak

Abstract
Drug addiction is a condition in which person become addicted to a particular drug and loses control over his mind and body. Addiction is caused specially by narcotic drugs i.e Pharmaceutical and Psychoactive drugs. Drug addiction includes both licit (alcohol, nicotine) and Illicit (cannabis, cocaine and opiates) substance addiction. In the present study data of 250 patients with socio-demographic profile has been analysed. There were 246 males and 4 females. Most patients belonged to the nuclear families (60%) and only 6% lived alone. Most of substance abuser were employed (84%). Out of employed patients, majority were self – employed(48%) while some patients worked in the private sector (30%) and only a small number of patients were employed in a govt. sector (6%). Most of the patients were living in the rural area (61%). Out of 250 patients 62% were married,35% unmarried and 3% divorced. Majority of age group of substance abusers of present study was between 20-35 yrs. Among all the patients dual/ multiple substance abuse/dependence cases were more (82 & 60) as compared to the single substance abuse/dependence. Among the single substance alcohol cases were more as compared to the heroin, opium, cannabis and injection and corex. In the dual/ multiple substance abuse/dependence the most common combination was of alcohol and tobacco. There is a need of medical education programs emphasizing hazard of various drug abuse. Various government and private organizations have to join hands to fight against alarming menace of drug abuse.

Keywords: Addiction, Alcohol dependence, Drug abuse, Illicit substance, licit substance.

Introduction
Drug addiction is a condition in which person become addicted to a particular drug and loses control over his mind and body. Addiction is caused specially by narcotic drugs i.e Pharmaceutical and Psychoactive drugs. DSM-IV and DSM-V criteria used for substance abuse/dependence to diagnose the addiction of substance abuse/dependence when diagnosed the patient. DSM-5 is the latest guidelines of Diagnostic & Statistical Manual of Mental Disorders which was published in 2015 for diagnosing alcohol used disorders (AUDs) or substance abuse disorders1.

Drug addiction includes both licit (alcohol, nicotine) and Illicit (cannabis, cocaine and opiates) substance addiction. The repeated drug consumption increases tolerance and dependence both physiologically and psychologically.

In whole world every country is facing the problem of drug addiction and drug trafficking. According to World Drug Report (2016), nearly 250 million people between age of 15–64 have used drug . A total of 12 million people inject drugs with 14% of living with HIV. The overall impact of drug use is increasing continuously2. Male are 3 times more using the drugs as compare to the women. World Health Organization (WHO) statistics on the drugs reported that 190 million people in whole world consume drug.

Drug abuse is becoming a major health problem in developing country like India. The substance abuse/dependence in youth has shown alarming dimensions in India. 1 million heroin addicts are registered in India,
according to a UN report and unofficially there may be more than five million. As per estimate prevalence of ever use of any drug is 63.7%. Cannabis, Heroin, and pharmaceutical drugs are the most frequently abused drugs. Frightening information is that of all alcohol, cannabis and opium abusers (21%), (3%) and (0.1%) are below the age of 18 yrs as per recent survey.

Injectable buprenorphine was the most commonly used opioids, followed by bhukhi/doda/opium and heroin. In Manipur and Nagaland PWID people aged between 18-24 years and older than 35 years have been reported to share needles/syringes and draw up drug from a common container.

In medical education an increase in substance abuse was observed. The reported prevalence of substance abuse was 20.43% among medical students. The most common reasons for substance use were relief from psychological stress like the changing of family background, community, new responsibilities and competition in the field of education as well as in employment and occasional celebration. So, to reduce these stress they starts doing experiments with many drugs like opium, heroin, cocaine etc which are easily available to them. Some other problems like child labor, street children and family histories of drug abuse are at higher risk. However more than 91.7% of students were aware of ill effects of these substances.

The scientific literature suggests that some drugs are more strongly associated with violence. These drugs include alcohol, PCP (phencyclidine), cocaine, amphetamines and barbiturates. Inversely, heroin and cannabis are generally associated with a weaker desire to use violence to resolve disputes.

However Heroin has high addiction potential and consumed in high quantity by abusers. From its abuse, addicts are also reported to be involved in illegal activities. There is a need of medical education programs emphasizing hazard of various drug abuse. Control of drug abuse include proper education of youth and proper treatment of addicts or group counseling.

Today, there is no part of world that is free from the curse of drug trafficking and drug addiction. Million of drugs addicts, all over the World, are leading miserable lives, between life and death. India too is caught in this vicious circle of drug abuse, and the numbers of drug addicts increasing day by day. Still there is lack of epidemiological data to combat the situation.

In the present study pattern and extent of licit and illicit drugs abuse/dependence in the patient of drug de-addiction centre, Pt. B.D.S. University of Health Sciences, Rohtak, Haryana has been analysed.

Material and Method

Information was collected from OPD (Out Patient Department) as well as the wards of the Drug De-Addiction Centre, Pt. B. D. Sharma University of Health Sciences, Rohtak during the study period from March’2017 to March’2018. The study was conducted after getting approval from institutional human ethical committee. A specialized questionnaire including all the details of the patients and pattern of substance abuse / dependence socio-demographic was designed. The questionnaire was filled only after getting the verbal informed consent from the patient as well as from their relatives. The patients who voluntarily involved in giving his/her information were later interviewed. Data of 250 patients & 100 controls was collected during the study period.

Information regarding socio-demographics (age, sex, area to which person belongs, no. of siblings), history of patient (marital status, education, employment, family income, current living arrangement), family history of substance abuse /dependence, details of substance abuse /dependence (name, initial age of consumption, mode of consumption, frequency per day), HIV screening, Involvement in any illegal activity & any previous treatment of drugs abuse / dependence was collected & analyzed statistically.

Result

In the present study data of 250 patients with socio-demographic profile has been analysed (Table 1). There were 246 males and 4 females. Sixty percent & patients belonged to the nuclear families, 34% to joint families and 6% lived alone. Eighty four percent substance abuser were employed and 16% patients were unemployed. Out of employed patients 48% were self – employed and 30% patients worked in the private sector. However the data reported no significant p-value at 5% level when statistically analysed. Age group of patients of present study varied between 20-35 yrs. Majority of patients were educated Upto 8th (33%) and followed by 9th & 10th standard (29%) (Table-1).

Among all the patients dual/ multiple substance abuse/dependence cases were more (82 & 60) as compared to the single substance abuse/dependence. Among the single substance alcohol cases (30) were more common as compared to the heroin, opium, cannabis, injection and corex were. In the dual/multiple substance abuse/dependence the most common combination was of alcohol and tobacco (Table 2)

![Fig 1: Marital status of substance users](image-url)
Discussion

Licit and Illicit drugs abuse/dependence is continuously increasing in Indian subcontinent and becoming a major threat to public health. People of rural and urban areas, along with sociodemographic factors. National Household Survey of Drug Abuse (NHSDA) in India and the United Nations Office of Drugs and Crime (UNODC) has undertaken with the objective of evaluating extent of use of various drugs of abuse in India.

Present study reported that dual/multiple substance abuse/dependence was more (33% & 24%) as compared to the single substance abuse/dependence. Among the single substance alcohol (12%) was more common as compared to the heroin (8%), Opium (7%), Cannabis(5%), Injection (4%) and Corex (2%). In the dual/multiple substance abuse/dependence the most common combination was of alcohol and tobacco.

As per available literature the prevalence of ever use of any drug was 63.7% .Tobacco was the most commonly used psychoactive substance. Prevalence of ever use of alcohol was 19.6%, followed by cannabis (3.8%), opium (0.6%) and heroin (0.2%). Tobacco and alcohol outnumbered illicit drug users in terms of extent of their use11.

Present findings showed that the Prevalence of licit or illicit drugs consumption is less in females (2%)as compared to male (98%). It was observed that 49% of patient belong to age group (20-35 yrs), Most of patients (94%) were educated. There were 60% cases of Nuclear families. As per available recent report prevalence of substance abuse was more among joint families12.

Many studies have been carried to know the prevalence of substance abuse in India. Acc. to survey 78% people said that user makes their first contact with drug through their friends. Among the states Punjab, Haryana and Chandigarh have highest takers of Heroin, opium and opioid in the country. In U.T. of Chandigarh prevalence of substance dependence was estimated to be 4.65%. Dependence on opioids, and sedative hypnotics were found to be 1.53% and 0.52% respectively. Prevalence of Injectable opioids was calculated to be 0.91%. Injectable buprenorphine was the most commonly used opioids, followed by bhukhi/doda/opium and heroin5. Increasing trends of Heroine among population is shattering the youth of Punjab10. There were 8% cases of heroine takers.

Easy availability and social acceptability of smoking to some extent and Use of substance like cannabis, opium, sedative, injection, heroin, was also reported in the studied group. Prevalence of drug addiction was quite high.

Studies done in India and in other countries have revealed higher prevalence and pattern of substance use among medical students and other college students as well as in common people. A higher proportion of young people were found to be using any of the substances when one or both of their parents were working or in government profession.

In the present study it was found that more males than the females used at least one substance of abuse. Most of them did so despite knowing the ill effects and legal consequences of such use. Some of the study participants had made attempts to quit in the past but failed to maintain due to lack of will power. Stress, relationship, peer pressure were the main factors leading to basic drugs use.

Conclusion

It is well known that substance abuse did not spare any part of the world, it has spread its roots in rural as well as in urban areas of country. Substance abuse has physical, mental & social health impact on human beings. Now, its alarming time, various Government and Private organizations have to join hands to fight against the menace of drug abuse. There is a need to focus on preventive measures which may be in the form of education, legislation, campaigning, advertisement on television as well as in the newspapers. The ultimate goal is to reduce the magnitude of substance abuse, no matter
what strategy to be followed. Strategy must include the early identification of the user & to provide the effective treatment as soon as possible.

Health Seeking Behavior among the Mothers of Under Five Children with Upper Respiratory Tract Infection

N. Siva1, Baby S. Nayak2

1Assistant Professor, School of Nursing Science and Research, Shrada University, Greater Noida, 2HOD Department of Child Health Nursing, Manipal College of Nursing, Manipal, Manipal Academy of Higher Education Manipal, Karnataka

Abstract

Background of the study: In India acute respiratory tract infections is one of the leading causes of morbidity and mortality in young children.1 In most developing and developed countries, it is observed that the health of the children strongly depends on their parental health care seeking behavior. Mainly health seeking behavior depends on parental knowledge, understanding of children illnesses and availability of health care facilities. Poverty and transportation are the key factors for health care seeking behavior.2

Statement of the problem: Health seeking behavior among the mothers of under five children with upper respiratory tract infection.

Objective: To assess health seeking behavior among the mothers of under five children with upper respiratory tract infection.

Keywords: Upper respiratory tract infection, under five children, health seeking behavior.

Introduction

One of the major causes of child mortality and morbidity rate is acute respiratory tract infection. Control of respiratory tract infections is a major problem in developed and developing countries. Due to acute respiratory tract infection (ARI) the proportion of death in the community is much higher and most of the children die at home, many of those infections taking their natural course without specific treatment.3

In India acute respiratory tract infections is one of the leading causes of morbidity and mortality in young children. In acute respiratory tract infection, (ARTI) children usually have symptoms like loss of appetite, difficulty in breathing, nasal blockage and also sucking difficulty in breastfed babies.1 In most developing and developed countries, it is observed that the health of the children strongly depends on their parental health care seeking behavior. Mainly health seeking behavior depends on parental knowledge, understanding of children illnesses and availability of health care facilities. Poverty and transportation are the key factors for health care seeking behavior.2

Materials and Method

Research approach: Quantitative Research approach was selected for this study.

Research Design: The research design selected for the study was a Non-experimental Cross-sectional Indescriptive research design was adopted for the study.

Research Variables: Health seeking behavior, Upper respiratory tract vision.

Demographic Variables: Age of the mother, Educational status of the mother, Monthly family income, Area of Living.

Setting of the study: The study setting is pediatric outpatient departments in selected secondary care hospitals of Udupi district, Karnataka. The descriptive cross sectional survey design was used for this study.

Population: Mothers of under five children with upper respiratory tract infections who are attending Pediatric OPDs of Dr. TMA Pai hospital, Udupi district.
Sample and sampling technique: Total 154 mothers of under five were selected by using convenience sampling technique.

Results

Results of the study have shown that that among 154 mothers majority 136 (88.3%) of the sample took their child to hospital during illness. Majority, 118 (76.6%) of the sample reported that distance to the hospital is the main barrier for them in seeking medical advice. Majority 134 (87.0%) of the sample were consulting multi super specialty hospital during child’s illness, most 92 (59.7%) of the mother took independent decision to take the child to hospital. Majority, 134 (87.0%) of the mothers were considering severe cough as the main symptom of respiratory tract infection.

Discussion

Among 154 mothers majority 136 (88.3%) of the sample took their child to hospital during illness. Majority, 118 (76.6%) of the sample reported that distance to the hospital is the main barrier for them in seeking medical advice. Majority 134 (87.0%) of the sample were consulting multi super specialty hospital during child’s illness, most 92 (59.7%) of the mother took independent decision to take the child to hospital. Majority, 134 (87.0%) of the mothers were considering severe cough as the main symptom of respiratory tract infection.

Majority 67 (43.5%) of the sample were using ginger and turmeric mixture to manage cough of the child at home and 71 (46.1) sample were using ginger with the turmeric powder to manage child’s running nose. Most 133 (86.3%) of the sample were consulting the doctor when child had fever.

Conclusion:

Mothers with graduation and above, middle class officials and those who were subscribing to news paper had better health seeking behavior than other mothers. The findings highlight that, the nurses and health care providers can play a significant role to educate the mothers’ regarding importance of seeking medical care and mode of transmission, early identification, management and prevention of URTI in under five children.

Conflict of Interest: There is no conflict.

Prevalence of Depression among Elderly in the Urban Field Practice Area of Rajarajeswari Medical College and Hospital: A Cross Sectional Study

A.C. Shyam¹, Naveen Kumar P.², Bhanushree³

¹Associate Professor, ²Assistant Professor, ³Junior Resident Department of Community Medicine, Rajarajeswari Medical College and Hospital, Bengaluru

Abstract

One of the important determinants of Mental health is age, old age not challenges physically but also with challenges affecting the mental and social wellbeing. The current prevalence of depression with the light of evidences from the community based studies is 36%, of which 86.1% of the elderly population had medical co-morbidities. This cross-sectional study was conducted in Channasandra, urban field practice area of Rajarajeswari medical college and hospital. The sample size was estimated to be 92.16 which was rounded off to 100. The study was carried out using GDS – 15, geriatric depression scale. From the above study, the prevalence of the depression among the elderly was found to be 38 (38%). of which 24 (63.1%) were suffering from moderate depression and 14 (36.8%) were suffering from severe depression. In the current study, it was found that depression was seen more among 30(78.9%) of the depressive subjects with medical co-morbidities, when compared with 42(67.7%) of the non-depressive subjects having co-morbidities. From the above study, prevalence of depression among the elderly was found to be 38% which influenced by illiteracy, medium standard of living.

Keywords: Mental health, Social wellbeing, Depression, Elderly.

As the age advances there will be normal aging of the brain, which results in deteriorating physical health and cerebral pathology, the overall Prevalence of mental and behavioral disorders tends to increase with age.¹ The current prevalence of depression with the light of evidences from the community based studies is 36%, of which 86.1% of the elderly population had medical co-morbidities.² Depression is a common problem among elderly. Among them, it is a cause of disability, social deprivation, and loneliness. Often it goes unrecognized because elderly attribute its symptoms to the aging process. Depression in elderly leads to increased use of health services by elderly thereby putting pressure on the already burdened health-care system.³

In India, the research on the elderly and their psychological problems is scarce; as Majority of Depressive disorders remain undiagnosed and untreated because of a wrong belief that it is a part of ageing and a social stigma.³ Hence this study was conducted using GDS-15 scale with an objective of assessing the

Introduction

India; second most populous country in the world. In India, according to Population Census 2011 there are nearly 104 million elderly persons (aged 60 years or above) in India; 53 million females and 51 million males. Both the share and size of elderly population is increasing over time. From 5.6% in 1961 the proportion has increased to 8.6% in 2011. For males it was marginally lower at8.2%, while for females it was 9.0%. As regards rural and urban areas, 71% of elderly population resides in rural areas while 29% is in urban areas.¹

One of the important determinant of Mental health is age, old age not challenges physically but also with challenges affecting the mental and social wellbeing.
prevalence of depression among the elderly and to find out the determinants responsible for it.

Methodology

This cross-sectional study was conducted in channasandra, urban field practice area of Rajarajeswari medical college and hospital; after getting approval from Institutional Ethical Committee. The sample size was estimated using the formula \( n = \frac{4pq}{L^2} \). The prevalence of depression, “\( p \)” among elderly persons was taken as 36\%. \(^3\) With precision of 10\%, using the above mentioned statistical formula which considers 95\% confidence limits, the sample size was estimated to be 92.16 which was rounded off to 100.

All the elderly population in channasandra that is the urban field area of Rajarajeswari medical college was enlisted by house to house survey, which was 492. of the 492 elderly population who were enlisted 216 were males and 276 were females. All the subjects were enlisted by alphabetic order of their names. Using the random table number, the subjects were recruited to the study until the desired sample size is met. Of the 100 selected study subjects, 40 were males and 60 were females.

The study was carried out using GDS – 15, geriatric depression scale. Each of the study subjects were interviewed separately. Information regarding the socio-demographic characteristics, financial status, and comorbid conditions were collected using a pretested structured proforma and data was entered into MS excel sheet and was analyzed using SPSS software version 21.

Results

From the above study, the prevalence of the depression among the elderly was found to be 38 (38\%), of which 24 (63.1\%) were suffering from moderate depression and 14 (36.8\%) were suffering from severe depression.

The socio-demographic characteristics and depression of the study subjects revealed that 11(28.9\%) were aged above 70 years. Among 38 study subjects suffering from depression, 21(55.2\%) were females and 17(44.7\%) were males. In the present study 22(57.8\%) of the subjects with depression were illiterate. When the depressive study subjects were classified according to the Standard of Living Index (SLI) it was noted that 21(55.2\%) of the subjects belonged to medium SLI, which was found to be statistical significant \( p=0.002^* \). From the study it was noted that depression was more among married subjects, 23(60.5\%); and also it was found that depression was more among the subjects who were from nuclear families, 20(52.6\%); however it was not statistically significant [Table 1].

From Table 2, it’s noted that depression is found among 30(72\%) of the financially dependent study subjects compared to depression among 8(21\%) of the financially independent study subjects. Depression was found to more among 18(60\%) of the subjects who were not receiving any financial assistance compare to 12(40\%) of the subjects who were receiving financial assistance; which is statistically significant.
In the current study, it was found that depression was seen more among 30(78.9%) of the depressive subjects with medical co-morbidities, when compared with 42(67.7%) of the non-depressive subjects having co-morbidities [Table 3].

When the relationship between insomnia and anorexia and depression was studied; it was noted that insomnia was more among 28(73.6%) of the depressive subjects compared to 14(22.5%) of the non-depressive subjects. Anorexia was also more among 30(78.9%) of the depressive subjects compared to 12(19.3%) of the non-depressive subjects, which was found to be statistically significant [Table 4].

**Discussion**

In the present study, the prevalence of depression among the study subjects was found to be 38%, when compared to the 10%-20% of the prevalence depending on the cultural variations, as estimated by WHO.  

In the study done by Sanjay TV et al., in Bangalore; a very similar prevalence rate of depression among elderly was noted. In that study the prevalence of depression...
was found to be 36% among the elderly study subjects.\(^3\) which was very similar to the prevalence of 32.4% found by Nair et al., in the study conducted at Dharwad.\(^6\)

In this study it was found that depression was more among the subjects belonging to medium SLI and illiterates, which was very similar to results found in the study done by Jain RK et al.,in Mumbai city.\(^7\) It was also evident in the study done Pracheth R et al.,\(^8\) this was mostly due to majority of the subjects were migrated from the rural areas to the urban areas, which had impact on their SLI.

In the study, it was noted that depression was significantly associated with the subjects who were financially dependent than compared to the subjects who were financially independent,

Which is also confirmed in the study done by Gupta et al., where in depression was less seen among the subjects receiving pension.\(^9\)

In our study, it was found that the depression among the study subjects who had medical co-morbidities. In the study done Kaneko Y et al., and Wong SY et al., co-morbidities were identified as important risk factors for depression\(^10,11\).

Depression was found to be significantly associated with insomnia among 28(73.6%) of the study subjects in our study which was statistically significant, a very similar result was found in the study done by Grover S et al.,\(^2\)

In the study done by Bharatwaz RS et al., depression was significantly associated with insomnia.\(^12\)

It was significantly found that the anorexia was more commonly associated with depression, which was found to be statistically significant. As per the DSM – IV criteria it is noted that the anorexia is the third most common symptom associated with depression and insomnia is the fourth commonest symptom to be associated with depression.\(^13\)

### Conclusions

From the above study, prevalence of depression among the elderly was found to be 38% which influenced by illiteracy, medium standard of living. It was also seen that depression was more among the financially dependent study subjects. It’s also confirmed from our study that depression is commonly associated with medical co-morbidities, insomnia and anorexia. Prevalence of depression is increasing and there is a need for further research on this topic.

Abstract

Breast cancer is dreadful and life threatening disease. The causative agent of breast cancer is still under research. Breast cancer affects one in eight women. The statistics shows that 6 percent of women in India die due to breast cancer. Breast cancer is the second important cause of death. Generally breast cancer is a malignant tumour that begins in the cells of the breast and eventually it spreads to the surrounding tissues. The disease can be treated if it is detected early. As stages increases, the chance of curing decreases. There are various imaging techniques that play a vital role in detecting breast cancer. This survey is an attempt to showcase various breast cancer detection techniques based on image processing technique.

Keywords: Breast cancer, malignant tumour, mammography, medical imaging.

Introduction

Breast cancer is one of the most common diseases among women and that lead to causes death under the age group of 15-54. The world health organization’s international agency for research on breast cancer estimates more than 150,000 women die due to breast cancer each year in world wide. Since breast cancer is leading disease in world at the right time is crucial. In the recent times, microwave imaging (MI) techniques are highly recommended in the context of safe and low-cost alternative mammographic approach for breast cancer diagnosis at a premature state. In order to develop the microwave imaging techniques lot of analysis has been made and implemented in laboratory. This literature is mainly focused on various techniques that are used to detect and treat this disease in early diagnosis: radiometry, radiography, digital mammography, endocrine therapy, space time beam forming, thermography, near-field microwave imaging, ultra-sound technique, tomography, microwave breast imaging system and microwave radar imaging.

Radiometry: Radiometry technique finds a major application in the early detection and diagnosis of breast cancer is shown in Figure 1.

Figure 1: Flow graph of radiometry

Microwave radiometry method is suggested for the detection of breast cancer at an earlier stage. It is suitable for detection of all kinds of stagnant and growing tumours. The working of the microwave radiometry is based on the screening and it is referred as the process of mammography wherein a passive, non-invasive, non-
ionizing procedure to determine thermal distribution rather than mass [1]. Radiometry is a technique for measuring electromagnetic energy in the form of thermal radiation in clinical thermography to measure the natural emission from the human body. Directly an antenna contact shall be matched to the tissue to obtain maximum radiated power coupling to the transmitter or receiver and if an mismatching occurs then it is identified the antenna is a non-contact and must be removed from the target of the relative permittivity becomes more significant results in a spectacular reduction in the surface emission of the radiometry or continuing to be noteworthy reflection in case of hyperthermia.

Radiography: Radiography is an imaging technique using X-ray (shown in Figure 2), gamma rays or other likely radiations to view the internal parts of an object [2]. The limitation is in the imaging of dense breast type which accounts for a large percentage of missed carcinomas in case of mammography. Other imaging strategies such as the ultrasound, trans-illuminating thermography, computed tomography, magnetic resonance imaging and radio-nuclide images to name a few for breast cancer detection.

![Figure 2: Courtesy: Breast cancer based on X-rays](https://radiopaedia.org/play/15923/entry/258932/case/18740/studies/18657)

Digital Mammography: Digital mammography is nothing but another sophisticated imaging technique in which the X-ray film is replaced by solid-state device oriented detectors that convert incident X-rays into electrical signals [3]. Digital mammography has great potential for improved radiographic imaging of dense breasts in the detection process. More over the adaptive thresholding process is carried over the breast area with an intention on classifying the fat and potential tumor or parenchyma tissues. This is a familiar methodology and has been accomplished in medical image processing.

Endocrine Therapy: Endocrine therapy (shown in Figure 3) adds, blocks or removes cancer cells from the infected area. One third of the breast cancer patients would undergo endocrine therapy. The receptor is a 66kDa intra-nuclear protein comprises of six functional areas and trigger transcription factor. ER status also make available of predictive information. Tumours missing ER and oestrogen receptor usually produce quicker than tumours having both ER and PgR [4].

![Figure 3: Flow graph of endocrine therapy](https://www.worldjbiolchem.com/vol6p231-239.htm)

Microwave Breast Imaging: Some of the specific fields like detection of unseen objects and non-destructive test of structures use the imaging technique by adopting the electromagnetic waves [5].

![Figure 4: Block diagram of microwave breast imaging](https://www.crcpress.com/etextbooks/)

Microwave imaging method is a very innovative and challenging to detect the early-stage of breast cancer.
is shown in Figure 4. This technique is solely dependent on electric parameters which survive among the normal and tumor breast tissue inside the microwave spectrum. By using the signals received from the breast, the breast image is again reconstructed. When the frequency increases simultaneously the resolution becomes higher and hence tissue loss increases. In terms of these conditions an ultra-wideband signal is suitable. To have the maximum disclosure to the human body the SAR (specific absorption rate) value is fixed to attain safety standards. The specific absorption rate provides the amount of power to be utilized in the tissue per volume. The microwave breast cancer imaging method should use the same frequency band to prevent the patient from health hazardous exposure. It is indicated that it is possible to detect even very small size tumor with low cost and also can acquire images rapidly when compared to other imaging techniques.

Ultrasound Imaging Techniques

Ultrasound imaging is commonly used to treat and diagnosis the breast cancer detection. This technology includes ultrasound elastography contrast-enhanced ultrasound, 3-D ultrasound automatic breast ultrasound and computer-aided detection of ultrasound. Ultrasound is very safe and yield pictures of the breast tissues using sound waves and also ultrasound which are directly placed into skin. A sound wave recovers computes and transmits with high frequency. Sound waves are the only source to create new images which can be used as follows: Ultrasound is used to diagnose breast deformity and Doppler ultrasound is used to approach blood supply in the breast [6]. It depicts the growing interest to employ ultrasound images to detect cancer. Breast Ultrasound imaging is far better than mammography in the following facts: (i) Ultrasound do not produce any radiation; it is more safe and convenient for patients. (ii) Ultrasound is obviously sensitive towards detection of abnormal tissues. (iii) High rate of false positives present in the mammography which leads to unwanted biopsies.

Space Time Beam-Forming: In this new technology numerous receiving antennas are utilized [7]. Vigorous and clear images are predicted because the speckled reaction from the tumour adds more contrast. A three dimensional image of retransmitted power is calculated by figure out the output power distribution. The tumour can be predicted because large amount of speculation happens around it. The technique of microwave imaging via space time beam-forming is projected for sensing early stage breast cancer. An ultra wide band is persistently passed on the signal that falls on the nearest exterior of the breast. The beam former concentrates on the retransmitted signal and facilitate on frequency dependent transmission effects. The dielectric property makes the contrast between normal and malignant tissues. The outcome of these method exhibits different numerical breast phantoms dependent particularly on FDTD models of the breast.

Thermography: A highly specific technique is used to predict the temperature changes on the surface of the skin [8]. Digital infrared thermal imaging (DITI) is utilized for viewing of breast cancer which also encloses an infrared thermal camera to capture the picture of various temperatures in breast area is shown in Figure 5.

Near Field Microwave Imaging: Balanced antipodal antenna is proposed to work as a sensor and it provides the signal to detect the breast cancer. Non-ionizing electromagnetic waves are used. It has the ability to send short electromagnetic pulses into the near-field without distortion low loss antenna directional
manner. It outlines the main features of active, passive and hybrid signal under investigation for breast cancer detection. Its main focus is on active microwave signal is particular microwave tomography and co-focal microwave imaging [10]. Near field microwave imaging technology is to explore the original structure of the body. Microwave imaging is purely radar based which explode the way of operating by sending a short time pulse of microwaves using one or two antennas [11,12]. There is a huge reduction in the size of the antenna.

**Microwave Radar Imaging:** Ultra-wide band (UWB) radar imaging technique assists to restructure the backscattered power distribution within the breast. Microwave radar imaging reorganizes the view of the image by accepting the replicated wave from objects. It is caused by measuring the dissimilarity present between the electrical dielectric possessions of malignant and normal breast tissues [13]. A reflection happens when the microwaves broadcast the breast with tumor. There are two important technologies made available till now they are Tomography and UWB radar system. The processing of UWB radar is mainly based on UWB pulses. Ad-hoc IC’s are required to compete with UWB in the time-domain [14].

**Tomography:** Tomography is one of the method of imaging by sections or sectoring, through the use of any kind of penetrating wave [15]. A coherent microwave signal is transmitted any one antenna. Electromagnetic approaches such as electrical impedance tomography and microwave imaging have been investigated in image accuracy for temperature monitoring. Tomography scan combines a series of X-ray images taken from different angles around our body is shown in Figure 6.

A multi-static UWB radar measurement system has been developed and carries out clinical trials to detect the breast cancer. The desired result of the system depicts a clear boundary and it is segregated from the fibro-glandular tissue.

**Conclusion**

In this survey paper, different techniques of detecting breast cancer by using mammographic imaging has been studied and discussed. Breast cancer is the second leading cause of death in women, so it is necessary to make research on the techniques to detect breast cancer. Early detection of breast cancer can increase the rate of survival.

A Study of the Engineering Maintenance Services of a Tertiary Care Hospital

A P Pandit1, Shithil Birthi2,

1Chief Medical Director, Chellaram Diabetes & Multispecialty Hospital, NH-4, Bavdhan, Pune,
2Student, MBA (HHM), SIHS, S B Road, Pune

Abstract

The engineering maintenance service is required in every hospital. It is more required as the hospital starts getting older. The study emphasis on the engineering maintenance service that is presently being carried on in the hospital and changes are recommended based on the study. The study has been done with the help of interviews and prospective study of the engineering maintenance happening in the hospital.

A new hospital may not require much of maintenance but as the hospital becomes older maintenance becomes an important part of the hospital. The hospital building is a highly complex unit and is subjected to rigorous demands as most of it is operational both day and night. Patient care is directly or indirectly dependent upon the performance of the hospital building, its utilities & services. Proper maintenance of the hospital building, its utilities & services is of paramount importance to the welfare of a patient and a major concern of the hospital administration.

Keywords: Maintenance services, Preventive maintenance, operating cost.

Introduction

Engineering Service utilization management is the evaluation of the mechanical, electrical, plumbing & other equipment necessity, appropriateness and efficiency of the use in the healthcare services or procedures. The investment on these equipment is said to be a good, only if it shows a utilization coefficient of 50% or above.

The purpose of this article is to find how good the equipment is utilized in hospital. These equipment in hospital constitutes nearly the 50% of the total investment. Keeping this in view, it is essential to ensure maximum service availability with minimum downtime. With the adaption of the proper maintenance technique and management system, one can utilize resources optimally and reduce the breakdown and related maintenance workload.

Hospitals have undergone a quantum change in concept and care provisioning from ancient days to present era. The information explosion and technological advances have revolutionized the medical care. The sophistication in the medical field has led to the development of specialized care centre in an attempt to provide high quality care. Modern medical technology has contributed immensely in improving the quality of healthcare and state of health profile of nations. The advancements has been mainly due to improved diagnostics facility, sophisticated equipments and spectacular progress in development in surgical procedures.

Medical equipment contributes to almost 40-50% cost in tertiary care hospital set up. The medical equipment though cutting edge technology at time of purchase poses a threat of inevitable obsolescence within 6-7 years of installation. This problem is compounded by fact that most of such equipments are imported and many few local reputed manufacturers exist in India. This leads to putting higher costs and further to lesser competitive edge and low utilization rate resulting in undesired operating margins.

The availability and utilization of various healthcare
equipment at all levels in the health system for effective and efficient delivery, was also emphasized in the Alma-Ata declaration at the international conference on primary health care in 1978, which was later included in to the strategy of health for all by 2000 AD.

Aim: To study the Engineering maintenance services and suggest recommendations for changes if any.

Objective: To do a prospective study and an interview with the staff to determine the shortcomings and suggest changes.

Scope:

➢ The study would include the engineering department as a whole.
➢ The staff of the maintenance team would be interviewed.

Review of literature: Buildings are required to provide a conducive and safe environment for various human activities. The extent to which buildings provide the required environment for the required activity is a measure of the functionality of the building. Hospitals are the most complex of building types. Each hospital is comprised of a wide range of services and functional units, such as diagnostic and treatment functions, hospitality functions, and the fundamental inpatient care or bed-related functions.

Nous Hospital Consultants regarded a hospital as not a mere building, but a complex social institution, composed of many groups representing a wide variety of interests and diverse needs that utilize the services of various medical, paramedical and support personnel to render all needed health care to the patients in its custody. It employs a wide variety of modern technologies and engineering services to support the process of healthcare using numerous biological, pharmaceutical, chemical and bio-chemical substances. It handles the dynamics of life and death situations during the process of rendering healthcare. A hospital building as a healing indoor environment needed in healthcare to prevent infection control. Ulrich described a hospital building to be a healthcare environment that should measurably improve patient outcomes, reduce or eliminate environmental stressors, provide positive distractions, enable social support and give a sense of control. The goal of every health institution is to provide patient care, and produce medical and health manpower. In furtherance of this goal, staff with expertise of the highest skill are motivated in an environment that is clean, conducive and patient friendly. Hospital buildings are places where care and cure should be available to the public, but due to lack of maintenance public hospital buildings have become a place where people working in the built environment and patients have allergic-like reactions to unspecified stimuli: reactions like dizziness, nausea, irritation of mucous membrane, eye and/or nasopharyngeal irritation and sensitivity to bad odour from human waste, poor toilet facilities, and insufficient cleaning method.

Maintenance works are complex in nature and therefore are carried out by directly employed labour while some are carried out by contractors. Accordingly, the mode of execution of maintenance works is a matter of policy. It is stipulates that in reaching a decision, the maintenance manager should compare the costs and services provided by the contractors with his own directly employed labour force, taking into account the availability of labour and the type and location of the building to be maintained, in accordance with this notion, contended that the choice should be made depending on which offers the greater advantage in terms of cost, quality and convenience.

The reasons for using in-house personnel to deliver maintenance services. Using in-house staff will give a better control of service levels. Estates Good Practice, in their research, showed that the unique nature of an institution’s estates, its location, availability of craftsmen and the preference of the estate director will all feature in the choice between direct or contract workers. According to them, the success of the operation will rely on management, adequate supervision and quality control.

The Chartered Institute of Building reiterated that the sizes, types and number of buildings to be maintained will invariably determine the source of manpower either in service or outsourcing.

Iyagba stated that outsourcing holds the promise of flexibility and profitability, but there may be disadvantages that are not at all obvious. Another major attraction, as noted by the author, is that it allows the business to focus on its core business and competencies, leaving peripheral and support functions to be serviced by outside experts.

Shohet, in his examination of the proportion of maintenance works performed by outsourcing versus in-
house provision in hospital buildings, reaffirmed that the choice of either method depends on the occupancy rate. This conclusion differs from that of previous studies on the subject. At standard or low occupancy levels, there is indeed an advantage as well as savings in the employment of a manpower composition in which the majority of the maintenance workers are external personnel.

**Methodology:** In order to understand the current concepts and latest techniques in engineering maintenance, updated information was obtained from various national and international journals and documentation’s from the worldwide web. The study was conducted in II phases.

**Phase I: Interview and discussion:** A review of available documentation followed by detailed discussions & informal interviews were held with the key officials, Engineers and other staff of the Engineering Services Department in order to appraise the organizational structure, staffing pattern and the nature of various tasks and responsibilities assigned to different functionaries of the Engineering Services Department.

**Phase II: Prospective study**

1. **Observation study:** In order to understand the maintenance methodology followed by the Engineering Services Department, various tasks and procedures were physically observed. The routine maintenance activities along with method of tackling various engineering breakdowns were ascertained by first hand observations at the Complaint offices and various maintenance sites.

2. The initial prospective study was carried out for three months, i.e., from 21st May, 2016 to 18th August, 2016 during which complaint registers at the offices of the various sub divisions of the Civil, Electrical and Air-conditioning divisions, of the Engineering Services Department, responsible for the maintenance of the Main Hospital were studied. All complaints received during this period were reviewed and grouped according to the type and nature of main maintenance breakdown and the maintenance methodology adopted thereafter.

**Observation and analysis:** The hospital has a list of complaints regarding maintenance that are registered by various staff working in the hospital. The register only records the complaint it doesn’t record what initiatives have been taken or the time taken to resolve the problem. Through direct observation the recordings were made.

The problems in the hospital were a great challenge, some of the problems were not solved until the last day of the study. The reason for delays were noted down in the interview. The main reason quoted by majority of the workers was delay in taking decisions and allocating funds for the issue.

The study done has observed that the maintenance done in the hospital has lot of room for improvement. The delays in attending the problems can be reduced with an efficient system. The management should look into the delays and try to ascertain as to why the delay is taking place and should try for reforms.

The management of the hospital can take steps and streamline the process of the maintenance service that is currently being provided in the hospital. The visibly delay in attending the problem affects the patient satisfaction and leads to the patient not getting the service expected from the hospital.

**Recommendations:**

**Complaint communication & registration:**

- A standard format for complaint communication needs to be developed and introduced which should indicate details like the ward, time and to whatever extent possible give information of the exact nature of the complaint.

- Standard complaint registers specific to each engineering wing need to be developed and introduced which should have a prescribed format of registration of complaints with a correlation to the engineering specialty.

- All complaints received by the Engineering maintenance staff must be recorded in the prescribed monthly complaint register. Telephonic complaints should invariably be followed on a prescribed written format.

- Wherever possible the complaint slip should be signed by the complainant with necessary remarks like satisfactory works done not done should be obtained from the complainant. The same should be returned to the inquiry clerk who in turn should write it down in the complaint book.
Maintenance Information System

- A ‘maintenance Information System’, must be evolved. Details of day-to-day complaints, special repair complaints and periodical repairs may be compiled on a monthly basis and circulated to respective sections of the Engineering Services and Hospital Administration.

- The Engineering Services Department must explore the feasibility of introduction of a Computerized Maintenance Management System.

**Preventive Maintenance:** There is a strong need to bring about a change in the maintenance methodology being followed at the hospital from breakdown maintenance in the current system to a system of preventive maintenance.

- There is an urgent need of creating a multi-specialty preventive maintenance system, which could comprise of team of engineers and various categories of maintenance staff from the various specialties of the engineering services.

**Training in Hospital Engineering**

- In keeping pace with the rapid technological advances in the field of hospital engineering is a need for developing a separate cadre of hospital engineers. They should be formally trained to provide solutions to the multi-dimensional engineering problems peculiar to hospitals.

- Training programs, workshops for the engineers and other technical staff must introduced for continued education in their respective field of specialization and updating their knowledge about the recent advancements in the field of hospital engineering and maintenance techniques and strategies.

**Conclusion**

The hospital maintenance department forms an integral part of the hospital. The maintenance service provided by the hospital shows how well the hospital responds to the requirements of the patient. This would in turn tell us about how the hospital cares about the patient. The maintenance services in the hospital needs to work on the recommendation given. The recommendation if acted upon would turn the hospital into a quality hospital. The services would improve and it would help in improving patient satisfaction.

**Conflict of Interest:** There is no conflict of interest.

**Source of Funding:** The study is not funded by any agency.

The study was done as a part of Summer Internship of MBA, and there was no direct intervention with patient care & hence no Ethical Issues were involved.

Effect of SAQ Training on Vital Capacity and Peak Expiatory Flow Rate among School Students of Rural Area

Anindya Bhowmik¹, Sandeep Kumar²

¹Ph.D Scholar, ²Professor & HOD, Department of Physical Education, Swami Vivekanand Shubharti University, Subhartipuram, Meerut, U.P., India

Abstract

The aim of the present study was to find out the effect of SAQ training on vital capacity and peak expiatory flow rate among the school students of rural area. To achieve the purpose of the study 40 boy students of 12 to 16 years aged group were randomly selected from the rural area. Tentulmuri Mahammad MSK in Tentulmuri, Kharagpur-II Block, Paschim Medinipur District, in West Bengal, West Bengal state in India was selected as rural area of the study. The participant’s were divided into two groups SAQ group and Control group, where was 20 participants in each group. SAQ group underwent SAQ training programme for 16 weeks duration,three alternative days in a week. The selected variables vital capacity and peak expiratory flow rate was measured by wet spirometer and Wrights peak flow meter. Before and after 16 weeks of experimental training the pre test and post test data was collected and pair t test was used to analyze the date. The data was calculated by Microsoft Office Excel 2007 software. The level of significant was set at 0.05. The funding were the vital capacity and peak expiratory flow rate significantly improved after 16 weeks experimental training programme.

Keywords: SAQ Training, Vital Capacity, Peak Expiatory Flow Rate, School Student, Rural Area.

Introduction

The metabolic activities within the cells of human body conduct by the atmospheric oxygen. The atmospheric oxygen enters in human body by the proper respiratory functioning. The increasing of lungs capacity means the development of the functional activity of respiration likes reduce the tidal volume and increase the inspiratory capacity and reserve volume, functional residual capacity, expiratory reserve volume, residual volume vital capacity and also total lungs capacity.¹ The current society is fully dependent on science and technology, so it is extreme challenge of human being to maintain their health and fitness. In this concept, the physical exercise is the main key to free from this suffers.² Whereas the regular physical exercise help to strengthen respiratory capacity.³⁻⁶ The obesity is one of the major problems in modern society. The previous studies find regular physical exercise also effective on increase pulmonary function of healthy adults.⁷⁻⁸

The term SAQ is derived from the first letters of both of the transitional Speed, agility and Quickness. SAQ exercises modern training system produces integrated effects of many physical capacities of any athletes within a single training programme.⁹⁻¹⁴ Thesaq training was significant to improve dynamic balance ability when it was conducted among the children of 7-11 years old.¹⁵ The key of SAQ training is quick and rapid body movement in preselected direction. When these exercise method was applied upon sports persons of several ages, it was bring the extreme physiological benefit.¹⁶⁻²¹ Some researcher were classified the saq drill exercise in without equipments and with equipments and their findings was the both method were significant to increase the physiological variables to the subjects.²¹ These exercise method also useful to develop physical capacity of adapted children.²²
Statement of the Problem: The aim of the study was to find out the effect of SAQ training on vital capacity and peak expiatory flow rate among the school students of rural area.

Objective of the Study:
1. To find out the effect of SAQ training on vital capacity among the school students of rural area.
2. To find out the effect of SAQ training on peak expiatory flow rate among the school students of rural area

Hypothesis: There will be significant different of SAQ training on vital capacity and peak expiatory flow rate among the school students of rural area.

Method

Subjects: The aim of the study was to find out the effect of SAQ training on vital capacity and peak expiatory flow rate among the school students of rural area. To achieve the aim of the study total 40 participants were randomly selected from a rural area high school. Tentulmuri Muhammad Muslim MSK in Tentulmuri, Kharagpur-II Block, Paschim Medinipur District, in West Bengal, West Bengal in India was selected the rural area a school of the present study. The participant’s age were ranged from 12 to 16 years.

Design of the study: Pre test and post test control group designed as applied in this study. The all participants were assigned into two groups SAQ group and Control Group. Where 20 subjects in each groups. The SAQ group was underwent an experimental SAQ training programme for 16 weeks and control group did not underwent any special training programme during experimental period.

Variables and Measurement

Vital Capacity: Vital Capacity was measured by Wet Spirometer. The spirometer was six liter container, filled with water upto one inch from the top and was counter balanced by a chain, which passed over free running pulley. The spirometer was placed on a table. The participant took deep breathed as possible, then he placed the mouth piece in between his lips and breathed out gradually and consistently until the most extreme volume of air was ousted, without taking in another breath. During breath out there was confirm that the exhaled air not escape through the nose and other sides. Dial of spirometer was followed to record the data, within three appropriate trails highest score was recorded in ml,

Peak Expiatory Flow Rate: Peak Expiatory Flow Rate was measured by Wrights Peak Flow Meter. The participant was held the instrument in his hands and took deep breathed as possible. Then he placed the mouth piece in between his lips and breathed out forcefully without taking in another breath. During breath out there was confirm that the exhaled air not escape throw the nose and other sides. Within three appropriate trails highest score was recorded.

Training Schedule

The result of vital capacity of control group, pre test was 2425 ± 525 and post test was 2435 ± 525.43. The mean different was shown as 10 and obtained t value was 146. The result of peak expiratory flow rate of pre test was 241 ± 60.51 and post test was 244 ± 56.68. The mean different was 3 and obtained t value was 1.55.

## Discussion

The present study shows that the selected 16 weeks SAQ training programme significantly improved the vital capacity and peak flow rate among the rural area school students. It has no doubt that the saq training is not a low intensity exercise. The quick and rapid body movement is required to find its better benefits. The several studies of saq training were conducted on the athlete’s to improve their physical ability (17-21) and neuromuscular ability (14,15). The present study was conducted on school students of rural area. Our study same as the previous studies(16-21) that analyzed the effects on physiological variables due to saq training programme among the athletes.

**Findings:**

1. After 16 weeks SAQ training programme vital capacity among the school students of rural area was significantly increased.
2. After 16 weeks SAQ training programme peak expiratory flow rate among the school students of rural area was significantly increased.
Conclusion

As per result of the study, it was conclude that the SAQ training was significant to improve the vital capacity and peak expiratory flow rate among the school students of rural area.

Ethical Clearance: The study was ethically approved by the Departmental Academic Integrated Panel of Department of Physical Education of Swami Vivekanand Subharti University, Meerut. The University also approves the present study under the code of practice Governing the ethical conduct of research. The letter of ethical approbation of this study also uploaded in another file.

A Study of Knowledge and Awareness Regarding Pulmonary Tuberculosis in Patients Under Treatment for Tuberculosis in Tuberculosis Unit Ambala City (Haryana)

Harshpreet Singh¹, Anu Bhardwaj², Zahid Ali Khan³, Anshu Mittal⁴, Muzamil Nazir⁵, Parul Jain¹

¹Post Graduate Student, ²Professor, ³Assistant Professor, ⁴Professor and Head, Maharishi Markandeshwar Institute of Medical Sciences And Research, Mullana (Ambala), ⁵Tutor, Maharishi Makandeshwar Medical College and Hospital, Kumarhatti, Solan

Abstract

Background: In 2015, out of the total annual estimated incidence of 9.6 million cases of tuberculosis worldwide, about 2.2 million were from India alone. Every day in India, more than 6000 persons develop tuberculosis and about 600 die of it i.e. on estimation 2 deaths are occurring every five minutes.

Objectives: To determine the level of awareness of tuberculosis patients regarding various aspects of tuberculosis.

Methodology: A cross sectional study was carried out on 340 tuberculosis patients registered during the study period of one year under RTNTCP DOTS regimen using a self-designed pretested, semi-structured proforma. Questionnaire contained information regarding socio-demographic profile of TB patients and knowledge about disease and its treatment.

Results: 50.3% of patients knew that TB is caused by germs/infection. 43.5% knew that TB spreads via air. 94.7% were aware of cough with expectoration as a symptom, while only 32.4% were aware about all the symptoms of TB. 64.7% knew that TB can be prevented by covering the mouth while coughing and 94.7% knew that TB is curable. 81.8% knew the duration of treatment to be 6-8 months. While 64.1% knew the consequences of not completing their complete course.

Conclusion: Awareness about tuberculosis was good in some aspects like symptoms but in some areas like regularity of treatment inadequate knowledge was present. Some myths like cure of tuberculosis by alternate medicine were also present.

Keywords: Awareness, Tuberculosis, socio-demographic profile.

Introduction

Tuberculosis was among the top ten causes of death for 2015. Worldwide in 2015, about 10.4 million people were estimated to be having tuberculosis out of which about 1.2 million were HIV positive. Also, worldwide about 1.4 million people died from tuberculosis in 2015.¹ About 9 million people become infected with tuberculosis each year and out of these about 3 million are either not diagnosed or officially not treated. These “missed” cases are especially important taking into account that tuberculosis is an airborne disease and each undiagnosed and untreated patient can infect as many as 15 persons per year.²

Various surveys in India from year 2000 to 2015, still show India to be the tuberculosis capital of the world. India accounts for 23% of the total number of tuberculosis cases globally. In 2015, out of the total
annual estimated incidence of 9.6 million cases of tuberculosis worldwide, about 2.2 million were from India alone. The incidence rate of tuberculosis in India is 167 cases per 1 lakh and prevalence rate is 195 cases per 1 lakh population. The mortality rate is 17 deaths per 1 lakh population. Everyday in India, more than 6000 persons develop tuberculosis and about 600 die of it i.e. on an estimation 2 deaths are occurring every five minutes.

Increased knowledge about tuberculosis is hypothesized to help patients in continuing treatment and completing the regimen. In this context the present study is conceptualized with the objective of finding knowledge of tuberculosis patients about various aspects of tuberculosis.

Material and Method

**Study Area:** The study was conducted in the Tuberculosis Unit (TU) Ambala city. There are 11 peripheral health institutions (PHIs) and 30 subcentres including 13 designated microscopy centers.

**Study Population:** A cohort of tuberculosis patients who registered for treatment during October 2015 to July 2016 formed the study population.

**Inclusion Criteria:** All patients (CAT- I and CAT-II) aged more than 15 years who registered in the Tuberculosis Unit Ambala city from October 2015 to July 2016.

**Exclusion Criteria:** Patients age equal to or less than 15 years.

**Study Period:** October 2015 to September 2016.

**Study Design:** Cross sectional study

**Study Tools:**

**Questionnaire:** The Questionnaire was a self designed pretested semi-structured proforma. The Questionnaire contained 2 sections:

**Section 1** contained questions related to the socio-demographic profile of the patients. There were questions regarding name, age and sex of the patients. Age was asked in completed years. Qualification of the subject was categorized into illiterate, primary, middle, high, secondary, and graduate. Marital status, Type of family, Residence whether rented or own house, Religion, Occupation type whether employed, unemployed, student or housewife and Average per capita income was ascertained.

**Section 2** contained questions related to knowledge about tuberculosis. Questions related to cause of tuberculosis whether by germs/infection, eating unhealthy food, hereditary or by person infected with tuberculosis. The method of spread of tuberculosis is by air, contaminated water/food, sharing clothes with infected person was also asked. Knowledge about the various signs and symptoms of tuberculosis was also asked. This section also included questions on method of prevention of tuberculosis and whether a cure was available for the disease. How long do tuberculosis patients need to take drugs and what happens if drugs were taken irregularly was ascertained.

**Study Strategy:** 363 patients registered for treatment during the study period. Out of these 340 patients fulfilled the inclusion criteria. The patients were informed about the purpose of the study and invited to participate. A written consent was taken from patients and they were interviewed using a self designed, pretested, semi-structured questionnaire. A minimum of 15 minutes was spent on each patient.

**Data Analysis:** Data was entered in MS Excel software version 2007 and compiled and analyzed using Statistical Program for Social Sciences (SPSS) version 22. Percentages were calculated for the various socio-demographic and awareness parameters.

**Ethics Consideration:** The present study did not impose any financial burden on the participants. Informed and written consent was taken from the participants before conducting the study.

**Results**

The total number of males in the study was 227(66.8%) while the females were 113(33.2%). The mean age was found to be 40.84 yrs ± 17.12. Maximum (28.8%) patients were educated upto middle school level followed by 22.1% who were educated upto high school level. One half of the tuberculosis patients were living in nuclear family while the other half were in joint family. According to religion, majority of patients (81.8%) were Hindu. Majority of the patients (64.7%) were employed. Majority of patients i.e. 74.7% were married.

Table 1 elucidates that maximum number of patients (50.3%) believed germs/Infection to be the primary cause of tuberculosis. Eating unhealthy food
was considered the cause by 14.7% and 2.6% believed it be hereditary. Others included smoking and alcohol as the cause of tuberculosis. Maximum number of patients (43.5%) believed air to be the main method of spread of tuberculosis. 15.9% believed that it spread by contaminated water/food, while 3.8% thought it spreads by sharing clothes with infected person. 1.8% thought there were other causes of spread of tuberculosis. 94.7% of the patients answered cough with expectoration as the most common symptom of tuberculosis. Out of all the patients, only 110 i.e. 32.4% answered all of these as the symptoms of tuberculosis.

Table 2 shows that regarding prevention, 64.7% (maximum) knew that tuberculosis could be prevented by covering the mouth with cloth while coughing. Majority (94.7%) of patients believed tuberculosis to be curable while only 0.9% believed otherwise. Majority (81.8%) knew correctly that the drugs have to be taken for 6 to 8 months. Maximum (64.1%) number of the patients believed that tuberculosis will not be cured if they take drugs irregularly or don’t complete their treatment. 28.5% believed that tuberculosis can be cured by alternative medicines, while 4.7% thought it would take longer time to cure if they took medicines irregularly. 2.6% were of the view that god will cure their ailment if they don’t complete their course.

Discussion

In the present study, it was observed that 50.3% of tuberculosis patients knew the cause of tuberculosis to be germs/ infections, 28.5% were of the view that it is caused from the person infected with TB, 14.7% thought eating unhealthy food to be the cause, 2.6% believed it to be a hereditary disease and 3.8% had other reasons. Similarly, in a study conducted by Dolma KG et al14, reported that 43.6% patients knew the cause of tuberculosis to be germs. Khalil S et al15 in their study at Aligarh reported that 66.7% of TB patients knew the cause to be germs, 5% thought the disease was hereditary and 18% thought it to be caused by alcohol, smoking and poor diet.

In the present study, it was observed that 43.5% of tuberculosis patients knew that TB spreads via air, 35% thought that it spreads via contact with tuberculosis patients, 15.9% thought that it spreads through contaminated food and water and 3.8% thought it spreads through sharing of clothes with infected person.
Similarly, in a study by Das R et al\textsuperscript{16} it was observed that 53\% of tuberculosis patients knew that it spreads via air and 17\% thought that it spreads by physical contact. Patil AR et al\textsuperscript{10} in their study observed that 30\% of TB patients knew it to be spreading by air and 39.6\% believed that it spreads by sharing food/clothes with TB patients. In a study by Khalil S et al\textsuperscript{15}, it was observed that 31.7\% of TB patients knew that it spreads via air (coughing), 50\% thought it spreads by contact and 16.7\% thought it to be spreading due to eating unhealthy food.

In the present study, it was observed that 94.7\% of tuberculosis patients knew cough with expectoration to be a symptom of TB, 86.5\% knew fever to be a symptom, 55\% knew about loss of appetite and 53.5\% about loss of weight. Only 32.4\% knew that all the above were symptoms of tuberculosis. Similarly in a study conducted by Mondal et al\textsuperscript{17} in Rajshahi, it was observed that 97.9\% TB patients knew cough was a symptom, 71\% knew about fever, 57\% about weight loss and 51\% about loss of appetite. Esmael at al\textsuperscript{18} in their study reported that 97\% TB patients knew cough to be a symptom. Similarly, Khalil S et al\textsuperscript{15} in their study reported that 86.4\% patients knew cough was a symptom, 50.5\% knew about fever, and 70\% knew about weight loss as a symptom.

In the present study, it was found that 64.7\% of TB patients knew that disease could be prevented by covering the mouth while coughing. Similarly, in a study by done by Patil AR et al\textsuperscript{10} in Maharashtra, found that 65.6\% of TB patients knew that Tuberculosis could be prevented by covering their mouth while coughing. Karampudi et al\textsuperscript{19} did a study in Vijaywada and observed that 74\% of TB patients knew that it could be prevented by covering their mouth while coughing.

In the present study, it was found that 94.7\% of TB patients believed that the disease was curable. Similar findings were seen in a study done by Paramasivanet al\textsuperscript{20} in Kerala which reported that 96\% of TB patients knew it to be curable. Study by Das R et al\textsuperscript{16} in Tripura also showed that 95\% of TB patients knew that tuberculosis was curable.

In the present study, it was observed that 81.8\% of TB patients knew the duration of treatment to be 6 to 8 months, 7.9\% thought it was 3 months, 8.2\% knew it was 10 months and 2.1\% thought it was 12 months. Similarly, in a study by Pramanik D et al\textsuperscript{21} in West Bengal reported that 66\% of TB patients knew the duration to be 6 months, 11\% knew it be for \( \geq 8 \) months and 8% didn't know about it. Similarly, Karampudi SN et al\textsuperscript{19} reported in their study that 70\% of tuberculosis patients knew that treatment duration was 6 to 9 months.

**Conclusion**

Knowledge regarding cough as a symptom was high however, knowledge about cause, spread and prevention was poor. Also, most patients were aware about correct duration of treatment. However, a third of the patients were not aware of the consequences of not completing the treatment. This indicates a need for more intensive education activities focusing on regularity of treatment.

Effectiveness of Active Release Technique Versus Myofascial Release Technique on Patients with Plantar Faciitis: A Comparative Study

Arul Pragassame S.1, Mohandas Kurup V.K.2, R. Santhose Kumar3

1Assistant Professor, 2Professor & Head of the Department, 3Divisions of PM & R, RMMC & H, Annamalai University, Tamilnadu, India

Abstract

**Background:** Plantar fasciitis is one of the most common causes of heel pain. The pain and discomfort associated with this disorder affect physical mobility and function dramatically. There are various conservative treatment strategies known to enhance symptoms of the condition including ice, heat, taping, electrical modalities, night splints, orthotics, stretching and strengthening. In addition, there are a number of soft tissue techniques such as Myofascial Release Technique (MFR) and Active Release Technique (ART) that may be effective in Plantar Fasciitis.

**Objective:** To find out and compare the effectiveness of Active Release Technique versus Myofascial Release Technique on pain and functional performance in patients with plantar fasciitis.

**Methodology:** Thirty patients who met the selection criteria were chosen for the study after receiving their informed consent. Participants were assigned randomly into two groups (Group A and Group B). Group A received the ART, whereas Group B received the MFR technique. Both groups jointly received ultrasound therapy and plantar fascia stretching exercise. The assessment of Numerical Pain Rating Scale (NPRS) and Patient Specific Functional Scale (PSFS) is made before and after the six day treatment schedule.

**Result:** Statistically significant improvements in NPRS (Z=3.44, P=0.001) and PSFS (t=10.2, P=0.001) were observed in group A patients. Statistically significant improvements in NPRS (Z=3.44, P=0.001) and PSFS (t=9.4, P=0.001) were noted in group B patients. When comparing group A and group B, NPRS (Z=2.59, P=0.009) showed significant differences between two groups and PSFS (t=1.92, P=0.06) was insignificant.

**Conclusion:** The study concluded that both the Active release technique and the Myofascial release technique are effective in reducing pain and improving functional performance in patients with plantar fasciitis. However, the pain reduction in the Active release technique group is significantly higher than in the Myofacial release technique group, but the functional performance shows similar effects in both groups.

**Keywords:** Active release technique, Myofascial release technique, plantar fasciitis, Ultrasound therapy, plantar fascia stretching exercise.

Introduction

Plantar Fasciitis is an extremely painful condition caused by inflammation and swelling of the plantar fascia, a dense band of tissue that runs across the bottom of the foot, starting at the back of the heel1,2. It is often caused by overuse, poor natural mechanics, overweight of the body, sports or unsuitable footwear. One of the most prevalent causes of foot pain is plantar fasciitis accounting for 11% to 15% of all foot conditions. The incidence of plantar fasciitis peaks in people between 40 and 60 years of age with no gender bias3.

Some of the sports that can predispose an individual include running, ballet dancing, aerobics, improper

Forty one patients were selected with Plantar Fasciitis, specified period using a convenient sampling method. The sample size was chosen during the Research Committee approved the study (PMR/2018). The University, Tamil Nadu, India. The Departmental and Rehabilitation (PMR), RMMCH, Annamalai

People with plantar fasciitis frequently complain about pain in the foot arch and heel. The pain may be severe when the foot is first pressurized in the morning or after sitting or standing for long time. Usually, the plantar fascia becomes stretched after walking about ten to twelve steps and the pain gradually diminishes. Physiotherapy treatment options for plantar fasciitis includes plantar fascia stretching, orthosis/night splint, taping, cryotherapy, ultrasound, contrast bath, iontophoresis, laser, phonophoresis, microwave diathermy. Also in some cases, massaging of the inflamed location serves as a temporary relief. ART is a very effective and new non-invasive hands-on technique, a patented movement-based massage technique to solve soft tissue issues in the body, including the fascia, muscles, nerves and ligaments. It is designed to identify and treat adhesions of scar tissue that interfere with the normal function of the body. It enables the therapist to: break-up restrictive adhesions, restore normal muscle and nerve sliding and restoring strength and flexibility to the foot completely.

MFR is a low load, long-term stretch to the myofascial complex that is designed to respond to ideal length, reduce pain, and enhance function. MFR usually includes slow, sustained pressure applied either directly or indirectly to restricted fascial layers. The aim of the study is to find out and compare whether the Active release technique and myofascial technique will provide better results in patients with plantar fasciitis, along with conventional treatment of ultrasound therapy and stretching exercise programs.

Materials and Method

The present study was a comparative study undertaken during September, October and November 2018 in the outpatient Department of Physical Medicine and Rehabilitation (PMR), RMMCH, Annamalai University, Tamil Nadu, India. The Departmental Research Committee approved the study (PMR/DRC-6/2018). The sample size was chosen during the specified period using a convenient sampling method. Forty one patients were selected with Plantar Fasciitis, 11 of them were excluded and therefore the study sample was 30 patients. The inclusion criteria for the study were (1) Clinically diagnosed cases of plantar fasciitis (2) Unilateral involvement (3) Both male and female (4) Age between 25-65 years (5) Those who are willing to take 6 consecutive days of treatment. The primary exclusion criteria were (1) History of recent fractures, any ankle/foot surgeries and pathologies (2) Subjects with fixed deformities of foot/ankle and knee joint (3) Subjects with impaired circulation in the lower extremities, peripheral neuropathies, etc. (4) Neurological disorders leading to impaired balance and coordination (5) Injection of corticosteroids in the heel before 3 months.

Study Procedure: Patients were informed of the purpose, study method and informed consent obtained individually for participation after screening for selection criteria. Demographical information were collected. Subjects were assigned randomly into two groups. Group A (N=15) received the ART, whereas Group B (N=15) received the MFR. Both groups jointly received ultrasound therapy and plantar fascia stretching exercises. The pain intensity measured with the NPRS and functional status by PSFS. The above assessment was conducted on the first visit with the patient before the start of treatment and again on the final day of treatment at the end of the 6th day. Evaluation of pre-and post-treatment was compared and analyzed statistically.

Outcome Measures

Numerical Pain Rating Scale: The NPRS is a subjective measure for individuals to rate their pain at an eleven-point numerical scale. The scale consists of 0 (no pain at all) to 10 (worst imaginable pain). Patients were asked to mark a point on the line corresponding to their perceived quantity of pain during the assessment.

Patient Specific Functional Scale: The PSFS is a self-reported, designed to evaluate functional changes, mainly in patients with musculoskeletal disorders. The PSFS enables patients to report their functional status as a clinical outcome measure at the baseline and at a follow-up session to determine if a significant change in functional status has occurred.

Treatment procedure: The treatment procedure was given for six days a week. The frequency was one session a day. All participants were received ultrasound therapy (8 minutes) prior to soft tissue mobilization and were instructed to perform the plantar fascia stretch as a home program. Hold for 30 seconds and repeat 3 times, twice a day.
Active Release Technique\textsuperscript{7,12}: Each session of the ART is a combination of examination and treatment. The patient is in the long sitting position. The therapist utilizes her hands to assess muscles or fascia texture, tightness and motion. Abnormal tissues are treated precisely by combining direct tension with very particular patient movements. The therapist will first start by shortening the affected limb muscle or fascia and then apply very specific hand pressure as we stretch the tissue is lengthened (patient moves muscle through movement). Treatment duration is 15 minutes per session, which is 6 days a week.

![Figure 1: Applying ART by using the finger pad in the plantar fascia](image)

Myofascial Release Technique\textsuperscript{13}: MFR is a technique for soft tissue mobilization. The patient is asked to lie prone with his feet out of the couch. He provides a pillow for assistance and patient comfort under his feet. The treatment area is cleaned and properly dried. The therapist assesses the painful region. Sustained mild pressure is provided, using the thumb, in the line with the planter fascia fibers from calcaneum to the toes. Pressure is kept for 90 seconds with 1 minute of rest interval. The treatment duration is 15 minutes per session, which is 6 days a week.

![Figure 2: Applying MFR by using knuckle in the plantar fascia](image)

Data Analysis and Results

Statistical analysis of the study was carried out using the “Statistical Package for Social Sciences” (SPSS-21). Wilcoxon matched pair test compared the pre and post comparison of NPRS, whereas Mann-Whitney ‘U’ test was performed between group NPRS comparison. The pre--post comparison of PSFS was performed by paired sample ‘t’ test as the variable was continuous. The comparison between two groups was performed through an independent sample ‘t’ test. The level of significance $\alpha=0.05$. The data were submitted in a tabular format.

The mean study population age was 40.07 years with the corresponding standard deviation of 12.53 in Group A, while it was 38.07 (11.66) years for Group B. The other baseline characters of group A and group B are shown in Table-1.

</table>

N:Number; SD:Standard deviation; %: Percentage.

The mean NPRS was 6.94±1.44 group ‘A’ and was reduced to 2.67±1.68 after treatment. The difference in the reduction was statistically significant ($z=3.44$, $p=0.001$). Similarly, NPRS was significantly reduced following treatment in group ‘B’ (Pre M=6.47±1.77, Post M=3.47±1.96). The mean degree of improvement
in Group ‘A’ was 4.27±1.28 while in Group was ‘B’ 3.0±1.13. The comparison between groups shows that there was a significant difference in NPRS improvement (Z=2.59, P=0.009). Hence, the improvement of Group ‘A’ in decrease pain following treatment was significantly higher than in Group ‘B’.

### Discussion

The study was detailed and tailored to compare, after 6 days of treatment, which treatment was best for both groups. This is consistent with the study by Riddle, DL, et al that suggests, plantar fasciitis is more likely to happen in people with obesity, who spend most of the day on their feet, or who have restricted ankle flexion. It affects both active and sedentary adults of all ages.

ART is effective in decreasing pain and improving functional performance. ART views plantar fasciitis as severe restriction of soft tissue that inhibits biomechanical movements. These constraints restrict the translation of tissues and influence the biomechanics of the entire body. ART to restore the free and unimpeded movement of all soft tissues and to restore optimum texture, resilience and soft tissue function.

ART can exert the stretching effect and release the restriction of scar tissue, increase blood circulation, range of motion and foot becomes less tender. Patients can actually stand comfortably on their feet. It has been hypothesized that ART can exert its effect by releasing restrictions on adhesions and scar tissue. James W. George et al evaluates the effects of ART on hamstring flexibility. Twenty male participants were received ART for 4 consecutive days. The results showed that the active release method increases the flexibility of hamstring.

The results of the study, consistent with the other study conducted by Andrew L. Miners et al 2011, described the subjective pain and functional improvements of a patient with chronic Achilles tendinopathy following a specific treatment plan. They found that a specific protocol of soft tissue mobilization using Graston Technique, ART and exercises, appeared to facilitate a rapid and complete recovery from chronic Achilles tendinopathy.

MFR has been shown to boost the proliferation of fibroblast, resulting in collagen synthesis that can
encourage healing of plantar fasciitis by replacing degenerative tissue with stronger and more functional tissue. Hence this technique is proposed to act as a catalyst in the resolution of plantar fasciitis.8

This stress and movement cause minor damage to normal tissues, leading to the release of inflammatory chemicals such as histamine and bradykinin. These chemicals will affect the local circulation and the nociceptors.18 It has been hypothesized that MFR can exert through lengthens and softens the fascia. Sumankuhar et al.19 determined the effectiveness of myofascial release in the treatment of plantar fasciitis and found that MFR techniques are significant changes in pain reduction and improvement of functional activity.

From the perspective of the previous study, there is only one study available which investigated the comparative effects of ART and MFR techniques. The resulting outcome supports the hypothesis of the Kage V.7 They investigated the effect of ART and MFR on subjects with plantar fasciitis and found that the ART and MFR together with conventional treatment are more effective in reducing pain and improving functional ability in patients with plantar fasciitis.

Limitation and Recommendation: The small sample size affects the validity of outcomes, therefore care should be taken to generalize these outcomes to a broader population. This study can be extended by separating patients by age and sex, and can be conducted to determine the long effect of ART and MFR.

Conclusion
The study concluded that both the Active release technique and the Myofascial release technique are effective in reducing pain and improving functional performance in patients with plantar fasciitis. However, the pain reduction in the Active release technique group is significantly higher than in the Myofacial release technique group, but the functional performance shows similar effects in both groups.

Ethical Clearance: Taken from Departmental Research Committee (PMR/DRC-6/2018).

Abstract

Objective: To know the expectation of a consumer population group of a dental hospital, and the preferences of patients while availing hospital services.

Methodology: A cross-sectional, pilot patient expectation survey (PES) was conducted using closed ended questionnaire among a Malaysian dental student population (N=317), studying in India, not yet exposed the clinical phase of dentistry, and not having referred to a dental hospital OPD. Results were statistically analysed for descriptive analysis.

Results: This study identifies expectations of study population when visiting a dental hospital, which may or may not be anticipated by the dentists, thus emphasising the importance of market research by way of PES. The results indicate significance of sensitizing clinician to patient expectations, to ensure success of private practice and institutional programmes.

Conclusion: It would be beneficial to use a PES to plan the same and sensitize physicians about expectations of patients, to ensure a higher chance of patient satisfaction. PES is a cost-effective method leading to evidence-based and rational use of scarce resources. Implementation of results of PES can become an essential motivation for patients to seek routine check-ups and treatment.

Keywords: PES, Patient satisfaction, healthcare market, health programmes.

Introduction

A paradigm shift is taking place in the healthcare market. Other than clinical excellence, healthcare providers now recognise the presence of other factors which play a role in determining their success or failure. The need for market research is becoming significant in the healthcare market. It helps an organization to keep abreast with consumer taste and preferences. However, the majority of hospital administrators do not invest in marketing research or track the effectiveness of their own institution’s advertising.¹

One of the most widely used method of market research in hospital has been patient expectation surveys from in-patients, out-patients or ‘potential costumers’. In this study, patient expectation survey has been conducted on the first year Malaysian dental/medical students, with knowledge that these students are most likely to avail the dental facility provided by their university considering them the ‘potential customers’ for the university health services.
This study is an attempt to reinforce the importance of knowing the customers' mind so that the resources available to the health care providers are best utilized, be it a corporate hospital or a private clinic.

Methodology: A cross-sectional, pilot patient expectation survey was conducted including 317 Malaysian dental and medical student population, studying in India, not yet exposed the clinical phase. A closed ended structured questionnaire was prepared according to the objectives of the study. We utilized online survey to collect responses in order to reach a wider population and respondent’s convenience.

The students who had already availed the dental hospital facility were excluded. In this case, the group would reflect a general expectation of a population having only a basic awareness or knowledge of dentistry.

Ethical Clearance for the study was obtained. Objectives of the study were briefly explained to the subjects and the confidentiality of the data was assured. Informed consent was obtained from all the participants.

Statistical analysis of the data was done using Statistical Package for Social Sciences (SPSS) version 13. Descriptive analysis was done to find the frequencies of the demographic variables and the various attributes that were questioned to the study participants. The questionnaire used is given below.

Results

Majority of the participants expected a waiting time of 10–20 minutes before being called in the consultation room and about 33 percent expected their doctor to spend about 5–10 minutes consulting their problems. (Figure 1 and Figure 2). Once with the doctor in the consultation room, majority of study participants expected their doctors to be polite and preferred only one nurse other than doctor and themselves. In the waiting area, majority (about 69 percent) of the participants expected sufficient seating capacity with high sanitation standards. (Table 1) More than 80 percent expected their doctors to listen to them and have a thorough discussion on the problem. About 67 percent expected their doctors to answer their questions and 68 percent did not expect their doctors to suggest a confirmatory investigation procedure. Another 58 percent expected a session on dental health / health education during their visits by the doctor (Figure 3). In addition, more than 75 percent did not expect their doctor to be a specialist as long as they are treated for their problems and they get well (Table 1).

Discussion

Patient Expectation Survey (PES) is one of the Market Research tools helpful in addressing decisions related to the delivery of hospital services. This could be an initial marketing activity of an upcoming hospital or could also be an on-going process for improvement, or in response to a certain problem being faced by the hospital.

Relation between patient expectation and patient satisfaction: Zemencuk et al\(^2\) have concluded that unmet expectations of the patients are associated with patient dissatisfaction.

Bedi et al\(^3\) explain this relationship using Expectancy-Disconfirmation Paradigm Model. They explain that if patients are viewed as consumers, a consumer model such as Expectancy-Disconfirmation model from marketing theories can be applied to healthcare provision. In this model, the assumption is that patients have expectations when they visit a hospital. These expectations arise from prior experience or word-of-mouth communication, third party information or cultural milieu. The degree to which these expectations are fulfilled can be measured and there is a relationship. The higher the perceived fulfilment of expectation is higher is the satisfaction. When fulfilment is lower than expectation, the lesser is the satisfaction. When expectations are low, they are easily fulfilled and satisfaction level is kept high and vice versa.

Disconfirmation of pre-consumption expectations is the key influence on consumer satisfaction.\(^4\)

- Positive disconfirmation: performances exceed expectations
- Negative disconfirmation: expectations are not met

Linder et al\(^5\) examined determinants of patient satisfaction and found that patient expectations were most important in determining patient satisfaction.

The economics of patient satisfaction: Basinsky et al\(^6\) suggest that the focus on quality has intensified because of the concern that health care is costly, may sometimes be dispensed inappropriately and inequitably. Friar B\(^7\) has suggested that just a 1% increase in satisfaction can produce up to a 3% increase in market capitalization.

The present study reveals that the expected waiting time is more and consultation time less. This is contrary to the usual belief. Most patients were found to expect dentists to listen to their problems and answer their questions. Management should sensitize doctors about patient expectations, which if heeded to, can improve the situation without any additional input in terms of resources.
58% of patients expected dentists to give them health education. This needs to be communicated to the doctors, as to how important it may be to patients and how it can positively affect patients’ psyche, resulting in higher satisfaction and better compliance to advise of doctor.

Nowadays, modern medicine is increasingly relying upon investigations and public have come to judge services by investigations asked for. In the present study 68% patients expect doctors to request investigations. Here doctors cannot be expected to order investigations just as patients expect, rather this information can be communicated to the doctor who in turn, can explain to patients why investigations are/ are not required. This will ease the anxiety of patients and result in better compliance with advice and result in improved satisfaction.

84% of patients expect doctors to be polite. If doctors are not perceived to be polite this can be a significant dissatisfied. Doctors especially in bigger sets need to be counselled and sensitized on this account.

Nowadays public is highly discerning and they expect hospitals to provide clean and hygienic environment with adequate civic amenities. In our study 69% of patients were shown to expect sufficient seating arrangements with drinking water and toilets with high sanitation level. As our hospitals/ clinics often lack these, patients feel dissatisfied. Health care professionals need to take regular measures to upgrade facilities and match expectations.

Specialist care has become a norm in contemporary health care world. However, in our study 76% patients do not prefer a specialist as long as they are getting a good treatment.

Privacy and confidentiality are important to patients and they would certainly prefer not to have any third person in the consultation room. Almost 60% of the patients want only doctor and nurse to be present during consultation. One could recommend that whosoever is present with the physician in the consultation room, should try to contribute and support the consultation process. This may result in more acceptability of the concerned person during the consultation process. We recommend more work in this area, since it is identified as a source of dissatisfaction for the patients. It appears that the cost of care is not a major issue for the patients. The reason may be that they are getting service of similar quality at a higher cost outside. This issue needs further research. Additionally, the present study indicates the expectation of a Malasian population group. These results cannot be generalized. Patient expectation depends upon a milieu of cultural, social and personal factors and hence each locale requires a separate PES.

Conclusion: This study identifies the various expectations from general public when they visit a dental hospital. This may or may not be anticipated by the dentists. It is always important to be in touch with what the target population expects, right through the trivial details, even using open ended questions. Sometimes it could be very small issues, which may not even require financial aid that may lead to satisfaction or dissatisfaction of patients. Moreover, the knowledge of the expectations of target population may also help the hospital direct its marketing strategy. Patient expectation survey can be considered as a pro-active marketing activity designed to have a better chance at achieving patient satisfaction. It would be beneficial to use a patient expectation survey to plan outpatient services and sensitize physicians about expectations of patients, to ensure a higher chance of patient satisfaction. Such an approach has also been found to be a cost-effective method for reaching large markets. Patient expectation surveys will lead to a evidence-based and rational use of scarce resources. However, it would be best to use such a patient expectation survey in conjunction with a patient satisfaction survey to complete the ‘before’ and ‘after’ picture. It can reasonably be concluded that in the current competitive healthcare scenario, patient satisfaction surveys in respect of a particular service can be an important market information and research tool in the hands of contemporary hospital administrators.

A Feasibility Study of Skill Transfer to Female Health Worker in Screening of Cervical Cancer and Breast Cancer

Radhika Joshi1, Asha K. Pratinidhi2, Vaishali Vhawal1, Pandurang Chougule3, Sujata Kanetkar4, Sunita Tata5, Satish Kakade2

1Department of Obstetrics and Gynecology, 2Department of Community Medicine, 3Department of Surgery, 4Department of Pathology, Krishna Institute of Medical Sciences, 5Director of Nursing Services, Krishna Hospital and Medical Research Centre, Karad (Maharashtra) India

Abstract

Screening is possible for cancer of cervix and breast which are the first two commonest cancers in women. Trained nurses know how to carry out vaginal examination hence there is a possibility of training them VIA, VILI and taking of PAP smears. Theoretically CBE can be taught to them so that any woman coming to the PHC for any reason can be screened for these two cancer sites. A study was therefore planned to find out feasibility of skill transfer of screening of cancer cervix and cancer breast. Thirty nine nurses were from KIMS and 8 from randomly selected 4 PHCs. After orientation in first session 12 hands on training sessions were taken. Two nurses were trained at a time. The technique and the lesions were demonstrated with the A. V. aids. After first three hands on training sessions, the trainee nurses were instructed to undertake screening on their own between two hands on training sessions. All suspected cases were called again on weekly training days for confirmation of findings of nursing staff. A theory and practical examination were undertaken at the end of the training. Thirty eight out of 39 nurses attended all the training sessions and could master the skill of screening the women for cancer cervix by VIA, VILI and could take PAP smear by the spatula as well as CBE. Nurses scored more than 50% marks with min. 57% and max. 78%. Difficulties encountered in the training like obtaining acetic acid and Lugol’s iodine at PHCs needs to be addressed. It is possible to do skill transfer for VIA, VILI and taking of Pap smears as well as CBE to nurses by 12 hands on training sessions. If nurses are trained in this way they can start opportunistic screening of the women visiting PHCs regularly in the PHCs in rural area and hospitals in urban area.

Keywords: Cervix Cancer, Breast Cancer, Clinical Breast Examination.

Introduction

Cancer of breast and cervix rank first and second and are very important public health problems in women above 30 years of age. Together they are responsible for more than 80% morbidity due to female cancers in India and the case fatality rate is very high due to late diagnosis of the disease[1, 2]. Screening for both cervical cancer[3] and breast cancer[4] is possible by Visual Inspection after application of Acetic Acid (VIA), Visual Inspection after application of Lugol’s Iodine (VILI), Pap smear, HPV testing and Clinical Breast Examination (CBE), mammography and ultrasonography respectively. About 70% population in India is still residing in rural areas where all screening facilities are not readily available. Auxiliary Nurse Midwives (ANMs) are posted in the Primary Health Centre (PHCs) and are routinely conducting normal deliveries. Thus theoretically nurses working in hospitals and ANMs working at PHCs can be taught the skill of VIA, VILI and taking of Pap smear. They can also be taught the CBE of Women.

Nursing students are taught vaginal examination and conduction of normal labor.Since facilities for mammography, ultrasonography and HPV testing are not available in all hospitals and also in rural areas, VIA/VILI, Pap smear and CBE are the only possible alternatives for screening of cancer cervix and cancer breast.

These screening procedures can be made available to the rural women with the skill transfer to the ANMs for early diagnosis and better prognosis due to that.
A project was therefore undertaken at Krishna Institute of Medical Sciences “Deemed to be University” (KIMSDU) to find out feasibility of skill transfer of screening of cancer cervix by VIA, VILI and PAP smear and screening of breast cancer by CBE.

**Material and Method**

The training of nurses was undertaken from November 2014 to October 2015. Out of 38 nurses, 19 were GNM, 17 were ANM and 2 were BSc nursing category, 31 were working at Krishna Hospital (KH) Karad and 8 were from randomly selected four PHCs from Karad Taluka. Qualified staff members from Department of Surgery and Department of Obstetrics and Gynecology taught the nurses in clinical examination of breast and visual inspection after application of 5% acetic acid and visual inspection after application of Lugol’s iodine as well as taking pap smears. After orientation and theoretical training for one day the nurses were given hands on training once a week for 12 weeks. The training sessions were arranged in KH for those nurses working in KH and at PHCs for those who were working at PHCs. The hands on training sessions were undertaken for two trainee nurses at a time, once in a week. During first three hands on training sessions the trainees were demonstrated the standard procedures of VIA, VILI, taking PAP smears and CBE and shown the lesions.

A careful and detailed CBE included inspection of both breasts in three position namely: I) with arm raised over the head, II) partial sitting and leaning forward, and III) sitting with hands pressed on the waist; followed by palpation of breast and auxiliary lymph nodes. After maintaining privacy, the patients were undressed to the waist examined in good light and facing the examiner. The lesions of both cervix and breast were shown with help of audio visual aids and the features distinguishing positive lesions from negative lesions were explained.

The trainees were given the hand outs and images of various lesions. During fourth training session, the nurses were made to carry out screening procedures for Ca breast and Ca cervix and the teachers corrected if there were any problems and ensured that the trainees had mastered the screening procedures and learnt the commonly seen lesions on the cervix and commonly encountered presentations of cancer breast. The trainees were now encouraged to carry out screening of breast cancer and cervical cancer on their own during the interval of two hands on training sessions and call all women having positive screening test on the day of hands on training for confirmation of their findings by the specialist. The theory and practical examinations were held at the end of the training for all nurses.

Informed consent of all women screened and all nurses participating in the study was obtained and Institutional Ethics Committee (IEC) clearance was taken before commencement of the project work. After theory and practical examinations, marks were given by the examiners appointed from gynecology and surgery specialty. The project was financially supported from intramural funds of KIMSDU.

**Results**

It was observed that all 38 out of 39 nurses regularly attended the training sessions and were keenly interested in learning the CBE and VIA, VILI and taking of PAP smears. It required some motivation to start screening women on their own after initial four sessions. But once started they did it nicely. On an average 10 to 15 women were screened by the trainees in between two training sessions.

For the theory examination, all the nurses got passing marks above 50%. The mean score was 69.5 ± 5.1 and minimum of 57 and maximum of 78. The performance of nurses from hospitals and PHCs was comparable.

Some students were eager and confident to learn but some were not confident. We convinced them that it is not difficult and motivated them to learn. There was some variation in the learning ability of the trainees.

During training sessions on CBE, it was observed that some nurses learnt the technique of CBE fast. Those who had problem with learning CBE were shy; less confident and less motivated. With repeated sessions and convincing them that they can do it, it was possible to transfer the skill of CBE to them. At the end of four sessions, all the nurses were comfortable and acquired the skill of inspection in all the three positions and palpation of breast as well as axillary lymph nodes. It was generally seen that the nurses were able to expose cervix well using Cusco’s speculum, apply 5% acetic acid, and inspect the cervix for the white patches showing abnormal areas. Then they could apply Lugol’s Iodine and do visual inspection for mahogany brown stain taken up by the normal tissue against which the unstained area of affected region could be seen as pale yellow or saffron yellow areas. It was observed that it was difficult for the nurses to work alone but in pairs they were able...
to carry out the screening very effectively as the helper would hand over the material and do documentation.

**Discussion**

Coccrane review\(^7\) on Self Breast Examination (SBE) has revealed that SBE has no impact on cancer mortality. There can be poor compliance with follow up and increased number of biopsies performed on benign lesions so at present screening by SBE is not recommended. Clinical Breast Examination (CBE) needs careful attention to technique and thoroughness. No trials are available for comparing CBE alone to no screening but Canadian National Breast Screening study-2 (CNBSS-2) included randomized screening of 39405 women aged 50 to 59 years into two groups. Group one was CBE alone and the second group was CBE with mammography. No mortality advantage was seen when mammography was added to an annual standardized 10- to 15- minute breast examination implying that careful, detailed, annual CBE may be as effective as a mammography screening programme. Clinicians who spend 3 minutes per breast and use proper technique have better sensitivity and specificity than those who do not. The American college of Obstetricians and Gynecologist recommended both SBE and CBE.

VIA and VILI are simple and efficient screening tests have low cost and high sensitivity in comparison to Pap smear. Hence, VIA and VILI can be used as an alternative screening modalities for cervical cancer in low resource setting like India\(^8-9\). The sensitivity of cytology increased significantly when combined with VIA or VILI\(^3\).

**Opportunistic Screening:** National Program for Prevention and Control of Cancer, Diabetes, CVD and Stroke (NPCDCS) \(^10\)has two components first relates to cancer and second relates to the rest of the diseases. There is now emphasis on optimization of scarce resources and provision of seamless services to the end customer and also ensuring long term sustain ability of the interventions. Screening by the ANMs at PHCs for the rural population and nurses working at hospital for urban population is feasible and should be included in the programme. Referral of suspected cases to appropriate institutions for further case management can be considered as a sustainable long term intervention for down staging of cancer there by improving the prognosis and healthy survival of patient.

Any patient attending OPD at a hospital or at a PHC for some complaint not related to cancer cervix or breast like relative accompanying patient, visitors coming to meet the in patient person,mother bringing their children for some complaints, can be screened. All women above 30 can be offered organized opportunistic screening.

It is possible to do skill transfer for VIA and VILI as well as CBE to nurses by 12 hands on training sessions. If nurses are trained in this way they can start screening the women visiting PHCs regularly as opportunistic screening in the PHCs in rural area and hospitals in urban area.

There is a possibility of all medical colleges developing hands on training course for screening of carcinoma cervix and carcinoma breast at district level. By including these screening procedures as a curricular activity of training for ANMs, GNMs and B. Sc nursing students, all nursing students graduating now onwards will be able to undertake screening tests of VIA, VILI, taking of PAP smears and CBE for screening the women for cancer cervix and cancer breast.

Government of India – is now giving emphasis on NCDs including cancers. The treatment is supported for the poor under Rajiv Gandhi Yojana. By the time the diagnosis is made it is often too late. So down staging of both important sites of cancers namely carcinoma cervix and carcinoma breast is possible by opportunistic screening\(^11,12\) in all small and big hospital for the urban population and in PHCs for the rural population if specific skill transfer programme is undertaken for already trained nurses.

It is thus possible to have screening of cancer cervix and breast as a routine activity on fixed days of week in rural and urban areas just like ANC or immunization.

**Ethical Clearance:** The study was approved by Institutional Ethics Committee of Krishna Institute of Medical Sciences “Deemed to be University”, Karad dated on 17.01.2014

Immediate Effect of Post Deep Neck Flexors Endurance Test on Neck Reposition Accuracy in Smartphone Addictors

Emmy Bucyana1, Ayyappan Jayavel2, Ndahiriwe Chance Christian3

1MPT Orthopaedics Student, 2MPT Biomechanics Student, 3Assistant Professor, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur

Abstract

Background: Neck reposition accuracy is the ability of the person to return to the specific starting point after a particular neck movement. Neck reposition accuracy error is a common issue in modern society but the sources of its development can be divers.

According to many researchers, along lasting neck reposition related errors disorganise different nerve conduction leading to muscle tone abnormalities around the neck and occiput, hence affecting the proprioceptive sensibility in the neck and cervical spine at large as well as eliciting associated musculoskeletal complaints.

The purpose of this study was to evaluate the immediate effect of Deep Neck Flexors endurance test on neck reposition accuracy.

Method and Procedures: A total of 30 subjects, age group 18-30 years and smart phone users at SRM Institute of science and technology, SRM College of physiotherapy, Kattankulathur.

Smart phone addiction scale (SAS) was used to assess the smartphone usage level, along with isometric neck endurance test, to assess immediate effects on the repositioning of the neck accuracy. Additionally a special gyro motion sensor device was used to assess the accuracy of neck repositioning before and after exercise/Test.

Outcome measures: SAS (Smartphone addiction scale) and gyroscope special device.

Results & Conclusion: Results showed a significant difference in head reposition errors after performing the endurance test with a P value less than .001 (p<.001) and a negative correlation between holding time during the test (Deep Neck flexors endurance test).

Keywords: Neck reposition accuracy; Neck Proprioception; Deep neck flexors endurance test.

Introduction

Neck neuromusculoskeletal disorders in the modern society is increasingly affecting individuals in different age groups, but the sources of its enlargement can be numerous and to various degrees which can mostly lead to different serious conditions.1

Kim et, al (2015), introduced that the modern society is developing musculoskeletal disorders due computers and smartphone usage. The prolonged usage of smart phone usage and computers are associated with weakness of muscles and Forward head posture. The authors continues positing that the deep neck muscles plays a crucial role in maintaining the neck in neutral posture and that are affected easily by the slouched posture.13
The use of electronic movement and sensors is increasing worldwide in the field of medicine. This can be explained by the fact that some devices are being designed to sense human movement in research and fall prevention programs in elderly. However few studies have attempted to do researches on their role in quantifying vital statistics.  

According to numerous researchers, long-lasting neck pain interrupts afferent nerve conduction prolonging the abnormal muscle tone of the neck and the occiput, shoulder girdle and the neck, hence unfavourably impacting the proprioceptive sensibility in the cervical spine and pain which can be acute, sub-acute or chronic or functionally disabling, depending on the duration. Different manipulative therapies and other techniques have been shown to improve function and independency to the patient.  

It was frequently noted by researchers in the past years that different neck structures dysfunctioning including sub occipital, deep neck flexors and mechanoreceptors have proven to impact proprioception in various patients.  

According to Revel et al. introduced the method of evaluating the ability of repositioning to the original starting position which he stated that it is dependent to cervical cephalic kinaesthetic sensibility.  

Proprioceptive sensibility along with the vestibular apparatus governs the information that lead the head to move and reposition accurately in relation to the trunk.  

But in a recent study by Pinsault et al. stated that vestibular is not responsible for head repositioning test hence supporting his test as cervical proprioceptive acuity. Where he finally noted that impaired cervical kinaesthetic sensibility is linked to various complaints that mostly lead to devastating problems including degenerative conditions, chronic pains, instability and disability.  

Although neck pain and instability can lead to a proprioceptive dysfunction, there is no consensus and a concrete literature to find out which standardized test for cephalic repositioning accuracy as well as homogenous results. It is with this regard that Strimtops et al concluded in his study that researchers have not yet come up with a reliable tests and measures as well as conclusive literature.  

**Purpose of the Study:** This study intended to assess the immediate effect of post deep neck flexors isometrics endurance test on neck reposition accuracy in smartphone addictors. The main aim was to compare the strength of deep neck flexors keeping in mind the normal value differences in relation to gender differences. The test was based on the current evidence suggesting its immediate impact while relating it to smartphone addictors.  

**Materials and Method**  
Study setting was at SRM College of Physiotherapy for a duration of four weeks. The findings were reported in both pre and post testing along with the number of seconds and the ability to maintain the position during the test, and then compared the Smartphone Addiction Scale scores and the duration of smartphone usage per day and in years.  

As the study aimed to assess effectiveness of deep neck flexors endurance test, A special electronic device that detect the change of movement (gyroscope) was used to assess the initial position of the head then the subjects were instructed to perform the movement in sagittal movements of the head. In other words the subject was instructed to fully flex the head and bring it back to the previous position.  

The next step was to perform the deep neck flexors endurance test while observing the smooth performance of the subject during the test in relation to the duration of holding the chin tuck while counting the seconds spent without changing the position.  

The normal duration for men is 39 seconds while for females it is 29 seconds. During the test the subject was instructed that he/she should do chin tuck and lift the head at least one inch off the couch and hold as maximum as possible.  

The test was stopped when the subject was unable to hold the head in chin tuck in a given seconds in relation to gender differences, or when the subject was releasing the head towards the couch or else opening of the neck folds due to chin tuck.  

Neck reposition then was reassessed by instructing again the subject to do the neck flexion to neutral position in sagittal plane movement. The device assessed the difference in error to bring back the neck to its original position.
Results

Table 1: Demonstrate the findings Pre and Post-test measurements in degrees of repositioning error

The findings from this study reported the improved accuracy after exercises from 11.5±5.36° to 7.5±3.85° (Table 1) meaning that there was a visible reduced error in neck repositioning after performing deep neck isometrics endurance exercises by using paired samples test, with a confidence interval of 95%.

![Post test errors](image)

Figure 1: Demonstrates the correlations between the holding time during the test (Deep neck flexors endurance test) and the smartphone usage time, which showed a negative correlation.

Discussion

Based on the findings of this study, the effects of isometrics neck endurance exercises were reported as immediate effects among smart phone addicts. The neck repositioning was improved immediately after exercises and it statistically shown a significant difference.

Similar study was done in South Korea, assessing exercises in smart phone addicts with musculoskeletal complaints and showed that shoulder retraction and protraction exercises resulted in improvement regarding pain and disability. Same findings also were reported by Vijay and colleagues in 2016, where the deep neck muscles endurance exercises improved forward head-neck posture.\(^{14}\)

In a study by Kim Eun-Young et al 2015, also reported an improvement of Neck disability Index of their subjects, while comparing the deep neck flexors static exercises with McKenzie cervical exercises although they came up with no significant change while comparing the outcomes in both groups. Therefore this study aimed to evaluate the influence of only deep neck flexors on neck neuromusculoskeletal disorders.\(^{12}\)

Another study done by Falla D et al, reported that deep neck chin tuck targeted exercises for strengthening has led to strength improvement.
Conclusion

The authors concluded that isometric endurance exercises had immediate effects on neck repositioning accuracy among young smartphone addicts. However, as the results did not show a statistical significance the findings should not be generalized in other population unless proved by big well controlled studies such as RCTs and systematic reviews.

Limitations of the Study: One of the limitations of the present study is that only a cross sectional study was used, assessing effects of neck endurance exercise test. This cross sectional study was done with the aim to check whether there would be an immediate impact of deep neck endurance exercises among young smartphone addicts.

The other limitation of the study is that the findings couldn’t be able to confirm with confidence the effects because exercises effects may take more sessions to have a significant impact.

The authors encourage more advanced study designs like RCTs; by implementing and assessing long term effects of this exercise test in the form of treatment in all smartphone users. This was assessed only once in smartphone addicts and normally the muscle adaptation to exercises require repetition for days to weeks of training, which suggest a comparative study to ascertain this conclusion; furthermore, the electronic device used in this study (gyro sensor) has been rarely used in medical studies therefore we recommend further studies for its reliability to confirm its ability to sense various human movements.

Recommendations: Further RCTs with follow up among smartphone abusers are recommended to confirm or ascertain with our findings. Prevention and health awareness programs in the university are needed to address this global health concern about smartphone addiction and inform the targeted population on the impact of smartphone not merely on the health also on the academic performance of those students involved.

Conflict of Interest: The Authors declare that there is no any conflict of interest in this study.

Ethical Clearance: Taken from SRM College of Physiotherapy Ethical committee.

Source of Funding: Self.

Gender Dynamics in Morality of Alcohol Addict and Non-Addict Young Indian College Students

Bhawani Singh Rathore¹, Uma Joshi²

¹Research Scholar, Amity Institute of Behavioral and Allied Sciences (AIBAS), Amity University Rajasthan, ²Dean, Humanities, Social Science and Liberal Arts; Former: Director, Amity Institute of Behavioral and Allied Sciences (AIBAS), Amity University Rajasthan, Jaipur

Abstract

Background: Alcohol consumption has been associated with gender roles and symbolizes masculinity. With a paradigm shift in values and morality in the modern times, its consumption and resultant adverse consequences on health, growth, productivity, is on a steep rise not only among males but also among young females, which is a great cause of concern. Values are imbibed early in life, though, not visible, shape or style of life and modus-operandi. Some research evidences of the association of decline in morality and rising incidence of addiction among youth and its adverse socio-cultural and politico-legal consequences worldwide inspired this investigation.

Methodology: It is an ex-post facto study of 200 young college male and female students in the age group of 18-24 years.

Result: Study shows an inverse association of addiction and morality (t= - 2.646) and no gender difference in morality overall (t=.372). Further, gender wise analysis reveals a significant association of morality with addiction among male addicts (t=-3.940), but has not proved significant among young female. The significant interconnected (F=6.981) of gender and addiction in morality indicates gender dynamics in addiction and morality hypothesis.

Conclusion: India being the youngest country, with a maximum population of youth in the world by 2020, emerges as the ambassador of promoting world peace and harmony. Rising alcohol addiction and its association with low morality among Indian male youth may block it. This study suggests a need to identify its pathways to block addiction and low morality and restoring world peace and harmony.

Keywords: Morality, Substance Addiction, Gender, Young.

Introduction

Youth are the future of the nation. They shape the state and status of any country. They are the drivers of any developmental trend and activity in society and major determinants of the extent of growth and development in any given society. India is the youngest country in the world, approximately 40 per cent of the Indian population is in the age range of 13 to 35.¹ But, this demographic dividend, if not used properly, may result in demographic disaster in India.² Alcohol addiction among youth has taken the shape of the epidemic in states like Punjab, Haryana and establishing its jaws in Rajasthan and other states as well in India. Such a scenario exist worldwide. The picture is grim if we look at the world trade and statistics on the substance addiction scenario with a turnover of around $500 billion, it is the third largest business in the world, next to petroleum and arms trade. About 190 million people all over the world consume one drug or the other.³

Alcohol addiction can damage relationships, cause poor academic performance, problems with the law and
reduced overall morality. Alcohol dependent youth encounter difficulty in working, experience more guilt and feeling of inadequacy and dissatisfaction when they fail to meet their standards. Youth are the ambassador of world peace and harmony and propeller of development of a country. If they are engulfed by alcohol addiction and resultant dip in the morality the future looks dismaying. Owing to the severe adverse effects of alcohol addiction, it remains one of the biggest cause of concern of the new millennium.

Drinking behaviour has been an important way to symbolize, and regulate gender roles, by making it a symbol of masculinity which promotes alcohol consumption among male population as compared to female, however, this practice is at a steep rise among young females also. Alcohol consumption has now been associated as a symbol of modernity, social status, power (in terms of gender equality) apart from other common socio-cultural influences among young and old both. This may indicate a paradigm shift in values in the modern times. Morality is one of the core values which include principles concerning right and wrong or good and bad behavior which may differ from person to person depending on their environment, and their belief system. It can be instrumental in a rise or fall of not only nations but the human race.

Though, some studies rule out faulty values as a cause of addiction, other demonstrate an association of low morality with alcohol addiction makes the situation look grim. Therefore, it is pertinent to study the gender dynamics of morality and alcohol addiction.

**Objective:** Studying gender differences in morality of addict and non-addict, college going Indian students youth.

**Material and Method**

Study design: Present study is an ex post facto investigation using contrast group comparison design. The study was conducted over a short period of three months from (August to October 2017) at four private colleges of Jaipur city. This is not an intervention based research and no clinical trials on samples were conducted.

**Participants:** The study used purposive nonprobability sampling technique to select a sample of 200 college going young Indian males and females (100= Addiction and 100= non Addiction) who was attending college regularly and were regular/frequent drinkers/ non-drinkers in the age range of 18-24 years. Alcohol addicts were identified by the peer referrals. Informed consent of the participants was obtained before conducting this study and those consented to participate were included in the study. The refusal/ dropout rate of participants for different reasons was 15%.

**Reason for choosing this sample for the present study:** It is painful to accept that the universities and the colleges (the educational institutions) are becoming the central places for the availability, trading, experimentation, peer pressure and succumbing to alcohol and drug behavior. As youth is said to be the most vulnerable stage, who is struggling between urge of independence and lack of direction, is exposed to all kinds of temptations (risky behaviour, adventures, peer pressure etc.) are more vulnerable to fall prey to substance addiction and its consequences. The college sample, therefore, becomes the fertile grounds for this study.

**Inclusion criteria:**

- Young Female College going students registered as regular students who were alcohol addiction.
- Young Male College going students registered as regular students who were alcohol addiction.

**Exclusion criteria**

- Students who are registered as a part-time/distance education.
- Occasional drinkers.
- Students who were clinically diagnosed with some mental or physical ailment for which they were taking medical or psychiatric treatment.

**Hypothesis of the Study**

1. There is no significant difference in the morality of addicted and non-addicted young college students.
2. There is no significant gender difference in the morality of college students.
3. There is no significant difference of morality in addicted and non-addicted young male college students.
4. There is no significant difference in the morality of addiction and non-addiction young female college students.
5. There is no significant interaction effect of gender and addiction in morality of young college students.

Procedure: The present study uses the subscale of the morality of self-reported multi-dimensional assessment of the personality questionnaire (MAP-A) by “Sanjay Vohra”). A complete enumeration of students was done and those present at the time of study visits and giving signed consent were included in the study. Statistical Package for Social Sciences, Version 22 for Windows (SPSS 22) was used to analyze the quantitative data. "t-test and F-test Analysis of variance at 0.05 level of significance was computed.

Findings of the Present Study

Discussion

Alcohol addiction is a major cause as well as an effect of many problems in our society and morality, though intangible, but deep rooted is associated with it. Attempting to know the underlying causes and pathways of the development of these problems is a pertinent route of investigation. [Table.1] shows the descriptive statistics (mean and SD) for comparison of morality among addiction and non-addiction young males and female college students. Significant difference in morality between the addict and non-addict, college students (t= -2.646, df=198, p=.009) [Table.2] of the present study does not confirm the first hypothesis and reveals a significant association between low morality and alcohol consumption. Insignificant difference in the scores of morality, of male and female college students. (t= .372, df=198, p=.711) [Table.2] confirms the second null hypothesis. Studying morality only among young males, significantly low morality scores of addict males in comparison to non-addict young males does not confirm the third null hypothesis (t= -3.940, df=98, p=.000). [Table.2] whereas, insignificant difference in morality of addict and non-addict female (t= .000, df=98, p=1.000) confirms the forth null hypothesis. Further, [Table.3] reveals a significant interaction effect (F=6.981, df=1, p=.009) of gender and addiction on morality which does not confirm the fifth hypothesis of the present study.

Present study reveals that among young females, alcohol addiction is not associated with morality but it is significantly associated in addicted male population scoring significantly low on morality. It is interesting to note that non addict males score significantly higher on morality than non-addict females, but addict males score significantly lower on scale of morality than addict
females. It reveals that morality seems to follow different pathways among male and female addicts. These results confirm the argument that young female revert to alcohol for social affiliation, assertion of parity in social norms and competing for masculinity (compensation for femininity and inferiority according to Aderian school of thought, 14 whereas, among young males it is associated with compromising with morality. Therefore, understanding the association of addiction and morality and how it is going to affect them, gender dynamics need to be considered. The society puts greater burden of morality on female alcohol addicts than male alcohol addicts. The present study refutes the common sense notion that low moral values are encouraging female college students to alcohol addiction. Although, the value deterioration and effacement of values in modern times is universal among both among males and females, and there is a steep rise in female alcohol addiction in recent past, however, such paradigm shift in value of morality is not associated with alcohol addiction in female as the case with the male population. Modern women find drinking alcohol morally and ethically correct. An increased autonomy and exposure to wider professional opportunities among women are growing and consuming alcohol seem to enhance as an expression of power and freedom without realizing how and when they become habitual drinkers. In western societies gender differences in drinking behaviour are already shrinking. 15 However, ruling out low morality as a cause of rising incidences of alcohol addiction among women raises the concern of disturbing social order, run the risk of losing a powerful social weapon of moral responsibility as a check against drinking practices and deterrent factor in recovery from addiction among young female. 16 Spiritual and religious practices and social and moral values serve as the guidance yardsticks for people themselves, their children and society as a whole. 17 Specially, in India, this burden is greater for women owing to greater responsibility she bears in home making and raising their children.

Alcohol addiction being epidemic among male college students and is associated with the morality, it reflects that morality in addict youth male is also at a point of decline. Looking at the broader scenario, youth is heading towards a double damage of suffering the disadvantages of alcohol addiction, which may reduce their will power and power of critical thinking 18 and lowered morality may tempt them to take wrong decisions and indulge in immoral practices which would be harmful to their personal and professional life and would be damaging to the image of the nation. It is to be further ascertaining the direction of the association of alcohol and morality (if addiction lowers morality or low morality promotes alcohol addiction among male college students?). We need to look for other factors responsible for rising incidences of alcohol addiction among female young college students than morality because it does not explain their alcohol addiction behavior.

Conclusion:

The present study suggests different gender dynamics to understand alcohol addiction and morality. Steep rise of alcohol addiction and decline morality among male Indian youth suggests that India with a maximum population of youth in the world by 2020, shall incur maximum threat and losses and bears vital responsibility in restoring peace and harmony in the world.

Role of Ultrasound in the Characterization of Thyroid Nodule in Correlation with Fine Needle Aspiration Cytology

Bikramaditya Swain¹, Sudhansu Sekhar Mohanty², Binit Gupta³, Gitanjali Satpathy⁴

¹Assistant Professor, ²Senior Resident, ³Post Graduate, ⁴Associate Professor, Department of Radio-Diagnosis, Kalinga Institute of Medical Sciences, KIIT University, Bhubaneswar, Odisha, India

Abstract
Nodular thyroid disease are a very common clinical finding, with an estimated prevalence on the basis of palpation that ranges from 3% to 7%. High resolution Ultrasonography (USG) is the most sensitive test to detect thyroid lesions. USG can identify thyroid nodules that have been missed on physical examination, isotope scanning and other imaging techniques. Fine Needle Aspiration Cytology (FNAC) is the gold standard diagnostic investigation for the thyroid nodules. USG of thyroid gland was performed in 70 patients with clinically detected thyroid nodule, in our study, over a period of 18 months, using USG with Color Doppler in GE VOLUSON S6 PRO and PHILIPS Affinity 30 with linear array transducer of 7-9 megahertz frequency. Ultrasonographic findings relevant to benign and malignant thyroid nodules were recorded and compared with fine needle aspiration cytology reports. Out of total 70 cases 64 cases (91%) were diagnosed as benign and 6 cases (9%) as malignant on Ultrasonogram (USG). Whereas in FNAC, 63 cases (90%) were diagnosed as benign and 7 cases (10%) as malignant. In this study, it was found that sensitivity for detecting thyroid malignancy on USG is 85.7%. The positive predictive value for detecting thyroid malignancy on ultrasound is 100%.

Keywords: Nodular thyroid; USG, FNAC, Sensitivity; Positive Predictive Value.

Introduction
The thyroid gland is unique and largest among all endocrine glands. Nodular thyroid disease is a very common clinical finding, with an estimated prevalence on the basis of palpation is 3% to 7%.¹ In a large population study (in Framingham, Massachusetts), clinically apparent thyroid nodules were present in 6.4% of women and 1.5% of men.² During the past two decades, due to the widespread use of ultrasonography (USG) for evaluation of thyroid and neck disease there is significant increase in the prevalence of clinically non-palpable thyroid nodules, calculated to be 20% to 76% in the general population. This caused an epidemic of thyroid nodules and the prevalence is same as that of autopsy data in 50% patients with no previous history of thyroid disease.³⁻⁵ Thyroid nodules are more common in elderly persons and in women than in men. Malignant thyroid lesions constitute approximately 5% of all thyroid nodules, independent of their size.⁶⁻⁷ There is considerable dilemma over whether clinically undetectable thyroid lesions should be assessed by fine needle aspiration cytology (FNA).⁷⁻⁸ The dilemma is due to uncertainty about the occurrence of malignancy in small thyroid lesions and also due to uncertain natural course of thyroid microcarcinomas.⁹⁻¹⁴ High-resolution USG has maximum sensitivity to detect thyroid lesions. USG can detect thyroid nodules which are missed on physical examination, isotope scanning and other imaging techniques.¹⁵ Characterization of thyroid nodules into benign and malignant nodules by USG, helps in taking decision whether to go for FNAC and also to plan further management of the patients accordingly. In this study, we have tried to find out the efficacy of USG in the evaluation of thyroid nodules.

Aims and Objectives of the Study:
1. To study the gray scale ultrasonographic features in patients presenting with thyroid nodules of different pathology.
2. To study the accuracy of gray scale and color doppler ultrasonographic features in differentiating benign from malignant thyroid nodule.

3. Correlation of ultrasonography with that of FNAC findings in differentiating benign from malignant thyroid nodules.

**Materials and Method**

Cross sectional study was done from September 2017 to May 2019 and based on inclusion and exclusion criteria, total 70 patients clinically suspected to have thyroid lesions, were undergone Ultrasonography (USG) in the Department of Radio diagnosis KIMS & PBM Hospital, Bhubaneswar, Odisha. All the patients were undergone fine needle aspiration for confirmation of ultrasound findings and establishment of final diagnosis after taking consent from them. Slides were sent to the Department of Pathology, KIMS & PBM Hospital for cytological analysis. Any history of receiving radioactive iodine in the past, any history of thyroid surgery in the past and swelling in the neck other than thyroid gland were excluded in this study. USG machine used was GE Voluson S6 with a 10 MHz linear probe. Mode of USG is B mode gray scale real time ultrasound and color doppler.

**Results**

Maximum number of 30 cases were found in the age group 31 – 40 and minimum of 3 cases were in age group 11 –20. Maximum number of cases were found to be females i.e. 49 patients(70%) and minimum number were male i.e. 21 patients (30%).

Most of the patients i.e. 42 (60%) cases showed a single nodule, 27.1% cases multiple nodules and 12.9% cases diffuse pattern. Maximum number of malignant nodules 5 out of 7 nodules (71.4%) were single.

Out of total 70 cases, 64 (91%) were diagnosed as benign and 6 cases (9%) as malignant by ultrasonography (USG). On the basis of FNAC, 63 cases (90%) were diagnosed as benign and 7 cases (10%) as malignant. [Table-6]

---

Discussion

**Age and sex distribution:** In present study, out of 70 patients with various thyroid disorders maximum number of cases were found from 3rd to 5th decades i.e. 42 cases (approximately 70%) and females constitute about 70% of total cases. According to Kapur et al, maximum number of solitary thyroid nodules were found in 3rd, 4th and 5th decade.16 According to Belfiore et al, 84.8% were females and 14.2% were males.17

**Nodularity:** In our study, 60% cases were having single thyroid nodule and 27.1% cases were with multiple thyroid nodules. Malignant lesions (5/7) were mostly seen in single thyroid nodules. Diffuse thyroid involvement were found in 12.9% cases and all of them were found to benign. In a study done by C Capelli et al a total of 6135 nodules were obtained of which 4495 patients had solitary nodules (73.2%) and 1231 patients (20%) had multiple nodules.18

**Echogenicity:** In present study, 31.4% cases were having hypoechoic nodules. Out of this, 8.6% cases were having malignant lesions and 22.8% cases were having benign lesions. This shows that hypoechoic nodules are suspicious for malignancy. 26 cases (37.1%) showed iso to hyperechoic nodules and 5 cases (7.1%) showed anechoic cysts where no malignancy seen. This suggests that iso to hyperechoic and purely anechoic nodules are benign. Solbiati et al found 62% hypoechoic nodules were malignant in his study.19

**Margins:** In present study, 88.6% cases were showing well defined, regular margins of thyroid nodules. Out of this, 87.1% cases were benign lesions and 1.5% cases were malignant lesions. 11.4% cases showed irregular margins of thyroid nodules, out of which 2.8% were benign and 8.6% were malignant lesions. This shows that irregular margin of a nodule favors malignant nature of lesions. Solbiati et al found
that 82% thyroid nodules with regular margins were benign and 55% thyroid nodules with irregular margins were malignant.  

**Calcifications**

In present study, all the cases showing macro calcifications were benign and all the cases showing micro calcifications were malignant. So our study shows significant associations of micro calcifications with malignancy.

**Peripheral halo:** In our study, malignant nodules showed thick incomplete halo and no halos where as benign nodules showed predominantly thin halo. According to Hoang JKet al, a thin, well-defined peripheral halo represents displaced blood vessels around the lesion and is considered highly suggestive of a benign nodule. Solbiati et al found halo in 36% of thyroid nodules and more in benign than in malignant (86% versus 14%).

**Vascularity:** In our study, 95.2% of benign nodules show predominantly peripheral and spoke wheel pattern of vascularity. 71.4% malignant nodules showed internal vascularity. One malignant case showed peripheral with internal vascularity and other one showed spoke wheel pattern of vascularity. Fobbe et al found that 80-90% of benign nodules showing peripheral vascularity where as 70% to 90% of malignant nodules showing internal vascularity with or without a peripheral component.

**Lymphadenopathy:** In our study, lymphadenopathy was seen in 6 malignant cases (85.7%). Presence of Lymphadenopathy with thyroid nodule is highly suggestive of malignant nature of thyroid nodule. Gorman et al found metastatic cervical lymph nodes with US in 80% of patients with medullary carcinoma of thyroid.

**Benign lesions:** In our study, colloid goiter was found to be the most common (77.8%) benign lesion followed by multinodular goiter (19%). Similarly, according to Goellner and Gharib, colloid goiter (40%) is the most common histologic diagnosis followed by follicular adenoma (18%) and adenomatous goiter in about 11% cases with a 16% malignancy rate.

**Malignant lesions:** In our study, out of 7 malignant nodules, maximum number of 4 cases (57.1%) were papillary carcinoma. According to Raj Gopal SK et al, percentage of papillary carcinoma was 60-65%.

**Diagnostic Accuracy of USG:** Sensitivity and positive predictive value for detecting thyroid malignancy on USG were found to be 85.7% and 100% respectively.

**Limitations:** In our study the number of malignant cases were less. Most of the diagnosis was made on the basis of cytology instead of histology. In cases of multiple nodules, only the dominant nodule was evaluated in our study.

**Conclusion**

Now-a-day’s high resolution USG is the first line imaging modality in patients with thyroid pathology because of its high sensitivity and specificity in the evaluation of thyroid nodules, diffuse thyroid diseases and in differentiating benign and malignant thyroid nodules. FNAC or histopathological examination is the gold standard investigation for the final diagnosis. However, the knowledge of the specific USG features may be helpful to target suspicious nodules and to avoid unnecessary intervention in the benign nodules. The most useful USG features of malignant nodules in this study were solitary nodule, peripheral thick incomplete halo or absence of halo, predominant solid composition, hypoechogenicity, poorly defined margins, internal vascularity, presence of microcalcifications and associated lymphadenopathy.

A Study of Impact of Voice of Customers for Admissions Department of a Quaternary Care Hospital

A.P. Pandit¹, Sandhya Sharma²

¹Chief Medical Director, Chellaram Diabetes & Multispecialty Hospital, NH 4, Bavdhan, Pune,
²SIHS, S B Road, Pune

Abstract

Most executives recognize that customer experience is important to their businesses. To compete on customer experience, companies need to consistently deliver a better experience. To do that, they need to understand the experience of customers they are managing today. This is why voice-of-the- customer (VoC) programs is such a priority for so many businesses; the ability to listen to your customers is crucial to your ability to compete on customer experience. VoC programs are the only way to systematically listen to the customers, we use this information to take action, and monitor performance over time.¹

From patient experience, an admission to a bed as an inpatient in an acute hospital is a major event, independent of this admission being an emergency or from a waiting list. When patients need an emergency admission, it is important to be admitted quickly and to an appropriate bed, avoiding unnecessary waiting times in the emergency room. On the other hand, if patients are being admitted from a waiting list for elective surgery, it is important to minimize the number of occasions that admissions are cancelled as a result of there being no bed available. ²

When patients have positive hospital experiences, they share their satisfaction with relatives, friends and neighbors. The exchange of positive patient experiences, helps hospitals builds good reputations. If a hospital overlooks patient feedback, it becomes vulnerable to price wars and loses its customers to competitors.

Admission department plays a vital role in the hospitals. It serves as the first point of contact for the patients and their attendants. Hence, a sober image of this department is necessary. It is a place where both the patients and the staff have to exhibit patience and understanding.

Keywords: Impact of Voice of Customer, Quaternary care Hospital, Admission Department.

Introduction

Health administrators and physician increasingly incorporate patients perspectives into healthcare; patient satisfaction has become a significant outcome.³,⁴ Because health care organizations operate in evermore competitive markets, patient satisfaction with services is a crucial factor in determining a health care organization’s competitive advantage and survival.⁵ Patient satisfaction also has become an increasingly important component of quality assessment.

Donabedian⁸ has urged for including patients perspectives as a key component of quality assessment since the early 1970s. The rise of consumerism has contributed to increase patients demand for information and involvement⁹. The shift toward continuous quality improvement that gained momentum in 1990s places meeting patient expectations at the core of medicine’s mission.¹⁰ Increasing lypatients at is faction measures are also being used to evaluate physician performance and determine physician compensation in academic and private practice settings.
Hospitals that are committed to providing excellent health care outcomes, including patient satisfaction, establish multiple programs and initiatives to achieve these goals. Measuring performance is essential to assessing the effects of continuous efforts to improve quality of care and ensuring the pursuit of excellence in hospitals. Increasingly, patient satisfaction is acknowledged as a key organizational performance measure. In addition to providing a unique perspective on the performance of a hospital, patient satisfaction is considered as a predictor of a patient’s willingness to follow treatment, to return for service, or to recommend a service to others. In the US, the Centres for Medicare and Medicaid Services (CMS) has identified patient experience of care as an important determinant of the performance payments to be made to acute hospitals. Thus, from fiscal year 2013 at least 0.3% of hospitals Medicare revenue (30% of the 1% withholds from participating hospital.

Diagnosis-Related Group payments) will be determined by their performance on these experience/satisfaction measures.

The world’s economy has largely become a service-oriented one, and service quality, regardless of the service being rendered, is a central issue for any kind of business. This is the reason why most organizations seek to satisfy the users (clients, customers, patients) of its products or services. Patient satisfaction forms one of the most important dimensions of quality of healthcare.

Customers are the most important stakeholders and their views on every aspect of the health care environment will have to be understood so that measures can be taken to satisfy them during their future encounters with the health care environment.

A critical challenge for health services in developing countries is to find ways to make them more client-oriented. Indifferent treatment of patients, unofficial payments to providers, lack of patient privacy, and inadequate provision of medicines and supplies are common, yet are rarely acknowledged by traditional quality assessment method. Assessing patient perspectives gives users a voice, which, if given systematic attention, offers the potential to make services more responsive to peoples’ need and expectation, important elements of making health systems more effective. Studies have shown that health care utilization, a long-standing concern for many developing countries, is sensitive to user perceptions of quality. For these reasons, patient perceptions of health services are now an important part of quality assessment in health care.

Aim: To study and analyze the Voice of the Customer for the Admissions Department of a Quaternary Care Hospital.

Objectives:

• To find out the major issues faced by the patients during the visit.
• To identify the key areas of the department providing dissatisfactory and poor services to the patients.
• To provide measures/recommendations for improved quality services.

Scope:

• Present study was conducted for the duration of 45 days.

Review of Literature

The hospitalization process has three main stages: an admission, an inpatient period and a final stage with the discharge process. An inefficient bed management in any of the three stages of the hospitalization can cause a mismatch between demand and capacity. It has been proved that when bed demand exceeds capacity, patient admissions and scheduled surgical procedures can be delayed or cancelled. Traditionally, it has been assumed that the variability in the demand comes from the emergency patient. Interventions focused primarily on emergency departments have had limited success. However, repeated case studies have shown that elective admissions are often the major cause of variation as they are more unpredictable than the emergency admissions.

In addition, the greatest variation is typically in the number of discharges and, therefore, efforts to reduce variation should start with the discharge process and not in the admission process. Then, to have information about planned discharges 24-h in advance would allow a higher planning and an optimal bed assignment. Moreover, the discharge process should start at the point of admission in the case of planned admissions, as in some cases the estimated length of stay without a medical complication is known. Discharge planning allows for a better and quicker bed assignment in hospitals and the development of nurses and other staff working in discharge coordinator roles. In this sense, it has been proved that multidisciplinary teams can
improve the delivery of health services and patient care. All admissions and discharges of the hospital should be centrally managed and planned, as single-department solutions may create or worsen bottlenecks in other areas.

During the hospitalization process, patient flow is a strategic aim for the healthcare enterprise. Hospitals can combine process management with information technology to redesign patient flow for maximum efficiency and clinical outcomes. Information is the foundation of any patient flow initiative. Patient flow is built upon the capture, integration and sharing of information, both within and across the different departments and staff.

**Fish Bone Diagram:** An Ishikawa diagram basically helps in understanding the "cause and effect relationship for solving a problem. It is a very helpful tool as it gives a pictorial representation of what is the cause of a problem or a phenomenon, what factors have a high/low impact to those problem/phenomena and how can the situation be resolved. The Ishikawa is drawn like a fishbone and helps a person to see the causes and effects in a particular relationship. The Ishikawa diagram looks like a fishbone, and is popularly known as the Fishbone Diagram. Ideally, an Ishikawa diagram has an oval/rectangular box at the right hand side. This box is labeled with the problem to be studied/effect. There is a horizontal line (which can be visualized as the back bone) and a number of bones (read causes) stemming out of it. There is a label for eachone of these, and these are on the lefthand side of the diagram. Each cause may have several contributing causes and these are marked by smaller lines.

When utilizing a team approach to problem solving, there are often many opinions as to the problem’s root cause. One way to capture these different ideas and stimulate the team’s brainstorming on root causes is the cause and effect diagram, commonly called a fishbone diagram.

The cause and effect diagram is used to explore all the potential or real causes (or inputs) that result in a single effect (or output). Causes are arranged according to their level of importance or detail, resulting in a depiction of relationships and hierarchy of events. This can help you search for root causes, identify areas where there may be problems, and compare the relative importance of different causes.

The fishbone will help to visually display the many potential causes for a specific problem or effect. It is particularly useful in a group setting and for situations in which little quantitative data is available for analysis. The fishbone has an ancillary benefit as well. Because people by nature often like to get right to determining what to do about a problem, this can help bring out a more thorough exploration of the issues behind the problem - which will lead to a more robust solution.

The rest of the fishbone then consists of one line drawn across the page, attached to the problem statement, and several lines, or ‘bones,’ coming out vertically from the main line.

**hy-Why Analysis:** A Why-Why Diagram is a Tree Diagram where each child statement is determined simply by asking ‘why’ the parent occurs, as below. It is thus very similar in use to a Cause-Effect Diagram, and techniques may be borrowed from Cause-Effect Diagram usage. Its simplicity can make it useful in less formal situations.

The Why-Why and How-How Diagrams together make a very simple toolset for finding causes of and solutions to problems.
Methodology:

**Type of study:** Descriptive study

**Place of study:** Chennai

**Time Frame:** The study was conducted over a period of one and a half months i.e. 10th May to 25th June 2017.

**Study variables:** Voice of Customers, Types of patients

**Population for the study:** In patients during the study period

**Exclusions:** Transit patients during the study period

**Study Procedure:** Data was collected from In-patients through the feedback form which is predesigned by the hospital.

**Data Analysis Tools:** MICROSOFT EXCEL 8.0 Software.

Fish Bone Diagram (Root Cause Analysis) Why-Why Analysis

### Observation and Results

**Table 1:** Responses for the feedback form

Figure 2: Responses for the feedback form
From the above figure, some inferences can be made such as:

- Majority of the patients were satisfied with the services and the overall experience at the hospital.
- The highest satisfaction has been recorded with respect to the doctors explanation of treatment to the patients followed by courtesy and compassion exhibited by doctors as well as nursing staff.
- The highest dissatisfaction has been recorded with respect to waiting time and discharge speed followed by communication and handling of queries.

The above feedback was obtained from 3 different avenues namely, in-patient, front line and post discharge. In-patient feedback referred to feedback obtained from the patients during their stay at the hospital. Front line feedback referred to feedback obtained by Guest Relation Officers during their interaction with the patients. Post Discharge feedback referred to feedback obtained after the discharge of the patients. It can be noted here that most of the feedback obtained is through Post Discharge followed by In-Patient and Front line feedback.

From the above figure, it can be inferred that a maximum of compliments are recorded through feedback obtained from patients during their stay at the hospital. This is followed by suggestions and finally complaints.
From the above figure, it can be inferred that a maximum of complaints are recorded through feedback obtained by the Guest Relation Officers in their interaction with the In- Patients. This is followed by suggestions and finally compliments.

![Post Discharge Feedback](image)

**Figure 5: Stratification of Post Discharge Feedback**

From the above figure, it can be inferred that a maximum of compliments have been recorded through feedback obtained from patients after their discharge. This is followed by complaints and finally suggestions.

![% of patients from each area for admission](image)

**Figure 6: % of patients from each area for admission**

A maximum of patients come for planned admissions (IP), followed by admission through the Emergency Department and Day care. 3% patients come under the transit category which has been excluded for this study.

A maximum of patients get admitted after being referred by the Emergency Medical Officer closely followed by Cardiologist, Ortho and General Surgeon. The other departments also contribute towards admission rates of the hospital.
Discussion:

The study shows results where majority of the patients have a higher satisfaction rate with the overall experience while still having a few complaints which have been recorded in 3 different avenues, namely, In-Patient feedback, Front Line feedback and Post Discharge feedback. Most of the feedback obtained is through Post Discharge followed by In-Patient and Front line feedback.

A maximum of compliments were recorded through feedback obtained from patients during their stay at the hospital while a maximum of complaints were recorded through feedback obtained by the Guest Relation Officers in their interaction with the In-Patients.

The study also shows that a majority of patients come for planned admissions (IP), followed by admission through the Emergency Department and Day care. Similarly, a maximum of patients get admitted after being referred by the Emergency Medical Officer closely followed by Cardiologist, Ortho and General Surgeon.

The leading causes for dissatisfaction of patients have been identified as:

- Courtesy and compassion of admission staff
- Accuracy of information provided by admission staff
- Adherence to time for bed allocation
- Response to queries by admission staff
- Waiting time for admission

Recommendations:

- The Staff of the hospital should possess a pleasant attitude towards the patients at all times in order to overcome & achieve 100% response of the patients as a part of the quality assurance program of the hospital. A mere smile on their face can go a long way in making a patient feel comfortable.
- Lack of coordination is what brings miscommunication to the forefront. This can be handled by having group meetings everyday where various scenarios are spoken about and virtually handled as a training session.
- Training sessions to all the staff handling admissions is necessary. Their performance and knowledge needs to be regularly reviewed to minimize incidences of patients being misguided by the uninformed staff.
- Allocation of the bed can be difficult during times of full occupancy which is the case usually with hospitals. Yet, this issue can be handled by speeding up the discharge process which was found to be the major cause for delay of patients vacating beds.
Planning ensured an early and certain discharge as well as a better bed assignment because there was information about which beds would be available. Therefore, the number of patient outliers in the hospital significantly diminished. A limitation of planning discharge was that not all of them were effectively real the following day. However, the importance of the planning was precisely to avoid improvisation of all the staff that participated in the discharge: physician, nurse, house officer, sanitary transport, families and patients and others. In fact, discharge process should start in the admission point, as it is the mismatch between demand and supply of beds that promotes delays and bottlenecks in the system.

Conclusion

When patients have positive hospital experiences, they share their satisfaction with relatives, friends and neighbors. The exchange of positive patient experiences helps hospitals builds good reputations. If a hospital overlooks patient feedback, it becomes vulnerable to price wars and loses its customers to competitors.

Admission department plays a vital role in the hospitals. It serves as the first point of contact for the patients and their attendants. Hence, a sober image of this department is necessary. It is a place where both the patients and the staff have to exhibit patience and understanding. A proper location of admission department, friendly staff and concise information about the admission process and charges is what is expected by the patient when it comes to a department of admission.

Ethical Clearance: The study was done as a part of Summer Internship of MBA, and there was no direct intervention with patient care & hence no Ethical Issues were involved.

Source of Funding: The study is not funded by any agency.

Conflict of Interest: Nill

Effect of Combination of Active Stretching and Deep Breathing Exercise for Pectoral Group of Muscle Tightness in Breast Feeding Mother

Neha Kadam1, Javid Sagar2

1Intern, 2Professor, Faculty of Physiotherapy, Krishna Institute of Medical Sciences, Deemed to be University, Karad, Maharashtra, India

Abstract

Objective: To determine the effects of active stretching along with deep breathing exercise for pectoral group of muscle tightness in breast feeding mother.

Method: A total of 60 subjects were screened as per inclusion and exclusion criteria and they were briefed about study and intervention. Informed consent was taken from the subjects. Subjects were selected on the basis of simple sampling method. The subjects which had pectorals muscle tightness was taken in the study. Pre and post treatment muscle length test measurement, chest measurement and respiratory rates was taken into consideration.

Conclusion: Various recent approaches are used in the treatment of subjects who are suffering from muscle tightness because of poor posture, but this study concluded that combine effect of active stretching with deep breathing exercise was effective in decreasing the muscle tightness and shallow breathing and increase chest measurement. It is proved from this study that combination of active stretching and deep breathing exercise has significant effect on pectoral muscle group tightness.

Keywords: Pectoral Muscle group, tightness, breast feeding mothers, chest measurements, muscle length test, chest measurement.

Introduction

Human beings have upright erect posture or bipedal posture1. Posture is attitude assumed by the body either with support during muscular inactivity, or by means of the co-ordinate action of man muscles working to maintain the stability or to form an essential basis which is being adapted constantly to the movement which is super imposed upon it2.

Poor posture is defined as when posture is inefficient, that is, when it fails to serve the purpose for which it was designed, or if an unnecessary amount of muscular effort is use to maintain it2. There are different anatomical features that lead to incorrect posture they are as follows:

- Laxity of ligamentous structures.
- Musculoskeletal tightness
- Muscle tonus
- Joint position and mobility

Muscle imbalance and muscle shortness also leads to incorrect posture. Excessive use of arm in front of the body and the necessity to lean forward which is occupational demand, this tensions usually occur in muscles round shoulder girdle and in next extensors2. The ability to relax is an important factor in reeducation, as some degree of useless and unnecessary tension is nearly always associated with poor posture2.

As it is advantage to baby while breast feeding if mother is in forward lean position so this is adapts to bad posture for mother2.
Stretching helps in relaxing the muscle which helps in further correcting posture and reducing pain caused by altered posture\(^4\); and Deep breathing exercises also helps in improving our respiratory functions and caused due to improper posture and further helps in relaxation\(^4\).

The first step of breathing awareness is the recognition of the relationship of body movement to the flow of air while breathing\(^5\).

**Method**

- Type of Study: Experimental study
- Study Design-pre and post test
- Sampling Method: simple random sampling
- Sample size: 60
- Study Duration: 3 months
- Place of study: Krishna Hospital, Physiotherapy Outpatient Department

**Materials**

- Consent form
- Data collection sheet
- Paper
- Pen
- Inch tape
- Stop watch

**Outcome measures:**

- Muscle length test
- Chest measurements
- Respiratory rate

**Procedure:** This study was an experimental study. Study designed as a pre-test and post-test. Subjects selects for this study from Krishna hospital, karad. The purpose of the study was explained to the patients. 60 patients were selected for the study on the basis of inclusion and exclusion criteria. Demographic and baseline assessments of the subjects were done on the first day. After the baseline assessments therapy was started on next day. Duration of therapy was 6 days. The values were assessed before and after treatment. The difference between the pre and post values were assessed and compared by student paired and unpaired t test.

**Interventions:**

- Warm up exercise:
- Joint rotation (10 min)
- Free shoulder exercise (2 min)
- Free elbow exercise (2 min)
- Free neck exercise (2 min)
- Free trunk exercise (4 min)
- Specific exercise:
  - Deep breathing exercise along with active stretching exercises: take deep breath in by nose, let the lung fulfill with air along with do active stretch; once the muscle get stretch, maintain that stretch and slowly exhale from mouth.
  - Type of stretching which is including in the therapy:
    - Wall stretch – stand against the outer corner of a room or in doorway. Bend your elbow a 99-degree angle so your upper arm is parallel to the floor at shoulder height. Place your forearm against the corner of the wall gently press your forearm on the wall and feel the stretch in pectoral muscle, hold the position 15 to 20 seconds and repeat 10 times, (10 times \(\times \) 2 set)
    - Elbow wrap stretch – sit cross on the floor. bring your arm behind your back and clap each hand around the opposite elbow or forearm. Hold for 20 to 30 seconds focus on lifting your collarbone and squeezing your shoulder blades together. Repeat for 10 times (10 times \(\times \) 2 set)
    - Camel pose – kneel on the floor with your knees hip width apart and your hand at your waist. Your toes can’t be tucked or the top of your feet can be flat against the floor; slowly reach back keep your hands on your lower back, push your elbow back; keeping your chest lifted, shoulders back, and core engaged, slowly push your hip forward, making sure to keep your chin down, if that still feel ok you can slowly release your head backward.

**Cool down:**

- Upper limb stretches
- Biceps stretch
- Triceps stretch
- Trapezius stretch

**Precautions:**

- Avoid excessive stretch which is very painful
- Always listen to your body
- During practicing breathing exercise concentrate on stretch
Results and Statistics

(1) Muscle length test:

Table no 1 - Comparison of pre and post muscle length test pectoralis major and pectoralis minor within the group.

<table>

In the present study pre-interventional mean score for respiratory rate was 21.733±1.364; whereas post interventional mean score was 15.467±1.770 respectively. Inter group analysis of respiratory rate score was done using paired ‘t’ test; p value of respiratory rate was <0.0001; t value of respiratory rate was 28.962. Inter group analysis of respiratory rate as shown statistically extremely significant.

Discussion

A woman’s body undergoes profound changes during and after pregnancy; the rounded shoulders and arched lower back increases because of bad posture adaptation. After delivery body needs to be kept in a correct posture during all activity to help the body or joint position to realign; the postpartum period is the
time when the woman has not totally recovered from the stress and strain place on her body. While breast feeding slouching over the baby can increase pectoral muscle tightness\(^1,3\).

Active stretching which was carried out independently by the patient after instruction and supervision by therapist; it is designed to improve the mobility of soft tissues and consequently increase ROM and flexibility\(^4\). Intensity of stretch was low intensity; duration of stretch 20 to 30 sec per stretch; mode of stretching was self-stretching.

Proper breathing control is important for successful stretch; breathing helps to relax the body, increase blood flow throughout the body. During the session patient took slow deep breath along with active stretch of pectoral muscle group, and slowly exhaled by mouth but stretch was maintained for 20 to 30 sec.

In this study, 60 subjects were assessed for eligibility, out of which 60 completed the study. Pre-treatment outcome measure for pectoral muscle group tightness was muscle length test, chest measurements, respiratory rate.

Inter group statistical analysis revealed statistically extremely significant. Pre and post value of muscle length test wastook. This was done by using paired t test, for pectoralis major mean\(\pm SD\) was 8.465\(\pm 0.7843\), \(p\) value (<0.0001), t value (36.291); for pectoralis minor mean\(\pm SD\) was 6.506\(\pm 0.6128\), \(p\) value (<0.0001), t value (27.792).

Inter group analysis of chest measurement score was done by using paired t test. Statistical analysis showed extremely significant difference. Mean\(\pm SD\) was 1.557\(\pm 0.2273\), \(p\) value (<0.0001), t value (37.994).

Inter group analysis of chest respiratory rate was done by using paired t test. Statistical analysis showed extremely significant difference. Mean\(\pm SD\) was 21.733\(\pm 1.364\), \(p\) value (<0.0001), t value (28.962).

In study has shown clinically significant changes in muscle length test, chest measurements, respiratory rate. These findings suggest that combination of active stretching and deep breathing exercise is effective for pectoral muscle group tightness in breastfeeding mother.

An exercise has been effective with patient with pectoral region tightness. Regular practice of stretching and breathing exercise in combination is very helpful to decrease the muscle tightness.

**Conclusion**

Various recent approaches are used in the treatment of subjects who are suffering from muscle tightness because of poor posture, but this study concluded that combine effect of active stretching with deep breathing exercise was effective in decreasing the muscle tightness and shallow breathing and increase chest measurement. It is proved from this study that combination of active stretching and deep breathing exercise has significant effect on pectoral muscle group tightness.

To Determine Spectrum of MRI Imaging in Vertebral Artery Dissection: A Radiological Study

P R Shaha, Manisha Luhana

1Professor, 2P. G. Resident, Department of Radiodiagnosis, Krishna Institute of Medical Sciences Deemed to be University, Karad

Abstract

Background: Vertebral artery dissection is a potential cause of posterior circulation ischemia that requires high-spatial-resolution imaging. The present study was conducted to determine spectrum of MRI imaging in vertebral artery dissection.

Materials and Method: The present study was conducted on 64 cases of vertebral artery dissection of both genders. All participants were imaged by 1.5 T super conducting magnetic resonance imager. The site of dissection was classified as V1 (prevertebral segment), V2 (intertransverse segment), V3 (atlantoaxial segment) and V4 (intradural/intracranial segment) using standard method of classification.

Results: Out of 64 patients, males were 34 and females were 30. Dizziness was present in 34, gait instability in 38, headache in 42 and altered mental status in 50. The difference was non-significant (P> 0.05). VI was seen in 1, V2 in 7, V3 in 36 and V4 in 20. The difference was significant (P> 0.05). Posterior circulation infarct was present in 25, cerebellar infarction in 11, cerebellar and medullary infarct in 9, occipital infarct in 12, subarachnoid hemorrhage in 2 and solitary lateral medullary infarct in 5.

Conclusion: Most common MRI finding was posterior circulation infarct, cerebellar infarction, cerebellar and medullary infarct, occipital infarct, subarachnoid hemorrhage, solitary lateral medullary infarct.

Keywords: Cerebellar infarction, MRI, Vertebral artery dissection.

Introduction

Vertebral artery dissection (VAD) accounts for 0.4 to 2.5% of all strokes in the general population, however, in young populations it comprises a substantial chunk (5-20%) of stroke patients. The diagnostic armamentarium for VAD includes both invasive and non-invasive modalities with the conventional angiography considered as the gold standard technique for its diagnosis.1

Vertebral artery dissection is a potential cause of posterior circulation ischemia that requires high-spatial-resolution imaging for the definitive diagnosis. Digital subtraction angiography (DSA) remains the gold standard for assessment of the vertebrobasilar arteries, with excellent spatial and temporal resolution. However, risks associated with conventional angiography include vascular injury, intracerebral complications, contrast medium nephrotoxicity and exposure to ionizing radiation.2

The diagnosis of VAD may go unnoticed or may get inordinately delayed owing to lack of high level of suspicion on part of physicians and for want of availability of comprehensive diagnostic modalities.3 Three-dimensional (3D) time-of-flight (TOF) MRA is important as a non-invasive examination to diagnose blood flow in the brain.4 TOF MRA mainly reflects the blood flow within the artery, representing the inner contour of the artery. Intramural dissecting haematoma shows a typical evolution of signal intensity related to
the paramagnetic effects of the products of hemoglobin breakdown and is frequently isointense to surrounding structures. Therefore, the diagnostic performance of TOF in the detection of vertebral artery dissection is poor. The present study was conducted to determine spectrum of MRI imaging in vertebral artery dissection.

**Materials and Method**

The present study was conducted in the department of Radio-diagnosis. It comprised of 64 cases of vertebral artery dissection of both genders. Ethical Clearance was obtained prior to the study.

General data such as name, age, gender etc. was recorded. Patients were examined clinically and MRI was done in all patients. All participants were imaged by 1.5 T super conducting magnetic resonance imager (Magnetom Avanto, Siemens Medical System). Presence of mural hematoma together with diminished lumen of the vessel or complete occlusion was diagnosed as VAD. The site of dissection was classified as V1 (prevertebral segment), V2 (intertransverse segment), V3 (atlantoaxial segment) and V4 (intradural/intracranial segment) using standard method of classification. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

**Results**

**Table I: Distribution of patients**

<table>
<thead>
<tr>
<th>Gender</th>
<th>Males</th>
<th>Females</th>

</table>

Table IV shows that posterior circulation infarct was present in 25, cerebellar infarction in 11, cerebellar and medullary infarct in 9, occipital infarct in 12, subarachnoid hemorrhage in 2 and solitary lateral medullary infarct in 5.

**Discussion**

With advances in non-invasive imaging vertebral artery dissection is now more commonly diagnosed as a cause of vertebro-basilar stroke in younger population. Vertebral artery dissections commonly involve intima as well as media with intramural hematoma usually located between the media and internal elastic lamina. The precipitating event can be an intimal tear that allows blood to seep from the lumen into the media or a hemorrhage from the vasa vasorum within the media.

True fast MR imaging with steady-state precession (true-FISP) is a coherent steady-state technique that uses a fully balanced gradient waveform to recycle transverse magnetization. True FISP is extremely rapid relative to black-blood T1WI and T2 WI and fat-suppressed T1WI. True FISP offers a high signal-to-noise ratio and imaging efficiency; true FISP provides reliable examination of blood vessels without the need for intravenous administration of contrast medium. However, true FISP is not suitable for the imaging of fast flow velocity.
because the reduction of signal intensity on true FISP is remarkable with a flow velocity of 50–100 cm/s, which corresponds to arterial flow velocity. Therefore, true FISP is not suitable for visualizing the inner contour of the artery but can provide information regarding the outer surface appearance of the intracranial arterial wall. The present study was conducted to determine spectrum of MRI imaging in vertebral artery dissection.

In this study, out of 64 patients, males were 34 and females were 30. Dizziness was present in 34, gait instability in 38, headache in 42 and altered mental status in 50. Auer et al. conducted a study in which fifty patients were studied: 17 had VAD and 33 had vertebral artery hypoplasia. Fusion images of the vertebral artery were reconstructed using a workstation. A receiver operating characteristic (ROC) analysis was conducted with a continuous rating scale from 1 to 100 to compare observer performance in VAD detection. Five radiologists participated in the observer performance test, and their performances with TOF images were compared with those using fused images. The observers found that the mean areas under the best-fit ROC curve for TOF images alone and fused TOF images were 0.66±0.05 and 0.93±0.04, which were significantly different.

We found that VI was seen in 1, V2 in 7, V3 in 36 and V4 in 20. Posterior circulation infarct was present in 25, cerebellar infarction in 11, cerebellar and medullary infarct in 9, occipital infarct in 12, subarachnoid hemorrhage in 2 and solitary lateral medullary infarct in 5.

Wessels et al. found that of the total 17 patients imaged with age range of 23-59 years (mean age 38 years), 11 were males and 6 were females. V3 was the commonest site of dissection (n=10) followed by V4 (n=4) and V2 (n=3). The most common pattern of dissection was steno-occlusive (n=15), whereas 2 patients had aneurysmal type of dissection. T1W images revealed intra-arterial thrombus in all the 17 patients. T2W revealed absent flow in vertebral artery in 5 patients. 3D TOF MRA revealed narrowed lumen in 10 patients and complete occlusion in 5 patients. One patient revealed intimal flap on 3D TOF MRA.

Conclusion

Authors found that most common MRI finding was posterior circulation infarct, cerebellar infarction, cerebellar and medullary infarct, occipital infarct, subarachnoid hemorrhage, solitary lateral medullary infarct.

A Study to Assess the Iodine Level in the Salt and Salt Preservation Practices among Homemakers of Selected Households at Mangaluru

Reziya Hafeez1, Leena K.C.2, Ananda S.3, Devina E. Rodrigues4

1MSc. Nursing, 2HOD, 3Asst. Prof., Department of Community Health Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, 4HOD, Dept. of Research, Father Muller College of Nursing, Mangaluru, Karnataka, India

Abstract

Background: Salt iodization is an accepted fact worldwide to correct the deficiency of iodine. It is a long chain of transport of iodized salt from the manufacturing site to the consumer’s home. During the process, it is said that around one quarter to half proportion of fortified iodine can lose.

Objectives: The descriptive study assessed the iodine level in the salt and salt preservation practices among homemakers.

Materials and Method: Iodine Spot Testing Kit was used to assess the iodine level in the salt and an observational checklist (9 items) and a self-reported rating scale (6 items) on the salt preservation practices was used to collect data from homemakers.

Results: 32 (31.06%) of salt samples were moderately iodized with iodine level of 7-14 ppm. Most of the households, 62 (60.2%) were practicing inappropriate salt preservation practices. There is a significant association of salt preservation practice scores with age ($\chi^2 = 16.45, p = 0.001$), education ($\chi^2 = 44.57, p = 0.001$) and experience in managing the kitchen ($\chi^2 = 38.53, p = 0.001$).

Conclusion: IEC activities can play a great role to improve the knowledge of homemakers regarding appropriate salt preservation practices.

Keywords: Iodine, salt preservation practices and iodine in salt.

Introduction

Iodine is an essential trace element for life and is the heaviest element commonly needed by living organisms. A decreased production of T3 and T4 and an enlargement of the thyroid tissue to obtain more iodine occur due to the deficiency of iodine, causing the disease known as goitre and many other disorders such as impaired mental function, hypothyroidism, cretinism and retarded physical development.[1] Salt iodization is accepted as the effective and viable long-term public health measure for the prevention and control of Iodine Deficiency Disorder (IDD).[2]

Nearly one-third of the world’s population lives in areas of iodine insufficiency. In areas where the iodine intake is <50µg, goitre is usually endemic, and when the daily intake falls <25µg, congenital hypothyroidism is seen. The existence of goitre in areas of severe iodine insufficiency can be as high as 80%. To provide 150µg/day of iodine, WHO recommends that iodine concentration in salt should be within the range of 20 to 40 mg per kg of salt at the point of production.[3] When all salt used in manufactured food is iodized, the lower limit 20 mg is recommended. Adequately iodized
salt is a salt sample which has ≥15ppm of iodine, at the household level.\[^4\]

Iodine deficiency disorders form the major trace element deficiencies of public health significance in India; several surveys have indicated that no state in the country is free from IDD and nearly two-thirds of children and women of the age group of 15-45 years across the country are estimated to be suffering from IDD.\[^5\]

Earlier iodine deficiency disorders were seen in Himalayan and hilly regions only, but now a day most of the people in the world especially Indian women are suffering from thyroid problems, despite of using iodized salt. This may be because of some faulty practices in preservation of salt. This has motivated the investigator to assess iodine level of salt and salt preservation practices at household level, so that appropriate interventions could be undertaken to reduce the prevalence of iodine deficiency disorders.

**Materials and Method**

**Study setting and sample size:** The research design selected for this study was descriptive correlative design. The study was carried out in Kumpala area, Kotekar post, Mangaluru, Karnataka. In the present study, samples consist of 103 homemakers who were selected by convenience sampling technique, based on inclusion criteria.

**Tools and techniques:** Iodine Spot Testing Kit was used to assess the iodine level in the salt \(r=0.84\) and an observational checklist with 9 items \(r=0.80\) and a self-reported rating scale with 6 items \(r=0.75\) on the salt preservation practices was used to collect data from homemakers.

**Data analysis:** The data was collected after obtaining prior permission from the concerned authority to conduct the study. The participants were assured about the confidentiality of their responses. The data was analyzed in terms of objectives of the study using both descriptive and inferential statistics. The data obtained was plotted in the master sheet.

**Results:** Majority of the subjects, 62 (60.2%) were between the age group of 31-40 years with the mean age of 35 ± 0.63. Most of the homemakers, 76 (73.8%) belongs to Hindu religion and 80 (77.6%) were residing in nuclear family structure. Most of the homemakers, 83 (80.6%) were having below 5 years of experience in managing kitchen with the mean experience of 3.5 ± 0.47. Half of the homemakers, 52 (50.5%) were spending less than 3 hours per day in the kitchen [Table 1].

Most of the salt samples, 71 (68.93%) were adequately iodized with iodine level ≥ 15ppm and 32 (31.06%) of salt samples were moderately iodized with iodine level of below 7-14 ppm [Table 2].

Most of the households, 62 (60.2%) were practicing inappropriate salt preservation practices [Table 3, Fig. 1].

There was a significant association of salt preservation practice scores with age \(\chi^2 = 16.45, p = 0.001\), education \(\chi^2 = 44.57, p = 0.001\) and experience in managing the kitchen \(\chi^2 = 38.53, p = 0.001\).

Fig. 1: Description on utilization of salt during cooking process

Discussion

Section I: Description of baseline characteristics of homemakers: The present study revealed that majority of the subjects, 62 (60%) was between the age group of 31-40 with the mean age of 35 ± 0.63 years. More than half of the subjects, 63 (60%) were under graduates and 52 (50%) were working women. The study findings are supported by the studies conducted by Gidey B, et.al in North Ethiopia and Gebrearegaw H, et.al in Gondar Town, Northwest Ethiopia where the results showed that the mean age of the participants was 38 years, 55.9% of the subjects were unemployed housewives and 23% had at least secondary school level in education.[6],[7]

Section II: Description of iodine content in the salt: The present study showed that 32 (31.06%) of salt samples were moderately iodized with iodine level of 7-14 ppm. The study findings are in accordance with another study conducted among 6-12 years school children in Gulbarga city of Karnataka where the results have showed that among the salt samples collected from retail shops and households, only 44.62% samples were adequately iodized.[8]

Section III: Description of salt preservation practices among homemakers:

Most of the homemakers, 71 (68.9%) were storing salt in plastic container, 7 (6.8%) in a metal container and 3 (2.9%) in salt packet itself. Seventeen homemakers, 17 (16.5%) were keeping the lid of container loosely closed and 3 (2.9%) were keeping it open. Most of the homemakers 50 (49.6%) were adding salt at the early beginning of the cooking and 22 (21.2%) in between
cooking. The study conducted in 2014 by Rashmi S, et al in Kanpur, India has also revealed that 99% of households were storing salt in kitchen itself and less than half proportion of the respondents (47%) were storing salt in glass jars followed by masaladan (23%).[9]

Section IV: Association between salt preservation practice scores and selected baseline characteristics: The present study revealed that there is a significant association of salt preservation practice scores with age ($\chi^2 = 16.45, p = 0.001$), education ($\chi^2 = 44.57, p = 0.001$) and experience in managing the kitchen ($\chi^2 = 38.53, p = 0.001$). The study findings are in accordance with a study conducted by Ebrahim S. in 2012 Basra City, South Iraq, where the results revealed that education and experience are significantly associated with level of iodine in the salt and salt preservation practices.[10]

Conclusion

Present study findings showed that most of the homemakers were practicing inappropriate salt preservation practices which affect the iodine level in the salt. Hence, IEC activities can play a great role to improve the knowledge of homemakers regarding appropriate salt preservation practices.

An Analysis of Agricultural Development in Tamilnadu with Special Reference to Madurai District

S. Thangamayan¹, Premalatha¹, S. Chandrachud²

¹Assistant Professor, ²Associate Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

The developmental plans in India have stressed the need for a revolutionary change in agriculture which can be brought about by the introduction of new and HYV of improved seeds, application of suitable doses of fertilizers and extensive use of pesticides. The ‘Green Revolution’ as it is otherwise called, has led to a large increase in production of food grains after 1966-67. The Community Development Projects (each covering 100 villages) were started in 1952. The main objective was to mobilize rural dwellers for labour-intensive agricultural productivity projects supported by certain land reforms, new village co-operatives in which the State would be a partner and national extension services. In the Second Five Year Plan, only 20 per cent of total outlay went to agriculture, which is lower than the percentage allotted in the First Five Year Plan. The literates and illiterates were 17.95 lakhs and 7.67 lakhs respectively in 2001. The population is spread over the entire district with 11.27 lakhs and 14.35 lakhs living in the rural and urban areas respectively. Government should encourage the farmers to start co-operative societies in the study area in order to develop a direct link between the wholesalers/retailers, processors and exporters to cut down the marketing cost incurred for lengthy channel. The Government should initiate action to improve market information system and market intelligence.

Keywords: Agriculture Development, Community Development, Revenue Divisions.

Introduction

The developmental plans in India have stressed the need for a revolutionary change in agriculture which can be brought about by the introduction of new and HYV of improved seeds, application of suitable doses of fertilizers and extensive use of pesticides. The ‘Green Revolution’ as it is otherwise called, has led to a large increase in production of food grains after 1966-67. The revolution has brought about self sufficiency in food grains in agriculture, reduced our dependence on foreign countries for food grains and generated progress in agriculture. The revolutionary change has attempted to break the chain of the vicious circle of poverty in Indian agriculture and paved the way for success mainly in the production of food grains. The review of agricultural development in India since Independence will show the telling impact of the new agricultural strategy. Indian agriculture during the 19th Century was almost of subsistence type. Production of food grains was mainly for consumption purposes and there has been very little rise in output. Indian agriculture is rich in resources but low in productivity. With 2.5 per cent of the world surface area, the country cultivates 163 million hectares, which is approximately 12 per cent of the world arable area. Comparatively in the world scene, Indian rice productivity is just 40 per cent of the Chinese yields, approximately one-third of the Korean yields and around 55 per cent of Indonesian yields. Agricultural development has received priority after independence in our five year plans. Efforts were made to overcome the technical constraints, institutional drawbacks, poor extension services, etc. In the First Five Year Plan, agriculture received top priority.¹ The agricultural development programmes included the Extensive Cultivation and the Community Development Programme. The Community Development Projects (each covering 100 villages) were started in 1952. The main objective was to mobilize rural dwellers for labour-intensive agricultural productivity projects supported by certain land reforms, new village co-operatives in which the State would be a partner and national extension services. In the Second Five Year
Plan, only 20 per cent of total outlay went to agriculture, which is lower than the percentage allotted in the First Five Year Plan. The approach to development was based on the selectivity of area and concentration of efforts and it was pursued in the Third Five Year Plan also. Institutional support to development was initiated. Inspite of the efforts made by the government, the chronic food shortage could not be wiped out. The Ford Foundation team visited India during January to April 1959 to suggest measures to overcome food shortages. The team submitted their report ‘India’s Food Crisis and Steps to meet it’. The team had found that there were no insurmountable obstacles to increase production. The team recommended intensive agricultural development through selected areas in the country, which have vast potential for improvement. Based on Ford Foundation’s recommendations the Intensive Agricultural District Programme (IADP) also known as the “Package Programme” was initiated in the year 1960-61. Seven districts were chosen initially for implementation of this programme. Thus there has been a conscious effort to improve agriculture through institutional and agrarian reforms and strengthening of agricultural infrastructure. From 1960-61, the emphasis shifted to measures for increasing agricultural productivity through the adoption of improved method and use of modern inputs. Technology was recognised as a measure to increase agricultural productivity. The IADP with improved seeds, improved farm tools, fertilizers and pesticides demonstrated the most effective way to increase agricultural production by the application of scientific knowledge which could be extended to areas with basic inputs. The seven districts in which the programme was implemented made considerable progress and then it was extended to 15 districts comprising the first group of 7 districts selected in 1960-61 and the second group of eight districts in 1962-63. In 1964-65, 114 districts were chosen for Intensive Agricultural Area Programme (IAAP) which was intensive agricultural development of a selected area.

The “New Strategy” for agricultural development initiated in 1966 called for an effective implementation of IADP and IAAP with the use of High Yielding Varieties. The HYVP assumed crucial importance in the agricultural development strategy. The HYV strategy aims to increase productivity of crops per acre through multiple cropping. The Fourth Plan put the New Strategy as follows: (i) to apply scientific techniques and knowledge of agricultural production at all stages, particularly in the fields, (ii) to select a few areas with assured rainfall and irrigation for concentrated application of a package of practices based on improved varieties of seeds, responsive to heavy doses of fertilizers and availability of inputs and to fix special targets of production of food grains. The first dwarf varieties of wheat were introduced in India by the scientists at the Indian Agricultural Research Institute (IARI), New Delhi in 1962-63 with the co-operation of Dr. Norman Borlaug. The Central Rice Research Institute at Cuttack and Rice Project Directorate at Hyderabad helped to introduce the new high yielding varieties of rice and new farm practices. There are at present 120 rice research stations in the country. The IARI is paying attention to the improvement of nutritional quality of major food grains such as wheat, rice, millet, maize, sorghum and so on. The area under HYVP which was 1.89 million hectares in 1966-67 had increased to 9.2 million hectares on the eve of Fourth Five Year Plan. In 1989-90, the area under HYVP increased to 26.53 million hectares which accounted for 31.6 per cent of the gross cropped area. The area under rice increased from 30 million hectares in 1950-51 to 56 million hectares in 1989-90, the production of rice stood at 20 million tonnes and 59 million tonnes respectively. There has been a tremendous increase in yield from 668 kg. per hectare to 1425 kg. per hectare over the period.

The Sixth Plan’s objectives include speedy implementation of land reforms, spread of new technology to more farmers and regions, using agriculture as a catalyst of income and employment generation in rural areas and promoting scientific, land-water use patterns based on consideration of ecology, energy conservation and employment generation. An overall view of recent trends in area under High Yielding Varieties shows that the annual rate of growth between 1980-81 and 1987-88 was 3.5 per cent. Agricultural production which suffered a setback during 1991-92 due to irregular monsoon in 1991 was expected to record a relatively high growth rate in 1992-93. Foodgrains production was targeted at 183 million tonnes during 1992-93.

The Tenth Five Year Plan (2002-2007) envisages an overall GDP growth rate of 8 per cent per annum. The National Agricultural Policy has envisaged:

- Growth that is based on efficient use of resources and conserves our soil, water and bio-diversity;
- Growth with equity, i.e., growth which is widespread across regions and benefits all farmers;
Growth that is demand-driven and caters to domestic markets as well as maximizes benefits from exports; and

Growth that is sustainable technologically, environmentally and economically;

Growth rate is excess of 4 per cent. The strategy to achieve the desired growth rate, exceeding 4 per cent, in the sector during the Tenth Plan, would be a regionally differentiated one based on agro-climatic conditions and land and water resources of different regions.

Source: District Gazette, Madurai District, No. 5, March 5, 2012-13.

Population of the District: According to the 2001 Census, the total population of the district was about 25.78 lakhs comprising 13.03 lakhs of males and 12.74 lakhs of females and with a density of 689 persons per sq.km. The density of Madurai district is higher than the densities of the State and the Nation. The proportion of women to men is 964 to 1000 in the Madurai district compared to the ratio of 978 to 1000 for the state. The literacy rate is 78.65 per cent. The literates and illiterates were 17.95 lakhs and 7.67 lakhs respectively in 2001. The population is spread over the entire district with 11.27 lakhs and 14.35 lakhs living in the rural and urban areas respectively. The birth rate is 20.6 per 1000 and the mortality rate is 8.4 per 1000, thus resulting in a natural growth rate of 12.2 per 1000.

Source: Annual Credit Plan, Lead Bank (Canara Bank), Madurai, 2008.

In Madurai district, Sedapatti block has the largest area of the total geographical area in the district. In terms of population, Thirupparankundram block has largest and Kallikudi block has smallest population in Madurai district.

**Irrigation:** Irrigation is one of the most fundamental inputs as it helps to relieve agriculture which hitherto was a gamble in monsoon and events like severe famine and semi-famine conditions. Moreover optimum utilization of land and resources can be obtained only with assured water supply and multiple cropping could be undertaken only with better irrigation. Irrigation helps in ‘increasing production per unit of land, particularly when used in appropriate combination with other inputs’. It is a proven fact that output per acre is higher in irrigated lands than in dry lands in India.9

**Fertilizer:** Intensive use of land leads to depletion of nutrients in the soil which has to be replenished with the use of manures and fertilizers to increase soil productivity. Mellor estimated that 53 per cent of the incremental food grains production in India during 1973-74 was attributable to fertilizer use and its contribution was expected to increase to 79 per cent during 1983-84. A Food and Agriculture Organisation (FAO) annual study has described the importance of fertilizer use as a spearhead of agricultural development. Because wherever efforts are made to raise agricultural efficiency and production for expanding populations, more fertilizers and manures have been invariably needed. The Intensive Agricultural District Programme (IADP) and High Yield Variety Programme (HYVP) increased the importance of fertilizers to compensate for the nutritional loss. The use of fertilizers has increased from 1.20 million tonnes in 1966-67 to 5.4 million tonnes in 1988-89.10

**Mechanization:** Farm mechanization is another essential input for increased agricultural productivity. Assured irrigation at appropriate time and quantity, uniform application of fertilizers, seed-bed preparation of a good quality and early harvesting and threshing to sow the next crop with well adapted machinery and implements can only lead to timely farm operations of satisfactory quality. Much-headway is made in this direction in States like Punjab, Haryana, Uttar Pradesh, Andhra Pradesh and Tamil Nadu. Economists differ as to the possible loss and gain of farm mechanization. On the one hand it is opined that “Mechanization therefore contributes to meeting these peak power needs with better land preparation and higher cropping intensity leading to substantially bigger harvests which in turn require more labour during post-harvest slack periods for threshing, storage, transport and even quadruple the number of field operations”.11

**Conclusion**

In the light of this study, this section presents of the details of agriculture. The economy of Madurai district is basically agrarian in character and a vast majority of its population is dependent upon agriculture for income and employment either directly or indirectly. The agricultural sector not only generates employment but also fulfills the food requirements of the growing population.12 the main crops cultivated in Madurai district are paddy, maize, cumbu, ragi, cotton, sugarcane and groundnut. of these crops, paddy and sugarcane are grown under irrigated conditions and the remaining crops are cultivated in irrigated and unirrigated conditions in Madurai district. The farmers in the study area were of the opinion that they could not achieve the maximum yield due to severity of diseases and pest attacks. It is suggested that the farmers should be educated properly to apply the pesticides at the prescribed level and this may be done through the agricultural department officer attached to the panchayat unions. The marketing cost
constitutes a major portion of the consumer price. Hence, Government should encourage the farmers to start co-operative societies in the study area in order to develop a direct link between the wholesalers/retailers, processors and exporters to cut down the marketing cost incurred for lengthy channel. The Government should initiate action to improve market information system and market intelligence. Existing techniques disseminating marketing information should be reviewed. Visual media like television can be used for providing market information to farmers of rural areas. Modern devices such as computers may be employed wherever necessary to make a meaningful estimate of marketable surplus and daily average price.

A Study on Problems Faced by Sipcot Industrial Labours in Reference to Cuddalore District

M. Vetrivel¹, K. Indira¹

¹Assistant Professor, Department of Commerce Department of Commerce, School of Management Studies & Commerce School of Management Studies & Commerce, VELS University, Chennai

Abstract

Welfare measures are having positive and significant effect on productivity of the organization. The welfare facilities will directly influence employee productivity. We are in the track of changing face due to various factors such as liberalization, privatization, globalization and also the recent global economic. So every organization is expected to meet the challenges by reshaping their labour welfare measures. It is found that better working conditions and welfare facilities are made available inside industrial units. However, it is suggested to take the following initiatives for further improvement. Maintenance of the parks and gardens needs to be improved. Safety training must be given periodically and the employees who are unaware of safety aspects must be identified and trained. Training for handling of the safety equipment must be given periodically for the employees.

Keywords: Labours problems, Industrial Units in SIPCOT.

Introduction

Labour plays a very important role in the industrial production of the country. The human resource managers are really concerned with the management of people at work. It is necessary to secure the corporation of labour force, in order to increase production and profit. The corporation of labour force is possible when they are fully satisfied with their employer and the working conditions of the job. In the past, industrialist and the employers believed that their only duty to their workers was to pay them satisfactory wages and salaries. Until recently, the labour force has been viewed as servant and the management as masters. In today’s context, the situation is totally different with the introduction of the concept on human resource management. Psychological researchers convinced them that the workers required something more important. In addition to providing monetary benefits, human treatment given to workers plays a very important role in seeking their cooperation. Human has unique significance in every organization because it makes possible the effective use of human resources along with material resource. Labour or workers welfare activities benefit not only the workers but also the management in the form of greater industrial efficiency.¹ The human resource managers realize that the welfare activities pay a good dividend in the long run, because they contribute a lot to the health, efficiency and moral of the workers.

Statement of the Problem: The researcher has identified the following problems of the study. Industrial units in SIPCOT were facing a number of problems such as poor infrastructural facilities, bad shape of roads, inadequate supply of water, short supply of raw material and power. Because of those problems a large number of units had been either closed or were at the stage of closure. Lack of proper attention to their location, uneconomic land development, delay in allotment of land, lack of housing facilities, lack of coordination among different government department and so on are the other problems.² They must be motivated to change their habits and their way of living since the present day problems require alteration of their behavior which are detrimental to health like pollution, unsafe drinking water, cigarette smoking, consumption of alcoholic liquor and the like. Hence, it is the responsibility of the employer to promote environmental health and thereby prevent diseases.

Objectives of the Study:

1. To find out the problems faced by the workers of select industrial units in SIPCOT, Cuddalore.

¹The human resource managers realize that the welfare activities pay a good dividend in the long run, because they contribute a lot to the health, efficiency and moral of the workers.

²They must be motivated to change their habits and their way of living since the present day problems require alteration of their behavior which are detrimental to health like pollution, unsafe drinking water, cigarette smoking, consumption of alcoholic liquor and the like. Hence, it is the responsibility of the employer to promote environmental health and thereby prevent diseases.
2. To suggest measures to improve the standard of labour welfare measures in the select industrial units in SIPCOT, Cuddalore.

**Hypotheses**

**H01**: “There is no association between problems of the workers and nature of industrial units in SIPCOT”.

**Methodology**: The present study has adopted the field survey method. A sincere effort has been made in the study to prove and analyze the Effectiveness of Labour Welfare Measures among the Selected Groups of Industrial Units in SIPCOT, Cuddalore. The present study is based on survey method; both primary and secondary data are used. All the objectives of the study are achieved by the data collection, analysis and interpretation of both primary and secondary data.

**Sampling Design**: The study is confined to three categories of industrial unit’s namely chemical industry, textile industry and pharmaceutical industry. From each category 200 workers were selected by adopting convenient sampling technique.

**Tools Used for the Study**: The collected data have been consolidated, tabulated and analyzed by using relevant statistical tools like Percentage analysis, Descriptive analysis, One Way ANOVA, t-test, Correlation analysis and Reliability test for Cronbach’s alpha and Kruskal-Wallis Test. The SPSS 20.0 package was utilized for analyzing the data. The interpretation of the study is done by using tables, graphs and charts to give meaningful results. For analyzing the data collected during the investigation, the following statistical values were used according to the relevance of its application.

**Level of Problems Faced by the Workers in the Sipcot Industrial Units:**

**Physiological Problems**: The term ‘Physiological’ would be a positive and dynamic concept. In common parlance, health would imply absence of disease. The World Health Organization has defined health a state of complete physical mental and social well-being and not merely the absence of disease or illness or infirmity. By providing a better healthy working condition employee efficiency and productivity could be increased and the problems of absenteeism also minimized.\(^3\)

Kruskal-Wallis Test has been applied to analyse the significant association between employee health problems and nature of industry in the SIPCOT industrial units and the following null hypothesis has formulated.

**H01**: “There is no association between problems of the workers and nature of the industrial units in SIPCOT”.

**H01 (i)**: “There is no association between physiological problems of the workers and nature of the industrial units in SIPCOT”.

</table>

**Source**: Computed from Primary data

It is clear from the Table: 1 that the urinal infection and headache and cold scored highest mean rank in the textile Industrial Units whereas body pain and back pain scored the highest mean rank in the pharmaceuticals industrial units. The highest mean score of itching of skin, eye problem and blood pressure is in the chemical industrial units. This highest mean rank indicates the level of problems in the respective industrial units.
The calculated chi-square values of headache and cold (25.782), urinal infection (7.666), body pain and back pain (17.576), eye problem (19.844) and blood pressure (17.844) are significant at five per cent level. The value indicates that there is a significant association between physiological problems and nature of industrial units in SIPCOT. Hence, the stated hypothesis “There is no association between physiological problems and nature of industry in SIPCOT industrial units” is rejected. However, the calculated chi-square values of diabetics (5.564) and itching of skin (3.251) are not significant. The value indicates that there is no association between physiological problems and nature of industry in the SIPCOT industrial units. Hence, the stated hypothesis “There is no association between physiological problems and nature of industry in the SIPCOT industrial units” is accepted.

**Psychological Problems:** The psychological well-being of the workforce is an important indicator of healthy industrial operations. Psychological problems are associated with pain and other health outcomes. It also results in occupational injury, absence, and recovery. The psychological problems decrease the ability of the workers. Kruskal-Wallis Test has been applied to analyse the significant association between workers’ psychological problems and nature of companies in the SIPCOT industrial units and the following null hypothesis has formulated. 

\[ Ho1 (ii): \text{There is no association between psychological problems of the workers and nature of industrial units in SIPCOT}. \]

Source: Computed from Primary data

It is clear from the Table: 3 that the depression and frustration variables scored highest mean rank among the workers in the chemical industrial units, whereas angry in the work spot scored highest mean score among the workers in the pharmaceuticals Industrial Units. The workers are lonely has the highest mean rank among the workers in the textile industrial units. This shows that the workers in the respective industrial units have more psychological problems than the other nature of the industry.

a. Kruskal Wallis Test, b. Grouping Variable: Nature of Company

Source: Computed from Primary data *Significant at five per cent level

The calculated chi-square values of depression (32.857), frustration (24.946), angry in work spot (8.307) and free lonely (23.028) are significant at five per cent level. The value indicates that there is a significant association between psychological problems and nature of industrial units in SIPCOT. Hence, the stated hypothesis “There is no significant association between psychological problems and nature of industrial units in SIPCOT” is rejected. However, the calculated chi-square value of forgetfulness (3.607) is not significant. The value indicates that there is no significant association between psychological problems and nature of industrial units in SIPCOT. Hence, the stated hypothesis “There is no significant association between psychological problems and nature of industrial units in SIPCOT” is accepted.

Common Problems

The problems which are not included in the other types of problems are in the common problems. In the present study, the common problems among the respondents have been measured with the help of problems. Kruskal-Wallis Test has been applied to analyse the significant association between workers’ common problems and nature of companies in the SIPCOT industrial units and the following null hypothesis has formulated.\textsuperscript{5}

Ho1 (iii): “There is no association between common problems of the workers and nature of industrial units in SIPCOT”.

It is clear from the Table: 5 that the work injuries, illness, poor supervision and inadequate training have scored the highest mean score among the workers in the chemical industrial units. Whereas heavy work load has scored highest mean score among the workers in the pharmaceuticals Industrial Units. This shows the level of common problems among the workers the Industrial Units.

**Source:** Computed from Primary data *Significant at five per cent level

The calculated chi-square values 37.305, 8.028 and 27.863 to the above respective variables are significant at five per cent level. The value indicate that there is a significant association between common problems and nature of industrial units in SIPCOT. Hence, the stated hypothesis “There is no significant association between common problems and nature of industrial units in SIPCOT” is rejected. However, the calculated chi-square values of pressure at work place (2.114) and risky nature of job (0.958) are not significant.\(^6\) The value indicates that there is no significant association between common problems and nature of industrial units in SIPCOT. Hence, the stated hypothesis “There is no significant association between common problems and nature of industrial units in SIPCOT” is accepted.

**Suggestions of the Study:**

- The industrial units have to improve the hygienic condition in the canteen and also to increase the nutrition food to the workers. The management should provide subsidized food in Canteen to the all workers.
- The workers state that there exists quality of first aid which has to be enhanced in the critical places. It is also suggested that considerable attention should be given for first aid appliances with quality of drugs and necessary medicines.
A safety committee has to be constituted in the SIPCOT industrial units to educate the workers about their responsibility during the hazardous situations. In order to render quality safety service, the members of the safety committee should undergo first aid training.

Adequate safety equipment and provisions shall be provided to maintain industrial peace and harmony.

The workers like to have appropriate, clean and adequate latrines and urinals at the workplace.

**Conclusion**

Welfare measures have positive and significant effect on the productivity of the organisation. The welfare facilities directly influence employee productivity. Once this relationship is established, high employee productivity may lead to high satisfaction. The analysis revealed positive response from almost all the workers. It is found that better working conditions and welfare facilities are made available inside industrial units. However, it is suggested to take the following initiatives for further improvement. Maintenance of parks and gardens needs to be improved. Safety training must be given periodically and the workers who are unaware of safety aspects must be identified and trained. Training for handling of the safety equipment must be given periodically for the workers.

Reducing Fertility Rate: A Threat to Leader States

Meenakshi¹, Tushinder Preet Kaur²

¹Research Scholar, ²Associate Professor, Mittal School of Economics, Lovely Professional University, Phagwara

Abstract

The aim of the study is to analyze the situation of fertility rate in the districts of Punjab. The state is passing through the stage of demographic transition with which the major socio-economic and demographic variables are leaving a strong impact on the demographic dividend. The change in age structure along with the change in literacy, per capita income, female work participation and urbanization, the fertility rate has fallen in leader districts. The laggard districts in the state are still the evidence to high fertility rate. The rural-urban differentials are further widening this gap and changing the total composition of demographic dividend for the years to come. Keeping these factual situations in mind, the study concentrates on analyzing the differentials in the fertility rate in districts of the state, collectively effecting the working segment—the demographic dividend, which could ultimately form a sound platform for the policy makers of the state.

Keywords: Economic Development, Demographic transition, Population, fertility rate, Demographic dividend.

Introduction

Punjab is going through the stage of demographic transition which further is leading to a crucial change in the age structure and demographic dividend of the state. As fertility declines, the proportion of children in proportion to the population of working age decreases, resulting in a lower dependency ratio. This further leads to increase in living standards and the material needs which starts the wave of consumerism to the extent that even a child becomes a source of happiness like many consumer goods. With the rise in per capita capital investments in infrastructure and basic social overhead and the creation of jobs for the available increasing population of working age group, a state or a country can reap the benefits of increased production associated with the decreasing proportion of dependents till the window of the demographic dividend is open. This “demographic bonus” can thus contribute significantly to economic growth and poverty reduction and further will decrease to the proportion to a major fall in the labor force for the years to come. Fertility rate, on the other hand, if stands very low gives a challenge to development programs with very less replacement of the population ultimately leading to decrease in labor force.

The Study Area: Punjab, a name given to the state from Persian dialect means “Five Rivers”, a land of five rivers with the Education Index (0.265) Health Index (0.780063), Income index (0.678) and overall Human Development Index (0.140154) stands on the 6th rank in India. Enjoyed the Green Revolution which brought economic prosperity for the state in the decade of seventies, Punjab shows poor ranking on demographic variable especially gender variable. This is one of the major cause of an adverse environment regarding demographic variables. A very considerable regional diversity in terms of social, economic and demographic characteristics prevails in the state. All the three regions of Punjab had a long history of economic and political happenings. Not only that, there is a striking variations in level of education especially female education, female work participation, dependency ratio, fertility rate, mortality rate, level of employment, per capita income etc. among the various parts of the state, effecting the livelihood of the people. All these indicators have a tendency to further shift the major variables like migration, employment, production, urbanization patterns and overall economic development of the state.

Literature review: The size of the family and the number of children per woman has fallen substantially in many countries over the period, especially after 1960. This trend is broadly favorable for sustainable development. High fertility is associated with increased risk of poor maternal health and mortality. In most of
the cases, women who have several children find it more difficult to work outside the home, thus having fewer opportunities to improve their economic and social status and that of their families\(^1\). With advances in the field of medicine and public health, there would be a further decline in the mortality rate. The higher the income, the higher the age at marriage. Higher age at marriage shortens the reproductive span which in turn, reduces the fertility rate\(^2\). Duza and Baldwin also found that the fertility decline in Tunisia, Sri Lanka and Malaysia could be attributed to rising age at marriage as the result of enhanced educational and occupational opportunities\(^3\).

William Sander studied the fertility behavior in United Nations for four periods and confirmed that economic factors, particularly the earning ability of women affect fertility, an increase in the earning ability of women results in an increase on the price of children thereby reducing fertility\(^4\). Becker in his ‘demand model’ of fertility behavior viewed children as ‘consumer goods’ and as with other goods an increase in income resulted in an increase in the ‘quality’ and ‘quantity’ of children\(^5\). Demographic factors like age at marriage, present family size, gender preference and socioeconomic factors like education, occupation, contraceptive practice, etc. were reported the determinants of desired family size\(^6\). Bogue studied the reasons of fertility decline in Western Europe and explained that education had the powerful impact in explaining the fertility differentials. Female education shows a negative relation with fertility\(^7\). Cleland and Rodriguez also found that the wife’s education had a slightly stronger influence on fertility than husband’s education. They also noted that in countries with low levels of development the impact of primary schooling was initially positive and only became negative among women who had completed a certain level of schooling. Only when primary school was completed did greater fertility control suppressed the loss of traditional birth spacing behavior associated with exposure to modern education\(^8\). Bongaartshas taken these socioeconomic factors as indirect determinants though one or more of the proximate determinants\(^9\). Income and education, being major players among the socio-economic factors. These studies contributed to variations in the level of fertility were essential for initiating planned efforts to control fertility\(^10\).

**Objectives:**

1. To examine the variations in fertility rate in the districts of Punjab
2. To examine the relation of fertility rate with other variables like literacy rate, per capita income, urbanization etc.
3. To analyze the differentials in fertility rate leading to the formation of demographic dividend of Punjab.

**Database and Methodology:** The study is based on secondary data. It is confined to all the districts of the state. It is a comparative analysis conducted on the fertility levels of the districts of Punjab. The statistical tables, techniques like correlation is used. The disparity pattern in fertility is also explained through diagrams. The source of data collection is the Census of Punjab 2001 & 2011, Economic Survey of Government of India and Reports on Gender profile 2011 by National Women Commission, India.

**Fertility rate in Punjab:** Fertility rate has fallen below the level of replacement fertility rate in Punjab. The concept that is widely associated with TFR is replacement level fertility. A TFR of 2.1 replacement fertility since an average of two births is needed to “replace” a mother and father but only if the births survive to reproductive age. An extra 0.1 birth is added to offset the effects of premature death, Higher fertility in developing countries occurs for a number of reasons all of which work synergistically and to varying degrees depending on the country, religion, culture, and socialnorms. These reasons include but are not limited as lack of availability to affordable family planning, religious restrictions on the use of family planning, a desire for more children as labor supply and for security in old age, a desire for one or more children of a particular gender, female literacy, and female participation in the workforce.

The change in the fertility rate of Punjab from 1971-2010 taking into consideration two major economically active phases of Punjab; the post green revolution era and the post reform era. The urban areas of Punjab had achieved the level of replacement fertility rate of 2.1 in 1998 while the state had reached into that phase in 2005. The rural urban gap of Punjab was 1.1 in 1971 and this gap has reduced to 0.1 in 2011. Many of the districts in Punjab had practiced positively towards gender statistics so as to make the land more comfortable for women.
The state has observed a sharp fall in the fertility rate after reform period with changing age structure, increasing working force including women, per capita productive investments, rising standard of living with changing life styles and higher per capita incomes, urbanization and positively responding gender variables.

Data source: Census of India-2001, 2011

Punjab is not only the ‘Basket of India’ but also the supplier of labor force to foreign lands, working on all types of manual projects outside which had led to the increase in the level of income of an average family. The fertility rate is less in SAS Nagar, Jalandhar, Kapurthala and Ludhiana and high in Ferozepur, Amritsar, Muktsar and Tarn Taran. On the contrary the unequal difference in rural to urban gap lies maximum in Amritsar, Ferozepur, Rupnagar and Patiala which shows that the rural areas of these districts have more fertility rate. Table -1 shows a percentage change in rural and urban literacy from 2001-11. The urban literacy is more than the rural literacy due to the basic infrastructural facilities available in the towns and cities. The leaders in rural and urban female literacy are Hoshiarpur, Sahibzada Ajit Singh Nagar, Gurdaspur and laggards are Mansa, Muktsar, Ferozepur and Sangrur.

TarnTaran, Moga, Ferozepur and Mansa observed a high fertility rate while Jalandhar, Hoshiarpur and Ludhiana have the low rate. The districts with the lower fertility rate and urbanization index have a strong impact on family structures and family health.

Data source Census of India-2001 and 2011

**Correlation with other variables:** If we look at table no 2 we find five variables linked to fertility rate. The very first variable is literacy rate which is strongly and inversely related to fertility rate. The other variable is per capita level of income which somehow not so strongly but inversely related to fertility rate. The fertility rate is higher in low as well as high income groups as Punjab is the land based economy with a preference to a baby boy who the social structure accepts as the real owner of land.

The third variable is urbanization which is leading to increase in bearing a child further leading to fall in fertility rate. The percentage of increasing young population and falling support ratio has a negative correlation with fertility rate.

**Correlation with gender variables:** The table 3 representing the gender variables especially the female literacy rate and the economically active rate of women has an inverse relation with fertility rate.

Table 3: District wise analysis of fertility rate and other variables-2011

</tr>
</tbody>
</table>
The differentials of gender gap are also less in leader districts with a strong positive linkage while rural urban differential have negative correlation with fertility rate, it is because the low differential of rural and urban can lead to even growth.

Conclusion

The fertility rate is one of the key variables which acts as a driving force in a developing economy. It has an impact on the growth rate of population leading drastic fall in labor supply further leading to inter and intra-regional migrations. The district wise study clearly deducts a negative correlation of literacy rate, urbanization, gender gap in literacy rate, female work participation and young population on fertility rate and the growth of an economy. Jalandhar, Sahibzada Ajit Singh Nagar and Hoshiarpur, are the front liners in declining fertility rate esp. the urban line of the districts. On the other hand, Mansa, Muktsar and Tarn Taran lag behind in urbanization, literacy rate, female work participation, female education and ultimately facing a higher fertility rate. The regional imbalance in the state is observed among different districts which makes an unequal regional zone. The state is marching ahead in production and infrastructural sectors but needs to concentrate on the wave of the demographic dividend and enjoy the window of opportunity before it closes down. To conclude with the district analysis of Punjab in fertility rate, the differentials in leaders and laggard districts should be taken into consideration so as to evenly grow with this demographic wave.

A Qualitative Study to Assess Selected Psychosocial Experiences of Clients Admitted in Step Down Wards at Selected Hospitals Hyderabad, A.P.

Beulah Jasmine Rao

Beulah Jasmine Rao, Assistant Professor, Department of Medical Surgical Nursing, School of Nursing Science and Research, Sharda University, Greater Noida

Abstract

Background of the Study: One of the most upsetting situations one could ever experience in one’s life is a sudden phone call that summons you to the hospital where a loved one has been admitted to the intensive care unit. In addition to high level of worry and upset, one finds them self into a strange environment of scary machines, unfamiliar devices. People with life threatening injuries and illnesses need critical care, critical care involves close constant attention by a team of specially trained health professionals; it usually takes place in an intensive care unit (ICU) or trauma center. Problems that might need critical care treatment include complications from surgery, accidents, infections, and severe breathing problems.

Problem statement: A Qualitative Study To Assess Selected Psychosocial Experiences of Clients Admitted In Step Down Wards At Selected Hospitals Hyderabad, A.P.

Objectives:

• To assess psychosocial experiences of patients admitted in step down wards.
• To analyze psychosocial problems according to their intensity.

Keywords: Psychosocial problems, psycho social experiences, depression, anxiety, step down wards.

Introduction

One of the most upsetting situations one could ever experience in one’s life is a sudden phone call that summons you to the hospital where a loved one has been admitted to the intensive care unit. In addition to high level of worry and upset, one finds them self into a strange environment of scary machines, unfamiliar devices. People with life threatening injuries and illnesses need critical care, critical care involves close constant attention by a team of specially trained health professionals; it usually takes place in an intensive care unit (ICU) or trauma center. Problems that might need critical care treatment include complications from surgery, accidents, infections, and severe breathing problems.

Monitors, intravenous (IV) tubes, feeding tubes, catheters, ventilators and other equipment are common in critical care units. These can sustain life but can also increase the risk of infection, while patients recover, and communication with health care providers and family members is an important part of making end-of-life-decisions. Intensive care unit is a very intense area and can create a great deal of tension and stress for patients and families, even though the ICU can be a frightening place and constitute a terrible time for family and the client who worry about the well being of their loved one, it is also a place of healing, because ICU is altogether combined with the experiences of patients recovering from and coming to terms with a critical illness.

And patients admitted to an intensive care unit present an unexpected life threatening condition generally with the expectation of those admitted after scheduled surgery, these patients will remain in their critical condition for various lengths of time and will need several types of life support, they will also receive various sedatives and analgesics to ensure the compliance with ventilation to induce some effect of comfort, as the event that takes these critical patients to
the ICU was unexpected, most patients will not be aware of their condition until late in their ICU stay and some of them only after discharge to the ward, however during the ICU stay they continue to have an emotional life, in a mixture of dreams, delusions and emotional experiences related to real events.  

Although various degrees of anxiety or depression that might delay and impair their recovery have been critically described in illness survivors, little is known about this and other neuropsychological sequel of critical illness, cognitive impairment and memory disturbances are those more frequently known and also it leads to post traumatic stress disorder (PTSD), these all depend on the previous health state more and on the existence of co-morbidities and on the aggressiveness suffered during the critical illness period.  

Not only these but neuropsychological and psychosocial sequel depend on the aggressiveness and also on the ability of patients to deal with the memories they retain due to their stay from that period, these memories may be of two types, factual memories and delusional memories which includes nightmares, hallucinations, paranoid delusional memories and dreams.  

Material and Method

Research approach: In the present study the “Qualitative approach was used to assess the selected psychosocial experiences of clients admitted in step down wards at selected hospitals, Hyderabad, A.P.”

Research Design: The research design is concerned with the overall frame work for conducting the Study. Descriptive design with narrative analysis was adopted for the present Study.

Variables: A variable is an attribute to a person or object that varies that it takes on different values.

Back ground Variable: In the study the back ground variables are Age, Gender, Occupation, Educational status, Income, Religion, Marital status, History of chronic/severe illness, Previous exposure of hospitalization, and Stay in the hospital, & clients with the history of major surgery.

Setting: Based on the setting and availability of the sample, the present study was conducted at MNR Hospitals, Sangareddy, and Andhra Pradesh.

Population: Population is the entire aggregation of cases that meet a designed set of criteria Politand Hungler (1999).

The population in this study is termed as accessible population.

Target Population: It refers to the elements, people, objects to which the investigator wants to generalize the research findings. In the present study the target population of the study was clients in step down wards.

Accessible Population: Accessible population refers to the aggregate of cases which confirm to the designed criteria and which is accessible to the researcher as a pool of subjects or objects. In the present study the population consists of clients admitted in step down wards at selected hospitals, Hyderabad, A.P.”

Sample and Sample Size: The sample will be clients admitted in step down wards at selected hospitals, Hyderabad, A.P.” and the sample size of the present study is 50.

Sampling Technique: Non probability convenience sampling technique was adopted for the present study.

Criteria for Selecting the Sample

Inclusion Criteria:

Clients who has stable condition
Clients who are able to communicate
Clients who are willing to participate
Clients who are admitted in step down units for not less than 5 days.
Clients who are able to understand Telugu & English.

Exclusion Criteria: Clients who are in highly unstable condition.

Findings:

Results

The present study selected to assess the selected psychosocial experiences among clients admitted in step down wards was effective in classifying the psychosocial problems among which Major psychosocial problem was Depression, Moderate psychosocial problem was Anxiety, and pain, psychosis and sleep disturbances were
considered as mild psycho social problems when tested using two tailed test and the Total estimated maximum score was 2500 and out of which depression constitutes for 1786 score, anxiety constitutes for score of 1575, whereas pain score is 1364, and sleep disturbances and psychosis scores were 1263 and 503 respectively. Hence descriptively and inferentially the study is reliable at 0.01 level of significance.

Conclusion

The present study attempted to evaluate the selected psychosocial experiences showed significant statistics to categorize Depression as major, Anxiety as moderate and Pain as mild psycho social experiences among clients admitted in step down wards using Karl Pearson co-efficient and cron Bach formula. Hence it is concluded that the nurses and the health care providers must identify psycho social problems and device method which makes the client environment less stressful thereby ensuring provision of quality nursing care to all the clients during their stay in the hospital. It is concluded that the data generated by qualitative interviews could be important to nurses & clinicians working in step down wards & ICU in improving the psychological status and psychosocial recovery of the clients. It is concluded that this study gives a reassurance when proper education is provided to the clients in step down wards during their stay in terms of an important service. It is concluded that there are several aspects of care that deserves further examination by service providers where they are leading factors for psycho social maladjustment for the clients admitted I step down wards.

Conflict of Interest: There is no conflict.

Cost Analysis of Intra Operative Anaesthesia Services in Tertiary Care Hospital

C. Lakshmi Venkatesh¹, Aileen J.², Narendranath V³

¹Post-graduate Student, Department of Hospital Administration, Ramaiah University of Applied Sciences, Gnanagangothri Campus, ²Assistant Professor, Department of Hospital Administration, Ramaiah University of Applied Sciences, Gnanagangothri Campus, ³Chief Hospital administrator, Ramaiah Medical College Hospital, New BEL Road, MSR Nagar, Bangalore

Abstract

Anaesthesia services was gradually skyed high mainly because of patient population, with the increasing patient population, severe financial burden associate with care accelerate throughout the universe. At present, hospitals will provide many services under single shelf. Large service organization will consider the high number of personnel which comprises of capital intensive nature of business. Various complexities will be necessitating for hospital management which will include robust costing system. This paper investigates and compares the how much cost incurred for twelve combinations of seven anaesthetic agents in intra operative services at Tertiary care Hospital. So the study consider and compare the twelve combinations of seven anaesthetic drugs (Propofol, Thiopentone, Isoflurane, Sevoflurane, Vecuronium, Atracurium, Cis-atracurium) which Anaesthesiologists usually prefer. From the study we found that hospital can save the 91.2% of Propofol yearly expenditure by replace with Thiopentone as an induction agent. At same consumption rate hospital can exclude the 77% of yearly expenditure of Sevoflurane with replacing the Isoflurane for intra-operative maintenance. Hospital can cut down the 63% of cis-atracurium yearly expenditure by replacing the relaxant Vecuronium. The study concluded that Thiopentone, plus Vecuronium plus Isoflurane highly preferred combination by Anaesthesiologists among all eleven combinations. This was mainly due to the fact that these combinations costs were very lower compared to other drugs and these combinations influenced the patients to recover from the surgery at very fast which in turn decrement the discharge time availed by the patients which sky-high hospitals to take care more number of patients at hospitals. Hence the hospitals can maintain efficiency at intra operative services, and the cost of drugs included in total surgery cost of patients. In addition to the overhead information assist the top management while making a strategic plan and decision-making activities while preferring drugs. As a result Changes in combination of drugs affect the entire process of intra operative services at Tertiary care hospitals can be precisely revealed.

Keywords: Cost analysis, Cost effective analysis, Anesthesia services, Intraoperative anaesthesia costing, Intraoperative anaesthetic agents.

Introduction

Health care center which is otherwise known as clinics which has a group of general medical professionals and nurses whose intention is to provide health care services to the people. The primary importance is to provide incessant and comprehensive care to the patients. In health care center, there are some of the patients who need instant service who admit in Intensive Care Unit (ICU). The patients who are at ICU face unconsciousness situation have been induce or maintain anaesthesia services for surgical treatment when they will be at operating room. An anaesthesia service includes General Anaesthesia (GA), Spinal Anaesthesia (SA) and Sedation or local anaesthesia for monitoring patients for managing anaesthesia caution. Anaesthesiologists role is to judge the present situation and provide pain relief as per the current status. Perioperative anaesthesia services comprises of making and keeping patients to be very much comfortable before, during and after surgery, monitoring body functions, address during
surgery and manage emergence of pain during surgery. Hence, the hospitals starts utilizing resources in modern era which will be procuring equipment for operation theatres, anesthesiologists, ICU, cath lab and pathology lab which will constitute doctor times will accelerate the cost incurred for availing the services. Therefore, patients constitute as a primary element for hospital treatment cost. It will be essential for health care center to get a program to control the expenses, while at precisely the same time they will offer top quality service to the patients\textsuperscript{8}. costing comprises of activities like classifying, recording and allocation of expenses for the purpose of acquiring services and presented the data in table or graph format which assist the management to make decision accordingly. Health care services can develop a costing system for anaesthesia services on the basis of cost data, statement and reports preparation can assist the management in making strategic plan to meet hospital needs. The primary purpose will be assembling the information regarding anaesthesia combination of medicines which Anesthesiologists prefer and analyzed in a way which can only help in strategizing, control and decision making regarding the anaesthesia services. The main objective of using cost analysis is to benefit the cost of services, investigate the cost of every activity associate with hospital services, reduce the cost and control the cost involved in it. Hence the researcher makes a standardized care in a changing health care system, to investigate the cost associate with the preoperative anesthesia services without compromising quality.

**Literature Review:** The aim of the conducted study was that ascertaining interventions that anaesthesiologists generate in decreasing the total costs involved in Post-operative anaesthesia care unit (PACU). The author considered samples as patients who underwent ambulatory surgery at Tertiary care center. Findings of the study revealed that using drugs like Propofol reduce PACU costs at the same time it increases early discharge of patients at hospitals. Hence, it concludes that major factor of PACU cost is distribution of admission but anaesthesiologists have a small control over it\textsuperscript{10}.

Revealed that intention of various health care services was on high profits. To accelerate the costs, finding out the actual cost involved in providing proportion of anaesthesia and how much it was actually cost was taken into account. Cost to charge ratio applied for all departments which revealed an outcome as differentiation identified among all departments. It further stated that there was a disparity of charges among patients in health care services. Hence, there is no relationship among cost and charges of services at hospital\textsuperscript{14}.

Stated that author made an investigation in computerized database which was maintained at operation theatre. The author estimated the costs incurred at General Anaesthesia especially for varicose vein and inguinal hernia surgery. He considered the anaesthetic drugs, procedure, and usage of drugs and so on. It was identified that merely twenty five percent of cost included drugs and disposables cost of anaesthetic. Further it stated that when comparing anaesthetic service with regional anaesthesia, 5 min longer to provide service whereas 10 min shorter for regional anesthesia especially for varicose vein surgery. Finally it concluded that staff costs depended on time spent for patients and then provision of a field block and sedation for inguinal hernia repair costs cheaper than regional anaesthesia\textsuperscript{13}.

Stated the author investigated the cost effectiveness of General Anaesthesia techniques for hip replacement surgery and then how to reduce the cost also investigated. The author investigated approaches for induction and maintenance. The findings stated that price tag on I.V strategy higher than inhaling the drugs at the same time maximum cost was belong to anaesthesiologist. At last it concluded that reduction in cost determined by means of considering the total price of GA procedure\textsuperscript{9}.

The primary focus was on investigating three method of General Anaesthesia in Gynecology department. While underwent Gynecological procedure, General Anaesthesia grouped into three groups as group 1, V and C among sixty patients. Findings revealed that decrement cost at group 1, post-operative nausea and vomiting accelerate at group C, shivering and requirement of analgesics were high at group V. Hence, it concluded that right combination of isoflurane and fentanyl or TIVA (Total Intravenous Anaesthesia) or both can offer services in a satisfactory manner \textsuperscript{5}.

**Materials and Method**

The present time driven activity based costing study was conducted in a tertiary care hospital, Bangalore. After getting prior approval from the hospital Ethical committee, the researcher proceeded with investigation which paved the way for them to know about anaesthesiologists and their utilization of combination of drugs.
The patients were randomly selected among who fall under ASA (American Society of Anaesthesiologists) grade I and ASA Grade II. Samples collected based on the availability of the Anaesthesiologist and General anaesthesia cases. Drugs included for induction (Propofol, Thiopentone,), Relexant (Vecuronium, Atracurium, Cisatracurium), Inhalation (Isoflurane, Sevoflurane). Based on above drugs, Anaesthesiologists had a different combination of utilization of drugs taken into account for intra operative services at Tertiary hospital. This includes

- Propofol+Isoflurane+Atracurium,
- Propofol+Sevoflurane+Atracurium,
- Thiopentone+Isoflurane+Atracurium,
- Thiopentone+Sevoflurane+Atracurium
- Propofol+Isoflurane+Vecuronium
- Propofol+Sevoflurane+Vecuronium,
- Thiopentone+Isoflurane+Vecuronium
- Thiopentone+Sevoflurane+Vecuronium
- Propofol+Isoflurane+Cis-atracurium
- Propofol+Isoflurane+Cis-atracurium
- Thiopentone+Isoflurane+Cis-atracurium
- Thiopentone+Sevoflurane+Cis-atracurium

The researcher also made an effort to know the anaesthesiologists perception on Induction, Inhalational and Relaxation drugs. For this researcher collected anaesthesiologists perception among one tertiary care hospital anaesthesiologists through a validated structured questionnaire.

**Measuring Tools:** Below were the statistical tools used to test the various combinations of drugs and Anaesthesiologists preference included

- Kruskal Wallis test
- Cronbach Alpha
- Tukey HSD

**Results and Discussion**

**Kruskal Wallis Test:** This method is used to check the relationship of two or more variables. We here have taken different combination of cost and average quantity consumption and checking the relationship between them

<table>

<td></td>
<td></td>
</tr>
</tbody>
</table>

A Kruskal-Wallis H test showed that there was a statistically significant difference in anaesthesia drugs p = 0.004 which was lower than 0.05 hence null rejected and alternate accepted, with a lowest mean score for Thiopentone plus Isoflurane plus Vecuronium 385.333.

Thiopentone+Isoflurane+Vecuronium are best because it had a mean value of 172.33 and p value as 0.02, compared to all combinations this is most reliable.

From the study we found that hospital can save the 91.2% of Propofol yearly expenditure by replace with Thiopentone as an induction agent. At same consumption rate hospital can exclude the 77% of yearly expenditure of Sevoflurane with replacing the Isoflurane for intra-operative maintenance. Hospital can cut down the 63% of cis-atracurium yearly expenditure by replacing the relaxant Vecuronium.

So, Thiopentone induction, Isoflurane inhalation anaesthesia and Vecuronium’s muscle relaxation saves the hospital more money compared to the other induction, inhalationalans relaxant drugs. The study concluded that Thiopentone, plus Vecuronium plus Isoflurane highly preferred combination by Anaesthesiologists among all eleven combinations.

**Survey among anaesthesiologists on Thiopentone and Isoflurane usage:**

![Number of anaesthetists preferred Thiopentone and Isoflurane](image-url)
In the above graph Among twelve anaesthesiologists three anaesthesiologists are strongly agreeing and 5 anaesthetists are agreeing for Thiopentone induction and three anaesthesiologists are dis-agree and one anaesthesiologist is strongly disagreeing the Thiopentone induction.

Six anaesthetists are strongly agreeing and six anaesthetists are agreeing the Isoflurane maintenance among twelve anaesthetists.

Discussion

With the help of cost analysis, it identified that the hospital can save the 91.2% of Propofol yearly expenditure by replacing Thiopentone as an induction agent. Propofol induction cost is high compared to the Thiopentone induction. According to the study intravenous anaesthesia is costlier than inhalational anaesthesia. At same consumption rate hospital can exclude the 77% of yearly expenditure of Sevoflurane with replacing the Isoflurane for intra-operative maintenance. Sevoflurane is very costlier agent than the Isoflurane. The price of sevoflurane is almost double than the Isoflurane. Hospital can cut down the 63% of cis-atracurium yearly expenditure by replacing the relaxant Vecuronium. Cis-atracurium price is slightly high compared with other relaxants. Hence from the above, it revealed that drugs cost least were Thiopentone, Isoflurane, and Vecuronium which will benefit anaesthesiologists and also hospital. Anaesthesiologists had a perception to utilize the drugs which had a rapid recovery of patients from operating room at the same time which had a low cost in nature. Finally, their preference was on Thiopentone, Isoflurane, and Vecuronium.

According to the study done in 1995 patients who underwent laproscopic gynecologic surgery inhaled Propofol saved cost of drugs, surgery cost and anaesthesia cost and recovery time whereas drugs like thiopentone induction cost lower and speedy recovery was not possible. Hence the author recommended Propofol drug. Tuskey HSD reveals that drugs including induction and extubation of anaesthetists whereas excluding induction and extubation have higher in using Thiopentone plus Isoflurane plus Vecuronium among anaesthesiologists.

As per the study, it revealed that Propofol usage at PACU, made the patients to recover soon at hospital. The present study depicted that highest number of Anaesthesiologists stated 20% of drug cost was included at total surgery cost.

According to the study (2014), comparison made between various combinations of drugs like ketamine, midazolam and Propofol and finally revealed that these combinations cost higher in group 3 (500 mg of propofol) whereas lower in group 1 (200 mg of propofol). The present study depicted that high number of anaesthesiologists preferred propofol induction due to its faster recovery. Using Excel sheet to code the data then it adopted percentage method to reveal the results of how the perception of Anaesthetist in providing services at hospital. Cronbach Alpha implemented in assessing how reliable the questions are framed in investigating the Anaesthesiologist perception at hospital. Then TUKEY HSD used to make a comparison between groups and identify which is best.

In this study we included only two induction drugs, two inhalational agents and three Relaxants with twelve possible combinations. We included only direct costs of the drugs; we excluded indirect cost and anaesthetists charges. Opinion Survey is limited for study conducted hospital.

Hospital should adopt the Thiopentone + Isoflurane + Vecuronium combination for anaesthesia practice, so hospital can save the money.

Conclusion

The researcher made an effort to investigate how much cost incurred for the anaesthesia agents in intra-operative anaesthesia services and to recommend the drugs which benefit the hospital in terms of consumption and cost. From the study among all drugs, Thiopentone for induction, Isoflurane for inhalation and Vecuronium for relaxation recommended. These drugs costs very lower compared to other cost and at the same time effect derived from the drugs really good. Hence above combination accelerate the hospital efficiency for intra operative services.

Prediction of Heart Diseases Using Hayes Process Macro Serial Mediation Model 6

Ruchi Mittal

Professor, Chitkara University Institute of Engineering and Technology, Chitkara University, Punjab, India

Abstract

Heart diseases are among one of the most common reasons of fatalities in the modern world due to a variety of life style and environmental factors. This study deals with the prediction of heart diseases in a population based on the relation between age and the maximum heart rate of a set of individuals. This relationship is also assessed with the introduction of two mediators namely resting blood pressure and cholesterol. The dataset for the study is the Cleveland dataset which is used by machine learning researchers. The data was subject to serial mediation Model 6 test based on Andrew Hayes PROCESS data analysis technique. The model test results have been presented and interpreted in light of the model test results.

Keywords: Heart diseases; Age; Maximum Heart Rate; Cholesterol; Resting Blood Pressure; PROCESS technique; Mediation.

Introduction

Data mining techniques are increasingly being practiced in almost every area which is based on finding knowledge from existing data to use it to strengthen the decision making of an organization. Almost every field, now days, is exploiting the advantage of data mining and machine learning algorithms to make the best use of the huge amount to data getting collected over the years in order to make appropriate strategies for the organization. Data Mining is a multidisciplinary approach which involves the statisticians, business analysts and data scientists to have a 360 degree view of the data and then draw some meaningful conclusions out of it by applying different techniques such as clustering, classification, prediction, and association analysis etc.

Healthcare is the backbone of every country. Healthcare covers detailed process of the diagnosis, treatment and prevention of disease, injury and other physical and mental impairments in humans. Healthcare, as an industry, is showing tremendous growth globally and due to increasing digitalization of health services, the healthcare industry has become a very significant source of data. The organizations around the globe can grow only when its people are happy and healthy, however, with the growing age of people, health needs become critical and require more and immediate attention. Therefore, a well managed healthcare system is the need of every organization to prevent its people from any health hazard, which will not only increase the efficiency of people but will also contribute to the growth of organizations and the nation. Healthcare programs are generating a lot of data about patients, symptoms, diseases, diagnosis, and treatment which is a waste if cannot be carefully analyzed in time. Healthcare organizations can use this data and can apply data mining functionalities to make predictions about the diseases, their symptoms, causes, and treatment and also can device the policies that can be offered. Thus, application of data mining has huge potential in healthcare segment provided that healthcare professionals develop their competency in the field. Healthcare is an important societal issue wherein the application of data mining and machine learning algorithms can greatly and directly impact the lives of people. Medical field, like other areas has been collecting a huge volume of data related to patient’s health record, their symptoms and the probability of a particular disease and the possible prescriptions. A lot of machine learning algorithms, such as classification through decision tree, SVM, Bayesian method, neural networks; regression; clustering; and association rule mining have already been explored in this area to identify patterns and making predictions in medical data. Researchers are using various machine learning tools and successfully making the descriptive and predictive models which can be deployed to effectively manage the healthcare segment with better accuracy and low error rate. These
tools not only include the techniques of modeling and making right predictions but also have the processes to handle various inconsistencies and prepare the data ready to be used for analysis.

**Review of Literature:** Previous studies³ outlined the importance of data mining in healthcare to strategize this domain by not only designing more effective recommendation systems, policies and profiles of the patients diagnosed with certain diseases, but also helps in identification and detection of diseases. The author reviewed the previous work in healthcare and the use of various tools and technique of data mining in this sector to optimize the cost and to improve the decision making. Another study summarized the review of data mining functions and techniques in healthcare and concluded that no one method in this sector is sufficient enough to address the issues in this sector and therefore, a hybrid approach should be followed to have better accuracy and improved predictions in medical diagnosis.⁴

One study⁵ noticed the need of data mining in heart diseases because of the growing rate of patients and the death rate due to this ailment. The study attempted to draw meaningful knowledge out of the huge and complex data pertaining to the heart diseases by using various data mining classification algorithms. The experiment was conducted to compare the performance of difference classification algorithms and judged that Naïve Bayes method gives maximum accuracy. Various data mining classification and prediction techniques were applied such as decision tree, neural networks, SVM, and logistics regression for predictive modeling on approximately 120000 instances to uncover the survivability of prostate cancer. Author concluded the study mentioning that accuracy of SVM algorithm is giving maximum accuracy in the given data. Author also discussed several issues in data understanding and data preparation that should be carefully considered for improved results of predictive modeling.⁶

In a Heart Disease Prediction Model using SVM-Decision Trees-Logistic Regression (SDL) the authors proposed a framework including a union of regression, SVM, and decision tree in order to correctly anticipate the heart disease. The author followed rule-based approach to collate the validity of different mentioned data mining algorithms to improve the effectiveness of the predictive model.⁷ Five different data mining algorithms were compared to study whether the customer will clear his debts or not? The study was conducted on large data samples and the results indicate that the neural network, regression and mixed approach for modeling are more accurate in prediction, however, in terms of interpretation of the results, decision tree and regression are the best as in decision tree, rules are generated which can easily be understood and in regression analysis, the significance of the attributes can be easily observed, however, the other schemes such as neural networks and memory-based reasoning, the interpretation of the analysis is complicated.⁸

A previous study⁹ identified the need of controlling hospital infections using data mining for public health supervision. The author then used the association rule mining approach and developed a unique system to achieve the objective. Author came up with some interesting rules that can really benefit the hospital system in controlling the infection.

Thus, in view of the extant literature, previous research highlights the importance of healthcare and the role played by data analytics in better prediction of diseases.

Keeping in consideration previous research, the aim of this study is to predict the likelihood of heart diseases in a population based on the relation between age and the maximum heart rate of a set of individuals. This relationship further assessed with the introduction of two mediators namely resting blood pressure and cholesterol. Specifically, the following sequential equation is tested:

\[ X \rightarrow M_1 \rightarrow M_2 \rightarrow Y \]

**Method and Tools**

The dataset was procured from the open access Kaggle database. The dataset is called the Cleveland database which is popular with machine learning researchers and consists of 14 attributes. This study used four attributes namely:

- Age
- Serum cholesterol in mg/dl
- Resting blood pressure
- Maximum heart rate achieved

Only the complete data (pertaining to the four select attributes) consisting of 324 elements (respondents) was selected from the entire dataset consisting of 456 elements (respondents).
The PROCESS Macro SPSS was the tool applied to the research model based on the dataset. PROCESS technique was developed by Hayes. \(^{10}\) PROCESS is a “macro” that can be installed in SPSS or SAS software and it can perform all the mediation, moderation and relationship testing same as (SEM) Structural Equation Modeling. \(^{11}\) Although, the developer of the PROCESS macro pin point certain benefits over SEM. The first benefit is ease of use as PROCESS requires less coding and it can generate same results as render by SEM. Another, advantage of PROCESS is that it estimates each equation of the regression model separately whereas in SEM all the equations are calculated simultaneously using iteration through maximum likelihood estimation method. \(^{11}\) In the current study, the researchers have used model 6 (two mediators) (Hayes, 2013). In this model, we have one independent variable one dependent variable and two mediators between the relationship describing independent and dependent variable (i.e. \(X \rightarrow M_1 \rightarrow M_2 \rightarrow Y\)). Where, \(X\) is the independent variable (Age of the respondent), \(M_1\) is the first mediator (Cholesterol level of the respondents), \(M_2\) is the second mediator (resting blood pressure) and \(Y\) is the dependent variable (maximum heart rate of the respondent). In such as model we can test the direct relationship between input and output variables and at the same time we can test the indirect relationship between these variables. Here we can test the mediating effect of cholesterol level of the respondents on the relationship between age of the respondents and maximum heart rate of the respondent. Also we can test the mediating effect of blood pressure reading of the respondents on the relationship between age of the respondents and maximum heart rate of the respondent. We can also test whether there is a serial mediation effect of blood pressure reading of the respondents and cholesterol level of the respondents on the relationship between age of the respondents and maximum heart rate of the respondent.

*********** DIRECT AND INDIRECT EFFECTS ***********
Interpretation: An observation of figure 2, table 1 and table 2 shows that age is significantly and positively related to resting BP, which means that an increase in age leads to an increase in resting BP. Similarly, age is significantly negatively related to maximum heart rate, which means that an increase in age leads to a reduction in heart rate. No significant relationship was discovered between resting BP and maximum heart rate.

An observation of figure 3, table 3 and table 4 shows that there is no significant relationship between age and cholesterol. However, there is a significant negative relationship (at 90% confidence level) between cholesterol and maximum heart rate. This implies that an increase in cholesterol leads to a reduction in maximum heart rate.

The outcome of the PROCESS procedure is based on the relationships hypothesised as per figure-1.

For the outcome variable cholesterol, age is not a significant predictor of cholesterol. For the outcome variable resting blood pressure, age is a significant predictor of resting BP but cholesterol is not a significant predictor of resting BP. For the outcome variable maximum heart rate, age is a significant predictor (inverse relationship), cholesterol is a significant predictor at 90% confidence level (inverse relationship) while resting BP has no significant predictive power of maximum heart rate.

Observing the output of the direct and indirect effects, the direct effect of X -> Y is age has a significant effect on maximum heart rate.

For indirect effects, there is no evidence of any mediation effect of $M_1$ or $M_2$ on the relationship between X and Y.

Conclusion

The study is based on the Cleveland heart diseases dataset which, in this study, was subject to direct tests between two variables namely age and maximum heart rate and the indirect tests between these two variables where cholesterol ($M_1$) and resting blood pressure ($M_2$) were the mediating variables. The mediation model (indirect) was not significant whereas the direct relationship between age (X) and maximum heart rate (Y) was significant. Age is also significantly related with resting blood pressure (direct relationship). A significant relationship was also discovered between cholesterol and maximum heart rate. However, no significant relationship was found between (1) resting blood pressure and maximum heart rate and (2) between age and cholesterol. The model testing was done using PROCESS Model 6 serial mediation technique.

Availability of Data and Materials: The data generated during the research are available from the corresponding author on reasonable request.

Funding: The author received no financial support for the research, authorship, and/or publication of this article.

Abstract

Staphylococci are ordinary microorganisms found mostly on the skin and nose of 20 to 30% of healthy adults. They are generally harmless, however are harmful if they enter the blood system. They penetrate skin defenses and cause staphylococcal infections. Staphylococcus Aureus is the most common types of staphylococcus that causes staphylococcal infections. MRSA is a type of staphylococcus bacteria that is resistant to antibiotics called beta-lactams antibiotics and other more common antibiotics, for example, penicillin and oxacillin. MRSA causes infections in different parts of the body. It is important to get care for MRSA infections as soon as possible. If left untreated, MRSA can quickly spread throughout the body and cause life-threatening problems. Health care workers who come into contact with MRSA patients should maintain high standards of hygiene and take extra care while treating those patients.

Keywords: Information booklet, Methicillin-resistant Staphylococcus aureus, Staff Nurses.

Introduction

Antibiotics are type of antimicrobial drug which are also called as antibacterials, that prevents growth of bacterial infections. Antibiotic is the one which kill and reduce the growth of bacteria.1

Though antibiotics are used to prevent the bacterial infection, some of these bacteria can continue to live. These existing bacteria have the capacity to fight back against the antibiotics. If the bacteria continue to resist the antibiotics, it will no more prevent and kill the bacteria. So this indicates that the bacteria are stronger. It can easily increase its number and will cause infection to others. By this, many antibiotics are unable to resist the MRSA.

In recent years the resistance against the antibiotics increased because, people are not consuming prescribed amount of antibiotics. They just skip it and because of this the bacteria continues to live and develop a resistance. These negligence give space for bacteria to grow and it leads the bacteria to fight against the antibiotics which is used to prevent the bacteria.2

Staphylococcus aureus is a gram-positive bacterium normally seen on the skin and mucous membranes in most of the grownups and it seems to be less danger. Even though, S. Aureus can cause illness, numerous antibiotics namely cephalosporins, tetracycline can treat this bacteria.3

MRSA is a kind of a bacteria which resist a number of antibiotics, that used to treat this bacteria. From this it is clear that, MRSA infection cannot be treated or cured easily like any other bacterial infections.4

MRSA can cause severe problems like pneumonia and surgical site infections. If not treated properly it will cause sepsis and death. MRSA is commonly spread by direct contact with the infected person. Nurses in the hospital should have proper knowledge about MRSA.
The aim of this research is to prepare nurses with the latest information on the diagnosis, treatment and management of MRSA infection to help them improve the care of the patients and protect themselves.

**Materials and Method**

An evaluative approach with pre-experimental one group pre-test post-test design was used for this study. 75 staff nurses were selected by non-probability purposive sampling technique based on inclusion and exclusion criteria.

**Inclusion criteria**
- Completed General Nursing and Midwifery or B.Sc Nursing or Post Basic B.Sc Nursing.
- Available during time of data collection.

**Exclusion criteria:**
- Post Graduate Nurses, ANM’s.
- Infection control team nurses, sister in charges, floor supervisors, Nursing Superintendent, Assistant Nursing Superintendent.
- Who have already undergone in service programmes on MRSA.

Ethical clearance was obtained from Yenepoya Ethics committee. Data was collected by demographic proforma and structured knowledge questionnaire. Reliability of the tool was obtained by split half method (r = 0.81), which indicates tool was reliable. The purpose of study was explained and consent was obtained from the study participants. Pre-test of knowledge taken on day-1 followed by distribution of information booklet and post-test conducted on day-5 to assess effectiveness of information booklet by using same structured knowledge questionnaire.

**Results**

Results of the study data was analyzed based on the objectives and hypothesis using descriptive and inferential statistics.

**Hypothesis:** Hypotheses were tested at 0.05 level of significance.

- $H_1$: Mean post-test knowledge scores will be significantly higher than the mean pre-test knowledge scores.

- $H_2$: There will be significant association between pre-test knowledge scores and selected demographic variable.

**Section 1: Description of demographic characteristics**

Data in the table 1 shows that nearly half of the subjects (54.7%) belonged to the age group 21-30 years. Most of the subjects (62.7%) were female. Half of the subjects (50.7%) were qualified with BSc nursing. Most of the nurses (41.3%) had experience more than one year. Most of the nurses (29.3%, 24%) were working in surgical wards and ICU respectively.

**Section 2: Assessment of level of knowledge**

**Table 2: Frequency and percentage distribution according to level of knowledge N=75**

</tr>
</tbody>
</table>

The obtained p value is <0.05. It indicates that there was a significant difference between mean pre-test and post-test level of knowledge. Hence H$_1$ was accepted and H$_0$ is rejected and concluded that the information booklet enhanced the knowledge of staff nurses regarding MRSA.

### Table 4: Paired ‘t’ test to find effectiveness of information booklet in each area. N=75

Data in the table 4 depicts that the mean difference is higher regarding general knowledge (1.38) followed by clinical features and management (1.11) and types and causes (0.82). The study result indicates that least effectiveness in the knowledge score was found regarding types and causes (area II) and highest effectiveness was found regarding general knowledge (area I).

The findings of the study revealed that post-test knowledge score was significantly higher in all the areas than pre-test knowledge score which shows the effectiveness of information booklet.

### Section 4: Association between mean pre-test knowledge scores and selected demographic variables.

**H$_0$**: There will be no significant association between pre-test knowledge scores and selected demographic variables.

M= Median (13) p > 0.05

Data in the above table shows that, there was no association found between pre-test knowledge scores and selected demographic variables such as age in years, gender and educational qualification, since the obtained p value was > 0.05.

Chi-square test was used to find the association between pre-test knowledge scores and selected demographic variables.

The obtained p value was >0.05. There was no significant association between pre-test knowledge scores and selected demographic variables. Hence H₂ was rejected and H₀₂ is accepted.

**Discussion**

**Major findings of the study**

**Section 1: Description of demographic characteristics**

In the present study, nearly half of the subjects (54.7%) belonged to the age group of 21-30 years followed by subjects (41.3%) in the age group of 31-40 years. Most of the subjects (62.7%) were females. Majority of the subjects (50.7%) were qualified with Basic Bsc Nursing, followed by subjects (38.7%) qualified with Diploma in Nursing. Most of the nurses (41.3%) had above 1 year of professional clinical working experience. Majority of the subjects (29.3%, 24%) were working in the surgical wards and ICU respectively.

Above study finding is supported by study conducted by Ellen A. Sussin Mississippi to determine nurses knowledge of MRSA, their attitude towards MRSA patients, and how well they comply with MRSA protocols. 46 nurses participated in the study in which 9 were males and 37 were females. 86.96% of the respondents had 0-5 years of experience, 2.17% had 6-10 years of experience, 4.35% had 11-15 years, 2.17% had 16-20 years, and 4.35% had above 20 years. 45.65% worked in acute care, 4.35% worked in outpatient care, 39.13% worked in inpatient care, 2.17% worked in home health, and 8.70% selected “other” to describe their work setting.

**Section 2: Assessment of level of knowledge among staff nurses regarding MRSA**

In the present study, during pre-test nearly half (49.3%) of subjects had good knowledge, followed by subjects (42.7%) had poor knowledge and only few (8%) of them had very good knowledge. In post-test, majority (65.3%) of the subjects had good knowledge and only few (20%) of them had poor knowledge. The finding of the study has revealed that there is an urgent need to educate the staff nurses on MRSA.

Above study finding is supported by study conducted by Adriana Maria da Silva et al. to evaluate the knowledge of a nursing team from a public hospital in Brazil regarding MRSA. A total of 318 professionals from different units participated in the study. Results showed that 43.7% of the professionals from nursing team did not know basis of the Staphylococcus aureus resistance to methicillin. According to the analysis, the nursing teams knowledge and perception of MRSAsusceptibility was limited.

**Section 3: Effectiveness of the information booklet on knowledge regarding MRSA**

In the present study, the knowledge scores of staff nurses regarding MRSA showed that, post-test
mean knowledge score was higher (15.17±4.07) when compared with pre-test mean knowledge score (11.74±4.61). It was also evident from the paired ‘t’ test (p value is < 0.001; P < 0.05). The results of the study indicates the effectiveness of information booklet in enhancing knowledge score of staff nurses on MRSA by using interventional measures in the form of information booklet.

Above study finding is supported by study conducted by Tintu Chacko et al – in Mangalore among primiparamothers to evaluate the effectiveness of information booklet on knowledge regarding importance of birth spacing. 60 samples were selected for the study. By using descriptive and inferential statistics the data were analysed. The result revealed that 81.7% of primipara mothers had poor knowledge score with a score range of 0-12, 11(18.3%) had average knowledge score with a score range of 13-25 and none of them had good knowledge score with a score range of 26-37. In pre-test the mean knowledge score was 7.96 and in post-test the mean knowledge score was 31.15. A significant difference was seen between pre-test and post-test knowledge scores (t=28.945, P<0.05). The study also showed that, demographic variables such as educational status, income and previous knowledge were significantly associated with knowledge scores. The study concluded that, information booklet was an effective educational intervention to enrich the knowledge of primipara mothers.7

Section 4: Association between mean pre-test knowledge scores and selected demographic variables.

The Chi-square (χ²) computed in the present study showed that there was no significant association between pre-test knowledge scores and selected demographic variables such as age in years, gender and educational qualification, since the obtained p value was > 0.05.

Above study finding is supported by study conducted by Philomena Fernandes et al - in Mangalore among staff nurses to evaluate the effectiveness of an information booklet on knowledge regarding prevention and management of perineal tear during normal delivery. 40 staff nurses were selected for the study. The collected data were analysed using inferential and descriptive statistics. It is evident from the study that, there was a significant difference between pre-test and post-test knowledge scores(t=23.09, p<0.05). The study concluded that the information booklet was effective in increasing staff nurses knowledge regarding prevention and management of perineal tear during labour and there was no significant association between the knowledge score and demographic variables (p>0.05).8

Conclusion

The main aim of the study was to assess the knowledge of staff nurses on MRSA and teach them about it. Teaching was given through the information booklet which helped the staff nurses to gain knowledge on MRSA. The finding indicates that there was lack of knowledge among staff nurses regarding MRSA and information through various means like information booklet is an important source for improving the knowledge. With my study I was able to improve the knowledge of staff nurses. So in conclusion we can say that the information booklet is an effective method for improving the knowledge.

Maternal and Perinatal Outcome in Patients with Meconium Stained Liquor in First Stage of Labour: A Retrospective Study

Tanu Bhati¹, Sunil Takiar², Kalpna Kulshrestha³, Sukla Debbarma⁴

¹Junior Resident, ²Head of Department, ³Assistant Professor, ⁴Senior Resident (OBG), SIMS, Hapur, U.P.

Abstract

Objectives: To study the perinatal and maternal outcome in patients with meconium stained liquor in first stage of labour.

Methodology: This retrospective study was carried out on 180 antenatal females reporting for delivery between 36-40 weeks gestation with single live fetus in cephalic presentation & results were recorded.

Results: In our study, 56.66% of the babies among the meconium liquor (study) group were admitted in NICU against 28.88% in the clear liquor (control) group. 2.22% of the babies in the study group developed HIE as compared to none in the control group. 16.66% of the babies developed septicemia in the study group as compared to 4.44% in the control group.

Conclusion: Perinatal morbidity and mortality was significantly higher in the meconium liquor group as compared to the clear liquor group. The rates of Complicated (Caesarean section and instrumental) delivery were also reported to be higher in the study group.

Keywords: Meconium, cardiotocography, instrumental delivery, meconium aspiration syndrome.

Introduction

10-20 % of term pregnancies are associated with meconium stained liquor. Meconium is a green, viscous liquid that first appears in fetal ileum by 10 wks gestation. The passage of meconium in utero and its aspiration during intrauterine life or when the baby takes its first breath can result in meconium aspiration syndrome and hence result in significant perinatal morbidity and mortality. Factors such as placental insufficiency, maternal hypertension, pre-eclampsia, oligo-hydramnios or maternal drug abuse (tobacco, cocaine) result in intra-utero passage of meconium¹.

Amniotomy is recommended to detect passage of meconium in utero during labour. Amniotomy is also recommended in labour to detect meconium stained liquor when the fetal heart is non reassuring. Continuous fetal heart rate monitoring (cardiotocography) is recommended once meconium stained liquor is detected. Several mechanisms are proposed for causation of detrimental effects of meconium in fetus. Meconium reduces the levels of zinc in amniotic fluid which may reduce the antibacterial property, predisposing to intraamniotic infections. In presence of fetal stress such as fetal hypoxia, the gasping action of fetus may aspirate the meconium into the lungs where meconium may neutralize the action of surfactant and promote lung tissue inflammation by activating neutrophils and macrophages. In persistence of hypoxia, meconium aspiration can lead to pulmonary vascular hypertrophy and pulmonary hypertension.

It has also been found to be associated with increased risk of cerebral palsy, neonatal seizures and encephalopathy. Meconium aspiration syndrome can still occur even when caesarean section is done, and, considerable morbidity may result both to newborn and mother. Meconium aspiration syndrome occurs in about 5% of deliveries with meconium stained amniotic fluid² and death occurs in about 12% of infants with meconium aspiration syndrome³. Facilities like CTG and fetal blood sampling to detect detrimental effect on fetus are

not available in most of the hospitals in India. It is for this reason that this study was undertaken to compare the outcomes in the two groups.

**Materials & Method**

**Study Design:** A Retrospective study

**Venue:** SIMS, HAPUR, U.P.

**Sample Size:** 180 Patients with single live fetus in cephalic presentation between 36-40 weeks.

All women meeting the selection criteria were selected and divided into two groups on the basis of presence or absence of meconium in liquor in 1st stage of labour. Group with meconium stained amniotic fluid was labeled as exposed (study group) while the other group with clear or meconium free amniotic fluid was labeled as unexposed (control group). The records were taken on the basis of demography, fetal heart rate abnormality, mode of delivery, Apgar score at 1 minute after birth, NICU admission and related complications.

**Inclusion Criteria:**
- 36-40 completed Weeks pregnancy
- Single live fetus in cephalic presentation
- No other identifiable high-risk factor

**Exclusion Criteria:**
- Previous Caesarean section
- Gross congenital anomaly
- Chorioamnionitis
- Cord prolapse
- Absent fetal heart variability, late deceleration, fetal bradycardia.
- Multifetal gestation
- Maternal disease (Diabetes mellitus, pre-eclampsia).

A total of 180 patients meeting the study criteria were allocated into two groups, namely, meconium stained liquor group (90 patients) and clear liquor group (90 patients).

The maternal and perinatal outcomes were subsequently compared between the two groups.

In this table we compared mean maternal age (in years), mean gestational age (in weeks) & mean birth weights between meconium stained liquor & clear liquor groups. It included 46 booked patients in meconium stained liquor group compared to 52 in clear group. It included 44 un-booked patients (meconium group) as compared to 38 in clear group.

</tr>
</tbody>
</table>

* - Incidence >100% as same child may figure in other categories too.

56.66% of the babies among the meconium liquor group were admitted in NICU against 28.88% in the clear liquor group. 2.22% of the babies in the meconium group developed HIE as compared to none in the clear group. 16.66 % of the babies developed features of sepsis in the study group as compared to 4.44% in the control. Comparing both the groups, the p value of NICU admission is 0.0001 & p value of Neonatal sepsis is 0.007.

Discussion

The passage of meconium in utero may be a sign of fetal maturity or may reveal fetal hypoxia or increased vagal stimulation. It is often assumed that, an abnormal fetal heart rate in the presence of meconium stained liquor, indicates fetal hypoxia and acidosis, especially in the setup where additional diagnostic facilities like cardiotocography and fetal scalp blood pH estimation are not available. Although meconium is sterile, its passage into amniotic fluid is important because of the risk of meconium aspiration syndrome (MAS) and its sequelae. The presence of meconium in liquor during labour is known to be associated with an increased risk of perinatal mortality. The average gestational age in exposed group was 39.66 weeks while in unexposed it was 38.30 weeks with no statistical difference, probably because of shorter interval gestational age, as only cases from 36 weeks to 40 weeks of gestation were included in this study. Similar results were obtained when data was compared for perinatal outcome in both the groups.

In the study by Becker et al, no statistically relevant difference was noted in Apgar values of defined subgroups. Only 14 babies out of 2246 studied had unsatisfactory Apgar scores. 10 (0.9%) of them were in MSAF group and 4 (0.4%) in control group (p-value 0.108). In the study by Patil et al, 19% of babies with MSAF had unsatisfactory Apgar scores. In the study by Wong SF, 29% of MSAF vs 19.4% of clear amniotic fluid had low 1 min Apgar scores. The results were comparable to our study with 20 % of patients in the meconium group having unsatisfactory Apgar as compared to 11.11% in the clear liquor group with a relative risk of 1.94%. In the study by Desmond et al, incidence of birth asphyxia was 26.66%. Both, the modes of delivery, as well as foetal outcome, were affected by the presence of meconium stained liquor as compared to clear liquor group. Presence of meconium, hence, should be monitored closely and additional monitoring facilities such as CTG, if available, can guide the obstetrician to decide the mode of delivery and any other necessary intervention in time. Meconium Stained Amniotic Fluid
in presence of low Apgar scores is directly responsible for high neonatal morbidity and mortality.

In the study by Becker et al\(^5\), 17.4% of patients in meconium group had caesarean section compared to 9.6% in control group (p-value <0.01). Similarly, in study by Wong SF\(^7\) 13.2% of MSAF vs 8.8% of clear amniotic fluid had Caesarean section.

These results were comparable to the results obtained in our study. 31.1 % of the patients in meconium group had caesarean section as compared to 21.1% in the control group. The difference was statistically significant. In the study by Patil et al\(^6\) , 42% of the patients with MSAF had caesarean section while in study by Goud et al\(^9\) , incidence of thin and thick MSAF (35% & 29%) was noted in normal vaginal delivery and (65% & 71%) in cases of caesarean section. In the study by Naveen S et al\(^10\) , 49.1% of MSAF cases had caesarean section while 10.4% of clear amniotic fluid cases had caesarean section.

**Conclusion**

Perinatal morbidity and mortality were significantly higher in the meconium group as compared to the clear liquor group. The rates of caesarean section/instrumental delivery were also reported to be higher in the study group. The incidence of NICU admissions, respiratory distress in newborn, birth asphyxia, Apgar score<3 at birth, mechanical ventilation for resuscitation were all significantly higher in the meconium liquor group.

Patients who underwent caesarean section for fetal indication had a significantly better perinatal outcome as compared to those who underwent vaginal delivery.

Patients detected with MSAF at a cervical dilatation less than 4cm had a better perinatal outcome as compared to those detected at > 4cm probably because patients who were detected with meconium at cervical dilatation less than 4 cms were immediately taken up for caesarean section in view of prolonged amniotomy to delivery interval while those who were detected with meconium at cervical dilatation more than 4 cms were given a trial of vaginal delivery provided the fetal heart was normal. They were taken up for caesarean only when fetal heart showed any abnormality or when any other indications for caesarean were detected.

Salivary pH as a Factor in Oral Health and its Correlation with Diet

Swathy S., Muralidharan. N.P.

1Undergraduate Student, 2Reader, Department of Microbiology, Saveetha Dental College, SIMATS, Saveetha University, Chennai, Tamil Nadu

Abstract

Aim: The study aims to determine how Indian foods affect salivary ph. This study also includes assessment of correlation between different food items and occurrence of dental caries.

Methodology: 100 subjects were included in this study. By means of a questionnaire, they were asked to choose the food they consume predominantly on a daily basis. Their salivary pH values were noted down with the help of pH paper. DMFT index was used to assess their risk for dental caries.

Results: 87 percent of individuals consumed rice every day. Among these individuals, 64 percent of them had DMFT scores greater than 5 and 72 percent of them had an acidic pH. Also, there was no significant differences between the pH values of vegetarians and non-vegetarians. This may be because the non-vegetarians in this study consumed meat only rarely or twice or thrice in a week. The survey results were coded using Microsoft Excel (2007) and percentage information was obtained for each category of comparison. Statistical analysis was done using SPSS software (version 20; independent T-Test was used).

Conclusion: In this study population, there is a direct influence of diet (mainly carbohydrates) in the development of caries.

Keywords: Caries, diet, pH, risk, saliva.

Introduction

Dental caries is the most prevalent dental disease\(^1\). The aetiology and pathogenesis of dental caries are multifactorial, that is, there are so many factors that contribute to the pathogenesis of dental caries and the factors are prone to alterations depending on the time and environment. So, one cannot exactly determine the and quantify the amount of progression of caries. Kyes demonstrated that dental caries is infectious transmissible disease\(^2\). Streptococcus has been associated with prevalence of dental caries \(^3\). Streptococcus forms a part of the normal microbial flora in the oral cavity. It is in the presence of other factors that cavitation occurs. So, Streptococcus alone cannot cause a cavitation and cavitation occurs in the presence of other factors which renders the organism cariogenic. The aim of any treatment should be to eradicate the causative agent in order to avoid recurrence. Eradication of the causative agent can be completely achieved if the infection is prevented at an earlier stage. This applies for eradication of dental caries as well. The nature and composition of saliva plays an important role in maintaining and protecting the oral health by balancing the physiological and biochemical parameters and by the process of remineralisation.

Saliva is a complex fluid which is secreted by both minor and major salivary glands\(^4\). Saliva has a wide range of applications in diagnosing systemic and oral health. Saliva is used as a diagnostic tool in monitoring plasma concentrations of medicines or other substances\(^5,6\). Saliva plays an important role in caries prevention since it has buffering capacity that helps in balancing
mineralisation imbalances in the saliva. If the pH of saliva is greater than 6, the saliva contains phosphate in very high concentrations with regard to hydroxyapatite. When the pH falls below the critical level (5.5) the hydroxyapatite dissolves and the phosphates are released in an attempt to restore the pH balance (7). Low buffering capacity is usually associated with caries development because of its impaired neutralisation of plaque acids and reduced re-mineralization of early enamel lesions (8,9). An association between low caries levels and high salivary buffering capacity has been also demonstrated (10,11). If the buffering potential is not compromised, caries activity cannot occur. Also, in the presence of early caries activity, promoting remineralisation will inhibit the progression of caries. There are many potential remineralising agents such as fluoride, xylitol, bioactive glass etc, which can be used to remineralise tooth structure rather than removing caries and replacing it with a filling (12).

This study includes evaluation of the oral hygiene status by means of an OHIS index. Bacterial plaque is a biofilm that covers all the oral structures. Major components of the plaque includes salivary proteins and macromolecules (13). If the plaque has a more alkaline pH than saliva or crevicular fluid, calculus formation occurs (14). This study takes into consideration the salivary pH and the diet and correlates it with the prevalence of dental caries which is evaluated by means of DMFT index.

**Materials and Method**

For a population of 130 individuals, the sample size necessary was calculated to be 97, with 5% confidence interval and 95% confidence level. This study included 100 subjects from a random population of 130 individuals of the age group 20-60. By means of a questionnaire, the information about the food they consume predominantly on a daily basis were collected along with the information about the frequency of consumption of that particular food. The frequency was obtained in terms of everyday consumption, consuming twice or thrice a week and rare consumption. From the survey it was found that the predominant components in diet for this population included rice, wheat and meat. They were hence classified according to their diet into vegetarians and non-vegetarians. Those who consume meat were classified as non-vegetarians and those who did not consume meat were classified as vegetarians. The saliva was collected in a sterile dispenser by asking the subjects to spit normally. The diet history and saliva was collected in the morning 2 hours after breakfast. Their salivary pH values were noted down with the help of narrow range pH strip. The pH strip had pH markings - 5.0, 5.5, 6.0, 6.5, 7.0, 7.5 with corresponding standardised colour codings from yellow (5.0, 5.5) to green (6.0, 6.5) to blue (7.0, 7.5). One third to one half of the pH paper was dipped into the saliva once and left undisturbed until colour change occurred. The colour change in the pH strip was compared with that of the standardised colour for different pH values. The colour which matched closely similar to the colour change in the pH strip was designated the corresponding pH value (figure 1). For comparison pH values were noted down as being acidic (pH values- 5, 5.5, 6, 6.5, 7) or alkaline (7.5). The neutral pH 7 was considered under acidic pH since it indicates progress towards acidic pH suggestive of caries activity. DMFT was used to assess their risk for dental caries. The number of decayed teeth, the number of missing teeth due to caries and the number of fillings in every individuals oral cavity was assessed by clinical examination. The DMFT scores were obtained by adding the number of decayed, missing and filled teeth. Teeth missing due to periodontal compromise or trauma was excluded by asking for history of mobility or trauma respectively. Only teeth which were lost or extracted due to cariogenic progress was considered. The survey results were coded using Microsoft Excel (2007) and percentage information was obtained for each category of comparison. Statistical analysis was done using SPSS software (version 20; independent T-Test was used).

![Figure 1: Determining the pH of saliva using a pH paper.](image)
Results

As mentioned earlier, based on their responses, it was found that the common dietary intake was confined to rice, wheat and meat predominantly. The consumption of other food items showed inconsistent frequency of consumption and therefore excluded from the study. From table 1, 87 percent of individuals consumed rice every day. Among these individuals, 64 percent of them, had DMFT scores greater than 5 and 72 percent of them had an acidic pH. 12 percent consumed rice twice or thrice in a week. 1 percent of the population reported to consume rice rarely. 1 percent of the population consumed wheat every day. Among these individuals, 50 percent of them had DMFT values greater than 5 and 60 percent had an acidic pH. 92 percent of the population consumed wheat twice or thrice in a week and 7 percent consumed wheat rarely. Similarly, 7 percent consumed meat every day. Among these individuals, 43 percent had DMFT greater than 5 and 52 percent of them had an acidic pH. 85 percent consumed meat twice or thrice a week and 8 percent consumed meat rarely.

From table 2, 27 percent of the subjects were vegetarians and 73 percent of them were non-vegetarians. Among the vegetarians, 53 percent had DMFT values greater than 5 and 42 percent of them had an acidic pH. Among the non-vegetarians, 48 percent of the subjects had DMFT values greater than 5 and 42 percent of them had an acidic pH.

</table>

From table -3, it is observed that, 82% of those who maintain excellent oral hygiene have DMFT values less than 5 and 28% of those with poor oral hygiene have DMFT values less than 5. 90% of the individuals who maintained a fair but not good oral hygiene had a DMFT score greater than 5 (highest DMFT score of the 4 categories). 72% of the individuals whose oral hygiene was poor, had DMFT scores greater than 5.

Independent T-Tests done using SPSS revealed a statistically significant relationship between oral hygiene and prevalence of dental caries (p value < 0.05). There was no statistically significant relationship between dental caries and dietary intake as seen between the vegetarians and non vegetarians.

Discussions

Salivary pH plays an important role in determining the mechanism of dental caries. Bacteria in the biofilm ferment dietary carbohydrates and cause production of
Acids as by-products of metabolism. Due to this acid production, the pH of saliva decreases and becomes acidic. Hence, acidic saliva will result in and is suggestive of demineralisation\(^{(15,16)}\). The progress of dental caries depends on balance between demineralisation and remineralisation. While remineralisation of the tooth will lead to reversal of carious lesion, demineralisation will result in cavitation. Here comes the role of saliva as a buffer. The saliva restores the pH of the biofilm by losing calcium and phosphate to the tooth structure. If this buffering capacity is impaired, the carious process will continue and spread\(^{(17)}\).

In this study, acidic salivary pH was found in 65% of the population. The everyday consumption of rice and wheat is directly related to the increase in acidic pH. Rice contains increased amount of carbohydrates than wheat. However, wheat also contains carbohydrates but in lesser quantities.

Since caries prevalence and progression is multifactorial, wide range of studies report various prevalence rates and various risk factors which keep changing from time to time and between different individuals. A study by Gokul et al, reported that consumption of oily food and non-vegetarian food results in alkalinity in the pH of saliva\(^{(18)}\). In this study, there was no significant differences between the pH values of vegetarians and non-vegetarians\(^{(18)}\). This may be due to the fact that only 7 percent of the population consume meat everyday and they consume carbohydrates in their diet predominantly. 93% of those who consume meat, reported that they consumed meat either twice or thrice a week or rarely. A study by Stephan and Miller was the first article to be publishes regarding the association between salivary pH and diet. In this study, they showed that the pH of the saliva lowered significantly within 3 minutes after human teeth were rinsed with sucrose solution\(^{(19,20)}\). In this study, the percentage of subjects with acidic pH is increased (72%) in those who consume carbohydrate every day. Also, in the percentage of subjects with increased acidic pH, an increased DMFT values were observed \(^{(18)}\). In a study by Bowen et al, it was proven that the frequency of consumption of cariogenic food contributed significantly to the progression of caries\(^{(21)}\). This finding is consistent with the present study in which those who consume rice, wheat every day have an increased percentage of DMFT values greater than those who consume twice or thrice a week or rarely. In a study by Gopinath, it was found that 45% of those who had high caries incidence (DMFT>5) had acidic pH. This study involved 40 individuals-20 of them had DMFT>5 and 20 of them had DMFT=0. The study showed that salivary flow rate, salivary pH and the buffering capacity of saliva in the high caries group was significantly lower when compared to the control group\(^{(22)}\). This finding is similar to that of the present study in which the the percentage of subjects with high DMFT scores also have a low salivary pH, that is acidic salivary pH.

In this study, there is no statistical significance found between caries prevalence and diet\(^{(23)}\)\(( p \text{ value } > 0.05)\), though the percentage difference indicated that prevalence of dental caries was associated with carbohydrate containing diet. However, statistically significant relationship between oral hygiene and diet was observed in this study \((p \text{ value}<0.05)\).

**Conclusion**

Dental caries is multifactorial and is caused by various factors of which salivary buffering capacity, diet and oral hygiene are considered in this study. Though saliva has buffering capacity, the composition of saliva is influenced by diet. Increased consumption of carbohydrates is easily metabolised by oral flora and results in a lowered pH. However, in this study population, it is evident that maintenance of good oral hygiene influences the incidence and prevalence of dental caries rather than the diet. Caries prevalence was not significantly different between the vegetarian and non-vegetarian groups, but caries prevalence was higher in individuals who did not maintain good oral hygiene. So, results from this study emphasises on the importance of maintaining good oral hygiene.

An Analytical Study on Physical Activity, Functional Capacity and Sleep Health in Patients with Type 1 and Type 2 Diabetes

V. Prithiha¹, T. Senthil Kumar², N. Venkatesh³, S. Sridevi²

¹MPT (Cardio Pulmonary Sciences), ²Assistant Professor, ³Professor and course chairman, Faculty of Physiotherapy, Sri Ramachandra Medical College and Research Institute (Deemed to be University), Chennai, India

Abstract

Background: Diabetes prevalence and complications are increasing which emphasizes the need of management in various possible ways. Physical inactivity tends to decrease the functional capacity. Similarly, physical activity and sleep are interrelated. Due to dearth of details on the physical activity level, functional capacity, sleep debt levels and their relationship in diabetic population, this study was taken.

Objective: To measure Physical Activity level, Functional capacity, Sleep debt and the relationship between them in type 1 and type 2 Diabetics.

Method: In this observational study on diabetic patients of 30 –65 years age without any diabetic complications, the Global Physical Activity and Sleep Inventory Questionnaire were used to evaluate Physical Activity and Sleep debt. Functional capacity was assessed by 6-minute walk test. Body Mass Index, Waist Hip ratio, Blood sugar were measured. Data were analyzed by Mann-Whitney U test, Chi-square test, Odds ratio, Spearman correlation method using SPSS software 15.1 version.

Results: The physical inactivity was higher in type 1 diabetic patients (93.33%) than type 2 (69.67%). By odds ratio, type 1 diabetic individuals had more risk of Sleep debt. Patients with low Physical Activity level had more Sleep debt and there was significant (p< 0.05) negative correlation between Physical Activity level and Sleep Inventory score in type2 diabetics.

Conclusion: Type 1 diabetic had low physical activity level in spite of having functional capacity similar to type 2. Sleep debt was more in type 1 diabetic and individuals with low physical activity level. Thus difference exist between type 1 and 2 diabetes in the physical activity and sleep debt, which needs to be considered during exercise training diabetic management.

Keywords: Physical activity- Functional capacity- Sleep debt- Type 1 diabetes-Type 2 diabetes.

Introduction

Diabetes is a leading global health problem with global prevalence of 8.8% and about 79.2 million affected in India by 2017(1). The Physical activity recommendation for diabetic patients - 150 minutes per week of moderate - vigorous physical activity(2)(3). The variations in the Physical activity level among Type 1 and type 2 diabetic patients is not known. The functional capacity tends to decrease if the individuals are being less active for longer period. Presently Sleep deprivation is also a major health problem and it has an effect on physical well-being. Diabetic patients have sleep disturbances due to poor glycemic control or due to sleep disturbance, the glycemic control may be alternated (4). In diabetic management, Sleep is also one component to be addressed, as study says there is association between

Ph.No: 9444368189
sleep duration (either little or more) and diabetic prevalence and impaired glucose tolerance (5). As sleep is linked with diabetes and physical well-being, it has to be addressed and its effects on physical activity have to be analyzed for better management and prevention. Thus in this study, the Physical activity level, functional capacity and Sleep debt in type 1 and type 2 diabetic patients was analyzed for the better understanding to formulate exercise strategies for management and prevention of diabetes.

Method

This was a cross sectional study done with Institutional ethics clearance on patients with type 1 and type 2 diabetic patients during September 2017 to March 2018. The subjects in age group between 30 to 65 years; diagnosed to be diabetic more than 1 year and being able to read and understand English were included in the study by obtaining informed consent. Patients with sensory neuropathy, foot ulcers or other serious musculoskeletal problems were excluded. Anthropometric measures BMI and Waist Hip ratio were measured and laboratory details like Fasting Blood Glucose, Post Prandial blood glucose values were noted.

The recruited subject’s Physical activity level was evaluated using Global Physical Activity Questionnaire (GPAQ) which collects information on physical activity participation in 3 domains (activity at work, travel to and from places and recreational activities) and time spent on sedentary behavior (6)(7); Sleep debt was assessed using Sleep Inventory Questionnaire consisting of 17 items to which the respondent simply responds with ‘‘yes’’ or ‘‘no’’. To score this test, the number of ‘‘yes’’ responses is simply counted from the total score of 17. The score above 7 is set as a cutoff point denoting the individual has evidences of sleep debt (8). Functional Capacity by Six-Minute Walk Test conducted in a level corridor of 30 m long with markings for every 2.5 mts. The distance walked by the individual, pre and post vital changes and other complaints (if any) reported were noted (9).

Statistical Analysis: In this study the variable distribution was tested by Shapiro-wilk’s test. The baseline characteristics age, BMI, WHR, FBS, PPBS are described by their mean and standard deviation values; gender is described by counts and percentages. For comparison of Physical activity level, Functional capacity among Type 1 and Type 2 diabetes group, the Mann – Whitney U test is used. For sleep debt analysis among type 1 and type 2 diabetic patients, Odds ratio and the Chi-square test, were used, as indicated, p values < 0.05 were considered to be statistically significant. Spearman rho correlation was done to assess a potential association between Physical Activity level and Functional capacity; Physical Activity level and Sleep Inventory score and between Functional capacity and Sleep Inventory score in both type 1 and type 2 Diabetes. Analysis was done by using SPSS software 15.1version.

Results

In this study, the proportion of female patients was higher in both type 1 and type 2 diabetic group. Both type 1 and type 2 diabetics were overweighted. The fasting and post prandial Blood Sugar level was higher in type 1 than type 2 diabetes. The changes in Physical activity level among type 1 and type 2 diabetes was statistically significant with the p value of 0.01, when categorized into Physically inactive (< 600) and Physically active (> 600) (Table 2). There were higher odds (1.61) of sleep debt in type 1 Diabetes than type 2 (Table 3). Sleep debt was more among both type 1 and also in type 2 diabetic individuals with low Physical Activity level(p< 0.05) (Table 4).

Correlation analysis

Type 1 Diabetes: Correlation analysis in type 1 and type 2 diabetes were done by using Spearman’s Rho Correlation method. There was very weak negative correlation between Physical Activity level (GPAQ score) and Functional capacity (6MWD) with p value of 0.37 (statistically not significant) suggesting that if the Physical Activity level increases, the Functional capacity decreases. There was very weak positive correlation between Physical Activity level (GPAQ score) and Sleep Inventory Score with p value of 0.57 (statistically not significant) suggesting that if the Physical Activity level increases, the Sleep Inventory score decreases which means that by increase in Physical Activity level, there was decrease in Sleep debt. There was very weak negative correlation between Functional capacity (6MWD) and Sleep Inventory with p value of 0.399 (statistically not significant), suggesting that if the Functional capacity increases, the Sleep Inventory score decreases which means that by increase in Functional capacity, the Sleep debt decreases.

Type 2 Diabetes: There was weak positive correlation between Physical Activity level (GPAQ score) and Functional capacity (6MWD) with p value of 0.07 (statistically not significant), suggesting that by increase in Physical Activity level, there was an increase in Functional capacity. There was moderate negative correlation between Physical Activity level (GPAQ score) and Sleep Inventory score with p value of 0.017 (statistically significant) suggesting that if Physical Activity level increases, the Sleep Inventory score decreases which means that by increase in Physical Activity level, there was decrease in Sleep debt. There was very weak negative correlation between Functional capacity (6MWD) and Sleep Inventory with p value of 0.399 (statistically not significant), suggesting that if the Functional capacity increases, the Sleep Inventory score decreases which means that by increase in Functional capacity, the Sleep debt decreases.

*Spearman Rho Correlation

Discussion

Physical activity level among type 1 and type 2 diabetes: The incidence and pathogenesis of diabetes can be accelerated due to physical inactivity and can lead to subsequent morbidity and mortality. Similarly by being physically active, the progression of diabetes can be retarded reverted. The result of the present study shows that majority of the type 1 and type 2 diabetic individuals had low physical activity level. In type 2 diabetics, 69.6% and in type 1 diabetes, 93.33% of individuals had low physical activity. This emphasizes the need of Physical activity in the management of diabetes. Previous study has shown difference in Physical activity level among type 1 and type 2 diabetes. The present study is in accordance with the same study, but was done in a South Indian population using GPAQ Questionnaire. In the present study, by categorizing Physical Activity level - type 2 diabetic patients showed
similar results. But larger percentage of type 1 diabetic individuals were with low physical activity level. The changes in Physical activity level of type 1 diabetic patients may be due to cultural and regional variations when compared to western countries. There were larger percentage of female patients and many were home maker by occupation. This may be an reason for reduction in Physical activity level where the need of being physically active in moderate to vigorous level is less and recreational and leisurely activities differs from western population to Indian population.

**Functional capacity among type 1 and type 2 diabetes:** Functional capacity was assessed by 6 Minute Walk Test and there was no significant change in the functional capacity among type 1 and type 2 diabetes. Though the functional capacity was similar in both groups, the six minute walk distance achieved by both group was less than that of the healthy individuals. Thus recommendation of physical activity is emphasized for improvement of functional capacity. Low exercise capacity is associated with higher adiposity and poor glycemic control in type 2 diabetics \(^{(12)}\)(\(^{(13)}\)). In this study even though both types had similar functional capacity, the majority of type 1 had low physical activity than the type 2 diabetes. This may be due to the facts like fear of hypoglycemia, tiredness or sedentary life style \(^{(14)}\). Thus the exercise or physical activity prescription needs extra care in type1 diabetes by considering their functional capacity and the factors that hinders from being physically active.

**Sleep debt in diabetes:** The sleep factor has been considered as it has an effect on both diabetes and physical activity level \(^{(15)}\). Poor sleep pattern in 64% of their study participants has been reported before \(^{(16)}\). In present study there were higher odds of sleep debt in type 1 diabetes affecting PA more than type 2 diabetics. The sleep debt was more among the individuals with low physical activity level and it was reduced as the physical activity level increases. It highlights the importance of considering sleep evaluation and management in diabetic patients in India.

**Correlation analysis in type 1 and type 2 diabetes:**
The results of correlation analysis states that, in type 2 diabetes - the physical activity level is positively correlated with functional capacity and negatively correlated with the sleep inventory score. Thus it states that by improving Physical Activity level, the Functional capacity improves and the sleep debt is also reduced. Similarly Functional capacity is negatively correlated with Sleep Inventory score, indicating that with increase in sleep debt the functional capacity can be affected. But in type 1 diabetes, the correlation analysis states that Physical activity level is negatively correlated with functional capacity. This was because; the individuals’ active participation in day to day Physical activity is less, in spite of having good functional capacity. Unlike type 2 diabetes, the effects of physical activity on sleep is not similar in type 1 diabetes. There may be other factors that influences the sleep quality. Functional capacity is negatively correlated with sleep inventory score suggesting that with increase in sleep debt the functional capacity is affected.

**Conclusion**

This study concludes that both type 1 and type 2 diabetic individuals had larger proportion of individuals with low physical activity level and low functional capacity. Type 1 diabetic patients are less active, in spite of having better functional capacity when compared to type 2 diabetes. Sleep debt is more among type 1 diabetes and in diabetic individuals with low Physical Activity level. Therefore Physical activity, Functional capacity and Sleep debt are important components to be considered in management of diabetes for evaluation and prescription of Physical activity or exercise.

Title: Knowledge, Attitude and Practice Regarding Hepatitis B Infection among Nursing Staff of Tertiary Care Hospital in South India

Pallavi A. Potdar1, Ashutosh B. Potdar2, Vivek R. Raikar3

1Associate Professor, Department of Community Medicine, D. Y. Patil Medical College, Kolhapur; 2Associate Professor, Department of Forensic Medicine, D. Y. Patil Medical College, Kolhapur; 3Assistant Professor, Department of Obstetrics & Gynecology, Prakash Institute of Medical Sciences and Research, Islampur

Abstract

Background: Hepatitis B is the major global concern and leading cause of morbidity and mortality. It can be prevented with strategies like safe and effective vaccination, increasing awareness and by adhering to universal precautions.

Objectives: To evaluate knowledge, attitude and practice towards Hepatitis B infection and vaccination status against Hepatitis B among staff nurses working in CMCH &RC.

Material and Method: A cross sectional descriptive study was conducted in CMCH & RC, Irungalur, Trichy. Study population included 145 nursing staffs through purposive sampling technique who were contacted in person from various departments at the time of study. The data was analyzed using appropriate statistical software SPSS version 22.

Results: Among the study participants 64.7% had adequate knowledge regarding Hepatitis B. Around 16% were not fully aware about mode of transmission, 23% did not know that it spreads through unsterilized instruments while, 46% were not fully aware about the vaccination schedule & 20% of them did not know that its preventable. About 86.5% had positive attitude towards Hepatitis B. Out of total 145 nurses, 22.4 % didn’t follow the recommended practices towards prevention of Hepatitis B. Out of the total 145 participants, 35% nurses were not vaccinated against Hepatitis B at the time of our study.

Conclusion: One third of the nursing staff are not fully aware about the Hepatitis B infection. Around 16% nurses are not aware about mode of transmission of Hepatitis B. One third of the nurses are not vaccinated against Hepatitis B at the time of our study. Health education programs should be conducted on regular basis to increase level of knowledge and preventive practices in order to protect nursing staff from acquiring this deadly infection.

Keywords: Hepatitis B, knowledge, attitude, practice, staff nurses.

Introduction

Hepatitis B is an acute systemic infection with major pathology in the liver, caused by Hepatitis B virus (HBV) and transmitted usually by the parenteral route. Although an effective vaccine is available, but still it continues to be a major public health concern.1 Hepatitis B virus (HBV) infection has been a major cause of morbidity and mortality among health care workers.2 About two billion individuals have been infected with HBV at some point worldwide in time in their lifetimes and 360 to 400 million people (5% of the world’s population) are chronic carriers.3,4 HBV and its consequences are estimated to cause 600,000 deaths each year, a tenth of deaths worldwide.1

Corresponding Author:
Dr. Vivek R. Raikar
Assistant Professor, Department of Obstetrics & Gynecology, Prakash Institute of Medical Sciences and Research, Islampur
e-mail: vivekraikar789@gmail.com
B shows variable clinical manifestations ranging from asymptomatic HBV carriers to complete liver failure, and it becomes chronic, often progresses to chronic Hepatitis, cirrhosis, and hepatocellular carcinoma. Majority of HBV infections are sub-clinical, as a result approximately 80% of all infections are undiagnosed. It has been estimated that 14.4% of hospital workers are infected with HBV and HCV. Universal work precautions as defined by Centre for Disease Control, are a set of precautions designed to prevent transmission of Hepatitis B/C virus, Human immunodeficiency virus (HIV) and other blood borne infections when providing first aid or health care. Universal work precautions apply to blood, other body fluids containing visible blood, semen, and vaginal secretions. Hepatitis B is the most commonly transmitted blood borne infection. If a nurse is exposed to the blood of HIV/HBV infected patient, she is 100 times more likely to be infected with HBV than HIV. The risk of acquiring HBV infection from occupational exposure is at least 30% from percutaneous or mucosal exposure to blood and body fluids from a patient with acute or chronic HBV infection. About 66,000 Hepatitis B viral infections are reported per year due to needle stick injuries. In India, the carrier rate of HBsAg in hospital staff has been found to be higher (10.87%) than in voluntary blood donors (6%) and in the general population (5%). As health-care workers (HCWs) remain at a high-risk of transmission by skin prick with infected or contaminated needles and syringes, also through accidental inoculation of minute quantities of blood during the surgical and dental procedures, it is very important for them to follow proper measures of infection control and prevention. Nosocomial transmission can be prevented by the vaccination of health care workers. Hepatitis B vaccines, for prevention have been evaluated in clinical trials to determine protective level of serum antibodies, i.e. Anti-HBs. Persons who respond to HBV vaccine with titers of anti-HBs 10mIU/ml or greater are protected against acute and chronic HBV infection. Nurses are probably the most common health care staff exposed to needle prick injuries and contact with infectious fluids. They are exposed to this risk right from there student career. Hence it is important that nurses as well as nursing students should have a thorough knowledge regarding Hepatitis B to minimize the health care settings acquired infections among them and other health personnel. Knowledge and attitudes of health care workers plays a key role in prevention of spread of infection. Therefore, the present study was conducted to assess the knowledge, attitude and vaccination status among staff nurses, regarding Hepatitis B.

**Objectives of the Study:**

1. To assess the knowledge, attitude and practice regarding Hepatitis B infection among staff nurses working in CMCH &RC, Trichy.
2. To study vaccination status of the study participants.

**Methodology:**

- **Study Design:** Hospital-based Cross sectional study.
- **Study Setting:** CMCH &RC.
- **Study Population:** 145 staff nurses.
- **Duration of the study:** 2 months (February – March 2017).
- **Sampling technique:** Purposive sampling.
- **Tools for data collection:** Structured questionnaire.

**Method of Data analysis and interpretation:** Data was analyzed according to objectives of the study using descriptive and inferential statistics and was presented in the form of tables, graphs. We adopted scoring system for assessing knowledge, attitude and practice. There were totally 16 questions for assessing knowledge, 5 questions each to assess attitude and practice. For each correct answer 1 score was given and wrong answer was given 0 score. Any score above 8 was labeled as good knowledge while less than 8 was considered as poor knowledge. Attitude was scored by giving 1 for positive attitude and 0 for negative attitude. Score above 3 was considered as satisfactory for attitude and practice. Practices regarding Hepatitis B were assessed by giving 1 score for correct practice to prevent the infection while 0 for incorrect practice.

**Data collection tool:** The nurses were contacted in person according to their availability in various departments. Information regarding purpose of the study was given to the participants and after receiving consent to participate in the study, Data was collected using pre-designed, pretested structured questionnaire through face to face interview. Confidentiality of the collected information was fully assured to the participants. Pilot study was done and necessary changes in the proforma were done to increase accuracy of the results. Data was designed to study socio-demographic factors.
Results

Out of the total 145 study participants, majority i.e. 68.24% were in the age group of 25-30, followed by 27.42% in the age group of 30-35 and 4.34% were above 35 years of age.

As shown in Table -1, among the study participants 64.7% had adequate knowledge regarding Hepatitis B infection. But around 16% are not fully aware about mode of transmission, 23% did not know that it spreads through unsterilized instruments. Around 7% nurses were unaware of universal safety precautions, while 46% of them did not know the full vaccination schedule.

About 86.5% had positive attitude towards preventing Hepatitis B. (Fig-1) Around 92% nurses felt that vaccination should be taken compulsorily in order to prevent the disease. While 18% did not feel that universal precautions should be followed at workplace, around 15% felt that it’s not necessary to report each case of needle stick injury and 8% of the nurses had negative attitude towards following biomedical waste management guidelines.

When we studied the actual responses regarding practice, 77.6% of the participants followed recommended practices towards Hepatitis B (fig-2). Around 65% nurses have undergone screening to rule out Hepatitis B, 8% nurses don’t use gloves and masks while handling hospital wastes, while only 65% of them have completed vaccination. Around 3% of them don’t follow biomedical waste management guidelines.

Fig 1: Responses to attitude regarding Hepatitis B.
Knowledge: Regarding awareness about Hepatitis B in our study, 81.4% of the study participants were aware of it. This finding is almost similar to study done in Andhra Pradesh among nurses of a teaching hospital. Around 76.6% of our study subjects knew that causative agent of Hepatitis B is a virus, which is almost similar to findings from research in Andhra Pradesh. The knowledge regarding all modes of transmission is 71.02%, in our study while it was 76% according to findings of study conducted at Punjab. In our study group 83.4% knew that Hepatitis B can be transmitted through needle stick injury; which is better than a similar study done in Lucknow which showed only 50% were aware of it, while it was only 40% in another study conducted in central part of India.

In the present study about 93.1% had knowledge about universal safety precautions and biomedical waste management. This finding is in agreement with another study conducted in a teaching hospital in North India. In the present study, 55.3% of staff nurses had in detail knowledge about prevention of Hepatitis B through vaccination; this is in contrast to another research conducted where 95% were aware of vaccination.

A major concern is regarding knowledge about post exposure prophylaxis. In our study, 83.4% had knowledge regarding the availability of post exposure prophylaxis. This is better than another study where only 20% had knowledge about post exposure prophylaxis.

Attitude: Around 24.7% of our respondents believed that they were not at risk of contracting Hepatitis B infection due to their profession in contrast to findings of study conducted at Indore, 73% of the respondents thought that they were not at risk of infection. 36.3% respondents believed that they cannot acquire Hepatitis B infection from their patients. Nearly 95% of study subjects thought that Hepatitis B vaccination must be compulsory. This finding agrees with similar study conducted in Lucknow. 86.2% of our study sample were of the idea that reporting each and every case of needle stick injury is essential which was comparable with results obtained in Lucknow. This was better when compared with study done in Central India where 53.3% of respondents only think that recapping of needles is dangerous. In the present study, 83.4% think that universal safety precautions must be strictly followed.

Practice: According to our study findings, around 90% nurses wear gloves and masks routinely while handling hospital waste while according to reports of the research done at Lucknow, 60% of the nurses follow guidelines correctly. In our study about 28% of nurses were exposed to needle stick injury while according to findings of study conducted at Indore, 46% of nurses were exposed to needle stick injury.

Vaccination status of our study participants was compared with the studies carried out in various parts of India. We got following results:

- SetiaS et al: 64.1%
- Reang T et al: 78.2%
93% - Saroshe S.
65% - Mahore R et al
50% - Shukla M et al
65% - Present study.

Universal safety precautions were followed by 81% of our respondents while it was 60% according to the results of the study done at Lucknow. This finding is in agreement with other study done in North India. Similarly, in our study 71.1% of the participants had the habit of using needle destroyer similar results were obtained in Lucknow study. Around 97.2% of nurses follow biomedical waste management guidelines in our study. This finding is better than the study conducted in Lucknow where only 65% followed it.

Conclusion

There is urgent need to raise the awareness about Hepatitis B among nurses who are continuously at risk in order to prevent the spread of fatal infection. Vaccination of the unvaccinated nurses on priority basis is recommended.

Effectiveness of Puppet Show on Knowledge about Child Safety Based on Learning Styles among School Children at Udupi District in India

Josvita Sandra Fernandes¹, Anice George², Manjula³

¹MSc Nursing Student, ²Dean, ³Assistant Professor in Community Health Nursing Department, Manipal College of Nursing, Manipal Academy of Higher Education, Manipal, Karnataka, India

ABSTRACT

Introduction: Child injury is a global public health issue. Creating awareness on child safety among children is very necessary for the better understanding of the problems among children.

Objective: to identify the learning styles, incidence of child injury, knowledge regarding child safety, effectiveness of puppet show as a teaching method in improving the knowledge on child safety, find the difference in the knowledge scores regarding child safety among 5th and 6th standard students with different learning styles.

Methodology: A total of 111 participants from 5th and 6th standard were selected for the study, using multistage cluster sampling method.

Results: Among 111, most (55%) were visual learners and remaining were auditory learners. The overall occurrence of child injuries (involved 4 areas i.e road injury, pedestrian injury, sports and playground injury and good touch and bad touch) was 98.19% among study participants. In the pre-test, majority of the participants (76.6 %) had poor knowledge and 23.4 % had satisfactory knowledge and none of them had excellent or good knowledge on child safety. In the post-test 36.9 % had excellent knowledge and 38.7 % had good knowledge, 24.3% had satisfactory knowledge and none had poor knowledge. Puppet show was effective in increasing the knowledge level on child safety (Z=-9.153, P=0.001). Puppet show as a teaching method, does not make any difference in the knowledge grasping capacity of students with different learning styles (Z= -1.626, P = 0.104).

Conclusion: The study concluded that puppet show as a teaching method is a useful and effective teaching strategy which can be utilised in order to teach the students.

Keywords: Knowledge, child safety, puppet show, learning styles.

Introduction

Child injury is a global public health issue. In 2011, World Health Organisation (WHO) estimated that over 6, 30,000 children under the age of 15 died because of injuries. A large number of these injuries (for example, drowning, burns, falls) occur in or around the home.¹ The leading cause of death for child injuries were due to transportation. There were also a substantial number of pedestrian and pedal cyclist deaths among children (Center for Disease Control and Prevention [CDC] 2015).² Hence creating awareness on child safety among children is very necessary for the better understanding of the problems among children. Teaching can be fruitful, by
identifying different learning styles among them which plays an important role in the future life. Learning styles have individual differences. There are different teaching methods which aid in learning, and puppet show is one among them. Puppets change the ambiance of whole classroom by creating more opportunities for creativity, collaboration, critical thinking, and curiosity. 

Amy & Larisa (2004) conducted a study with the aim to measure the relation between the uses of puppetry as a teaching method in the classroom among 32 elementary schools of Brooklyn, New York. The study findings showed that puppetry is a very significant teaching method for students. Puppetry outshines by increasing students’ interest in learning, which contributes in increasing their attention and involvement in classroom activities.

Materials and Method

The researchers used a quantitative approach and quasi-experimental pre-test post-test design in the study. The study was conducted for a period of 1 year. In the study, two schools were selected comprising of 120 students, out of which 9 were absent during the pre-test and were excluded from the study. The sample size required was 38 in each group. But the researcher enrolled all the remaining students, who met the inclusion criteria in the study, which led to a total sample size of 111. On the next day pre-test was conducted by administering the structured knowledge questionnaire on child safety to both the groups to assess their knowledge on child safety, which was followed by providing intervention to both the groups on the same day i.e. teaching on child safety using puppet show as a teaching method. After 8th day post-test was conducted by administering the knowledge questionnaire once again to both the groups to find the effectiveness of puppet show on knowledge about child safety.

Ethical Consideration: Administrative permission and ethical clearance were obtained before data collection. Informed consent from parents of the participants and assent from participants was also obtained before conducting the study.

Statistical Analysis

The data were analysed by using Statistical Package for the Social Sciences (SPSS) version 16.0. Frequency and percentage was computed to analyse the sample characteristics. As the data did not follow normalcy, non-parametric test were used to analyse the data; Wilcoxon signed rank test to assess the effectiveness of puppet show on child safety and Mann Whitney U test to find out the difference in the median post –test knowledge scores regarding child safety among 5th and 6th standard students with different learning styles.

Results

Out of 111 participants, most (75.7%) of them belonged to the age of 10 to 11 years and the mean age was 11 years (63.1%); 54.1% were studying in 6th standard; 51.4% were males and most (50.5%) belonged to joint family. 57.7% of the participants father were skilled workers; 79.3% mothers were unskilled workers; majority (65.8%) reported that they had previous knowledge on child safety; and 36% of them acquired knowledge from television. Most (55%) of the participants were visual learners and remaining 45% were auditory learners.

The overall occurrence of child injuries (involved 4 areas i.e road injury, pedestrian injury, sports and playground injury and good touch and bad touch) was 98.19% among the study participants. Most (41.4%)
of the injuries occurred while talking to friends and walking beside the road carelessly; while riding bicycle on the road (45%) and while riding the bicycle at a very high speed (40.5%). Majority (91%) had injury while running in the ground. Only 26.1% participants had fracture of lower limbs. Few of them (14.4%) reported that a stranger touched them with bad intension, while travelling in the local bus either by standing or sitting. The overall occurrence of child injuries was 98.19% among study subjects.

Majority of the participants (76.6%) had poor knowledge and 23.4% had satisfactory knowledge, whereas none of them had excellent or good knowledge. In the post-test 36.9% had excellent knowledge and 38.7% had good knowledge, 24.3% satisfactory and none had poor knowledge. The puppet show was effective in increasing the knowledge on child safety among 5th and 6th standard students ($Z = -9.153, P<0.05$).

The puppet show as a teaching method, does not make any difference in the knowledge grasping capacity of students with different learning styles (visual learners or auditory learners) ($Z=-1.626, p=0.104$).

Discussion

The present study findings showed that majority of the participants (76.6%) had poor and 23.4% had satisfactory knowledge, whereas none of them had excellent or good knowledge. In the post-test 36.9% had excellent and 38.7% had good knowledge, 24.3% satisfactory and none had poor knowledge. These findings are supported by a study conducted by Indhumathy & Thenmozhi (2016) to assess the knowledge and practice on road safety regulations among 50 primary school children in a rural community, Chennai, India. The results of the study showed that most (32%) of them had inadequate knowledge, 40% had moderately adequate and 28% had adequate knowledge on road safety regulations. Study findings of Devanarayan, Frederick & Soni (2016) found out that majority (74.33%) had highest knowledge in the area of cycling on roads and least knowledge in the area of walking on the road (43.83%). Majority (71%) had average knowledge and 29% had good knowledge on road safety measures. Study conducted by Amy & Larisa (2004) also found there was a positive correlation (0.63) between use of puppets and student attention: puppetry is a very significant teaching method for students, puppetry outshines by increasing students interest in learning which contributes to their attention and involvement in classroom activities.

The present study revealed that among 111 students majority (55%) of the participants were visual learners and remaining were auditory learners (45%) as the study included only 2 types of learning styles. The study findings are supported by a study conducted by Prithishkumar & Micheal at Tamil Nadu, India, who found that among the students who answered the Visual Auditory Read/Write and Kinaesthetic (VARK) learning style questionnaire, 86.8% were multimodal in their learning preference, and 13.8% were unimodal. The commonest learning preference was the bimodal category with the highest percentage seen in aural kinaesthetic (33%) and aural + read/write (16.5%). Another study conducted by Vishrutha, Prarthana, Chaitra and Vandana (2016) to know the preferred learning styles and to find out whether gender differences exist in the learning patterns, Mangalore, Karnataka. Among 175 students of age group 13-15 years. The results showed that in general, 44.6% students preferred unimodal, 20.6% bimodal, 13.1% trimodal and 21.7% quadraramodal learning styles. Among 95 females 44.2% preferred unimodal, 20% bimodal, 10.5% trimodal and 25.3% quadraramodal whereas among 80 male participants 45% preferred unimodal, 21.3%, 16.3% and 17.5% preferred bimodal, trimodal and quadraramodal learning patterns respectively. When compared with male and female participants, the most preferred leaning style was aural with a score of 58.3% and 78.6% respectively. Therefore the study concluded that choosing the best preferred way of learning can help the students as well as teachers to achieve a common goal.

The present study revealed that there is a significant difference in the median pre-test and post-test knowledge scores (Z = -9.153) which is statistically significant at 0.05 level and it is inferred that puppet show was effective in increasing the knowledge level on child safety among 5th and 6th standard students.

A study conducted by Mathew (2014) on effectiveness of structured teaching program on road safety measures among primary school children in selected schools at Bangalore, India showed that the structured teaching program was highly effective with the p value of 0.001 and unpaired t value was 15.73. The study findings of Kohli (2014) which was conducted among school children at selected urban schools in Ludhiana, India, showed that the pre-test mean knowledge score of experimental and control group was 19.66 and 19.91 and post test score was 31.94 and 21.41 respectively and also the teaching program was found effective in increasing the knowledge with the horizontal t test value between pre-test and post-test of experimental group was 18.06 (p = 0.001) and vertical t test value between post-test of control and experimental group was 198.67 (p = 0.001).

Limitations of the Study: The study is limited to 5th and 6th standard students of selected schools in the rural areas of Udupi district. Therefore generalization of the study can be done only to the similar population

Conclusion

The study concluded that puppet show as a teaching method, more effective for visual learners when compared with auditory learners in terms of increase in knowledge and is an effective teaching strategy which can be utilised in order to teach the students.

Impact of Blood Pressure on Cognitive Functions of Middle-Aged Male and Female Individuals

K. Amritha Mahalingam¹, Manjunatha Aithala², Lata Mullur³

¹Post-graduate Student, ²Professor, ³Associate Professor; Department of Physiology, BLDE (Deemed to be University) Shri B. M. Patil Medical College, Vijayapura, Karnataka, India

ABSTRACT

Background: The relationship between Blood pressure (BP) and cognitive function (CF) has not yet been established with evidential matter. However, many studies are there which proved the negative impact of increasing Blood pressure (BP) on cognitive function (CF), with studies, “for” and “against” the observation, both in equal proportion. However, less studies have probed the gender influence as a factor which can affect the interaction of BP with CF. Hence, we aimed to evaluate the association of BP and gender with CF.

Method: The cross-sectional study is conducted on 90 middle-aged male and female subjects aged 40-60 years. Anthropometric and physiological parameters were measured using standard techniques and CF assessed with the help of MMSE. The correlation between BP and CF has been done and the results compared between males and females.

Results: There was statistically significant positive correlation detected between Systolic BP (SBP), Diastolic BP (DBP), Mean arterial BP (MAP) and the MMSE scores only in males with no such correlation found in female subjects.

Conclusions: In this study of middle-aged subjects, it was found that with increase in BP (SBP, DBP & MAP) level within the prehypertensive range, there can be improvement in the CF, only in males. This effect may be because of a probable gender influence on the interaction between BP level and CF in middle-aged men, who have adequate androgens stores in the body, which has a neuroprotective effect in the men, which is lacking in the perimenopausal woman.

Keywords: Blood pressure; cognitive function; mini-mental status examination; mean arterial pressure; gender.

Introduction

In 1947, average life expectancy in India was 32 years with birth rate being high and few people surviving till old age. With the advancement in medical sciences and implementation of family planning program, the crude birth rate and death rate declined significantly with the average life expectancy of an Indian going up to 68.3 years¹. Along with this development comes the burden of various diseases, or sequelae or complications of diseases afflicted during middle-age (Diabetes Mellitus, hypertension, obesity, coronary artery disease etc.) in the elderly. However, age-associated cognitive impairment transcending to dementia and precipitating later into Alzheimer’s Disease (AD) is associated with worse scenario. Dementia is a neurodegenerative disease. It has multiple factors influencing it, resulting in varying prognosis, subjected to inter-individual variation. It is associated with huge morbidity and socio-economic impact. The various factors affecting cognitive function (CF) are age, gender, level of education, socio-economic status, intelligence, blood pressure level etc. Cognitive brain function constitutes the ability to work with the information in a meaningful way, irrespective of domain, and applying it in future, after judging it².
Because of these varied factors affecting an individual's CF, it turns out to be personalised, dynamic entity, which evolves based upon the information fed, experiences faced and conclusions arrived. One of the most important factor affecting cognitive function profoundly is age. Ageing affects the individual in a myriad number of ways, with elderly being the most common group afflicted by dementia. However, the changes in the physical structure of the brain are concretely linked with respective changes in CF. The most common domains of Cognitive function affected by age are attention and memory. Even higher level of cognitive function which includes language processing and decision-making also are adversely affected by it, showing a decline as age progresses.

Another factor being blood pressure(BP), which when maintained within the prescribed range, can not only halt the progress of on going damage of cognitive function in the middle-aged, but also reduce the risk of dementia in future in the late-life. Many studies also stress upon the gender-based unequal affliction of Alzheimer’s dementia to be due to hormonal make-up of the individual, along with his or her genetic make-up. Normally, females show better performance in certain domains like verbal fluency, perceptual speed, accuracy and fine motor skills. On the other side, males outperform females in certain domains like spatial, working memory and mathematical abilities. There is a lot of dearth in studies which can elucidate the effect of BP on CF, taking into account the effect of gender, association or no association can be ascertained in middle-age subjects, belonging to the category of normotensives or prehypertensives.

In this scenario, to throw further light upon a probable link between BP and CF, with the influence of gender, our study aimed to evaluate alteration in CF in relation to BP of male and female subjects.

**Materials and Method**

A cross sectional study was conducted in the Department of Physiology, Shri B. M. Patil Medical College, Hospital and Research Centre, BLDE (Deemed to be University), Vijayapur, Karnataka. 90 healthy volunteers, including technicians, clerks, poens, daily wagers, of age between 40 and 60 years with Normal BP, Systolic Blood pressure(SBP) <120 and Diastolic Blood Pressure(DBP) <80 mmHg & Prehypertension (SBP between 120-139 mmHg and DBP between 80-89 mmHg) were selected randomly. Among them, 66 were male and 24 were female. Subjects with a history of Diabetes Mellitus, secondary hypertension, Stroke, Head injury, CHD-congenital heart disease, CAD-coronary artery disease, VHD-valvular heart disease, Cardiac arrhythmias, PVD-Peripheral vascular disease, those on any Psychiatric medication, those with any Kidney disorders, those with any Liver disease, those on medications – antihypertensive, antiarrhythmics, anticoagulants history were excluded.

After getting Institutional Ethical Committee clearance, informed consent was obtained from all the participants. The cognitive function is assessed by the Mini-Mental Status Examination(MMSE). The criteria of minimum high school education of the patients are considered for the assessment of cognition by MMSE scale. The MMSE assesses five areas of CF including orientation, attention, calculation ability, recall and language.

**Result interpretation:** The maximum score is- 30

**MMSE:**
- 26-30-normal cognitive function
- 25-Borderline cognitive function
- 20-24-cognitve impairment
- <20- Dementia.

**Statistical Analysis:** Data analysis was performed using SPSS Software Version 17. Continuous data was presented using Mean ± SD. Results were presented using diagrams. Unpaired ‘t’ test/Mann Whitney U test were used to test difference between two groups on continuous variables. Correlation Coefficient was used to find the correlation between Cognitive functions and other variables. Scatter Diagrams were also used to show the correlation between Cognitive variables and other variables. A probability value (p value) of less than or equal to 0.05 at 95% Confidence interval was considered as statistically significant.

**Results**

Table 1 depicts the anthropometric parameters measured in males and females. There is a statistically significant difference between them pertaining to height with the male subjects showing Mean ± SD values as 162.3 ± 9.24 and female subjects’s value being, 151.67 ± 5.36. Similarly with respect to weight also, the male
subjects showed statistically significant higher value of 67.53 ± 9.77, when compared to females, who showed the value to be 60.41 ± 6.33. There was no such statistically significant difference found with respect to Body Mass Index (BMI), when males were compared with females, with their values being 25.39 ± 3.30 and 26.19 ± 2.53 respectively. With respect to body surface area (BSA) however, male subjects showed statistically significant higher values of 1.70 ± 0.13, when compared to female subjects’s values being 1.54 ± 0.103. According to table 2, there was no statistically significant difference noted in between male and female subjects with respect to physiological parameters, namely, Pulse rate (PR), SBP, DBP, Mean Arterial Pressure (MAP), Pulse pressure (PP).

In Table 3 also, there was no statistically significant difference in between male and female subjects pertaining the MMSE scores used to evaluate the CF. According to table 4 and the following correlation graphs, our study shows that there is a statistically significant positive correlation between SBP, DBP, MAP & MMSE scores only in case of males when compared to females.

In our study as in Table - 3 & Figure -1 to 3 Correlation between MMSE and Physiological parameters -SBP(P≤0.001*), DBP (P=0.0227*), MAP (P=0.037*) showed significant difference in Males compared to Females and in PR,PP -No significant difference noted in Males compared to females.

Discussion

Results of our study shows there is a statistically significant positive correlation between systolic blood pressure (SBP), diastolic blood pressure (DBP) and mean arterial blood pressure (MAP), with MMSE scores only in males, implying a probable gender influence on the blood pressure (BP) affected cognitive function (CF) or on CF alone, which is to be assessed and discussed. Age-associated cognitive decline (CD) becomes apparent only in elderly individuals who are more than 60 yrs old.

The above-mentioned gender disparity pertaining to CF has always been debatable, without any established cause, surrounded with many speculations. However, according to Nicolas Cherbuin et al, the main type of BP which had the potential of causing this disparity was MAP. Accordingly, the elevated MAP was associated with greater regional gray matter volume and on contrary, the reverse effect was found in females wherein smaller regional gray matter volume was observed. It also asserted that it was largely due to elevated DBP values which led to higher MAP levels and not SBP. Subsequent inference being that greater regional gray matter led to better cognitive performance in males, which is in agreement with our study. Therefore, we can infer that there is a mysterious interaction between MAP levels and brain physiological mechanisms which led to this gender disparity.

The positive correlation between SBP and DBP with MMSE scores can be explained by the study done by Brut VL et al who proved that prior to 50 yrs of age, it is men who are more prone for hypertension when compared with premenopausal women. However, after menopause the situation slightly reverses, with females becoming equally predisposed to the same. This observation was authenticated by Wiinberg et al who found that BP increases both in men and women with aging, but however, the mean BP was 6-10 mm Hg higher in males compared with females, as evidenced by 24 hr ambulatory BP recording device. Therefore finding of positive correlation between BP levels and MMSE (CF) can be attributed to the genetic constitutional differences in between males and females.

According to Janowsky JS, it is the androgens deficiency in the elderly, which led to cognitive decline mediated by loss of significant synapses in hippocampus, increased amyloid deposition and changes in neurotransmission in prefrontal cortex. Therefore, we can interpret that men in middle-age have adequate androgen levels which may act as neuroprotective agent, thereby preventing the onset of cognitive decline in them. One of the other findings in our study being no statistically significant finding observed in females, does not rule out the effect of BP on the CF. It is just a matter of perspective. We can say that there is no cognitive decline seen, due to the neuroprotective nature of Estrogen in them. Our study included perimenopausal women, without enquiry into their menstruation status which might prove to be a limitation of this study.

At the level of genes, however, there is one study which suggests the APOE4 mediated cognitive deficit, is an essential risk factor in the future development of AD, especially in the elderly females. However, one has to keep in mind the subjective cognitive decline (self-perceived cognitive worsening without any impairment in cognitive performance) is an essential risk factor for memory decline, mild cognitive impairment and AD, which was not assessed in my study, as it being a cross-sectional study and not a prospective study associated with a follow-up into the future, which happens to be another limitation of my study.

However, it remains unexplored whether the hormonal influence and genetic constitution of an individual interacts with the factor involved in pathogenesis of hypertension like Renin-Angiotensin system, in a co-ordinated manner or act independently to influence the CF in a positive or negative manner. Therefore, more studies should be conducted to address this gender disparity, so that the prediction of cognitive impairment or dementia or AD, becomes easy, which can in turn change the trajectory of the CF for the better, in asymptomatic early stages itself.

Conclusion

We would like to conclude on the note that gender influence may have an established effect on CF of an individual, without concrete evidence of a probable hormonal influence being responsible for it which is not for certain, due to various studies, “for” and “against” studies. Likewise, there may be gender influence even on the BP levels, which varies with age, such that men are always at high risk of getting afflicted with hypertension when compared to premenopausal women, the disparity being neutralized when postmenopausal women get compared with men.
Limitations of the Study: One of the key limitations of the study is the total number of subjects who participated in the study, who should be in much larger numbers to enhance the power of association between BP and CF in males compared with females. Secondly, in this study, the menstruation status of the female subjects was not enquired into, which can be a limitation of this study. Finally, in case of a prospective study design, one can more firmly assert or deny the level of association of the gender on the BP affected CF.

Prevalence of Work Related Musculoskeletal Disorders among Sugarcane Farmers in Muzaffarnagar, India

Shahrukh Chaudhary¹, Zuheb Ahmed Siddiqui², Prachi Tiwari², Junaid Jameel³

¹Bachelor of Physiotherapy (BPT), ²Assistant Professor, Department of Rehabilitation Sciences, School of Nursing Sciences and Allied Health, Jamia Hamdard; ³Physiotherapist, Dr. Baba Saheb Ambedkar Hospital, Rohini, New Delhi

ABSTRACT

Background: India is agrarian economy with millions of people involved in farming and agricultural related activities. The agricultural tasks involve risks that are associated with development of musculoskeletal disorders among farmers. Thus in our study we attempt to analyze the prevalence of musculoskeletal disorders among sugarcane farmers of Muzaffarnagar district in Uttar Pradesh.

Method: A total of 120 male subjects aged between 20 – 60 years were recruited based on the inclusion criteria. Nordic Musculoskeletal Questionnaire was used to identify the presence of Musculoskeletal Disorders.

Result: The descriptive analysis of data revealed four common musculoskeletal disorders affecting sugarcane farmers: lower back pain (55%), knee pain (44%), Shoulder pain (23%) and Upper back pain (13%)

Conclusion: Based on the findings of this study, it is hereby recommended that sugarcane farmers should be enlightened on a regular basis on the high prevalence of the WMSDs among them, and the precautionary measures to be taken in order to prevent the development. Age of farmers, their years of working and the long hours they spent working in a standing position may be significant factors that contribute to the high prevalence of the WMSDs among them. The most commonly affected body parts included the low back, knees and upper back.

Keywords: prevalence, sugarcane farmers, musculoskeletal disorders, Nordic

Introduction

India is one of the largest producers of sugarcane in the world after Brazil. The sugar industry is one of the important agro-based industries that contribute to the development of economy and support about 50 million farmer families. Muzaffarnagar located in western Uttar Pradesh is primarily agrarian with 78.13% geographical

area under cultivation. Sugarcane is the main cash crop in this part.

Farming is one of the most important occupations in India. It is generally perceived as a healthy outdoor occupation. However, numbers of studies have classified farming as a risky and hazardous job. Because of the nature of farm work, farm workers are at particular risk of developing the musculoskeletal disorders (MSDs), besides a large number of other health problems. Farming was rated as one of the most dangerous occupations in the United States way back in 1990 when the national safety council of the United States acknowledged agriculture as one of the three most hazardous sectors in the working world.

Agricultural farmers and workers engage in activities which require physical labour for a long duration of time and they are exposed to multiple risk factors of
MSD including abnormal posture, lifting heavy loads, exposure to vibration, slips and falls and other manual labour which makes them more prone to develop MSDs. Based on the International Labour Organization, Globally 74% of the agricultural workers are living in Asia and Pacific regions. Since 68% of the population is living in rural areas, agriculture-based activities play an important role in improving the rural economy of India. Agriculture and its related activities have provided nearly 60% of the employment opportunities in India. Work-related musculoskeletal disorders are found to be associated with work absenteeism, loss of productivity and economic loss to the worker, industry and the nation. Agriculture and its allied sectors have contributed to 18.2% of the Gross Domestic Product (GDP) of India for the year 2013-14. Presence of MSDs among agricultural workers will result in a reduction in their work capacity which may reflect in a reduction in economic contribution from agriculture sector. The agriculture sector in India is mainly unorganized with only 2.4% of the agricultural activities are being formal. Though measures have been taken by Government of India to enhance the availability of social security measures to a large section of informal agricultural workers, coverage of health insurance and other social security services remains less for these workers and hence the health of the farmers is more or less neglected.

Hence, this study was designed to investigate the prevalence of the WMSDs among sugarcane farmers, the most commonly affected body parts, the risk factors of the WMSDs among sugarcane farmers in Muzaffarnagar, Uttar Pradesh.

Material and Method

The present cross-sectional study was conducted in selected villages of Muzaffarnagar, Uttar Pradesh (India). A screening list was administered and only those subjects were considered for the study that fulfilled the inclusion and exclusion criteria. Using convenient sampling method, a sample of 120 full-time sugarcane farmers aged between 20 – 60 years, able to read and understand the local language Hindi and with a working experience of minimum 2 years was included in the present study. Farmers with a history of spinal trauma or known diabetic were not included. Farmers with any neurologic, cardiovascular or psychiatric illness were excluded. Part-time farmers involved in other jobs besides farming were also excluded.

Subjects were explained about the purpose and nature of the study. Consent for participation was obtained and necessary instructions were given before administration of the tool. There was no further assistance or prompting to the respondents. All the subjects were assured of the confidentiality of their responses. Subjects were interviewed for musculoskeletal discomfort using Nordic Musculoskeletal Questionnaire. Subjects were asked whether, at any time during the last 12 months and/or 7 days they have had any trouble in the lower back, shoulders, neck, upper back, elbow, wrist, hand, hip, thigh, knee, ankle and feet. Specific questions then concentrated on each anatomical region.

Statistical Analysis

Statistical analysis was done using SPSS 20.0 version software. Descriptive statistics was used to analyze subjects’ characteristics such as age, height, weight, BMI, working experience. Percentage and ratios were used to calculate the prevalence of musculoskeletal disorders.

Result

A total of 120 male subjects participated in the study. Their demographic data were analyzed by comparing means of descriptive analysis. Their age, height, weight and BMI was recorded (Table 1). The mean age (in years) was 44.01 ± 8.31. Table 1 gives details of the mean and standard deviation of these data. The work experience of the subjects and working hours per day and working days per week is depicted in Table 2. The farmers had a work experience of 22.6 years on an average. About 72.5% of participants worked 5 days per week, 16.6% worked 4 days per week and 10.9% worked for about 2 – 3 days per week. Out of 120 farmers, about 63.3% worked 8 – 10 hours a day. Another 16.7% and 9.2% were working for 6 -8 hours and less than 6 hours a day respectively.

Based on body region wise analysis (Table 4) the most common WMSDs reported among the participants included lower back pain (55.8%), knee pain (44.2%) and shoulder pain (23.3%). Some participants reported multiple body parts of discomfort while others had a single body part of discomfort. The musculoskeletal problems in 12 months prior to being interviewed are depicted in Table 5 with low back, upper back and shoulder having
most problems. Table 5 shows musculoskeletal problems in one week prior to participation with low back, knee and shoulder having the most musculoskeletal problems.

### Discussion

The study was designed to evaluate the prevalence of the WMSDs among sugarcane farmers in Muzaffarnagar, Uttar Pradesh. The prevalence of the WMSDs among the Sugarcane farmers was observed to be 51%. Pain due to musculoskeletal discomfort affects almost all parts of the body depending upon the physical movement characteristics and work setup. In this cross-sectional study, we found a high prevalence of WMSDs in sugarcane workers. From the results, we found that prevalence was more in the lower back (50%), knee (44%), and shoulder (23%). However, this particular study found results different from other similar studies in which workers had a high prevalence of wrist pain. Workers engage in sugarcane cutting activities, they work approximately for 7-8 hours. Such activity usually happens for many consecutive days.

The first factor related to WMSDs was that of repetitive motions. In our study, during the sugarcane cutting, the sugarcane workers swung their arms over their heads and bent their bodies repetitively when they cut sugarcane and moved residual grasses for approximately 4 hours per day. Such motions place the average sugarcane workers at risk of developing WMSDs because they often lead to both muscle spasms and poor blood circulation. Moreover, tendons, joints, and other soft tissues eventually became fatigued and subsequently injured\(^1\), \(^16\). This finding is in agreement with previous studies, which also indicated that repetitive motions will eventually result in WMSDs\(^17\).

The second factor related to WMSDs was an awkward posture. Sugarcane workers repetitively pulled bunches of sugarcane, lifted them, and then threw them into trucks. As they were doing that they continually contorted their bodies and lifted their hands above their heads. They also tiptoed on their feet. When the farmers did the work, they repetitively moved their arms and legs in manners that were inconsistent with natural anatomical postures. All this led to excessive workloads for both their muscles and tendons as the workers continually need to maintain their body balance. This finding was...
similar to previous studies among both rubber workers in Malaysia\textsuperscript{19} and farm workers in the United States\textsuperscript{20, 21}.

The third factor that was related to WMDSs was forceful exertion. For example, sugarcane workers had to engage in work that required various strenuous such as lifting the bunches of sugarcane. Lifting and forceful movements also put these individuals at risk of developing WMDSs as they repeatedly lifted, pushed, and pulled large and heavy objects. When those objects were moved, the workers' spines were repeatedly subjected to high-pressure forces. When their spines received high pressure for excessive periods of time, the workers were at risk of losing their balance. In this case, the workers experienced muscle strain, muscle stress, and pain in their back\textsuperscript{20}. This was in accordance with other studies that show a relationship between forceful exertion and WMDSs\textsuperscript{21}.

The repetitive movements resulting from manual sugar cane cutting make the attention and concentration required for this activity very difficult, which raises the probability of musculoskeletal disorders. The symptoms reported are work-related and the prevalence of MSDs would increase over time due to cumulative exposure\textsuperscript{22, 23}. The workers involved in this study used to perform repetitive tasks. Low back pain was found the highest symptoms followed by the hip & knee (Low back & knee pain is associated with prolonged standing, exerting or twisting the torso). The result of this study showed that the highest prevalence of MSDs pain was found on the low back, knee, and then less commonly affected the neck and the hand/wrist.

The workers in our study performed highly repetitive tasks and maintained a static posture for up to an hour at a time. Other studies also showed that repetitive tasks have been found to be associated with WMDSs\textsuperscript{21}. The symptoms of neck and shoulder pain are also significantly related to repetitive work\textsuperscript{19}. Repetitive activity in a short period of time also increases the prevalence of hand and wrist injuries\textsuperscript{23, 24}. The result of the study found that the prevalence of MSDs pain on the hand/wrist 14%. The result might relate to the flexing or extending the wrists during cutting the sugarcane\textsuperscript{24, 25}. The results of this study show a high prevalence among sugarcane farmers. Based on the results, preventive measure for reducing exposure level and consequently preventing MSDs can be prescribed.

**Conclusion**

Based on the findings of this study, it is hereby recommended that sugarcane farmers should be enlightened on a regular basis on the high prevalence of the WMDSs among them, and the precautionary measures to be taken in order to prevent the development. Age of farmers, their years of working and the long hours they spent working in a standing position may be significant factors that contribute to the high prevalence of the WMDSs among them. The most commonly affected body parts included the low back, knees, upper back and shoulder.

**Future Research**

Further study is needed to study another criterion like functional assessment. Studies with a large sample are needed to find out an association and establishing the contribution with a greater amount of certainty about the different risk factors on farmers.

**Source of Funding:** Self

**Conflict of Interest:** There is no conflict of interest related to this manuscript

**Ethical Clearance:** All the procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2000 (5). Informed consent was taken from the subjects prior to the study.

Effectiveness of a Training Program on Improving the Knowledge, Attitude and Skill in Providing Cardiopulmonary Resuscitation (CPR)—An Intervventional Study

Swapnil Thulung¹, Melita Sheilini², Soumya Christabel³

¹MSc Nursing, ²Assistant Professor (Selection Grade), ³Assistant Professor (Senior Scale), Dept.of Medical Surgical Nursing, Manipal College of Nursing Manipal, MAHE, Manipal

ABSTRACT

Background and Aim: The key factor in any cardiac arrest situation is the amount of time lost before a patient is shifted to the hospital. This study aimed to develop awareness among the study participants in cardiac emergencies and to enhance their knowledge, attitude and skill in performing hands-on Cardio Pulmonary Resuscitation (CPR), to bring down the rate of deaths due to sudden cardiac arrest outside hospitals.

Subjects and Method: The study was conducted using pre-experimental research design and convenient sampling technique was used to select 80 employees working in a selected institute as study participants. Data was collected over a period of six weeks using three different tools viz. structured knowledge questionnaire, attitude scale and skill checklist on CPR.

Results: In the pre-test 26.2% of the participants had average level of knowledge and 73% had poor knowledge on CPR, whereas in the post-test 42.5% had good knowledge and 55% had average knowledge on CPR. Only 20% of the participants had favorable attitude towards CPR in the pretest, which did not have a significant change during the post-test as 82.5% of the participants still maintained unfavourable attitude. However the skill of the participants increased from 100% of the participants being unskillful in the pre-test to 76.2% gaining the basic skills on CPR and the rest of the participants were given remediation until they became skillful.

Conclusion: The training program was effective in increasing the knowledge, and teaching the participants with skills of providing CPR.

Keywords: Attitude, Cardiopulmonary Resuscitation, Knowledge, Clinical Skill, Education

Introduction

Cardiac arrest is an emergency situation both in the hospital and out of hospital, if not attended on time it considerably adds to the mortality of a given population. Cardio Pulmonary Resuscitation (CPR), a part of Basic Life Support (BLS) – is one such skill, which if initiated on time can improve the survival rate and prevent the burden of death due to sudden cardiac arrest.¹

Sudden Cardiac arrests are very common cause of death all around the world as they can happen to anyone at any time. As per the statistical update published by the American Heart Association (AHA) in 2013, the incidence of out-of-hospital cardiac arrest is around 326,200 annually and the average survival rate is 10.6% and survival with good neurologic function is 8.3%. About 88% of cardiac arrests happen outside of hospitals so there is a high likelihood that an average citizen will be the first one on scene and may be able to save the life of person experiencing sudden cardiac arrest. Rescuer education and the quality of training given are critical factors in delivering effective CPR.¹⁻³ A study conducted
in North Carolina by Hansen MC, Kragholm K, Pearson AD, Tyson C, Monk L, Myers B et al amongst 4961 patients, during the years 2010-2013, with out-of-hospital cardiac arrest on whom resuscitation was identified and attempted. First responders were police officers, firefighters, rescue squad, or life-saving crew trained by state wise initiatives to perform basic life support and the use of automated external defibrillators (AEDs) until arrival of the Emergency Medical Service. The study reports that the combination of bystander CPR and first responder defibrillation increased from 14.1% in 2010 to 23.1% in 2013. Even the rates of survival with favourable neurological outcome increased from 7.1% in 2010 to 9.7% in 2013 and were associated with CPR initiated by ‘by-standers’.

The current study aims at creating awareness among the study participants, in cardiac emergencies and to enhance their knowledge, attitude and skill in performing hands-on CPR, with a view to bring down not only the rate of deaths due to sudden cardiac arrest outside hospitals, but also to improve the rate of survival amongst victims who experience cardiac emergencies in “out of hospital” scenario.

Materials and Method

This study was an evaluative pre-experimental study conducted among the employees of a selected institute in Udupi district, Karnataka. The objectives of the study were to assess the knowledge, attitude, skill in providing Cardiopulmonary Resuscitation (CPR) among the employees and to determine the effectiveness of the training program on Cardiopulmonary Resuscitation (CPR) among the employees. Informed consent was obtained from the participants.

Convenience sampling technique was used for the selection of the participants and the sample consisted of all the security personnel working in the institute. The sampling criteria included current employees who were physically able to participate in the study and could read and write in English and Kannada or Hindi. The tools that were used to collect the data were demographic proforma, structured knowledge questionnaire on CPR, attitude scale on CPR and skill checklist on CPR.

The data were collected over a period of six weeks. In the beginning, a pre-test was conducted for all participants on their existing knowledge on CPR by asking them to answer twenty self-administered multiple choice questions and their attitude towards the training program on CPR was assessed by asking them to fill a ‘three point’ rating scale on different aspects of the training program on CPR. A single rater assessed their skill on CPR. During the skill test, participants were supposed to perform the sequence of CPR on a standard manikin, and a rater evaluated their skill using a checklist based on the 2015 American Heart Association (AHA) guidelines. The skill checklist included checking for unresponsiveness by shouting and shaking the manikin, asking for help and calling EMS, checking the carotid pulse, baring the victim’s chest and locating the CPR hand position, performing the first cycle of compressions, and giving two breaths after the first cycle of compressions. For each step, the participant got one score for appropriate performance and zero for inappropriate one. A total score of 14 was given for complete performance in all steps. A single rater evaluated all the tests. After the pretest, all the participants attended a CPR training program on the same day for three hours in which techniques of CPR was taught to them by means of power-point presentation and live demonstration. Post-test on knowledge, attitude and skill were conducted in the similar way after seven days using the same tools that were used in the pretest.

Results

The collected data was analyzed using SPSS (Statistical Package for the Social Sciences) version 20 for Windows. The data was analyzed anonymously and expressed as means and percentage. Wilcoxon signed rank test and paired t-test were used for statistical analysis, and p-value of <0.05 was considered statistically significant.

Out of 80 participants, majority 68(85 %) were in the age group of 20-40 years and 59(73.8%) of the participants were males and 21(26.2%) were females. Majority 54(67.5%) had education less than 10th standard and none of the participants had any previous training or knowledge on CPR (Table 1).

</tbody>
</table>

Further statistical analysis showed that there was significant increase in knowledge (t=7.565 p<0.01) and skill (t= 7.908 p<0.01) after the training program on CPR (Table 5). But there was no significant change in attitude (t=1.479 p=0.14) after the training program (Table 6).

The increase in post-test scores in knowledge and skill were significantly associated with the training program as the p-value in both knowledge and skill was <0.05. However the p-value of attitude was >0.05 and it was inferred that the training program on CPR brought significant change in the post-test scores of knowledge and skill.
Discussion

A number of studies have been done all over the world among different category of sample to show the efficacy of bystander initiated Cardio Pulmonary Resuscitation in saving the lives of the out-of hospital cardiac arrest victims. The present study showed that there was significant increase in knowledge and skill after the training program on CPR, however there was no major changes in the attitude scores of the participants.

The findings of this study are supported by an observational study conducted in Nepal in the year 2012, which was aimed at exploring the level of knowledge and attitude on Basic Life Support (BLS) among medical and paramedical staff (N=150). The findings revealed that the participants had inadequate knowledge on BLS. CPR training significantly influenced the BLS knowledge of the participants. Those who had received some CPR training within 5 years obtained the highest mean score of 8.62 ± 2.49, whereas those who had training >5 years back and without training obtained mean score of 5.54 ± 2.38 and 6.1 ± 2.29 respectively. The study concluded that the knowledge of trained personnel was better than those of untrained ones.

In the present study there was no significant changes in the attitude scores of the participants after the training program. This finding is supported by a survey conducted by Chew.S.K et al (2009) at Malaysia among 55 dental students and 73 school teachers to assess the willingness to perform bystander CPR after completion of their BLS training. The findings showed that, only 29.0% of the total 128 participants said that they would offer to perform CPR under any cardiac arrest condition and 69.0% said that they would just offer to call the ambulance but they would not offer to perform CPR. When analyzed separately, only 16.4% of school teachers said that they would perform CPR as compared to 45.5% of dental students (p<0.001). Thus the study findings concluded that knowing how to perform CPR does not necessarily translate into willingness to perform CPR.

Another survey was conducted by Narayan RPD, Biradar VS, Reddy TM, Bk S at Bangalore in the year 2015, which aimed to assess the knowledge and attitude on Basic Life Support (BLS) among the dental interns and post-graduate students. The findings showed that dental interns and postgraduate students had average knowledge about BLS. Among 202 participants, 121 (59.9%) had a positive attitude and 81 (40.1%) had a negative attitude towards BLS. Hence the investigators concluded that Cardiopulmonary resuscitation (CPR) should be considered as part of the dental curriculum. Workshops on a regular basis should be focused on skills of CPR for dental students.

Conclusion

American Heart Association strongly recommends that all victims of cardiac arrest should receive, at a minimum, high-quality chest compressions. The training program was successful in improving the knowledge, attitude and skills of security personnel in providing Cardio Pulmonary resuscitation (CPR). This may improve the out of hospital survival rate of cardiac arrest victims, which the participants come across during their service and may help them in saving many lives.

ABSTRACT

Aim: To comparatively evaluate the protecting efficiency of mandarin collar aprons as against the open collar aprons.

Settings and Design: Cross-sectional randomized comparative study

Methods and Material: Ten post graduate students were given a verbal written set of instructions to be followed during the study. Each study participant was made to wear an open collar and a mandarin collar aprons separately on two different days. The microbial samples were collected using a sterile swab from the chest area of the street clothing at the beginning of the day at dental clinic (Pre patient care) and at the end of the day at dental clinic (Post patient care). The obtained samples were microbiologically analyzed and the difference in the colony count between the two types of aprons were compared.

Results: Significantly more number of gram positive cocci were seen in open collar apron group, when the difference between the pre work and post work colony counts were compared (p=0.031).

Conclusion: Mandarin collar aprons offer significantly better protection of the street clothing of the dental health care providers than the closed collar aprons against the colonization of gram positive cocci.

Keywords: White coat, protection, efficiency, dentists

Introduction

Infectious diseases and cross infections are the challenging domains unavoidably present in all the health care systems of many countries.[1] Thus, adaptation of appropriate biosafety measures becomes vital component while considering the safety of the health care worker as well as the patient.[2,3] In dentistry, professionals are exposed to pathogenic microorganisms present in oral cavity and the surrounding environment (nose, throat, and respiratory tract).[3] The well documented ones include various nosocomial pathogens, such as methicillin-sensitive Staphylococcus aureus (MSSA), methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant Enterococci (VRE) and gram negative organisms, MRSA being the most pathogenic organism.[4]

Cross-infection in dental field is highly expected. It can occur through infected aerosols, blood, saliva, body fluids, devices, instruments or environmental surfaces.[4,5] The concepts of infection control are strictly embraced in the dental profession after the identification
of risks associated with the Hepatitis B virus in 1970s and Human Immunodeficiency Virus in 1980s.\textsuperscript{[6]}

According to the CDC guidelines 2003, use of personal protective equipment (PPE)/Personal protective clothing (PPC) is the vital component to prevent cross infection and cross contamination in dentistry.\textsuperscript{[7]} The PPC includes head cap, gloves, footwear, eye-wears, masks and lab coats (apron). The lab coat/apron is an integral part of PPC and it covers the uniform, street clothing, and skin, thus protecting them from possible contamination due to blood, body fluids and other potentially infectious materials.\textsuperscript{[2]} Apron acts like a safety barrier, which allows the Dental Health Care Provider (DHCP) to work in a high-risk environment while ensuring prevention of transmission of disease to him/herself and rest of the family members.

Two designs of aprons (Open collar apron and Mandarin collar apron) are popularly available in the market. However, there is insufficient evidence to recommend a particular design of apron to be used by DHCP. Thus, the present study was conducted to comparatively evaluate the protecting efficiency of mandarin collar aprons as against the open collar aprons on street clothing.

**Materials and Method**

It was a cross-over randomized study conducted at Manipal College of dental sciences, Mangalore. The processing of the collected microbiological samples were done at Department of Microbiology, KMC hospital, Mangalore. The total study duration was 6 months and the sample size was 10.

**Sample size calculation:** The sample size was calculated based on the study by Reis RF et al \textsuperscript{[3]}, using an alpha of 5 % with the corresponding z value of 1.96 in an established formula, the minimum calculated sample size was 10 participants, each of them being evaluated twice separately for the protective efficiency of open collar and mandarin collar aprons.

The study participants were postgraduate students from the Department of Paedodontics and Preventive Dentistry and the Department of Conservative dentistry and Endodontics of Manipal College of Dental Sciences, Mangalore. Ten postgraduates belonging to either of the departments were included in the study if they had at least 5 patient treatment appointments of 45 minutes each. Those who had any known skin infections and/or taking any topical/systemic antibiotics were excluded from the study. Study subjects who didn’t follow the given set of written instruction on the day of the study were also excluded.

Ethical approval for the study was obtained before initiating the study from Institutional Ethics Committee of Manipal College of Dental Sciences, Mangalore (Ref No: 16125). The study participants were provided with written information sheet, which detailed the purpose of the study and the study procedure. Approval to participate in the study was taken in an informed consent form after allowing them to read and understand the information sheet.

**Procedure:** Verbal and written instructions were given to all the study participants on duration of wearing the apron, washing and usage criteria. A set of new open collar and mandarin collar aprons were provided to all the study participants and they were expected to wear the aprons above the street clothing on the day of study as every other day. The aprons and street clothing worn on the study day by all the study participants were laundry washed at a single center. The postgraduates were told to wear their laundry washed fresh street clothing on the day of study and their aprons were carried to the Clinics in well sealed pouches. Each participant was made to wear open collar and mandarin collar aprons on two different days (allocation was done randomly using toss of coin). The usage criteria for both the aprons were same. Study participants were strictly asked to not to leave the clinic premise during study duration.

**Method of Sample collection:** The sample collection was done twice a day for each participant while wearing a particular type of apron (either open collar or mandarin collar) - Pre patient care (8.30 a.m) and Post patient care (1.30 p.m). The collection of microbiological sample from the Street clothing was performed under aseptic condition by the technique of rolling a swab, which consisted of passing the swab on the chest area of the street clothing. Sterile swabs (with a wooden stick handle) moistened in Brain Heart Infusion medium were used for the sample collection.

**Culturing and the identification of the bacteria:** The swabs were cultured on blood agar and Mac Conkey agar. The inoculated media were incubated aerobically
at 37°C for 24 hours and examined for total bacterial counts and the presence of other possible pathogens according to standard protocol. The bacteria were identified by assessing colony characteristics, Gram reaction, motility and biochemical tests as per previously described protocols.[8]

**Statistical Analysis:** The statistical analysis was done using SPSS Version 15.0. The comparison between open collar and mandarin collar aprons for each category of microorganisms was done using Wilcoxon sign rank test. The values were represented in percentiles and mean ± SD. Level of significance was considered as p ≤ 0.05.

**Results**

Table 1 presents the comparison of the pre patient care and post patient care difference in colony count for each category of microorganisms between open collar apron and mandarin collar apron. Staph aureus, E coli, Klebsiella, Diptheroids, Acitenobacter Baumannii, Staph epidermis, Staph citreus and few other Gram Negative Bacilli (GNB) showed similar median values of colonization and there was no statistically significant difference between pre patient care and post patient care contamination level viz these organisms (p values of 0.25, 0.25, 0.5, 1.0, 0.75, 1.0, 1.0 and 0.43 respectively), when mandarin collar apron was compared to open collar apron. However, the difference between pre patient care and post patient care of open collar apron was highest for Acitenobacter Baumannii, E coli and GNB than that of the mandarin collar, though it wasn’t statistically significant. However, significantly more number of colonies were seen in open collar apron group, when the difference between the pre patient care and post patient care colony counts of total gram positive cocci (including even staph aureus, staph epidermis, staph citreus) were compared (p=0.031).

**Table 1: Comparison of the pre patient care and post patient care difference in colony count for each category of microorganisms between open collar apron and mandarin collar apron as done using Wilcoxon sign rank test**

**Discussion**

No doubt that the PPC or apron is a biosafety measure in the health care field, when improperly used, may become a source of infection.[6] Also, when the aprons are improperly designed may not offer complete protection. The two known designs of aprons used by the dental health care workers are: open collar aprons and mandarin collar aprons. The mandarin collar aprons hypothetically should offer better protection than the open collar aprons. However, the evidence in support
of this hypothesis is still lacking in literature. Thus, this study was done to comparatively evaluate the protecting efficiency of mandarin collar aprons against the open collar aprons.

Chest was chosen as the site for determining the type and amount of existing microbial flora on the street clothing, at the end of the working day. Microbial contamination was thought to be highest in the chest area due to the direct contact with blood, saliva, aerator splashes during the clinical procedure.\[^{9,10}\] Since mandarin collar aprons cover the chest area, sample collection from here also helps in evaluating the effectiveness of the Mandarin collar of the lab coat in prevention of bacterial colonization on the street clothing.

To take of the possible confounding factors, the sample collection was done for each subject twice- pre work and post work and the difference was compared. Also, a specific set of instructions were given both verbally and in written form to all the study participants and it was looked that they were strictly followed during the study.

The results of the present study showed that the street clothes of the dental care provider were highly colonized with GNB and acitenobacter after patient care in both the groups. These findings are in contrary to the studies done by Wong D et al[^9], Banu A et al[^11], Priya H et al[^12], Malini M et al[^13] where authors found considerably higher colonies of gram positive cocci among all the tested health care workers. However, these studies evaluated the microbial contamination of the white coat/apron whereas the present study evaluated the microbial contamination of the street clothing, thereby assessing the protective efficacy of the aprons. Also, the studies by Wong D et al[^9], Banu A et al[^11] were done at a hospital set up in contrary to the dental set up of the present study. Study by Qaday J et al[^14] showed the presence of GNB too in the contaminated white coat, however at a hospital set up.

Reis PF et al[^2] reported in their study that the major colonizers of the dental coat used by professionals are of genus staphylococcus followed by Klebsiella and Enterobacter. Staph aureus, staph epidermis, staph citreus, Klebsiella were isolated from the street clothing even in the present study, thereby suggesting the presence of these organisms in any dental set up and vulnerability of dental care providers to subsequent infections. These infections are of clinical significance and concern, especially the ones caused by Staphylococcus aureus. Staphylococcus aureus is considered one of the most important pathogenic bacteria and is responsible for series of infections in human beings.\[^{15}\] Treatment of infections caused by staph aureus is a challenge due to its high resistance to various drugs.\[^{12}\] Another interesting finding of the present study is when staph citreus, staph epidermis, staph aureus were individually compared there was no statistically significant difference found between open collar and mandarin collar. However, when all the gram positive cocci put together compared, the mandarin collar apron showed significantly low contamination of the street clothing.

Our study showed E coli were unable to colonize the street clothing of the dental care provider, when he/she wore mandarin collar apron, where as their number increased when the care provider wore an open collar apron. However, this difference was not statistically significant and there are no supporting evidence in the literature to state this finding.

Microorganisms are omnipresent, so undoubtedly they colonize in all the favorable conditions, to which even the street cloth worn under the white coat is not an exception.\[^{16}\] While contamination of skin and clothing by “splashes” or touch is practically unavoidable in any health care set up including dentistry, the white coat worn over personnel clothing plays a pivotal role in offering the personal protection.\[^{10, 12}\]

**Limitations:** The present study was conducted with a small sample size. Also, we included postgraduate students posted either at Conservative Dentistry and Endodontics and Peadiatric dentistry. The type of possible contamination may vary in other clinical and non-clinical departments. Thus, future studies are advised evaluating the protecting efficiency of aprons on a larger sample size including study participants from all dental specialties.

**Conclusion**

Within the limitations, results of our study suggest that mandarin collar aprons offer better protection of street clothing compared to the closed collar aprons.

ABSTRACT

Background: Dengue fever is a preventable infection, and success of dengue control depends largely on good knowledge, attitudes and practices of targeted communities towards the disease and its preventive measures.

Method: Cross-sectional study was conducted with sample size of 95 in each area. The study was carried out during the inter-epidemic period (April-June 2018). Simple random sampling technique was used to select the samples. A validated pre-tested questionnaire was used to collect the data. Analysis was done using proportions and chisquare test.

Results: The majority (94.8%) of the respondents in this study had known about Dengue fever. More than half (53.1%) of people were practicing preventive measures against Dengue. No significant difference in knowledge regarding the dengue, its vector, its breeding places and active biting time was found between the semi-urban and rural population, however there was a significant difference in knowledge about common symptoms in semi-urban and rural populations.

Conclusion: Preventive practices are not found to be satisfactory. Thus behavior change communication is the need of the hour. Strengthening of surveillance along with periodic health education to the community by the health personnel is required.

Keywords: Dengue Fever, Preventive Practices, Awareness, Behavior Change Communication

Introduction

Dengue fever is a systemic Arboviral disease caused by the dengue virus and transmitted by bite of infected female Aedes mosquitoes¹. Infections can also be transmitted through blood transfusion, organ transplantation and vertically from mother to child.²-⁶ Although infection with dengue virus may be asymptomatic, it may lead to a wide spectrum disease that ranges from non-severe fever to potentially fatal clinical manifestations.¹,⁷,⁸

Globally, 294 million inapparent and 96 million apparent dengue infections were estimated in 2010.⁷ Dengue virus has five serotypes⁹, and infection with a certain serotype usually confers lifelong serotype-specific immunity, but a temporary immunity to other serotypes. Moreover, more frequent and severe complications can occur in subsequent infection with a different serotype.¹⁰,¹¹ Due to the absence of effective antiviral agents, efforts focus on interrupting human-vector contact through targeting the adult vector and its immature stages by eliminating its breeding habitats in and near households.¹,¹² Nevertheless, the incidence of dengue fever epidemics is escalating, and its endemic transmission expands to a wider geographical range.⁷

Vaccines are in the way to prevent Dengue, one promising vaccine the recombinant live-attenuated tetravalent dengue vaccine (CYD-TDV), commercially
known as Dengvaxia is available but the Strategic Advisory Group of Experts on Immunization recommends the introduction of CYD-TDV only in high-endemicity settings, i.e., where seroprevalence rates of the virus are 70% or greater in the age group to be targeted by vaccination. The major underlying cause of dengue outbreaks in India is unplanned urbanization, development of slums and deficient water management systems leading to the proliferation of the mosquito breeding sites and thereby facilitating the spread of the disease. Recently dengue has been epidemic in India in the year 2017, where Tamil Nadu has one of the highest numbers of about 23,294 cases (NHP 2018) and 65 deaths.

Dengue fever is a preventable infection, and success of dengue control depends largely on good knowledge, attitudes and practices of targeted communities towards the disease and its preventive measures. Community involvement after educational campaigns could be more effective than insecticide spraying alone in reducing mosquito breeding habitats and hence in preventing and controlling dengue.

Hence this study was planned to assess and compare the knowledge, attitude and preventive practice regarding dengue among adults in rural and semi-urban populations in the field practice area of a private Medical college on the outskirts of Chennai in Thiruvalur District.

Materials and Method

The study was approved by the Institutional Ethical Committee. Sample size calculated was 95 in each area taking 65.5% awareness in Rural population and 45% in slum community with a confidence level of 95% and an allowable error of 17.5%. The study was carried out during the inter-epidemic period (April-June 2018). Simple random sampling technique was used to select the samples. A validated pre-tested, semi-structured questionnaire was used to collect the data pertaining to dengue from participants, which included information pertaining to the mode of spread, clinical symptoms, vector characteristics and preventive measures.

At the end of the interview, health education was delivered by providing important information related to dengue fever through a pamphlet.

Results

The study was conducted among 192 adult participants with a response rate of 100% (96 from semi-urban and 96 from the rural population). The socio-demographic characteristics such as gender, age, literacy and occupational status of the study sample are shown in Table 1. On comparison of study subjects based on gender, the majority of females were interviewed in both areas. On comparison of occupational status between semi-urban and rural population, in semi-urban area majority belonged to semi-skilled occupational category while in a rural area nearly half were unemployed (Table 1).

In the present study 94% of the people correctly told about Dengue transmission, the knowledge was found to be slightly more in semi-urban area (95.7%) than in rural area (92.1%). In the present study only 15.9% people knew about the type of mosquito causing dengue.

More than half 56.6% people had knowledge regarding active biting time of Dengue mosquito, this was found to be more in semi-urban area (59.1%) than in rural area (53.9%).

84.1% respondents reported correctly about the breeding places of Dengue mosquito in this study. In the present study when inquired about the symptoms of dengue more than two third of the respondents 76.9% reported fever as the common symptom, this knowledge was found to be significantly higher (86.5%) in semi-urban than in rural areas (59.4%). Regarding the most life-threatening complications of dengue only one third of the participants, more than half (51.6%) in semi-urban area and only 16.8% in rural area stated that the complications were bleeding, shock and fever. The difference was found to be statistically highly significant.

In the present study 95.8% people in total reported that they will approach the hospital if they get fever during dengue outbreaks. This was found to be more in semiurban area (97.9%) in comparison to rural area...

(93.8%). Nearly 64.6% people expressed their desire to participate in Dengue awareness program. This was found to be significantly higher in semi-urban (86.5%) population in comparison to rural (42.7%) population. This difference is statistically highly significant.

In the present study when asked about the self-medication for fever during dengue outbreaks, one third of the total population expressed they will go for that. Attitude of Self medication was found to be significantly more in Rural area than in semiurban area. (Table 3).

Regarding the practice towards dengue prevention, more than half (53.1%) of the participants were covering the water containers tightly. This practice was found to be more in semi urban area (57.3%) in comparison to rural area (49.0%). About 52.6% of the total participants were using one or the other methods of Personal protection against mosquito bites. This practice was found to be more in rural areas (56.3%) in comparison to semi-urban area (49.0%) (Table 4).

</table>

In the present study 18 participants reported that someone from their families was diagnosed with Dengue in last one year. Dengue cases were reported more from Semiurban area (13 people) than in rural area (5) the difference was found to be statistically significant(Table 5).

### Discussion

The current study had documented the knowledge, attitude and practices of preventive and control measures regarding Dengue in a selective semi-urban and rural area near Chennai. The majority (94.8%) of the respondents in this study had known about Dengue fever. A similar study in Delhi had reported a high level of awareness (96.3%).

In a study done in Brazil 78% of subjects knew about dengue whereas, in Thailand, knowledge about dengue was 67%. The study done in Kuala Kangsar district found that 78% of subjects knew about dengue.

While there was no significant difference in knowledge regarding the dengue, its vector, its breeding places and active biting time between the semi-urban and rural population, there was a significant difference in knowledge about common symptoms in semi-urban and rural populations. Thus subjects in semi-urban were better aware of common symptoms of dengue. This might be due to the recent awareness campaigns and programs in the semi-urban study area, as a result of the recent dengue epidemic.
In our study, around 56.6% of the participants had correct knowledge about the biting habit of Dengue mosquito. However in the study conducted by Malhotra G et al only 4% of the participants had the knowledge about biting habit of Dengue mosquito. 84% of participants in our study knew about breeding places of Dengue mosquito which was similar to the study done by Matta et al who reported 79.8% respondents knew about breeding place of mosquito.

In the present study self-medication for fever during dengue outbreaks was reported by 22.9% in semi-urban and 35.41% in the rural area which clearly shows that the knowledge about self-medication has to improved drastically in both rural and semi-urban area.

Regarding the practices to prevent dengue, 53.1% of people were covering their water containers tightly and 49.0% of semi-urban people and 56.3% of rural people are using either mosquito repellents/nets/full sleeve clothes and it was found to be less as compared with Malhotra G et al who reported 59.5% of slums and 70.5% of rural population were practicing either mosquito repellents/nets/full sleeve clothes. However in a study done in Pondicherry, almost everyone (99.3%) used some form of personal protection measures. In this study no significant difference was found in preventive practices between semi-urban and rural populations.

In the present study occurrence of dengue in the past one year was found to be marginally higher in semi-urban (13) than in rural (5) area even though they have better knowledge regarding dengue and its transmission. In a similar study conducted by Chellaiyan VG et al nearly 4 people were exposed to dengue previously in Kanchipuram district of Tamil Nadu.

**Conclusion**

Knowledge and attitude regarding dengue fever are found to be good in the study population. However preventive practices are not found to be satisfactory. Thus behavior change communication is the need of the hour. Strengthening of surveillance along with periodic health education to the community by the health personnel is required. Mass media in the form of TV and radio plays an important role in reaching out to the masses. Mass media should be used by the Government to improve the knowledge and preventive practices regarding the Vector-borne diseases including Dengue fever.

Maternal Deaths in Transkei Region of South Africa: A Case Report

B.L. Meel

Research Associate, Faculty of Health Sciences, Nelson Mandela University, Port Elizabeth, South Africa

Abstract

Every day, approximately 830 women die from preventable causes related to pregnancy and childbirth. Ninety-nine percent of all maternal deaths occur in developing countries. Its incidence is higher in women living in rural areas and among poor communities, according to the World Health Organization (WHO) in 2015. The objective of this case report is to highlight the problem of maternal deaths in the Transkei region of South Africa. A 31-year-old woman was brought to hospital with a history of bleeding vaginally. She was not complaining of labor pain, only of bleeding profusely. When the patient collapsed, cardiorespiratory resuscitation (CPR) was started, and the patient was defibrillated. Intubation was carried out and IV adrenaline was given, but there were no signs of recovery. Resuscitation was called off, and the patient was declared dead.

The patient was the mother of five children. She had delivered four children vaginally, and one by caesarean section. At autopsy, the woman was found to be obese and pale. There was a copious amount of blood in the peritoneal cavity. A full-term mature fetus was floating on the umbilical cord, and lower segment of the uterus was found ruptured. The history, pathophysiology and cause of death are discussed in this report. Preventive measures are suggested. In conclusion, the incidence of maternal death is unacceptably high in the Transkei region. The matter needs urgent attention.

Keywords: Maternal deaths, ruptured uterus, medical negligence.

Introduction

Globally, an estimated 287,000 maternal deaths occurred in 2010, a decline of 47% from the levels in 1990, but far below the 75% reduction required by 2015. Maternal mortality has declined only slowly, although the annual rate of decline at global level has risen, from 2% between 1990 and 2000 to 3.4% between 2000 and 2010. The occurrence of maternal mortality is more concentrated in certain regions, with sub-Saharan Africa and Southern Asia accounting for 56% and 29% respectively. The risk of a woman in a developing country dying from a pregnancy-related cause is about 23 times higher compared to a woman living in a developed country.

The figures on maternal mortality in South Africa are inconclusive. Reports vary considerably in their claims. A report submitted in Parliament (2013) indicated that thousands of women die each year in South Africa before, during or soon after childbirth. According to this report, the South Africa maternal mortality rate was 300 per 100,000 in 2010. The maternal mortality rate in the country is higher than in several of its neighboring countries, including Botswana (160 per 100,000) and Madagascar (240 per 100,000), but lower than in Zimbabwe (570 per 100,000) and Lesotho (620 per 100,000). Another source of report is the Health News Service, which has mentioned that South Africa has cut maternal deaths from 189.5 per 100,000 births in 2009 to 132.9 per 100,000 births in 2012/13. However, the rate is still high, far from meeting international commitments to cut maternal mortality to 38 per 100,000 births by
2015 as part of the global Millennium Development Goals (MDGs).\(^5\)

In developed countries the prevalence of uterine rupture in women who have had a previous caesarean section is in the region of 1%, whereas in women who have not had caesarean sections, it is extremely rare (< 1 per 10000).\(^6\) Uterine rupture is a serious obstetric complication causing high morbidity and mortality, particularly in less and least developed countries.\(^6\) A major risk factor in uterine rupture is obstructed labor. Black African women have a high incidence of contracted pelvis.\(^7\) Other risk factors for uterine rupture include multiparity and particularly grand parity.\(^8\) A series of five cases reported by the author in 2004 showed that there were several avoidable causes of maternal deaths necessitating improved services in the Transkei region. A review of current institutional policies, protocols, and practice guidelines may help to reduce the number of maternal deaths.\(^9\) The purpose of this case report is to highlight the problem of maternal deaths in the Transkei region of South Africa.

**Case history:** A 31-year-old woman who was living in a deep rural area of Transkei and who was expecting her fifth baby was brought to hospital with a history of bleeding vaginally. Blood was dripping down on the floor. She was not complaining of labor pain, only of bleeding profusely. The patient was drowsy, confused and pale on examination. She was put in the left lateral position, and attempts were made to insert an intravenous line (IV), but this proved to be difficult, as she was obese. Staff tried to insert the IV line on the hand, forearms, cubital fossae, feet, and right side of the neck, but failed. The medical officer on duty was called to help. An ultrasound examination showed placenta praevia grade IV in the transverse position and no fetal heartbeat was detected. The patient’s pulse and heartbeat were not palpable. Cardio-respiratory resuscitation (CPR) was started and the patient was defibrillated. Intubation was carried out and IV adrenaline was given, but there were no signs of recovery. Resuscitation was called off, and patient was declared dead, as the pupils were fixed and dilated and there were no pulse, heartbeat or any sign of respiration.

**Fig. 1:** Floting full-term foetus with attached umbilical cord taken from abdominal cavity

The patient had delivered four children vaginally and one by caesarean section. She attended an antenatal clinic about one and a half months earlier, and was asymptomatic, without any abnormality detected on urine examination. At autopsy, the woman was obese and pale. There was a copious amount of blood in the peritoneal cavity. A full-term mature fetus was floating in the uterus (Figure 1). The uterus was 20 x 14 x 4 cm in size. The lower and anterior segment of the uterus was ruptured (Figure 2). An umbilical cord attached to the fetus was separated. The fetus was full-term and 2.9 kg in weight.

**Fig. 2:** Ruptured lower segment of uterus

**Discussion**

Mthatha (Umtata) was the capital city of the former Republic of Transkei. It is a poverty-stricken area located in the coastal area and is now part of the Eastern Cape Province of South Africa. The poor socio-economic status
of people in this region, along with poor health services rendered by the government, is affecting them seriously. The poor and weak, such as women and children, are most affected, as they face hazardous situations on a daily basis. The poor also have less chance of survival in emergencies because they have less access to health services. The poor socio-economic status of the patient was associated with a high risk of adverse events such as inadequate medical management. This happened in the case of this patient, who noticed bleeding at 5:00, but only reached hospital at 9:00. There are mud roads in the area and there is a shortage of ambulances. Moreover, there was no qualified specialist, who could have taken a decision and operated immediately. This could have saved the life of this unfortunate patient and her baby. Poor women in remote areas are least likely to receive adequate health care.

Women die as a result of complications during pregnancies. The major complications are severe bleeding, infection and high blood pressure. Severe bleeding kills a woman within an hour if she is unattended. Rupture of the uterus is a very uncommon complication, but it is not that uncommon in this region (Figure 1 and 2). The patient was not complaining of labor pain, but of bleeding profusely, which must be considered an ominous sign, and she should immediately have been taken to theatre for a caesarean section. Labor pain occurs because of uterine contraction, and a ruptured uterus is unable to contract.

There is delay in reaching hospitals, which are under-resourced anyway. Poverty, distance, lack of information, inadequate services and cultural practices are the factors contributing to maternal deaths in this region. These factors must be considered so that South Africa can meet the MDG 5 maternal health goal - to reduce the maternal mortality rate by three-quarters and achieve universal access to reproductive health.

South Africa is a country where there is a first and a third world together. There are large disparities within the country. The health care services are also extremely poor in the former Transkei region, resembling those in Afghanistan, whereas they may be extremely good, up to first world standard, in metropolitan cities Cape Town. There are no statistics to support this claim, but circumstantial evidence suggests that the rate of maternal deaths in the former Transkei region is very high. The phenomenon is under-investigated, under-reported and information on maternal deaths in this region is under-disseminated, despite the fact that government places great emphasis on maternal deaths. Almost all of these deaths occur in low-resourced settings, and most could have been prevented.3 Maternal mortality is a health indicator that shows very wide gaps between rich and poor and between urban and rural areas, both between countries and within them.3 The high number of maternal deaths in some areas of the world reflects inequities in access to health services.11

In the case studied, the medical officer who was putting the patient in the lateral position, carrying out an ultrasound examination and putting IV lines in this patient, was in fact wasting time. In this case it would have been possible to save the mother and baby, if someone had been competent enough to carry out an emergency caesarean section. The medical personnel responsible for this unfortunate mishap could face possible litigation for negligence or omission, in respect of the death of the patient as well as the baby. At least it would have been possible to save the baby if a caesarean section had been performed in the perimortem period.9 A review of current institutional policies, protocols and practice guidelines, plus training of rural doctors, may help to reduce maternal mortality in this region of Transkei.

Sudden Death in a Road Traffic Accident: A Case Report

Meel B.

Research Associate, Faculty of Health Sciences, Nelson Mandela University, Port Elizabeth

Abstract

Road traffic accidents are associated with deaths due to different mechanisms. Loss of blood as a result of multiple injuries is the commonest in majority of cases. The severity of these injuries depends on the force of impact of a vehicle. The speed, type of car, and direction of impact are the main determining factors in causation of injuries.

This article presents uncommon cases of RTA deaths. The first case is one of instantaneous death by a head on collision. There were multiple large lacerations on both legs and thigh associated with fractures of leg, thigh and pelvic bones, but almost no blood was found at the scene. The foul play was suspected. The history and autopsy findings have been discussed.

Keywords: Sudden, cause and mechanism, death.

Introduction

Road traffic accidents lead to 1.2 million deaths worldwide.\(^1\) WHO estimates that by 2020 these accidents will rank third place.\(^1\) It is difficult to ascertain that how many of them are not really died in accidents. Motor vehicles could be used as a weapon either to conceal the crime. In case of charge, it will only amount to be culpable homicide not to a murder. Injuries sustained in road traffic accidents (RTA) are the same as any other mechanical trauma caused by blunt, sharp and penetrating objects. These result in death or disability of an individual depending on the severity of injuries.

Generally, sudden and instantaneous deaths are not common in RTAs. An injured person survives for some time as compensatory mechanisms try to maintain milieu interior. In RTA’s victims generally die of head injury, hemorrhage or asphyxia depending on the site of injury. Intentional RTA’s are very difficult to investigate, and therefore, remain unrecognized at autopsy. It may be a safe way to commit a crime. Most RTA victims are poorly autopsied, as the immediate cause of death is easily determined. Sometimes the sequence of events needs to be reconstructed, as the relatives will want foul play to be excluded.

Case history: XY a 25-year old young woman met with an accident while she was driving a small car. She had a head on collision and died at the scene of the accident. When she was removed from the car, there was hardly any blood around the body. The investigating officer also noticed this. The boyfriend suspected foul play, as the tearing of muscles looked very much like incisions.

HIV/AIDS Management (Stellenbosch), Research Associate, Faculty of Health Sciences, Nelson Mandela Metropolitan University, Port Elizabeth 6031 South Africa

Fig. 1: Road Traffic Death in Absence of Bleeding
At autopsy, there were multiple linear lacerations on both legs and thighs with fractures of right femur, right tibia & fibula and the pelvis (Figure 1). There were minor contusions and abrasions on the front of chest and forehead. All internal organs were intact.

**Discussion**

Road traffic accidents cause number of injuries of varying degrees. Some result in instantaneous death. Injuries vary from simple abrasions to complex combination of lacerations, sharp cuts, and occasionally penetrating injuries. Often the victims bleed to death. The rapidity of bleeding will decide how soon the victim will die. This will again depend upon the site of injuries that has severed the blood vessels. Sooner the bleeding is stopped, the better it is for survival of the victims.

Despite the large wounds in the legs and only a small amount of blood in the pelvis though the bone was fractured, the victim succumbed quickly (Figure 1). This leads to the hypothesis that the heart may have stopped suddenly or there was sudden peripheral vasoconstriction. She may have died so fast that there was no time to bleed. Blunt force can affect the function of organs without leaving anatomical marks. Important example is fatal cardiac arrhythmia after an impact to the chest. ² (Nordrum, 2005). Extreme sympathetic stimulation can also lead to ventricular fibrillation and sudden death.

Release of vaso-constrictive paracrine by the endothelium lead to vasoconstriction. Vasoconstriction temporarily decreases flow and pressure within the vessel, helping formation of platelet plug. ³ A study on cardiac and regional hemodynamic effects of histamine N-methyltransferase inhibitor metoprine in hemorrhage-shocked rats has showed that histaminergic system activation leads to mobilization of compensatory mechanisms in hemorrhagic shock. ⁴ Careful examination of victims at autopsy will help to rule out any foul play. Although, there may be homicide accidents, it is so difficult to prove homicide intentions. Insurance policy and compensatory damage claims will perhaps have a greater influence on the investigation of the circumstances of the accident, the extent of examination of the injured, and the number of accident reconstructions.

Complete history of an accident along with meticulous autopsy could help in finding out any clue about the intention of criminal mind. Forensic pathologist should take some extra steps in revealing the facts and explain to relatives the true nature of events.

The Role of Dermacyn Solution in the Treatment of Infected Diabetic Foot Ulcers in Basrah: A Randomized Clinical Trial Study

Abdulhussein K. Marzoq¹, Raya Habeeb Abdulimam²

¹Orthopedic Department, Alfiyah Teaching Hospital, Basrah, ²Health Promotion Division, Public Health, Department, Basrah

Abstract

Dermacyn (super-oxidized solution) is a new therapy used as topical dressing in open wounds. The aim of the study is to assess the effectiveness of Dermacyn solution as topical dressing in infected diabetic foot ulcers (DFUs). This is a randomized clinical trial study, done in Al-Fayha Diabetic Foot Clinic between Jan. 2018 till May 2019. Sixty-six adult Type 2 diabetic patients divided into two groups, group A (n = 33) using (Dermacyn) while in group B (n = 33) using Normal Saline (N/S). Mean age of patients (52.65 ± 8.14) years. Most of patients in group A (81.8%) are improved with healed ulcers while (48.5%) of patients in group B with the same outcome with significant statistical difference.

There is very significant statistical difference in healing time between group A (Dermacyn) (40.74 ± 3.84) days and group B (N/S) (51 ± 3.41) days. The Dermacyn was effective.

Keywords: Basrah. Diabetic foot ulcers. Dermacyn, Infection.

Introduction

About 25% of diabetic patients develop diabetic foot ulcers (DFUs)¹. More than half of cases (56%) of DFUs will be infected.

Lower limb amputation in one-fifth of cases of infected DFUs². Diabetic foot lesions are the most cause of hospital admissions of diabetic patients³.

Peripheral neuropathy is the main etiology of developing DFUs⁴. Testing loss of protective sensation:

1. 10 g monofilaments (Semmes- Weinstein)
2. Standard 128 Hz tunning fork
3. Pin-prick sensation
4. Ankle reflexes⁵

Vascular examination include clinical sign and symptoms of PAD and palpation of pedal pulses in both feet, measurement of Ankle brachial index (ABI)⁶. University of Texas is one of the classification of diabetic foot wounds. University of Texas system classification (UT) consist of 4 grades and 4 stages, it shows greater association with increase risk of amputation and prediction of ulcer healing⁷.

Diabetic foot infection (DFI) start as traumatic wound in most of the cases. The infection is diagnosed by clinical signs and symptoms of the inflammation. There are three types of infections in diabetic patients mild, moderate and severe⁸.

The important factors of treatment of infected DFU consist of multidisciplinary team, control of blood sugar, foot care and debridement of infected wound conditions.

Many topical agents are used for infected ulcer, povidone, iodine, eusol, hydrogen peroxide and other topical agents used in the past for infected wounds.

Each one have their own complications. Dermacyn (Super oxidized solution) is a new therapy with electrochemically processed aqueous solution and neutral PH. It is safe and efficient⁹.
Super oxidized solution effective and safe against bacteria, viruses and fungi.\textsuperscript{10,11}

The aims of this study to assess the effectiveness of Dermacyn solution as topical dressing in infected diabetic foot ulcers DFUs as compared with Normal Saline and to evaluate the time of healing of the DFUS (healed, unhealed, minor amputation, major amputation).

**Patient and Method**

**Study design:** This is a randomized clinical trial study was taken in Al- Fayha Diabetic Foot clinic, Basra, Iraq, between January 2018 till May 2019. The total number of patients were sixty-six with infected diabetic foot wounds. After taken informed consent from the patients, patient divided into 2 groups by alternative assign way in a 1:1 ratio, group A using daily wound dressings with Dermacyn Solution (Super oxidized solution) (legal manufacture Oculus Innovative Sciences, Inc Petaluma, CA 94954 USA) and group B using daily wound dressing with normal saline. We preferred not to use povidone – iodine solution due to its toxic effect on human fibroblast and delayed wound healing.\textsuperscript{12}

**Exclusion criteria:** All patients with peripheral arterial disease (PAD) were excluded from the study.

**Investigations:** The diagnosis of infection depend on clinical basis and assessment of severity according to Infectious Diseases Society of America (IDSA)\textsuperscript{8} while wound classification by UT System classification\textsuperscript{7}.

Full history, general examination of patients, local examinations of the foot lesions, laboratory investigations (Hb, WBC, RBC, HbA1c and Renal Function test) were performed to all patients. According to HbA1c, patients are considered as uncontrolled diabetes (7-9) % and poor diabetes control as HbA1C > 9.0 %\textsuperscript{13}.

**Standard treatment of the patients:**

1. Control of blood sugar
2. Multi-disciplinary team approach to all patients.
3. The empirical antibiotics therapy depends on the severity of the infection and most likely microorganism were used.

The definitive antibiotic was started after obtaining the result of deep tissue specimen’s culture and sensitivity within 3 days to be continued until the recovery of infection.

4. Surgical wound debridement to all patients in this study done in the Operative Theater. At the final step of the surgical debridement, cleaning the wounds with normal saline and take tissue specimens and send it in special sterile container within 10-20 minutes to the laboratory for culture and sensitivity only aerobic culture.

5. After the surgical debridement of DFUs start to irrigate the wound in the operating theatre with either Dermacyn solution or Normal Saline solution as topical wound dressing.

6. Start daily dressings with gauze soaked with Dermacyn or normal saline for 8 weeks, and follow up the patients for a year to assess the outcomes of infected DFUs which were:

   a. **Healing:** continuous viable epithelial covering over the ulcer.\textsuperscript{14}

   b. **Unhealed ulcer:** not complete re-epithelization of the wound.\textsuperscript{14}

   c. **Minor amputation:** limited to the toes or at level of the foot, not need prosthesis for walking.\textsuperscript{15}

   d. **Major amputation:** those above the level of ankle, wither below knee, knee disarticulation above knee and hip disarticulation.\textsuperscript{15}

**Statistical analysis:** The data (variables and outcomes) were collected for both groups and statistical analysis was done using SPSS version 19. The significant difference between two groups is when p value <0.05.

**Results**

**Demographic and disease characteristics of the studied groups:** Each group contain 33 infected diabetic foot ulcers, male to female ratio(13/20) in group B and (11/22) in group A. Mean agein group A was (52.58+8.37) years and (52.73+8.05) years in group B. Duration of diabetes mellitus(D.M) was 12.24+4.75 years in group A and 12.86+ 4.66 years in group B. Duration of symptoms in group A was 21.12+11.5 days and in group B was 21.97 days.

Ten cases (55.6%) of the uncontrolled diabetic patients were in group B while twenty five case (52.1%) of poorly controlled diabetic patients were in group A. According to type of treatment of D.M, most of cases (58.3%) of group A were in oral treatment while most
cases (54.8 %) of group B in insulin treatment and oral, and yet all these differences were not significant statistically as shown in Table 1.

**Investigation characteristic of the studied group:** Most of severe infections (IDSA classification) were in group A (57.1%) while most of moderate infection (55.3%) in group According to wound classification (U.T), most of cases of group A were Grade 2 Stage B (60.6%) while most of cases of group B were Grade 3 Stage B (60.6%). The most frequent Microorganisms (before wound dressing) for group A is E. coli (36.4%), while it is staphylococcus aureus for group B (N/S) about (30.3%). Although there is some differences between group A and B in IDSA classification, wound classifications and type of Microorganism, the differences are not significant statistically between the two groups seen in Table 2.

**The outcome of diabetic foot ulcers in the studied groups:** The outcome shows most of the patients in group A (Dermacyn) (81.8%) are improved with healed ulcer while (48.5%) of patient in group B ended with healed ulcer. 3 cases (9.1%) ended with unhealed ulcer ingroup A while 6 cases (18.2%) ended in group B. 3 cases (9.1%) ended with minor amputation while 8 cases (24.2%) in group B. As in Table 3 and this difference is significant statistically.

**The Duration of healing of diabetic foot ulcers in the studied groups** shows there is very significant statistical difference in healing time between group A (Dermacyn) 40.74+ 3.84 days and group B (N/S) 51+3.41 day, As in Table 4.

**Distribution of outcomes of diabetic foot ulcers among types of diabetes control:** highest percent of our studied sample was poorly controlled diabetes and from patients of uncontrolled diabetes more than half of them ended with healed ulcer as well more than 68.8% of poorly controlled diabetes ended with the same outcome, and the difference between the type of diabetes control was not significant regarding the outcome as seen in Figure 1.
